Cable Laying Strategy

(incorporating the Cable Attenuation Report and the Cable Protection Plan)

Submitted for approval pursuant to the discharge of Section 36 Consent Condition 25 and the Marine Licence Conditions 3.2.1.2 & 3.2.1.7

### Cable Laying Strategy Overview

#### Purpose and objectives of the Plan

This Cable Laying Strategy (CLS) has been prepared to address the specific requirements of the relevant condition attached to the Section 36 Consent (S.36) and Marine Licence issued to Aberdeen Offshore Wind Farm Limited (AOWFL).

The Marine Licence issued to AOWFL requires the approval of a Cable Attenuation Plan (Condition 3.2.1.2) and a Cable Protection Plan (CPP) (Condition 3.2.1.7). It has been agreed with the Marine Scotland - Licensing and Operations Team (MS-LOT) that both the Cable Attenuation Plan and the CPP can form part of the CLS document. As such, the term ‘Cable Laying Strategy’ or ‘CLS’ used throughout this document refers to the information provided in relation to the requirements of the conditions relating to the CLS, the Cable Attenuation Plan and the CPP.

The overall aim of this CLS is to set out the procedures for the installation of the Inter-array cables and Offshore Export Cables (OECs), and details relating to cable layout and specifications.

This CLS confirms that the Cables (Inter-array and OECs) to be installed and the installation processes employed align with those considered in the original Application, and that construction and operation -related mitigation measures detailed in the Application will be applied during installation and operation where relevant.

All relevant method statements developed by contractors involved in the European Offshore Wind Deployment Centre (EOWDC) must comply with the procedures set out in this CLS.

#### Scope of the Plan

This CLS covers, in line with the requirements of the S.36 Consent and Marine Licence conditions, the following:

- Details of the location and construction methods for the Inter-array cables and OECs (including the method of burial and protection);
- The technical specification of the cables;
- Electromagnetic Field (EMF) attenuation of the Cables;
- The results of survey work including intertidal habitat and relevant species surveys that have informed cable routing (and also geophysical, geotechnical and beach topography surveys);
- Monitoring of cables during the operational life of the Development and measures to address exposure of cables; and
- Confirmation that the construction methods described within this CLS align with those considered in the Environmental Statement (ES), Supplementary Environmental Information Statement (SEIS), Marine Licence, S.36 Consent and Marine Licence Application.
Structure of the Plan

This CLS is structured as follows:

Sections 1 and 2 set out the scope and objectives of the CLS and set out statements of compliance.

Section 3 sets out the process for making updates and amendments to this document.

Section 4 provides an overview of the Development.

Section 5 provides detail on the key constraints considered and the detail on the surveys conducted to inform cable routing.

Section 6 details the location and layout of cables and the micro-siting tolerances.

Section 7 provides the technical specification of the cables and their components.

Section 8 presents the Cable Attenuation Plan describing EMF attenuation.

Section 9 provides detail of the installation procedures and cable laying methodology.

Section 10 presents the Cable Protection Plan describing the cable protection that will be required.

Section 11 describes the inspection procedures and maintenance surveys to be carried out after installation and during operation.

Section 12 provides information to demonstrate compliance with the original Application, and how the mitigation proposed in the Application will be delivered.

Appendix A demonstrates compliance with the original Application and mitigation set out in the ES and SEIS, and Appendix B details the ES and SEIS commitments relevant to this CLS.

Plan Audience

This CLS is intended to be referred to by relevant personnel involved in the construction of the EOWDC, including AOWFL personnel, Contractors and Subcontractors. Compliance with this CLS will be monitored by AOWFL and reported to the Marine Scotland Licensing and Operations Team.

Plan Locations

Copies of this CLS are to be held in the following locations:

- At AOWFL Head Office;
- At the premises of any agent, Contractor or Subcontractor (as appropriate) acting on behalf of AOWFL;
- At the AOWFL Marine Coordination Centre; and
- With the Ecological Clerk of Works (ECoW(s)).

| Construction                               | As defined by the Section 36 Consent, (as per section 64(1) of the Electricity Act 1989, read with section 104 of the Energy Act 2004), construction is defined as follows:  
  “construct”, in relation to an installation or an electric line or in relation to a generating station so far as it is to comprise renewable energy installations, includes:  
  • placing it in or upon the bed of any waters;  
  • attaching it to the bed of any waters;  
  • assembling it;  
  • commissioning it; and  
  • installing it.                                                                                     |
<p>| Construction Method Statement (CMS)        | The Statement to be submitted for approval under Condition 13 of the section 36 Consent.                                                                                                                                   |
| Contractor                                 | Any Contractor/Supplier (individual or firm) working on the project, hired by AOWFL.                                                                                                                                       |
| Design Envelope (Rochdale Envelope)        | Describes a number of components and all permanent and temporary works required to generate or transmit electricity to the National Grid including the wind farm and the offshore export cable.                                                                 |
| Development                                | The European Offshore Wind Deployment Centre electricity generating station in Aberdeen Bay, approximately 2 km east of Blackdog, Aberdeenshire, as described in Annex 1 of the section 36 Consent. |
| Development Area                           | The area which includes the wind turbine generators, the Inter-array cables and part of the Offshore Export Cable Corridor, including any other works, as shown in Part 4 of the Marine Licence (named as Lease Boundary in the Marine Licence). |</p>

1 INTRODUCTION

1.1 Background

On 26 March 2013, Aberdeen Offshore Wind Farm Limited (AOWFL) received consent from the Scottish Ministers under Section 36 (S.36) of the Electricity Act 1989 for the construction and operation of the European Offshore Wind Deployment Centre (EOWDC - also known as the Aberdeen Offshore Wind Farm) and on 15 August 2014 a Marine Licence was attained under section 25 of the Marine (Scotland) Act 2010 (reference 04309/16/0). This Marine Licence was most recently varied on 30 September 2016 (reference 04309/16/1).

The Development is located approximately 2 to 4.5 km offshore to the north east of Aberdeen, Scotland, within Aberdeen Bay. The Offshore Export Cables (OECs) will each be between 3.7 – 4.4 km long (maximum total length ~8 km) and will reach landfall at the adjacent coastline in Aberdeen Bay located at Blackdog (Figure 1).

A further overview of the Development is contained in Section 4 of this document.

AOWFL is a company wholly owned by Vattenfall and was established to develop, finance, construct, operate, maintain, and decommission the EOWDC.

1.2 Objectives of this Document

The S.36 Consent and Marine Licence contain a variety of conditions that must be discharged through approval by the Scottish Ministers/Licensing Authority prior to the commencement of any offshore construction works. These requirements include the approval of a Cable Laying Strategy, a Cable Attenuation Plan and a Cable Protection Plan. The aims of these plans are to set out the specifications and the procedures for the installation of the OECs and the Inter-array cables (Cables), provide details of the attenuation of field strengths of both OECs and Inter-array cables, and set out details of any cable protection required.

The relevant conditions setting out the requirements for a Cable Laying Strategy, a Cable Attenuation Plan and a Cable Protection Plan for approval, that are to be discharged by this document, are presented in full in Table 1.

It has been agreed with MS-LOT that both the Cable Attenuation Plan and the Cable Protection Plan can form part of the Cable Laying Strategy document. As such, the term ‘Cable Laying Strategy’ or ‘CLS’ used throughout this document refers to the information provided in relation to the requirements of the conditions relating to the Cable Laying Strategy, the Cable Attenuation Plan and the Cable Protection Plan.

This CLS has been prepared in order to satisfy the relevant conditions attached to the Offshore Consents and therefore focuses solely on the offshore and intertidal elements of the Development.

<tr>
<td>S.36 Consent</td>
<td>Condition 25</td>
<td>No later than six months prior to the commencement of cable laying, a Cable Laying Strategy (&quot;the Strategy&quot;) must be submitted by the Company to the Scottish Ministers for approval by the Scottish Ministers following consultation with SNH and any such other advisors as may be required at the discretion of the Scottish Ministers.</td>
<td>This document sets out the CLS for approval by the Scottish Ministers. Consultation to be undertaken by Scottish Ministers.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The Strategy must include the details of the location, the construction methods, and the monitoring methods for the grid export cables and cable landfall site.</td>
<td>Section 6 (location), Section 9 (construction methods) and Section 11 (monitoring methods).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The Strategy must also include the survey results of an inter-tidal habitat and relevant species survey which will help inform the cable routing location.</td>
<td>Section 5</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The Development must be constructed and operated in accordance with the Strategy.</td>
<td>Section 2</td>
</tr>
<tr>
<td>Reason</td>
<td></td>
<td>To safeguard coastal processes in the wider Aberdeen Bay. To ensure all environmental issues are considered in the location and construction of the export and inter array cables. This must include coastal processes and benthic and intertidal habitats.</td>
<td>Section 5</td>
</tr>
<tr>
<td>Marine Licence</td>
<td>Condition 3.2.1.2</td>
<td>The Licensee must, no later than six months prior to the Commencement of the Works, provide the Licensing Authority for their written approval a report detailing current ‘best practice’ relating to the attenuation of field strengths of cables by shielding or burial designed to minimise effects on electro-sensitive and migratory fish species.</td>
<td>Section 8 sets out information on the attenuation of field strengths of cables for approval by the Scottish Ministers.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Such ‘best practice’ guidance as is identified must be incorporated into the Construction Method Statement and the Cable Laying Strategy, in respect of which conditions 13 and 25 respectively of the Section 36 consent relates.</td>
<td>Section 8 and incorporated into Construction Method Statement (CMS) and CLS (this document).</td>
</tr>
<tr>
<td>Marine Licence</td>
<td>Condition 3.2.1.7</td>
<td>In the event that cable protection is required the Licensee must, as soon as is practicable following the Licensee learning that it is required, submit a Cable Protection Plan (&quot;CPP&quot;) to the Licensing Authority for their approval, in consultation with SNH, MCA, NLB and any other advisors as required by the Licensing Authority.</td>
<td>Details on the need for cable protection is provided in Section 9, with details of the cable protection provided in Section 10 for approval by the Scottish Ministers. Consultation to be undertaken by Scottish Ministers.</td>
</tr>
</tbody>
</table>

**Table 1 - Consent conditions to be discharged by the CLS**
The CPP must include surveys that will be undertaken to identify scour protection / armouring works required to protect the cable. The CPP must be incorporated into the Construction Method Statement, in respect of which condition 13 of the Section 36 consent relates. The installation of any cable protection must not commence until the CPP has been agreed in writing by the Licensing Authority.

### 1.3 Linkages with other Consent Plans

This CLS sets out the specifications, layout, and installation methods of the Cables, and any associated cable protection. Ultimately, however, it will form part of a suite of approved documents that will provide the framework for the construction process – namely the other Consent Plans required under the S.36 Consent and the Marine Licence.

Indeed, Condition 3.2.1.2 and Condition 3.2.1.7 of the Marine Licence (see Table 1 above) requires this CLS (and those documents incorporated into the CLS) to be, so far as is reasonably practicable, consistent with another specifically named consent plan: The Construction Method Statement (CMS) (required under Condition 13 of the S.36 consent). The purpose of the CMS is to detail the methods that will be implemented during the construction of the EOWDC, including Inter-array cables and the OECs.

The CMS will be submitted for approval by the Scottish Ministers and consistency between the CMS and the CLS (and those documents incorporated into the CLS) will be achieved by ensuring that all relevant documents are consistent with the terms of any previously submitted or approved documents.

### 1.4 Structure of this Cable Laying Strategy

In response to the specific requirements of the S.36 Consent and Marine Licence conditions, this CLS has been structured so as to be clear that each part of the specific requirements has been met and that the relevant information to allow the Scottish Ministers to approve the CLS has been provided. The document structure is set out in Table 2.

2 STATEMENTS OF COMPLIANCE

2.1 Introduction

The following statements are intended to reaffirm the AOWFL commitment to ensuring that the Development is constructed and operated in such a manner as to meet the relevant requirements set out by the Offshore Consents, as well as other broader legislative requirements.

2.2 Statements of Compliance

AOWFL, in undertaking the construction and operation of the EOWDC, will ensure compliance with this CLS as approved by the Scottish Ministers (and as updated or amended from time to time following the procedure set out in Section 3 of this CLS).

AOWFL, in undertaking the construction and operation of the EOWDC, will ensure compliance with other relevant Consent Plans, as approved by the Scottish Ministers, and as identified in Section 1.3 above.

AOWFL, in undertaking the construction and operation of the EOWDC, will ensure compliance with the limits defined by the original application and the project description defined in the Environmental Statement (ES) and Supplementary Environmental Information Statement (SEIS) and referred to in Annex 1 of the S.36 Consent in so far as they apply to this CLS (unless otherwise approved in advance by the Scottish Ministers / the Licensing Authority).

AOWFL, in undertaking the construction and operation of the EOWDC, will comply with AOWFL Health, Safety, Security and Environment (HSSE) systems and standards, the relevant HSSE legislation and such other relevant legislation and guidance so as to protect the safety of construction personnel and other third parties.

AOWFL will, in undertaking the construction and operation of the EOWDC, ensure compliance with all other relevant legislation and require that all necessary licences and permissions are obtained by the Contractors and Subcontractors through condition of contract and by an appropriate auditing process.
3 UPDATES AND AMENDMENTS TO THIS CABLE LAYING STRATEGY

This CLS sets out the specifications and the procedures for the installation of the Cables, provides details of the attenuation of field strengths of the Cables and set out details of any cable protection required.

Where it is necessary to update this CLS in the light of any significant new information related to the Inter-array cables and/or OECs, AOWFL proposes to use the change management process set out in Figure 2; identifying such information, communicating such change to the Scottish Ministers, redrafting the CLS if required, seeking further approval for the necessary amendments or updates and disseminating the approved changes/amendments to responsible parties.
Figure 2 CLS Change Management Procedure

Ongoing review of CLS by ECoW and AOWFL Consents Team

- Significant change to Cables specifications or installation processes as set out in current CLS
  - Change communicated to MS-LOT
    - MS-LOT advise no update/amendment to current CLS required
      - CLS unchanged
    - Requirement to update or amend CLS
      - AOWFL Consents Team amend/update CLS and re-submit to MS-LOT for approval
      - Amended and approved CLS circulated in place of previous CLS and changes notified to relevant parties by AOWFL Consents Team

- No change to Cables specifications or installation processes as set out in current CLS
  - CLS unchanged
4 DEVELOPMENT OVERVIEW

4.1 Introduction

This section provides a brief overview of the EOWDC relevant to the CLS and Figure 1 shows the location of the Development in Aberdeen Bay.

4.2 Development Overview

The Development will consist of the following main components:

- 11 Wind Turbine Generators (WTGs);
- Three legged jacket substructures each installed on suction bucket foundations;
- A network of circa 9.7 km of Inter-array cables; and
- Two buried or mechanically protected, subsea OECs, totalling up to ~8 km in length, to transmit the electricity from the Wind Turbine Generators (WTGs) to the cable landfall location at Blackdog, within Aberdeen Bay, and connecting to the onshore buried OEC for transmission to the onshore substation and connection to the National Grid network.

Further details of the Development layout and design will be set out, for approval, in the Design Statement (ABE_ENV_BD_0017).
5 CABLE ROUTE AND INSTALLATION CONSIDERATIONS

5.1 Introduction

The reason stated for the requirement of a CLS within the S.36 Consent Condition is in order to ensure that all environmental issues are considered in the location and construction of the Cables. As such, this section provides information on the key constraints that have determined cable routing, installation and protection methods including the results derived from relevant survey work.

5.2 Key Constraints Identified

The routing of the OECs has been driven fundamentally by the location of the point of connection to the National Grid and the new onshore substation that forms part of the Development.

There are a small number of physical spatial constraints within the Development Area and the Offshore Export Cable Corridor (OECC) and the surrounding area. The following constraints have been taken into account in defining the route for the OEC and/or Inter-array cables, and are shown in (Figure 3):

- The Ministry of Defence (MoD) Backdog Firing Range – a small arms firing range on the coast, with an associated exclusion zone at sea;
- The Maritime and Coastguard Agency (MCA) designated anchorage area just to the north of the Aberdeen Harbour boundary;
- The presence of layers of consolidated glacial material; and
- The location of navigation buoys.

Several features of potential archaeological interest were also identified by geophysical surveys which have informed the route of the OEC and Inter-array cables.

The following sections summarise the surveys that have provided data relevant to assessing potential constraints on cable routing (or installation methodologies) and provides a brief overview of the results of each survey.
Figure 3 Key Constraints relevant to the Offshore Export and Inter-array cables
5.3 Constraints to Cable Routing and Installation Identified by Surveys

A series of geotechnical, geophysical, benthic (subtidal and intertidal) and beach topographical surveys have been commissioned by AOWFL to understand conditions within the Development Area and the Offshore Export Cable Corridor (OECC). The results of these surveys have been considered in defining the routing and installation of the OEC and Inter-array cables. A summary of relevant pre-construction surveys conducted is provided in Table 3 below.

**Table 3 - Summary of pre-construction baseline surveys conducted in relation to the Development Area and the Offshore Export Cable Corridor.**

</table>
The sections below summarise the findings of these surveys as relevant to the OEC and Inter-array cable routing (as set out in Section 6 this CLS) or installation methods (as set out in Section 9 of this CLS) as appropriate.

5.3.1 Geophysical Surveys of the Development Area and the OECC

The general bathymetry of the Development Area and OECC is characterised by sloping seabed as you move offshore, deepening to the east north-east. The depths within the 2010 bathymetry survey range from 0.8 m to 35.1 m below Lowest Astronomical Tide (LAT).

In the shallow inshore section, depths increase from 0.8 m to 6 m in an irregular channel. To the east of this channel, there is a series of linked narrow bank features running parallel to the shore. In places, the depth decreases to 2 m below LAT. These banks are asymmetrical, with the steeper side facing west. The seabed then slopes east-south-east with decreasing gradient, continuing to decrease further offshore.

Surface geology identified from geophysical surveys determined that the sediments over most of the Development Area and OECC were predominantly slightly silty sands, which are frequently shelly. In the inshore region of the OECC there are outcrops of glacial (clayey) till (Figure 4).

Depositional ripple features are apparent towards the intertidal area, with megaripples within the gravel areas and other features in the silty sand up to 1,500 m from the shoreline.

Surveys of the Development Area and OECC conducted in 2010 detected a total of 262 magnetic anomalies. These included three outfall pipes running out from shore and the route of a disused telecoms cable. There were numerous small magnetic anomalies across the Development Area. Given the possibility of ordnance in the area these may indicate small metallic objects such as unexploded ordnance (UXO).

The 2007 surveys confirmed a surface veneer of sandy sediments within the Development Area, although absent in some locations nearshore (where the till outcrops at the surface),
which increases in thickness (up to 8.5 m) with increasing distance offshore. Within the nearshore area, maximum sandy sediment thickness is apparent in the region characterised by sand bar features.

The purpose of the geophysical survey carried out in 2016 was to obtain detailed sub-bottom profiler data covering 400 m x 400 m survey boxes at all 11 WTG locations. Additional bathymetry data was collected covering a 200 m wide corridor of the Inter-array cable and the OEC routes. Surveyed depths ranged from approximately 0.7 m above LAT to 32.6 m below LAT across the survey area. From the sub-bottom profiler data, four seismic horizons were interpreted throughout the site, which confirmed that seabed sediments consisted predominantly of sandy sediments underlain by clay. The thickness of the sandy sediments increased from approx. 1 m below seabed level at the shallowest WTG location, to 8.5 m at the deepest WTG location.

5.3.2 Geotechnical Surveys of the Development Area and OECC

The offshore geotechnical surveys carried out between 2013 and 2016 have revealed that the seabed generally comprises of very loose to dense sand (Forth Formation), normally 1-2 m thick, but at the deeper side of the site the thickness increases to as much as 8.5 m. The surface sands (top 1-2 m) tend to be densified probably as a result of wave action.

The sand layer is underlain by glaciomarine clays (St Abbs Formation) and has been identified across most of the site to a maximum thickness of approximately 15 m. Underneath this formation lies the Wee Bankie glacial till (clayey with boulders, cobbles and gravel), which at the nearshore section outcrops at seabed and extends to the rockhead of the Old Red Sandstone. From geophysical seismic datasets it can be inferred that the rockhead tends to dip towards east-northeast (ENE) direction from 2-5 m below seabed in the nearshore section to 25-30 m BSB at the farthest part of the site.

5.3.3 Intertidal Ecology Survey

Intertidal ecology surveys of the cable landfall location were undertaken in 2011 using standardised Phase 1 mapping methodology. Habitats along the intertidal zone were mapped using European Nature Information System (EUNIS) habitat classes to level 3. Biotopes or other notable features such as species of conservation concern, covering less than 5 m² were recorded using referenced target notes.

The results of these surveys were reported in the Onshore Environmental Statement and indicated that the intertidal zone was dominated by two zoned habitats which have been categorised as B1 and B1.1 according to the EUNIS database:

- EUNIS B1 Coastal dunes and sandy shores: The intertidal zone is dominated by very exposed littoral sands which extended into the infralittoral zone and which also provide sediment for the sand dune system present in the supralittoral zone.
- EUNIS Habitat type code B1.1 sand beach driftline: This narrow habitat band occurs just above the normal tide limit providing material for embryonic sand dune
development. There was scant evidence of such development although some sea rocket and isolated patches of marram grass were evident.

The beach is described as exposed and undergoes constant aeolian shifting. There are few associated habitats and thus few opportunities for a diversity of intertidal marine fauna, the only evidence of shellfish being discarded shells of common cockle (*Cerastoderma edule*), pod razor shell (*Ensis siliqua*), common tortoiseshell limpet (*Yectura tessulata*) and white furrow shell (*Abra alba*) indicating the presence of shellfish beds beyond the littoral zone. Mobile crustaceans such as amphipods were also noted along the shoreline and in particular beneath drift material.

The limited boulder areas recorded in some locations at the low tide mark provided holdfast opportunities for seaweeds such as bladder wrack (*Fucus vesiculosus*) and gut weed (*Ulva intestinalis*). The only other recorded species were communities of barnacles (*Balanus sp.*).

### 5.3.4 Subtidal Benthic Surveys of the Lease Boundary and OECC

A subtidal benthic survey was conducted in 2010, which indicated that the seabed consisted of fine and muddy sand. Inshore areas had lower mud content than the deeper stations further offshore. The predominant species present were the polychaete worm *Notomastus latericeus*, and the bivalves *Nucula nitidosa* and *Tellina fabula*. The infaunal communities increased in diversity and numbers with distance from the shore and are characterised by two biotopes: *Nephtys cirrosa* and *Bathyporeia* spp. in infralittoral sand (SS.SSA.IFiSa.NcirBat) in inshore areas and *Abra alba* and *Nucula nitidosa* in circalittoral muddy sand or slightly mixed sediment (SS.SSA.CMuSa.AalbNuc) further offshore.

Trawl sampling indicated that *Crangon crangon* (brown shrimp), *Ophiura ophiura* (brittlestar) and *Liocarcinus holstatus* (a swimming crab) were the most dominant epifaunal invertebrate species. The distribution of these species was associated with muddier sediment types. The three most abundant fish species were dab (*Limanda limanda*), plaice (*Pleuronectes platessa*) and whiting (*Merlangius merlangus*); all three of which are commercial species. Plaice and dab were caught in greater numbers at the sandier inshore stations, especially plaice.

The 2010 subtidal benthic survey did not find evidence of any rare or protected subtidal benthic species or habitats in the Development Area and OECC.

### 5.3.5 Beach Topographical Monitoring Surveys

Shoreline topographic surveys were carried out in spring (April) and autumn (October or November), between 2010 and 2016, to investigate seasonal trends in beach topography and covering an area encompassing the landfall location. The observed changes in beach morphology along Aberdeen Bay evidenced from these surveys can, for the most part, be explained in terms of intra-annual (seasonal) variations in incident wave energy. For the September 2016 survey, this is particularly evident in the formation of a berm on the upper foreshore along the frontage. This is evident and visible along a number of cross shore profiles along Aberdeen Bay and locally within the Blackdog area.
However, some of the largest changes observed within the beach profiles, over the surveys to date, have occurred as a result of burn migration across the backshore/foreshore, rather than as a direct response to wave action. This is particularly evident in the case of the profiles in the vicinity of Blackdog Burn. Changes at these locations included dune retreat between 2013 and April 2016, which were likely driven by both fluctuations in fresh water flow volumes and local beach topography determined by the wave climate. No further dune retreat was observed between April and September 2016. At the same time no dune advance was observed over the same period. Based on field observations on the dune extent since 2010, significant dune toe advance is not expected in the short to medium term in the Blackdog area.

5.4 Summary of Key Constraints Identified by the Surveys

Geophysical and geotechnical surveys have indicated that in some areas of the OECC consolidated glacial sediments are present which may need to be avoided as a result of the difficulties associated with the use of burial tools (particular jetting burial tools) through this material.

A review of benthic survey data within the Development Area and along OECC and intertidal ecology survey data did not identify any sensitive habitats or species that are considered to be a constraint with regards to cable routeing or installation procedures.

The beach topographic surveys have demonstrated that the changes observed in beach morphology are consistent with the conceptual understanding of this coastline provided in 2012 by ABPmer, together with the more detailed engineering studies completed. The topographical survey data are being used to inform the ongoing OEC routing and installation engineering design process for the cable landfall location.
Figure 4 Seabed classification and sediment type within the Development Area and along the Offshore Export Cable Corridor
6 LOCATION AND LAYOUT OF INTER-ARRAY AND OFFSHORE EXPORT CABLES

6.1 Introduction

Condition 25 of the S.36 Consent requires that the CLS must include details of the following:

“the location, the construction methods, and monitoring methods for the grid export cables and cable landfall site”

The following sections describe the layout and location of the OEC, taking into account any constraints identified in Section 5. In addition, given that the reason for Condition 25 in the S36 consent makes reference to Inter-array cables, the layout and location of the Inter-array cables is also presented.

Cable laying techniques are described in Section 9 of this CLS.

6.2 Location and Layout

6.2.1 Offshore Export Cables

Two buried 66 kV subsea OECs will be installed to transmit the electricity from the WTGs to the landfall at Blackdog where they are then connected to the onshore export cables at the onshore transition joint bay (OTJB). The onshore export cables then run underground from landfall at Blackdog to the substation site.

At the landfall by the Blackdog Burn, two High Density Polyethylene (HDPE) ducts for the OEC will be installed by trenching methods between the OTJB and the offshore Kilometre Point (KP) 0.25 which will cross the Blackdog Burn, a small stream running on the beach parallel to the water line. The ducts will be approximately 150 m long, with the option of duct extensions of approximately 850 m in length currently being considered.

The OECs indicative configuration coordinates are presented in Table 4 below, with the layout of OECs presented in Figure 5.

AOWFL will provide the MCA with a chart detailing the KPs, once the design has been finalised.

6.3 Route Refinement and Micrositing

The final locations and layout of the OECs and the final layout of the Inter-array cables remain subject to possible minor route refinement.

Prior to cable installation, an in survey will be completed by the Contractor or Subcontractor to confirm there are no additional unknown hazards present (such as boulders and UXO). A Remotely Operated Vehicle (ROV) may be used during the in survey but this is yet to be confirmed. Should any hazards be identified, further minor modifications to the location or protection of cables may be proposed. These will not constitute significant changes to this CLS and these minor modifications are referenced as cable micrositing.

A pre-lay survey will be undertaken a couple of weeks prior to the start of the installation of the Cables to determine the reference level for the cable burial and any further micro-siting requirements.

With the PLGR (Pre lay Grapnel Run) any nets or other objects might be removed from the cable route just prior (approximately one month) the cable installation campaign.
Figure 5 Offshore Export Cables layout and Inter-array cable layout (subject to micrositing)
7 TECHNICAL SPECIFICATION OF CABLES

7.1 Introduction

The OECs and Inter-array cables will all be three core 66 kV steel sheathed, armoured submarine power cables. The cables will be made up of a three copper-core conductor of a 400 mm$^2$ cross section.

7.2 Cable Components

Figure 6 shows the key components of the 66 kV Cables for a 400 mm$^2$ cross section cable and the main features of the Cables are described below..

7.2.1 Power Cores

The Cables will be comprised of three power cores of copper and the cores will be insulated with crosslinked polyethylene (XLPE). For waterproofing each core will have an outer aluminium foil laminate sheath.

7.2.2 Fibre Optic Element

The cables will be fitted with a fibre optic core, within cable interstices, to provide the necessary functionality for WTG control and instrumentation systems.

7.2.3 Assembly

Appropriate filler materials (e.g. ropes or extruded polymeric profiles) will be included within the cable interstices to provide a robust and stable base for the application of armouring.

The cables will have a galvanised steel wire outer armour layer protected from corrosion using a bitumen based compound. The armour layer encloses the cores, the fibre optic cable and any fillers. A serving wrapped over the armour layer will be comprised of polypropylene yarns (antifriction) appropriately specified and sized to meet installation and operational requirements.

8 CABLE ATTENUATION PLAN

8.1 Introduction

Condition 3.2.1.2 of the Marine Licence requires that the Cable Attenuation Plan must comprise the following:

"a report detailing current 'best practice' relating to the attenuation of field strengths of cables by shielding or burial designed to minimise effects on electro-sensitive and migratory fish species"

The following section provides details of the attenuation of electromagnetic field strengths of the cables that will be installed at the EOWDC. As detailed in Section 7, it is important to note that the same specification of Cables will be used for both OECs and Inter-array cables. As such, the following information is considered to be representative of the EMF characteristics of the cables that will be installed at EOWDC.

8.2 Current Industry Best Practice

In relation to the current ‘best practice’ on EMF, National Policy Statement EN-3 refers to the assessment of EMFs in relation to fish (Paragraph 2.6.75). The document suggests that where mitigation is applied, it is expected that the residual effects of EMF on sensitive species from cable infrastructure during operation are likely to be not significant. The mitigation described (Paragraph 2.6.76) includes the use of armoured cables and cable burial to a sufficient depth (with indicative burial depths of up to 1.5 m for OEC and 1.0 m for Inter-array cables, dependent on geological conditions), both of which are suggested for the EOWDC. It is also important to note that the construction and shielding of the cables to be used at the EOWDC will be in line with current industry standards.

8.3 Electromagnetic Fields

This section summarises the results of a desk based assessment on the attenuation of electromagnetic fields associated with the OECs and Inter-array cables for the 400 mm² core cables.

The study calculated the magnetic field magnitudes at a given distance from the 66 kV cables at indicative burial depths of 0.6, 1 and 2 m. The insulation and sheathing of the cable power cores, and the burial of the cables, encourage shielding of EMF.

The magnetic field generated by a single conductor at a given point was calculated using the Biot-Savart Law. When there are three conductors (a three core cable) such as the Inter-array cables and OECs being used for the EOWDC, the magnetic field can be calculated using the superposition of fields of a single conductor.

The predicted EMF attenuation from the 400 mm² cables are shown in Figure 7-9 below and the predicted EMF attenuation values are shown in Table 6. The x axis on Figure 7-9...
indicates the horizontal distance in the model, with the cable situated at the mid-point arc length of 30,000 mm (30 m), and the y axis indicates the magnetic field strength (µTesla). The plots also show the magnitude of magnetic field at multiple heights from the seabed (0 m, 5 m and 10 m).

**Figure 7** The magnetic field expected from 400 mm² 66 kV export cable assuming 0.6 m burial depth

**Figure 8** The magnetic field expected from 400 mm² 66 kV export cable assuming 1 m burial depth

The predicted magnetic field of any of the cables buried to 0.6 m is expected to be below the earth’s magnetic field (assumed to vary between 25 µT and 65 µT). As such, at the indicative target burial depths of the Inter-array cables of up to 1.0 m, and OECs of up to 1.5 m, EMF emissions at the seabed are expected to be significantly lower than the earth’s magnetic field (Table 6).
9 CABLE INSTALLATION METHODOLOGY

9.1 Introduction

Condition 25 of the S.36 Consent requires that the CLS must include details of the following:

“the location, the construction methods, and monitoring methods for the grid export cables and cable landfall site”

The following sections set out the cable laying techniques for the OECs and the Inter-array cables.

9.2 Offshore Export Cable Installation and Preparation Works

An indicative installation sequence for the OECs is presented in Figure 10.

Greater detail on each of the stages in the installation process (Stages 1 – 7) is then provided in the subsequent sections.

Figure 10 Offshore Export Cables Installation Sequence

- Stage 1: In survey for route design and UXO investigation
- Stage 2: Landfall Installation (duct installation by trenching, optional extension)
- Stage 3: Route Clearance (PLGR)
- Stage 4: Pre-surveys to determine reference level
- Stage 5: Shore landing of OEC
- Stage 6: Offshore cable laying
- Stage 7: Post-lay cable burial

All Cables will be transported to site direct from the point of manufacture by sea on the Cable Laying Vessel (CLV).

Details of the proposed construction vessels are set out in the Vessel Management Plan (VMP) (required under Condition 24 of the S.36 Consent).
9.2.1 Stage 1 – In survey
An in survey will be conducted to determine the seabed conditions and to identify possible UXO’s. An ROV may be used during the in survey but this is yet to be confirmed. This data will be used to finalise the detailed cable routes.

9.2.2 Stage 2 - Landfall installation
As detailed in Section 6, this CLS describes two different methodologies that are being considered by AOWFL for the installation of the OECs. Due to ongoing engineering studies, AOWFL is currently unable to confirm which methodology will be employed and as such, are presenting two options for approval:

- Onshore ducts, crossing the Blackdog Burn (approximately 150 m in length) installed by trenching and float in of cable; and
- Onshore ducts (approximately 150 m in length) installed by trenching with a duct extension (approximately 850 m in length).

The final selected installation methodology will be taken forward once engineering studies are complete and will be notified to the Licensing Authority prior to the commencement of the landfall installation works.

According to the dynamic coast project online tool, the coastline at Blackdog is undergoing accretion rather than erosion. It is considered that the cables are less likely to become exposed because of this. However, AOWFL is also concerned, about changing coastal processes that could put the cable at risk of exposure through erosion, and therefore will design the landfall with an aim to minimise the risk of cables becoming exposed through the life of the Project.

Option 1 – Onshore duct and float in
Between the OTJB and the beach, a duct for the OECs of approximately 150 m in length will be installed. A trench will be made by excavators and the prefabricated duct will be lowered into the trench to reach the indicative target cable burial depth of up to 1.5 m. The onshore duct has to cross the Blackdog Burn, a small stream running on the beach parallel to the water line. For this crossing the course of the Blackdog Burn will be temporarily adjusted by creating a dam and pumping water to the downstream side of the dam, prior to the installation of the ducts using an open cut trenching method. When the installation of the ducts has been completed the original course of the Blackdog Burn will be reinstated. The flow of the burn will be monitored after reinstatement to verify it returned to its original course. During the onshore pull in of the cable, floatation devices will be attached to the cable. The cable will be floated towards the shore and pulled through the onshore duct to the OTJB.
Option 2 – Onshore duct and duct extension

This duct will be extended to the -5 m LAT line (circa 850 m), where the CLV will remain afloat independent of the tidal cycle. The duct will be produced in one length and towed to a temporary storage location. At the same time a backhoe dredger will excavate two trenches parallel to each other. The depth of the trenches will be determined based on an indicative target burial depth of up to 1.5 m. The duct will be pulled into the trench. After the installation of the duct, the trench will be 50% backfilled (Figure 12). The end of the duct will be at -5 m LAT. This is the location where the CLV always stays afloat. Approximately 150 m of ducting will be installed onshore between the OTJB and the beach and connected to the offshore part of the duct.

During the onshore pull in of the cable, the end of the pipe will be recovered and the cable will be pulled directly into the duct to the OTJB (Figure 13). After completion of the pull in the pipe end will either buried or covered with rock bags/mattresses.
Figure 12 Trench Backwashing

Figure 13 Example of a cable pull in into a HDPE duct end
9.2.3 Stage 3 – Route clearance (PLGR)

Seabed debris, such as fishing gear and abandoned wires or chains, can be detrimental to cable lay and cable burial operations and there is a risk that the cable installation tools, intended to be used to bury the cables, could become entangled or stuck. Therefore, approximately one month prior to the start of cable laying operations, the OECC will be cleared of any surface debris crossing the cable routes by the use of a Pre-Lay Grapnel Run (PLGR).

A vessel will be mobilised together with any required positioning equipment and a grapnel assembly. A variety of grapnel types are available and suitable pre-determined grapnel will be selected prior to PLGR.

The PLGR vessel will tow a seabed deployed grapnel along the centreline of the cable route (re-runs will be conducted where the grapnel has not stayed within the target corridor). The grapnel tow winch will be fitted with a strain gauge which will detect the rise in tension when it encounters debris. Any debris encountered will be recovered to the deck of the vessel wherever possible for appropriate licensed disposal ashore.

9.2.4 Stage 4 – Pre-surveys to determine reference level

A couple of weeks prior to the installation of the OECs, the survey vessel will perform a pre-lay survey. This will be undertaken prior to the CLV being loaded with the cable and arriving at the site. The pre-lay survey is designed to ensure no changes to the seabed have occurred that will affect the cable installation since the previous in surveys and inform any further micro-siting requirements.

9.2.5 Stage 5 – Shore Landing of OECs

Once the HDPE ducts have been installed on the beach, and the pre-lay surveys have been completed, installation of the OECs will commence. Cable installation will be undertaken by the CLV where the OEC lengths will be loaded onto a cable carousel.

As detailed above, the following methodologies are being considered for the landfall of the OEC:

1. Onshore duct, crossing the Blackdog Burn (approx 150 m) and float in; and
2. Onshore duct (approx 150 m) and duct extension (approx 850 m).

Option 1- Float in

For option 1, the cable installation will be by a floating pull in from the CLV to the beach. The CLV will set up on anchors at approximately KP 1.0 (-5 m LAT line). The burial tool will be over boarded and driven towards the duct end on the beach. The onshore winch will pull the cable towards the shore while on the CLV floatation devices will be attached to the cable and the cable will be paid out. During the float in the burial tool will be located on the beach and the cables will be pulled through the tool.
When the cables have reached the shore, an excavator will guide the cable head into the simultaneous lay and burial tool, if necessary. The excavator can later help the cable into the duct entry if necessary. To reduce the required pull forces the cables can be lubricated with vaseline (environmental friendly) before it enters the onshore duct if required.

Once the cable has been pulled in and the required overlength of a minimum of 10 m is at the OTJP (in the case of pulling to the substation area the overlength is not yet defined), the floatation devices will be removed and the cable will be positioned on the seabed. The cable will remain secured to the winch. The winch will keep tension on the cable, while the simultaneous lay and burial tool starts burying the cable using the chain cutter mode from the beach towards the CLV. The simultaneous lay and burial tool, will be recovered when it has passed the consolidated glacial material area (approximately KP 1.0). The remainder of the cable will be surface laid and post lay buried.

**Option 2-Pull in through duct**

For option 2, a duct will be installed to the position where the CLV will be anchored. The end of the duct will be recovered onto the chute of the CLV and the cable will be pulled through the duct with the onshore winch. To reduce the required pull forces the cable can be lubricated with vaseline (environmental friendly) before it enters the duct end on the CLV if required.

During the pull in the burial tool will be located on the deck of the CLV. After completion of the shore landing the OEC will be surface laid. The entire route will be post lay buried. After completion of the OEC installation the pipe end will be either buried or covered with rock bags/mattresses.

9.2.6 Stage 6 – Offshore Cable Laying

Once the landfall operation is completed, the CLV will move off along the cable route for surface laying of the OECs. The CLV will move along the cable route and the carousel and tensioner will pay out the OECs in line with the speed of the CLV.

Prior to load out of the jacket foundations, equipment and materials for the pull in and termination operation will be stored and fastened on/in the WTG jacket. The messenger wire for the cable installation will be pre-installed in the yard.

The CLV will position itself near to the receiving wind turbine (AWF05 or AWF09) to install the cable through the WTG Internal J-tubes. The internal J-tubes are steel tubes that allow the installation of cables by providing a conduit through which the cables can be pulled. A tower team will be transferred to the jacket prior to the CLV’s arrival, after which the CLV will position itself at a stand-off distance from the structure. The messenger wire will then be recovered onto the deck of the CLV.

The OEC will then be connected to the messenger wire, and the Cable Protection System (CPS) will be mounted on the cable during cable pay out to the WTG. The cable will be protected from the outside of the bellmouth into the seabed. The cable will be pulled into the
WTG jacket and secured for subsequent stripping and termination into the turbines junction boxes.

If visibility allows, an ROV will carry out a final visual inspection of the installed CPS and cable. Once completed, the pull in cable trenching and burial will commence.

9.2.7 Stage 7 – Post-Lay Cable Burial

Subsea cables are exposed to a range of threats from both natural and anthropogenic sources. Cables can be protected by armouring and by seabed burial. The most reliable form of cable protection is generally recognised as being burial into the seabed. The level of protection required for a cable is a function of the nature of the external threat, the strength of the seabed soils and the depth of burial. During installation, the surface laid OECs will be trenched into the seabed to an indicative target burial depth of up to 1.5 m by a trencher from the CLV vessel. The Inter-array cables will have an indicative target burial depth of up to 1.0 m.

During cable trenching operations, a seabed trenching tool will be launched from the CLV. The surface laid cable will be straddled by the trencher to engage the water jetting swords. The seabed trenching tool will then complete a first trenching run to bury the cable. Progress of the burial operation will be largely dependent on the nature of the seabed sediments.

It is anticipated that cable burial will be primarily achieved by the use of a water jetting seabed trenching vehicle capable of performing jet trenching in softer sediments or cutting in stiffer soils (Figure 14, Figure 15). Such jet trenching vehicles will use nozzles mounted on jet swords to inject water at high pressure into the soil surrounding the cable which fluidises the seabed in the immediate vicinity allowing the cable to sink under its own weight, before the soil re-settles over the top. To maximise post-trenching cable cover and to minimise the disturbance of sediment away from the trench, site specific trencher settings will be derived based on the soil conditions to ensure disturbed sediment is monitored and managed efficiently throughout operations.

When a section of the cable is not lowered to the required trenching depth during the first jetting pass, a second and/or third jetting pass can be performed to lower the cable to the required depth.

In the unlikely event that the cables cannot be buried to a depth sufficient to provide adequate protection due to, for example, unexpected ground conditions, additional cable protection may be required along those sections where inadequate burial is achieved. In this unlikely scenario, the Licensing Authority, SNH, NLB and the MCA will be informed and further details on the proposed additional cable protection would be submitted for approval.
Figure 14 Examples of seabed cable trenching tools (cutting and jetting)

Figure 15 Trencher in jetting mode
A close fitting CPS will be installed on the OECs and Inter-array cables between the seabed and the J-tube interface to protect and stabilise the cable (Figure 16). The CPS will consist of articulated split pipes and bend restrictors to protect the cables from dropped objects, current induced fatigue, dynamic wave action, vibration and other local hazards at this interface.

In the unlikely event that the cables cannot be initially buried to a depth sufficient to provide adequate protection due to, for example, unexpected ground conditions, additional cable protection may be required along those sections where inadequate burial is achieved. In this unlikely scenario, AOWFL will seek MS-LOT agreement in consultation with SNH, NLB, MCA and SFF if required.

*Figure 16 Example of a CPS at a J-tube*

The anticipated approach to Offshore Export Cable burial is as follows:

**Additional protection at duct end**

If a duct is installed to KP 1.0, the end of the duct will be on the seabed after the completion of the pull in of the OECs (options 2). The section of the duct extruding from the seabed will be either protected with concrete mattresses or rock bags (Figure 17), buried after the installation of the cable using the trenching tool or lowered using Mass Flow Excavation. If additional protection is required at the duct end, AOWFL will provide details to and discuss with the MCA.
If a float in of the OECs is undertaken (option 1, Figure 18) the first section of cable (approximately KP 0.15 – KP 1.0) will be buried with the burial tool. Due to the consolidated glacial material located in the inshore area, a trencher fitted with a cutting tool (as shown in Figure 19) will be used up until the point where the trencher has passed the consolidated glacial material area. In chain cutting mode, the cable will run through the upper bellmouth and leave via the cutter depressor, above the chain. No additional cable protection will be required.

Figure 18 Example of a cable float in
Figure 19 Example trencher in chain cutting mode

**KP 1.0 to WTG AWF05 & AWF09**

For this section of the cable route, the jetting tool will be used to bury the cables to an indicative target burial depth of up to 1.5 m. It is anticipated that the OECs will be buried along the entire route.

### 9.3 Inter-Array Cable Installation

An indicative installation sequence for the Inter-array cables is presented in Figure 20. Stages 1 – 3 of the sequence below will be undertaken in a single campaign in relation to both OECs and Inter-array cables. Details are provided in Section 9.2.1, 9.2.3 and 9.2.4.

Greater detail on each of the stages in the inter-array cable installation process (Stages 4 – 7) is then provided in the subsequent sections.
Figure 20 Inter-array Cable Installation Sequence

| Stage 1 | • In survey for route design and UXO investigation |
| Stage 2 | • Route clearance (PLGR) |
| Stage 3 | • Pre-surveys to determine reference level |
| Stage 4 | • First end cable pull into J-tube on WTG jacket |
| Stage 5 | • Cable laying |
| Stage 6 | • Second end cable pull into J-tube on WTG jacket |
| Stage 7 | • Post-lay cable burial |

9.3.1 Stage 4 – First end cable pull in

Each first end pull in will consist of a direct transfer of the cable end from the CLV to the jacket (Figure 21). A brief summary of cable first end pull-in operations is provided below:

- Pull-in equipment and personnel will be transferred to the jacket;
- Prior to pull-in, a cable protection system (CPS) (as described in Section 10) will be fitted to the cable end on board the CLV. The CPS will provide stability to the cable and protect its integrity both during and post-installation;
- The CLV will recover a pre-installed messenger wire from the jacket which will be attached to a winch wire, and the wire will be winched to the deck of the CLV and connected to the CPS;
- The CLV will then pay out the cable and CPS as the pull-in team on the jacket take in the pull-in winch wire;
- Cable payout from the CLV will continue until the CPS reaches the J-tube bellmouth. J-tubes are steel tubes mounted to the jacket structure that allow the installation of cables by providing a conduit through which the cables can be pulled. The tubes will run from the cable termination points on the jacket down inside the support structure and bend outwards in a ‘J’ shape terminating in a wide bell mouth at the seabed. An ROV could be used to monitor the position of the CPS in relation to the J-Tube bellmouth; and
When the CPS is orientated correctly, payout from the CLV will continue and the CPS will be latched into the bellmouth. Cable pull in will continue until sufficient overlength is pulled onto the jacket platform.

Figure 21 First end cable pull in

9.3.2 Stage 5 – Cable laying

The cable will then be laid by the CLV away from the J-tube on the first jacket towards the second jacket along the planned Inter-array cable route. The lay speed, vessel speed, cable departure angle and tension will be monitored and checked to ensure the cable integrity is maintained throughout the lay.

On completion of the route length, the end of the cable will then be cut, sealed and prepared for second end installation operations. Cutting will take place on the deck of the CLV. The second end will be temporarily laid down in readiness for pull-in through the J-tube of the second jacket structure.

9.3.3 Stage 6 – Second end cable pull in

Once the CLV reaches the jacket at the second end, the following procedure will be followed during second end pull-in:

- As with first end pull-in, the pull-in equipment and personnel will be mobilised to the jacket;
- The CPS will be installed on the cut and sealed cable end on board the CLV;
The CLV will then recover the messenger wire and attach the pull-in winch wire from the second jackets to the cable end. The cable and subsea quadrant will then be passed down the deck and over boarded;

- The cable will be fed into the J-tube bellmouth on the jacket structure and the CPS will be latched into the bellmouth. The subsea quadrant will be lowered as the cable is pulled in to the jacket. Finally, the quadrant will be tilted to lay the cable down on the seabed (Figure 22). The quadrant will then be retrieved and the final bight of cable will be pulled out to the jacket by the winch.

This process will then be repeated for the remaining Inter-array cable lengths, connecting the jackets.

*Figure 22 Quadrant at chute*

9.3.4 Stage 7 – Post-lay cable burial

The post-lay cable burial techniques for the Inter-array cable installation will be undertaken in the same manner as for the OECs. Section 9.2.7 provides information on the cable burial techniques that will be used. It should be noted that the indicative target burial depth of up to 1.0 m for the Inter-array cables differs from that of the OECs (up to 1.5 m).
10 CABLE PROTECTION PLAN

10.1 Introduction

Condition 3.2.1.7 of the Marine Licence requires that the Cable Protection Plan (CPP) must be submitted in the event that cable protection is required and must include the following details:

“The CPP must include surveys that will be undertaken to identify scour protection / armouring works required to protect the cable”

In relation to the surveys to identify the need for scour protection and armouring works, Section 5 provides a summary of the surveys that have been undertaken to ascertain the need for cable protection for the OECs and Inter-array cables.

The following section provides details of the cable protection that will be installed.

10.2 Cable Protection Requirements

It is the intention to bury all of the OECs and Inter-array cables as described in section 9; burial of the cables will provide the most reliable form of cable protection and the need for additional protection is not currently anticipated along the main cable lengths.

In the unlikely event that the cables cannot be buried to a depth sufficient to provide adequate protection due to, for example, unexpected ground conditions, additional cable protection may be required along those sections where inadequate burial is achieved (in the form of, for example, rock protection or concrete mattressing). In this unlikely scenario, AOWFL will seek MS-LOT agreement in consultation with SNH, NLB, MCA and SFF if required.

Where the cables approach the turbine structures, a close fitting CPS will be installed on the OECs and Inter-array cables between the seabed and the J-tube interface to protect and stabilise the cable (Figure 16). The CPS will consist of articulated split pipes and bend restrictors to protect the cables from dropped objects, current induced fatigue, dynamic wave action, vibration and other local hazards at this interface.

In addition, the OECs will be protected within the pre-installed HDPE duct from the OTJB, underneath the Blackdog Burn, out to the seaward duct exit point. The target burial depth of the duct will be up to 1.5 m below the seabed with the duct end laid down on the seabed. The section of the duct extruding from the seabed will be protected using either concrete mattresses or rock bags or buried after the installation of the cable using the trenching tool (Figure 17).
11 CABLE OPERATION AND MAINTENANCE

11.1 Introduction

Condition 25 of the S.36 Consent requires that the CLS must include details of the following:

“the location, the construction methods, and monitoring methods for the grid export cables and cable landfall site”

The following sections set out the monitoring and inspections that will be undertaken during the lifetime of the Development. The OECs and Inter-array cables will be subject to periodic inspection and remote condition monitoring using a distributed temperature sensing (DTS) system. In the Operation Phase, further cable surveys will be undertaken to confirm that cables remain adequately buried.

11.2 Cable Inspection Procedures

Following installation, an assessment will be completed identifying areas of cable at potential risk of exposure in the future. Monitoring will focus on any ‘at-risk’ areas identified. Subject to the findings of the surveys, the frequency of these will be adapted to the appropriate level of risk exposure.

AOWFL will use the installed DTS System to enable continuous remote monitoring of the cable. Any deviation from normal, which would suggest a section of subsea cable has become unburied, will be investigated by ROV and rectified. In addition there will be routine walk downs by AOWFL technicians of the onshore cable to ensure no sections of the cable have become unburied.

11.3 Corrective Actions

In the event of cable failure or exposure, cable sections will be replaced and/or re-buried or cable protection applied. Furthermore, the onshore consent (Aberdeenshire Council Planning Application No. APP/2011/2815) for the project dictates that the cable must be reburied if it becomes exposed on the beach.

In addition, in the event that any section of export or inter-array cable becomes exposed following installation, AOWFL will use reasonable endeavours to re-bury the cable (where technically feasible) as a preference prior to the use of additional cable protection material. In the event that the cables cannot be reburied, to a depth sufficient to provide adequate protection, additional cable protection may be required along those sections subject to exposure. In this unlikely scenario, AOWFL will seek MS-LOT agreement in consultation with SNH, NLB, MCA and SFF if required."
12 COMPLIANCE WITH APPLICATION AND ASSOCIATED ADDENDUM

12.1 Introduction

In addition to the conditions presented in Table 1, Condition 7 of the S.36 Consent states:

“The Development must be constructed and operated in accordance with the terms of the Application and the accompanying Environmental Statement and the Supplementary Environmental Information Statement, except in so far as amended by the terms of the Section 36 consent and any direction made by the Scottish Ministers.”

Section 12.2 sets out how the design parameters of relevance to the CLS comply with the Application, ES, SEIS and Annex 1 of the S.36 Consent letter.

Section 12.3 sets out that the commitments made in the Application, ES and SEIS will be delivered.

Section 12.4 outlines the post-consent consultation with regards to the Cables specifications that has been completed.

12.2 Compliance with the OECs and Inter-array Cable Installation Details Assessed in the Application, ES and SEIS

The ES and associated Supplementary Environmental Information Statement (SEIS) described a range of specification and layout options that could be applied during the construction and operation of the Development.

Since the S.36 Consent and Marine Licences were awarded, the design of the Development and approach to installation has been substantially refined to that described in this CLS (and in other relevant Consent Plans). In order to demonstrate compliance of this refined OECs design, installation methods and cable specifications described in the ES and associated SEIS are compared to the installation methods and specifications detailed within this CLS (see Appendix A).

Note that AOWFL proposes to use 66 kV cables rather than the 33 kV cables that were described in the ES and SEIS. Section 12.4 provides further detail on the consultation that has been undertaken in relation to this change and specifically in relation to EMF effects.

12.3 Delivery of the Cable Installation Related Mitigation Proposed in the ES

The ES and associated SEIS detailed a number of mitigation commitments relevant to the cable installation activities and operational phase. Appendix B sets out where each commitment has been addressed within this CLS.
12.4 Relevant Post-Consent Consultation

Since the award of the S.36 and Marine Licence, the project design optimisation process has progressed. As a result of this process, AOWFL is now proposing to use 66 kV cables rather than the 33 kV cables that were described in the ES and SEIS.

It is AOWFL’s understanding that the 66 kV cables remain within the consented design envelope since the available evidence suggests that EMF field strength is proportional to the current in the conductor cables. The use of 66 kV cables rather than 33 kV cables will reduce the current by a factor of 2 for the same power transmission so that EMF will be correspondingly reduced and the potential impacts on the environment will be no greater than (or less than) those described in the original Application.

Consultation has been undertaken with MS-LOT in relation to the cable specifications. Confirmation has been received from MS-LOT that the 66 kV cables may be considered to lie within the consented envelope and are therefore acceptable (MS-LOT email dated 10/12/15).

Table B1 presents the commitments made by AOWFL in the ES and associated SEIS to mitigation measures relevant to this CLS.

**Table B1 - ES and SEIS Construction-related Mitigation relevant to this CLS**

<table>
<thead>
<tr>
<th>Source and Reference</th>
<th>Details of Commitment</th>
<th>Implementation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ES - Project Description</td>
<td>Cables would be buried in the seabed to a sufficient depth, which would be determined by a burial protection study. Typical burial depths would be in the range of 0.6 m – 3 m.</td>
<td>Indicative target burial depth is up to 1.5 m for OECs and 1.0 m for the Inter-array cables. (Sections 9 and 10 of this CLS.)</td>
</tr>
<tr>
<td>ES - Project Description</td>
<td>Cable Installation All the subsea cables would be buried in order to provide protection from all forms of hostile seabed intervention, such as fishing activity (trawler and otter boards), dragging of anchors and the minor risk of dropped objects. The subsea cables are also buried to ensure stability in the tidal conditions and eliminate the risk of free-spans causing cable fatigue.</td>
<td>All cables will be buried where possible. (Sections 9 and 10 of this CLS.)</td>
</tr>
<tr>
<td>ES - Project Description</td>
<td>The periodic inspections would be carried out according to the supplier’s and Development specifications. The work scope typically includes function and safety tests, visual inspections, analysis of oil samples, inspection of subsea cables and scour protection.</td>
<td>Section 11 of this CLS</td>
</tr>
<tr>
<td>ES - Commercial Fisheries</td>
<td>Operational mitigation: Damage to fishing gear/vessels from exposed cables- Cable burial to 0.6 m depth. Implementation and adherence to standard offshore procedures.</td>
<td>Indicative target burial depth is up to 1.5 m for OECs and 1.0 m for the Inter-array cables. (Sections 9 and 10 of this CLS.)</td>
</tr>
<tr>
<td>ES- Marine and Maritime Archaeology</td>
<td>Avoidance, where practicable, is the preferred mitigation strategy for known cultural heritage assets. Minor amendments to the position of cable trenching and the configuration or placement of the foundation of WTG 8 (now called AWF07) were made prior to the submission of the ES. Best practice and effective monitoring may be partly achieved by implementing the Crown Estate reporting protocol. An Archaeological Plan will be included in the Offshore Environmental Management Plan (OEMP).</td>
<td>Surveys outlined in Section 5 demonstrate commitment to avoid known cultural heritage assets. Amendments to cable trenching position also made prior to ES being submitted. Archaeological Plan to be included in the OEMP.</td>
</tr>
<tr>
<td>ES- Salmon and Sea Trout</td>
<td>Cables will be buried</td>
<td>Indicative target burial depth is up to 1.5 m for OECs and 1.0 m for the Inter-array cables. (Sections 9 and 10 of this CLS.)</td>
</tr>
