11B Apportioning Effects to SPA Colonies During the Breeding and Non-Breeding Seasons

11B.1 Introduction

1 Following the advice received in the Scoping Opinion from the Marine Scotland Licensing and Operations Team (MS-LOT), the offshore ornithology assessment for the Development focusses on the potential impacts of collisions, displacement and barrier effects on six species of seabirds. These impacts may arise from interactions between the seabird populations and the Inch Cape Offshore Wind Farm (and its associated infrastructure). The seabird species of interest and the different impacts considered relevant to their populations in the breeding and non-breeding periods (as advised in the Scoping Opinion) are detailed below (*Table 11B.1*).

Table 11B.1 The seabird species and impacts scoped into the assessment according to breeding and non-breeding periods

Species	Seasonal period	Collision	Displacement	Barrier effect
Gannet	Breeding	✓	x	x
	Non-breeding	✓	x	x
Kittiwake	Breeding	✓	✓	✓
	Non-breeding	✓	✓*	✓*
Herring gull	Breeding	✓	x	x
	Non-breeding	✓	x	x
Guillemot	Breeding	x	✓	✓
	Non-breeding	x	✓	✓
Razorbill	Breeding	x	✓	✓
	Non-breeding	x	✓	✓
Puffin	Breeding	x	✓	✓
	Non-breeding	x	x	x
*Displacement and barrier effects to kittiwakes in the non-breeding period were assessed in a qualitative way only (following the advice of the Scoping Opinion).				

2 Each of the seabird species of interest is a qualifying feature of one or more breeding colony Special Protection Areas (SPAs) which have connectivity to the Development Area and the associated two kilometre buffer[1], and which have been identified in the Scoping Opinion for

---

[1] Although baseline surveys encompassed the Development Area and four kilometre buffer, the Scoping Opinion advised that the impact assessment should be focussed on the Development Area and two kilometre buffer (see *Chapter 11: Ornithology*).

inclusion in the assessment. Connectivity between these SPAs and the Development Area plus two kilometre buffer is determined using the mean maximum foraging range of the species (*Table 11B.*2, Thaxter *et al.* 2012)[2]. To determine the extent to which the predicted impacts can be attributed to the different SPA populations an apportionment exercise was undertaken. Where relevant, the apportioning of the impacts was undertaken in relation to both the breeding and non-breeding periods. This report presents the details of the approach and methods used for apportioning, along with the subsequent apportionment estimates.

Table 11B.2 Connectivity between the Development Area plus two kilometre buffer and seabird breeding colony SPAs as determined by the SPA being within the mean maximum foraging range of one or more qualifying features

Species	Mean maximum foraging range (km)	SPA			
		Forth Islands	Fowlsheugh	St Abbs Head to Fast Castle	Buchan Ness to Collieston Coast
Gannet	229.4	✓	N/A	N/A	N/A
Kittiwake	60.0	✓	✓	✓	x
Herring gull	61.1	✓	✓	✓	x
Guillemot	84.2	✓	✓	✓	✓
Razorbill	48.5	✓	✓	x	N/A
Puffin	105.4	✓	N/A	N/A	N/A

11B.2 Apportioning of impacts during the breeding period

11B.2.1 Methods

Impacts estimated for the Development

3   The seasonal periods that are used for each of the six seabird species are defined in *Appendix 11A: Offshore Ornithology Baseline Survey Report*. Following the advice provided in the Scoping Opinion, the apportioning of impacts during the breeding season was undertaken using a variation of the approach outlined in existing guidance (SNH, 2016). The Marine Scotland Apportioning Tool, which (at the time of writing) is in the course of development, was not available for use in the assessment[3].

4   The breeding colonies of each of the species of interest, which were within the mean maximum foraging range (Thaxter *et al.* 2012) of the Development Area plus two kilometre

---

[2] This is on the basis of the closest distance between the Development Area plus two kilometre buffer and the breeding colony of interest.
[3] Email of 07 November 2017 from MS-LOT to ICOL.

buffer were first identified. The Seabird 2000 census data 1998 – 2002[4] provided the source information on breeding colony locations, using the 'site' (as opposed to the 'sub-site') level for non-SPAs and the appropriate amalgamation of 'sites' for the SPAs.

5   For each species, the proportion of the impacts attributed to each colony within foraging range of the Development Area and two kilometre buffer was estimated on the basis of:

- The population size of each colony (as numbers of individuals) – N;

- The distance from each colony to the Development Area plus two kilometre buffer – D; and

- The proportion of open sea within the foraging range of each colony – Psea.

6   A weighting value (W) was then calculated for each colony population as:

$$W = (N / \text{Sum of } N) * (\text{Sum of } (D^2) / D) * ((1\text{-Psea}) / (\text{Sum of } (1\text{-Psea}))).$$

The weighting values for the different colonies were then summed, with the proportion of the impacts attributable to each colony being taken as the colony weight divided by the sum of the weighting values. The weighting assumes that colonies within foraging range of the Development Area plus two kilometre buffer would contribute more birds to the on-site population (and therefore experience greater impacts) where they are larger, are closer to the Development Area (and buffer) and have a smaller proportion of open sea within their foraging range. The effect of colony distance is treated as the square term (as opposed to the linear term) because the expectation is that bird densities would decrease in proportion to the increasing area of sea as distance from the colony increases (SNH, 2016).

7   For the purposes of this calculation, distance from the colony to the Development Area plus two kilometre buffer was measured from the approximate central points of each. In the case of the Forth Islands SPA, which comprises a number of widely distributed islands, the distance was taken to the island holding the largest population size (e.g. the Bass Rock in the case of gannet but the Isle of May in the case of kittiwake).

8   It is important that the count data for the colonies considered in the apportionment calculation should be concurrent, or at least derive from a similar time period (SNH, 2016). In the case of the colonies within foraging range of the Development Area plus two kilometre buffer, recent counts are available for the SPA colonies but for many of the non-SPA colonies there have been no counts since the Seabird 2000 census, undertaken from 1998 to 2002 (Mitchell *et al.* 2004). Therefore, to maximise the value of the existing colony count data, the apportionment calculation described above was undertaken in two steps (following the advice in the Scoping Opinion), as follows:

- Apportioning impacts with the SPA and non-SPA colonies included using the Seabird 2000 counts; and

---

[4] Source - http://jncc.defra.gov.uk/page-4460 [Accessed 15/05/18]

- For the proportion of the impacts assigned to the SPA component, re-apportioning these using the recent count data for the SPA colonies.

9   This two-step process was applied to all species other than gannet, for which there was only one non-SPA colony within mean maximum foraging range (i.e. Troup Head). A count for Troup Head was available from the same year (2014) as the most recent count of the Forth Islands SPA population (*Appendix 11A*), so that the apportionment calculation was undertaken in a single stage.

10   The Seabird 2000 colony count data used in the apportionment calculation were as used by Scottish Natural Heritage (SNH) in the apportionment calculations for gannet, kittiwake and herring gull undertaken for the 2014 *Appropriate Assessment of the Forth and Tay wind farms* (MS-LOT 2014), whilst for guillemot, razorbill and puffin the count data were extracted from the Seabird 2000 census data 1998 – 2002[4]. The recent colony counts used for the SPAs in step two were as provided by SNH in their scoping advice.

Impacts estimated for other wind farms

11   As advised in the Scoping Opinion, breeding season impacts from the other three Forth and Tay wind farms (i.e. Neart na Gaoithe and Seagreen Alpha and Bravo) were estimated quantitatively for incorporation into the cumulative impact assessment. Therefore, it was necessary to also apportion the impacts from these wind farms to the SPA populations with connectivity to the Development Area and two kilometre buffer. For the purposes of this apportionment exercise, Seagreen Alpha and Bravo were treated as a single site given that they are adjoining along their longest boundary.

12   The apportionment calculation for these wind farms was undertaken exactly as for the Development Area and two kilometre buffer, identifying those colonies with connectivity to each of these wind farms (plus a two kilometre buffer) in the same way as for the Development Area and two kilometre buffer.

11B.2.2 Apportionment estimates for the breeding period

13   Based upon calculations undertaken by the approach described above, the apportionment estimates for each of the key seabird species at each of the SPAs with connectivity to the Development Area and two kilometre buffer are presented below (*Table 11B.3*, with copies of the full data used to derive the estimates in *Annex 11B.1*). These estimates are presented for the Development and the other Forth and Tay wind farms.

Table 11B.3 The estimated apportionment of breeding period impacts from the Development and the other Forth and Tay wind farms for each of the seabird breeding colony SPA populations with connectivity to the Development Area plus two kilometre buffer

Wind farm	Species	SPA / colony	Seabird 2000 population estimate (individuals)[1]	Recent population estimate (individuals)[1]	Proportion of impacts attributable to colony / SPA when comparing across all colonies using seabird 2000 counts	Proportion of impacts attributable to SPA after re-apportioning of SPAs using recent colony counts

[1]The apportionment calculations are undertaken using the number of individuals estimated at the colony. For guillemot and razorbill this is the direct count of individuals but for other species it is the count of breeding pairs or apparently occupied sites multiplied by two. The recent estimates are as provided by SNH (email of 08 December 2017 from MS-LOT to ICOL).

[2]Recent count data are available for all gannet colonies included, so that the Seabird 2000 data are not used for this species (see text).

11B.3 Apportioning of impacts during the non-breeding periods

11B.3.1 Approaches used for each species

14 In contrast to the breeding period, for which the same approach to apportioning was applied to each species, the approaches used to apportion impacts to the different SPA populations in the non-breeding periods varied between species. This reflects differences in the passage movements and wintering areas used by each of the seabird species of interest, whereas during the breeding period a common approach is warranted on the basis that all of these seabird species are central place foragers (i.e. their available foraging area is constrained by the need to return to the breeding colony to attend nests and chicks). The approaches used to apportion impacts during the non-breeding period followed the advice provided in the Scoping Opinion, except in the case of herring gull for which a simpler (but more precautionary) approach was applied on the basis that the predicted impacts were small.

15 For guillemot and razorbill, impacts during the non-breeding period were apportioned using the breeding season estimates for these species. This was on the basis that many of the adults remain in the vicinity of the breeding colonies throughout the year, with frequent records of adult guillemots returning to their nest sites from October (Brown & Grice 2005, Harris *et al.* 2006). However, birds from these breeding populations may also winter further afield in the North Sea, whilst the wintering populations of both species in the Outer Forth region are likely to be augmented by birds from more northern breeding colonies (Furness 2015). Therefore, applying the breeding period apportionment to the non-breeding period is likely to overestimate the impacts to the SPA populations (and is precautionary).

16 For puffin, no assessment of impacts during the non-breeding period has been undertaken, as they migrate rapidly from their UK breeding areas, leaving the sea areas immediately adjacent to their colonies by late August (Wernham *et al.* 2002, Harris & Wanless 2011).

17 The advice from the Scoping Opinion for apportioning the non-breeding season impacts on herring gulls was to identify a suitable regional population for the Forth and Tay region, and to estimate the proportion of this population which is likely to derive from the regional SPA breeding population. This would be estimated within the context of UK breeding populations (particularly on the east coast) being augmented by large numbers of birds from northern Europe (Furness 2015), and a likely halving in the proportion of the wider population that comprises adult birds from SPA populations between the breeding and non-breeding periods (Furness 2015). However, because the estimated impacts to herring gulls were low it was considered sufficient to apply the breeding season apportioning estimates (which, for the non-breeding period, are highly precautionary).

18 Apportioning of the estimated collision impacts to gannet and kittiwake during the non-breeding season had to account for the passage movements of these species, which may take a proportion of the SPA populations through other offshore wind farms outside the Forth and Tay region. For both of these species, the non-breeding period was split into autumn and spring passage periods, and the apportioning estimates took account of offshore wind farms

in the UK North Sea and Channel for gannet and the UK North Sea for kittiwake. The approaches taken to apportioning the collision estimates from the relevant wind farms to the SPA populations of each of these species are detailed in the specific sections below.

19   The advice from the Scoping Opinion was that only a qualitative assessment of displacement impacts was required for kittiwake during the non-breeding season, whilst no assessment of displacement impacts on gannet was required (*Table 11B.1*). As such, no apportioning of non-breeding season impacts from displacement was required for either species.

11B.3.2 Apportioning gannet collisions during passage periods

Methods

20   The Forth Islands SPA is the only seabird colony SPA with connectivity to the Development Area and two kilometre buffer on the basis of breeding gannet as a qualifying feature (Table 11B.2). The approach taken to estimating the collisions to the Forth Islands SPA gannet population during the autumn and spring passage periods followed that used for apportioning collisions to the Flamborough Head and Filey Coast proposed SPA (pSPA) gannet population in the assessment for the East Anglia THREE wind farm (MacArthur Green, 2015a, Royal HaskoningDHV *et al.,* 2015), and was as agreed in correspondence between ICOL, SNH and MS-LOT[5].

21   This approach uses the Biologically Defined Minimum Population Scales (BDMPS) (Furness 2015) as its basis but with updated information on; (i) the sizes of some of the gannet breeding populations that are deemed to have connectivity to the North Sea during passage periods; and (ii) flight directions (from tracking studies), which enables re-estimation of the proportion of passage birds flying through the North Sea in autumn and spring.

22   The initial collision estimates for gannet at the UK North Sea and Channel wind farms during the autumn and spring passage periods are provided in the East Anglia THREE assessment (see Table 3.6 in Royal HaskoningDHV *et al.,* 2015). However, these estimates were updated in line with the report on Estimates of Ornithological Headroom in Offshore Wind Farm Collision Mortality (MacArthur Green, 2017), which provides a correction factor to revise the annual estimates on the basis of the differences in the 'as built' and 'as consented' wind farm designs. Where the 'as consented' collision estimate for a wind farm differed between the 'Ornithological Headroom' report and the East Anglia THREE assessment, then the value from the 'Ornithological Headroom' report was used as the basis for the calculation (following the advice provided by SNH[5]).

23   For the Development and the other three Forth and Tay wind farms, the collision estimates used were as calculated in the current assessment, using the 2017 design for the Development and the 2014 designs for the other Forth and Tay wind farms (*Appendix 11C: Estimation of the Development-alone and Cumulative Collisions*).

---

[5] Emails of 01 and 08 November 2017 from MS-LOT to ICOL, and of 8 November 2017 from ICOL to MS-LOT.

24   In addition, the seasonal periods for gannet used in the East Anglia THREE assessment differed from those used in the current assessment (and as advised in the Scoping Opinion). Thus, the autumn and spring passage periods were assumed to be September to November and December to March, respectively, in the East Anglia THREE assessment, whilst in the current assessment they were October to November and December to mid-March, respectively. Consequently, the passage collision estimates provided in the East Anglia THREE assessment (and as amended following MacArthur Green 2017) were corrected according to the differences in the assumed lengths of the respective passage periods (e.g. the collision estimates for the autumn passage period were multiplied by 0.67 to account for the shorter period assumed in the current assessment). This correction was not applied to the collision estimates for the Development or the other Forth and Tay wind farms because these had been calculated according to the seasonal periods advised in the Scoping Opinion.

25   To apportion the estimated collisions at each wind farm, it is assumed that during autumn passage, 63 per cent of gannets from the Forth Islands SPA population (comprising adults, immatures and juveniles) fly south through the North Sea and Channel, with the remainder passing around the north of Scotland before heading south on a route to the west of Ireland (Furness 2015). During spring passage, it is assumed that 27 per cent of gannets from the Forth Islands SPA population (comprising adults and immatures) fly north through the North Sea and Channel, with the remainder taking the westerly route north (Furness 2015, MacArthur Green 2015a). These percentages are used to estimate the proportion of the Forth Islands SPA population that take passage routes within which each wind farm in the UK North Sea and Channel occurs, according to whether the wind farm is north or south of the SPA.

26   During these passage periods, varying proportions of other gannet populations from elsewhere in the UK and northern Europe also pass through the North Sea and Channel, and it is assumed that there is even mixing amongst the birds from the various populations and amongst the different age classes of these populations. The estimated sizes of these populations and assumed proportions passing through the North Sea and Channel are taken from Table 2.2 in MacArthur Green (2015a).

27   Most of these other gannet populations derive from breeding colonies that are to the north of all of the wind farms in the UK North Sea and Channel, so that the proportion of each population that is assumed to have the potential to pass through these wind farms is constant. However, the Troup Head, and Flamborough Head and Filey Coast pSPA populations may pass through wind farms to the north or south of these colonies, as for the Forth Islands SPA population. These populations are assumed to use the same passage routes as the Forth Islands SPA population in equivalent (for Troup Head) or similar (for Flamborough Head and Filey Coast) proportions. Also, birds from the population only have potential to pass through wind farms that are to the south of this colony. As such, the total gannet population size estimated to have the potential to pass through the different wind farms in the UK North Sea and Channel differs between some of these wind farms.

28   The percentage of breeding adults in these populations is estimated to be 55 per cent during both passage periods (with an estimated 26 per cent immatures and 19 per cent juveniles during autumn passage and 45 per cent immatures during spring passage), as derived from

the stable age structure of a population model for gannet (Furness 2015). The values from this age structure are used to estimate the total number of birds from each population which contribute to the North Sea and Channel passage populations (subject to the proportions that take the different passage routes, as detailed above). This estimate of the breeding adult component differs from the estimate of 60 per cent in the Forth Islands SPA population, as calculated from the stable age structure of the Forth Islands SPA gannet population model that has been produced to inform the current assessment (*Appendix 11E: Population Viability Analyses*). However, incorporating the stable age structure estimate which is specific to the Forth Islands SPA population would make little difference to overall calculations.

29   Using the above information, the total gannet population that has the potential to pass through each of the wind farms in the UK North Sea and Channel during each of the autumn and spring passage periods can be estimated. The proportion of this total population that is attributed to the Forth Islands SPA population is then used to apportion the estimated collisions at each wind farm in each passage period to the SPA population. The values derived from this apportionment are then summed to give the total autumn and spring passage collision estimates for the Forth Islands SPA population. For the Development and the other Forth and Tay wind farms, the seasonal-specific age distribution, as recorded during the baseline surveys, is used to allocate these collisions to the different population age classes (*Appendix 11A* and *Appendix 11E*), with the age distribution from Furness (2015) applied to the collisions from the remaining wind farms in the UK North Sea and Channel.

Collision estimates for the Forth Islands SPA gannet population during autumn and spring passage periods

30   The estimated number of gannet collisions at each wind farm in the UK North Sea and Channel during both the autumn and spring passage periods, together with the proportion of these collisions attributed to the Forth Islands SPA population, is detailed below (*Table 11B.4*). Overall, a total of 117 gannet collisions are attributed to the Forth Islands SPA population during autumn passage and 63 during spring passage.

31   For the autumn passage period, 14 of the 117 collisions result from the Development and the other Forth and Tay wind farms, of which 13 are assigned to the breeding adult age class (based on 89 to 97 per cent of gannets being recorded in adult plumage in the respective surveys during the autumn passage period – *Appendix 11A* and *Appendix 11E*). The remaining wind farms in the UK North Sea and Channel account for 102 collisions, of which 56, 27 and 19 are assigned to the adult, immature and juvenile age classes, respectively (noting that the small differences in the above totals relate to rounding errors and that the actual calculations of the collision estimates use the values taken to one decimal place as in *Table 11B.4*).

32   For the spring passage period, 27 of the 63 collisions result from the Development and the other Forth and Tay wind farms, of which 26 are assigned to the breeding adult age class (based on 98 to 99 per cent of gannets being recorded in adult plumage in the respective surveys during the spring passage period – *Appendix 11A* and *Appendix 11E*). The remaining wind farms in the UK North Sea and Channel account for 36 collisions, of which 20 and 16 are assigned to the adult and immature age classes, respectively.

33   Therefore, during autumn passage a total of 69, 27 and 20 collisions of adult, immature and juvenile gannets, respectively, are apportioned to the Forth Islands SPA population. During the spring passage, a total of 46 and 17 collisions of adult and immature gannets, respectively, are apportioned to the Forth Islands SPA population.

Table 11B.4 The apportionment of gannet collisions estimated at UK North Sea and Channel wind farms to the Forth Islands SPA population during the autumn and spring passage periods

Wind farm	Autumn passage						Spring passage					
	Estimated population on passage route		Total collisions estimated at wind farm		Collisions apportioned to Forth Islands SPA		Estimated population on passage route		Total collisions estimated at wind farm		Collisions apportioned to Forth Islands SPA

[1]The total number of birds estimated to use the passage route differs between wind farms because the proportion of birds taking the passage route through the North Sea and Channel differs between colonies, so that the estimated number varies according to which colonies occur to the north and south of the wind farm (see text).

[2]Collision estimates for the consented design are taken from MacArthur Green (2017) and Royal HaskoningDHV *et al.* (2015), with precedent given to the estimate provided in MacArthur Green (2017) in the case of discrepancies between these two sources. MacArthur Green (2017) provides annual collision estimates only (as opposed to estimates for each seasonal period) so that the seasonal estimates in Royal HaskoningDHV *et al.* (2015) are adjusted accordingly in the case of such discrepancies.

[3]Collision estimates for the built design are calculated from the values for the consented design using the wind farm-specific conversion factors provided in MacArthur Green (2017).

[4]The seasonal adjustment is applied because of the differences in the seasonal periods used by MacArthur Green (2015a) and Royal HaskoningDHV *et al.* (2015) and those used in the current assessment (and as advised in the Scoping Opinion).

[5]Collision estimates for the Development and the other Forth and Tay wind farms are derived from the collision risk modelling undertaken for the current assessment and not from MacArthur Green (2017) and Royal HaskoningDHV *et al.* (2015). As such, no adjustment for seasonal period is required (see text).

11B.3.3 Apportioning kittiwake collisions during passage periods

Methods

34   Three seabird colony SPAs were identified as having connectivity to the Development Area
        and two kilometre buffer on the basis of breeding kittiwake as a qualifying feature – i.e. Forth
        Islands, Fowlsheugh, and St Abbs Head to Fast Castle (Table 11B.2). As for gannet, the
        approach taken to estimating the collisions attributable to these SPA kittiwake populations
        during the autumn and spring passage periods followed that used for apportioning collisions
        to the Flamborough Head and Filey Coast pSPA kittiwake population in the assessment for the
        East Anglia THREE wind farm (MacArthur Green 2015b, Royal HaskoningDHV *et al.* 2015). This
        approach is based upon the BDMPS for kittiwake (Furness 2015).

35   The initial collision estimates for kittiwake at the UK North Sea wind farms during the autumn
        and spring passage periods are provided in the East Anglia THREE assessment (see Table 3.7
        in Royal HaskoningDHV *et al.* 2015). However, these estimates were updated in line with the
        report on Estimates of Ornithological Headroom in Offshore Wind Farm Collision Mortality
        (MacArthur Green 2017), which revises the annual estimates on the basis of the differences
        in the 'as built' and 'as consented' wind farm designs. Where the 'as consented' collision
        estimate for a wind farm differed between the 'Ornithological Headroom' report and the East
        Anglia THREE assessment, then the value from the 'Ornithological Headroom' report was used
        as the basis for the calculation (following the advice provided by SNH – email of 1 November
        2017 from MS-LOT to ICOL).

36   For the Development and the other three Forth and Tay wind farms, the collision estimates
        used were as calculated in the current assessment, using the 2017 design for the Development
        and the 2014 designs for the other Forth and Tay wind farms (*Appendix 11C*).

37   In addition, the seasonal periods for kittiwake used in the East Anglia THREE assessment
        differed from those used in the current assessment (and as advised in the Scoping Opinion).
        Thus, the autumn and spring passage periods were assumed to be August to December and
        January to April, respectively, in the East Anglia THREE assessment, whilst in the current
        assessment they were September to December and January to mid-April, respectively.
        Consequently, the passage collision estimates provided in the East Anglia THREE assessment
        (and as amended following MacArthur Green 2017) were corrected according to the
        differences in the assumed lengths of the respective passage periods (e.g. the collision
        estimates for the autumn passage period were multiplied by 0.80 to account for the shorter
        period assumed in the current assessment). This correction was not applied to the collision
        estimates for the Development or the other Forth and Tay wind farms because these had been
        calculated according to the seasonal periods advised in the Scoping Opinion.

38   The North Sea kittiwake passage populations derive from breeding colonies in Britain and
        elsewhere in Europe, particularly Russia, Norway and the Faeroe Islands (Furness 2015). For
        the purposes of this exercise, the population-size estimates for these different colonies and
        countries are taken from Table 2.2 in MacArthur Green (2015b), as are the proportions of the

adult and sub-adult[6] birds from these populations that are considered to contribute to the North Sea autumn and spring passage populations (with these proportions being derived from Furness (2015) originally). Thus, it is assumed that 60 per cent of the adult kittiwakes from each of the Forth Islands SPA, Fowlsheugh SPA and St Abbs Head to Fast Castle SPA populations occur in the North Sea during both passage periods, whilst 40 per cent of the sub-adults from these SPA populations occur in the North Sea during autumn passage and 30 per cent during spring passage.

39   The number of sub-adult birds associated with each of the breeding populations that contribute to the North Sea passage populations is calculated on the basis of an estimated age structure comprising 53 per cent adults (as derived from a population model), so that the number of sub-adults equates to 89 per cent of the estimated number of breeding adults (Furness 2015, MacArthur Green 2105b). This age structure is a close match to the 55 per cent of adults derived from the SPA-specific population models produced to inform the current assessment (*Appendix 11E*).

40   The kittiwake colony population estimates used in the East Anglia THREE assessment for the three SPAs with connectivity to the Development Area and two kilometre buffer derive from slightly older counts (2012 – 2013) than those provided by SNH as part of their scoping advice. However, these older counts are a closer temporal match to the other count data used in this apportionment exercise and so are retained in the current calculation.

41   As for gannet above, it is assumed that there is even mixing of the birds from the different colonies and populations included in the apportionment calculation, as well as amongst the different age classes, within the UK North Sea. Thus, the autumn and spring passage period collision estimates for each wind farm in the UK North Sea are apportioned to each of the three SPA populations with connectivity to the Development Area and two kilometre buffer according to the proportion of the estimated total passage population represented by each of these SPA populations.

Collision estimates for Forth Islands SPA, Fowlsheugh SPA and St Abbs Head to Fast Castle SPA kittiwake populations during the autumn and spring passage periods

42   The kittiwake collision estimates for the wind farms in the UK North Sea during the autumn and spring passage periods are apportioned to the three SPA populations of interest (i.e. Forth Islands, Fowlsheugh, and St Abbs Head to Fast Castle) according to the proportion of the respective North Sea passage population which is estimated to comprise birds from each of these SPAs (*Table 11B.5*). This is estimated separately for the breeding adult and sub-adult age classes.

43   Based upon these estimated proportions, the estimated numbers of collisions at each wind farm in the UK North Sea for the adult and sub-adult age classes of these three SPA

---

[6] The term sub-adult is used where no distinction is made between juveniles and immatures.

populations during autumn and spring passage are presented in *Table 11B.6*. These data suggest the following autumn and spring passage collision estimates at each SPA:

- Forth Islands SPA - 3.8 adults and 1.8 sub-adults during autumn passage and 4.0 adults and 1.8 sub-adults during spring passage.

- Fowlsheugh SPA – 9.5 adults and 5.6 sub-adults during autumn passage and 12.0 adults and 5.3 sub-adults during spring passage.

- St Abbs Head to Fast Castle SPA – 3.4 adults and 2.0 sub-adults during autumn passage and 4.4 adults and 1.9 sub-adults during spring passage.

44   During the autumn passage period approximately 30 per cent of these estimated collisions (for both adults and sub-adults) are attributed to the Development and the other Forth and Tay wind farms, whilst during spring passage approximately 14 per cent are attributed to the Development and the other Forth and Tay wind farms (*Table 11B.6*). In contrast to the calculations for apportioning gannet collisions to the Forth Islands SPA during the passage periods (see *Section 11B.3.2*), the approach taken for kittiwake did not allow for the age distributions recorded during the respective baseline surveys (and as based upon plumage characteristics) to be applied to the passage collision estimates which were attributable to the Development and the other Forth and Tay wind farms. This is because the kittiwake apportioning relies on using estimates of the proportion of the different age classes from each breeding population which occur in the North Sea during each passage period.

45   The baseline surveys for the Development recorded 59 percent and 83 per cent of kittiwakes in adult plumage during the autumn and spring passage periods, respectively (*Appendix 11A*). The equivalent values for the other Forth and Tay wind farms ranged from 57 to 72 percent during autumn passage and 79 to 83 per cent during spring passage. However, age distributions as recorded from plumage characteristics will overestimate the proportion of breeding adults (because kittiwakes generally adopt adult plumage before reaching breeding age – *Appendix 11A*), whilst the contribution of the Development and the other Forth and Tay wind farms to the overall collisions apportioned to the three SPAs of interest during the passage periods was limited. Therefore, any underestimation of the passage period collisions apportioned to the Forth Islands SPA, Fowlsheugh SPA and St Abbs Head to Fast Castle SPA populations as a result of using an estimated stable age distribution with 53 per cent adults will be small.

Table 11B.5 The estimated autumn and spring passage populations of kittiwakes in the North Sea, with the proportional contributions of the Forth Islands SPA, Fowlsheugh SPA and St Abbs Head to Fast Castle SPA populations (after MacArthur Green 2015b)

Passage period	Age class	Number of individuals (with percentage of total North Sea population (adults plus sub-adults) represented by each SPA population age class)			
		North Sea	**Forth Islands SPA**	**Fowlsheugh SPA**	**St Abbs Head to Fast Castle SPA**
Autumn	Adults	480,815	3,720 (0.45%)	11,204 (1.35%)	4,084 (0.49%)
	sub-adults	349,028	2,182 (0.26%)	6,571 (0.79%)	2,395 (0.29%)
Spring	Adults	375,815	3,720 (0.59%)	11,204 (1.78%)	4,084 (0.65%)
	sub-adults	251,944	1,637 (0.26%)	4,928 (0.79%)	1,796 (0.29%)

Table 11B.6 The apportionment of kittiwake collisions estimated at UK North Sea wind farms to the Forth Islands SPA, Fowlsheugh SPA and St Abbs Head to Fast Castle SPA populations during the autumn and spring passage periods. The SPA collisions are presented according to age class (Ad = adults, Sub = sub-adults).

[1]Collision estimates for each age class of each SPA population are calculated by applying the percentage values from *Table 11B.5* to the seasonally adjusted wind farm estimate.

[2]Collision estimates for the consented design are taken from MacArthur Green (2017) and Royal HaskoningDHV *et al.* (2015), with precedent given to the estimate provided in MacArthur Green (2017) in the case of discrepancies between these two sources. MacArthur Green (2017) provides annual collision estimates only (as opposed to estimates for each seasonal period) so that the seasonal estimates in Royal HaskoningDHV *et al.* (2015) are adjusted accordingly in the case of such discrepancies.

[3]Collision estimates for the built design are calculated from the values for the consented design using the wind farm-specific conversion factors provided in MacArthur Green (2017).

[4]The seasonal adjustment is applied because of the differences in the seasonal periods used by MacArthur Green (2015b) and Royal HaskoningDHV *et al.* (2015) and those used in the current assessment (and as advised in the Scoping Opinion).

[5]Collision estimates for the Development and the other Forth and Tay wind farms are derived from the collision risk modelling undertaken for the current assessment and not from MacArthur Green (2017) and Royal HaskoningDHV *et al.* (2015). As such, no adjustment for seasonal period is required (see text).
