1 Introduction

This report has been prepared to set out the Best Practicable Environmental Option (BPEO) in support of the marine licence application for dredging and disposal at sea of dredge arising within the boundary of Port Edgar Marina, the 'Site', as shown on the City of Edinburgh Council drawing, **Plan 2 -** all drawings referred to in this report are included in **Appendix A**.

The aim of the BPEO is to provide confidence following pre-disposal sampling, that the dredge arising is suitable for disposal within the confines of Port Edgar Marina; whilst the objectives are to:

- Describe dredge arising material.
- Interpret chemical and physical analysis of pre-disposal sampling and demonstrate consideration for disposal options as required by Marine Scotland guidance.
- Identify, minimise, manage and mitigate for potential environmental impacts.
- Demonstrate a consideration for, and a commitment to manage through a bio-security plan, invasive non-native species (INNS) within the Site.

The operator, Port Edgar Marina Ltd, are seeking to obtain a Capital Dredging Licence (CDL) to carry out plough dredging of the east and west sides of the old West Pier situated in the west side of the marina basin. This area was historically dredged and utilised as a naval port. However, as this area has not been dredged within the past seven years it is classed as a new site as regards capital dredging.

As a result of sedimentation, the operator currently undertakes regular (annual) maintenance plough dredging (**licence No. 06629/19/0**),for the area shown on drawing **122592/7003**,to maintain a sufficient depth for the continued operation of the port as an active marina. Anecdotal evidence suggests that construction activity relating to nearby bridge piers in recent years may have caused an additional volume of sediment to be deposited local to and within the confines of the marina.

The foreshore surrounding the West Pier within the Port Edgar Marina is a Site of Special Scientific Interest (SSSI) (SNH site code 8163, Firth of Forth), a Special Protection Area (SPA) (SNH site code 8499, Firth of Forth), and is in close proximity to a RAMSAR[1] site. These designations apply due to the area supporting a number of migratory overwintering, breeding and non-breeding bird populations. The designated sites are shown on drawing **WS/122592A/0003**, which also shows the proposed dredging area in relation to these designated areas as well as the pre-disposal sampling locations, and the location proposed for disposal of dredge arising. The proposed dredging, which may affect these sites, is to a maximum of 1.5 m (variable) depending on depth encountered. The dredging undertaken will remove silt some of which is both anoxic and is contaminated with hydrocarbons, likely to have built up over the preceding decades since the West Pier was last utilised. Post-dredging, mud and silt will remain exposed at low-tide and will continue to provide valuable habitat as regards the qualifying features of the designated sites.

[1]RAMSAR Convention on wetlands of international importance, Ramsar, Iran, 1971

2 Proposed Dredging

Potential options considered as regards dredging are listed and considered below:

- Do-nothing
- Dredging via excavator and hopper-barge
- Dredging via water injection
- Dredging via plough

Do-nothing: capital dredging is required so as to achieve sufficient water depth for the installation of pontoons and mooring of vessels. If dredging does not take place, the siting of pontoons with the intention of bringing the West Pier back into economic use at Port Edgar would not be considered viable. Do-nothing is therefore not considered.

Dredging via water injection: this method has been previously been undertaken within Port Edgar by water injection. This method proved to be ineffective due to insufficient tidal current within the marina to remove and redistribute the excavated sediment - this method was therefore discounted.

Dredging via excavator and hopper-barge: dredging has previously been carried out using this method within Port Edgar. However, this proved to be inefficient when considering the commercial cost-benefit to the marina operator - this method was therefore discounted.

Dredging via plough: plough dredging is in line with current practice which has been consented for use by Marine Scotland at the marina associated with aforementioned licences for capital dredging and ongoing maintenance dredging; and is considered to be the most suitable option to move material from the area surrounding the West Pier to the disposal point shown at the north east corner of the marina. A dredging method statement is included as (**Appendix B**).

It is proposed that an initial 20,000m^3 will be dredged over a period of 30 days. It is anticipated that annual maintenance dredging will be required for up to 10,000m^3.

The dredge arising to be removed is predominantly of estuarine fine-grained sediments including silts and clays, deposited within the inter-tidal zone of the Forth Estuary. The sediment has been tested in accordance with the guidelines set out in the Marine Scotland pre-disposal sampling guidance document.

As a pre-requisite to the CDL, pre-disposal sampling with Port Edgar Marina was carried out on 30th September 2019 and consisted of three cores to a depth of 1.5m CD. Cores were recovered using a Specialty Devices Incorporate (SDI) Vibrocore-4D system. Recovered cores were delivered to a United Kingdom Accreditation Service (UKAS) accredited laboratory, and were analysed against Marine Scotland's standard suite of pre-disposal sampling parameters.

A summary of materials recovered from within the core samples taken and interpreted by, Aspect Land & Hydrographic Surveys Ltd in their Report of Survey (**Appendix C**), is provided in **Table 1** below. Cores were recovered from the locations shown on drawings **122592A/WS/0002** and **122592A/WS/0003**. Full results from laboratory analysis on contaminants are provided in **Appendix D.**

Table 1 Core sample descriptions from Sampling carried out 30th September 2019

Sample	Material Description
Core 1	0.0 to 0.5 m Dark Brown/ Black Silt 0.5 to 1.0 m Anoxic Black Silt 1.0 to 1.5 m Black/ Brown Silt
Core 2	1.0 to 0.5 m Black/ Brown Silt 0.6 to 1.0 m Silt 1.0 to 1.5 m Firm Silt
Core 3	2.0 to 0.5 m Soft Dark Brown Silt 0.7 to 1.0 m Soft Brown Silt 1.0 to 1.15 m Soft Brown Silt 1.15 to 1.5 m Stiff Silt

3 Results

A summary of results for contaminants across each of the cores (1, 2 and 3) is compared with the AL (1) and AL (2) thresholds outlined in the, Marine Scotland Pre-disposal Sampling Guidance Verion-2 November 2017, in **Table 3** and **Table 4** below.

Table 2 Lab Results of Contaminants and Exceedances of AL 1 & AL2

Contaminant of concern	**AL 1 threshold** mg/kg dry weight (ppm)	**Lab Results** mg/kg dry weight (ppm)	**Exceedance of AL1** mg/kg dry weight (ppm)	**Percentage exceedance** (%)

Nickel (Ni)	150	15.5	-	-
Lead (Pb)	400	32.8	-	-
Zinc (Zn)	600	67.1	-	-

4 Interpretation of results

When comparing results from the 2019 pre-disposal sampling, with results from the 2018 pre-disposal sampling reported in the 2018 BPEO report (**Appendix E**), fewer parameters exceeded the Marine Scotland thresholds. Whilst it is noted that the areas concerned with sampling undertaken during 2018 and 2019 were different, both areas are separated only by a short distance of approximately 150 m within the marina. It is considered likely that the distribution and concentration of contaminants in sediments within the marina is also likely to be affected by the tidal movements shifting sediments within the marina.

In total, 22 parameters were analysed. None of the metals recorded a value which exceeds the thresholds, compared with 2018 where each of the metals recorded a value in exceedance of the thresholds. Of the hydrocarbon parameters analysed, all recorded a value in exceedance of the thresholds. When compared against results from 2018, eight parameters recorded an increase, whilst seven recorded a decrease. Overall however, 13 out of the 22 parameters were shown to have improved when compared against samples analysed in 2018.

5 Environmental Impact

Consideration has been given to options as regards the disposal of dredge arising from the dredging activities. Options considered are listed below:

- Agricultural spreading
- Beach nourishment
- Construction industry
- Land reclamation, landfill and Incineration
- Sea disposal

Sampling undertaken has shown that the dredge arising is likely to contain contaminants in excess of Marine Scotland action levels. As such this means that dredge arising is likely to be unsuitable in respect of a number of the options outlined above. Considerations for each of the options have been outlined below:

Agricultural spreading: would require that the dredge material be pre-treated before it could be considered suitable for use, the contamination also presents a health and safety risk; combined with costs associated with transportation and handling of the material this option was not considered to be suitable.

Beach nourishment: due to the likely composition of dredge arising following pre-disposal sampling, the material was shown to consist almost entirely of fine silts and clays. This would make it unsuitable for such uses as the fine particle sizes are less stable and prone to accelerated rates of erosion.

Construction industry: uses for onshore construction including cement manufacture were considered; however, as the material has been classed as soft silty material it is not considered suitable for uses within the construction industry.

Land reclamation, landfill and incineration: given the likelihood of contamination within the dredge arising, costs associated with handling the anticipated volume of material, and the fine nature of particle sizes which makes the material unsuitable for engineering purposes, this option was also discounted.

Sea disposal: Bathymetric survey data, drawing **122592/7004**, indicates a significant change in depth immediately outwith the bounds of Port Edgar marina - this is the location of the main channel of the River Forth. The change in depth here and in particular the fast currents which flow within the main river channel which empties into the estuary, make a preferred location for disposal of plough dredging arising. This option was considered to represent the most appropriate option for dredging operations, taking account of the proximity of the disposal site resulting in minimal environmental impact, given the likely contaminated nature of the material, and the relatively short distance from where the material is required to be dredged from to where it is proposed to be deposited for redistribution.

It is considered that the material is largely similar in composition to that which has previously been plough dredged from within the marina and which is currently being disposed at the identified location at the entrance to the marina. As such, it is not considered likely that the disposal of further dredge arising at this location would result in an adverse environmental impact.

6 Consultation

Consultation feedback and advice received from SNH and Marine Scotland has been included as **Appendix F**.

7 Bio-security

A Bio-security Plan (**Appendix G**) in respect of the control and removal of invasive non-native species, specifically Japanese Wakame seaweed, was produced and written by APEM Ltd in October 2018. This plan has followed the 'simple approach' outlined by Scottish Natural Heritage (SNH) Biosecurity Planning Guidance. The operator is fully committed to the continued implementation of the plan which has been written cognisant of proposed dredging operations planned during the period between 1st January 2019 and 31st January 2022 on an annual of biannual basis.

8 Conclusions

We note the following conclusions with cognisance given to environmental impact in relation to the dredging and disposal of dredge arising:

- Proposed dredging of the area surrounding the West Pier will enable this area, which was historically utilised by the Royal Navy, to be brought back into active use.
- Sampling and analysis of proposed dredge arising has shown that the material consists almost entirely of fine estuarine silts which have been deposited since the West Pier became inactive.
- Interpretation of the laboratory results has shown that, whilst pre-disposal sampling has indicated exceedances of some Marine Scotland AL thresholds; when these were compared with results from a nearby area sampled during 2018 there is an overall improvement.
- A number of dredging options were considered, based on past experience of their application within Port Edgar. Of the options plough dredging were considered to be the most appropriate and is in-line with current practice at the marina. It is also considered to represent the most appropriate option taking account of the proximity of the disposal site resulting in minimal environmental impact from to transportation.
- As the proposed dredge arising is being kept within the confines of Port Edgar Marina, there is likely to be a minimal impact from the transportation of dredge arising due to the proximity of the proposed disposal site which is already in use, as opposed to removal of dredge arising off-site.
- Post-dredging and the removal of silt, mud which provides valuable habitat as regards the qualifying features of the designated sites namely the Firth of Forth SPA and SSSI will remain exposed at low-tides.

Dredging Method Statement

Dredging Method Statement

To allow operation within the west side of Port Edgar marina there is a requirement to dredge either side of the West Pier.

The total area for dredging is approximately one hectare and the proposed dredging will be to a depth of between 1 – 1.5 m (variable).

An initial volume of 20,000m^3 will be dredged, following which 10,000m^3 of maintenance dredging will be required annually to enable the continued use of the West Pier.

There is currently a maintenance plough dredging licence (**06629/19/0**) for a separate area within the marina which is dredged to enable operations to occur. Increased use of the marina has led to the requirement to utilize the West Pier to provide the additional capacity required.

The proposed method of dredging is plough dredging:

- Plough dredging operations will begin when there is adequate tide height for the vessels to operate taking into consideration the height of the vessels propellers above the plough to prevent materials being washed out of the plough.
- The ploughing chains will be set to suit the dredge depth required.
- Plough hoisting wires are pre-marked and calibrated to cope with varied water depth.
- Once there is adequate water depth at the south end of the West Pier the Forth Sentinel will commence ploughing operations.
- She will deploy her plough to the seabed allowing enough slack on the hosting wires to allow for final dredge depth.
- The vessel will work from North to south with the tide to achieve maximum working time.
- The material will be ploughed from the West Jetty location out to the 12m contour line outside the Marine where it will disperse.
- The process will be continued until the required dredge depth has been achieved.
- Dredge arising will be moved to the proposed disposal location at the entrance to the marina adjacent to the main channel of the Forth where tidal movements and fast currents will aid the redistribution of sediment.

This method described is in line with current licenced practice at Port Edgar marina.

1. INTRODUCTION

Aspect Land & Hydrographic Surveys Ltd (herein ALHS) were contracted by PORT EDGAR MARINA to carry out sediment sampling using vibrocores in order to licence a planned dredging campaign.

2. GEODESY & DATUM

The horizontal datum used throughout the data gathering phase of the survey was OSGB36 (OSTN15). Data has been rendered in OSGB36 Datum, British National Grid.

The vertical datum for all bathymetric data is Chart Datum which at Toft Pier is 1.24m below OD (Lerwick). OSTN15 defines OSGB36 National Grid in conjunction with the National GPS Network.

In this regard OSTN15 can be considered error free (not including any GPS positional errors). The agreement between OSTN15 and the old triangulation network stations (down to 3rd order) is 0.1m rms.

3. SCOPE OF WORKS

3 cores were to be recovered with the aim being to achieve a minimum core length of 1.5m.

The vibrocore sampling and testing procedures conformed to Marine Scotland Guidance notes http://www.gov.scot/Topics/marine/Licensing/marine/Applications/predredge

All analysis was completed by a laboratory accredited to the ISO17025 standard for marine sediment analysis, and also engages in inter-comparison analysis exercises such as QUASIMEME. The LOD and sensitivity requirements were met as per those set out in the CSEMP Green Book.

Vibrocore sampling was carried out in the areas depicted in Figure 1 below. Sampling was taken from the top, middle and bottom of each core recovered.

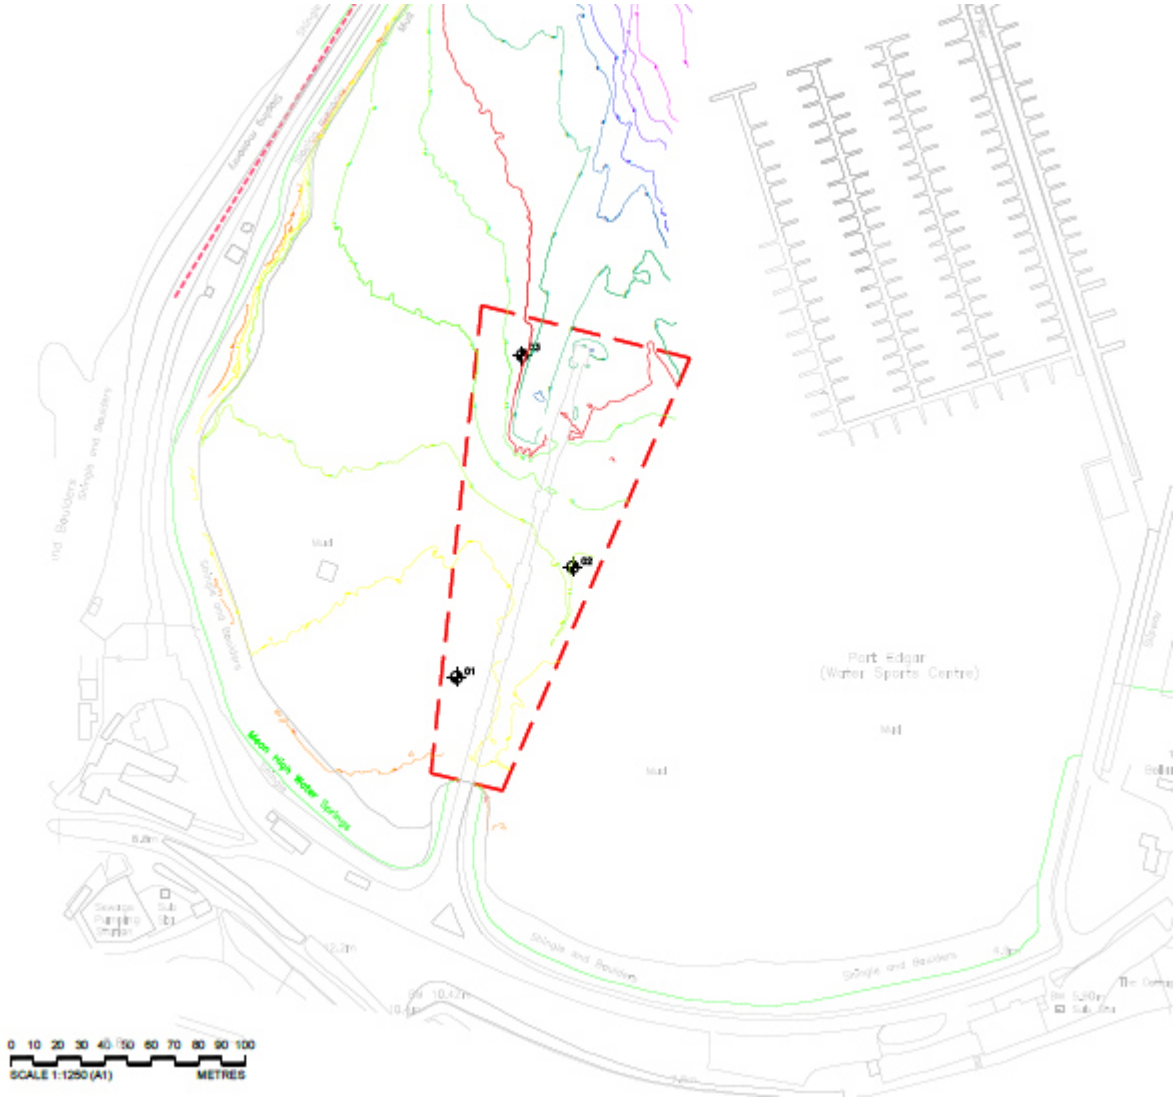

FIGURE 1 - PLANNED SAMPLE LOCATIONS AT PORT EDGAR MARINA

4. SEQUENCE OF EVENTS

Works were completed in the following order;

DATE	EVENT
30/09/2019	Mobilise Vibrocore Equipment to vessel at Port Edgar Marina
30/09/2019	Conduct Vibrocores
30/09/2019	Equipment demobilised
1/10/2019	Sub Samples taken and Frozen
2/10/2019	Frozen samples transmitted to Laboratory for analysis
12/11/2019	Sample analysis report received from SOCOTEC laboratory. Report generation and QA
15/11/2019	Report issued to client

TABLE 1 - SEQUENCE OF EVENTS

5. CONDUCT OF VIBROCORE SAMPLING

The vibrocore apparatus used was a lightweight SDI Vibrocore 4D system with 102mm aluminium extruded pipe being used to recover the core. The system does not rely on overall mass but the vibrational frequency of the equipment and liquefaction of surrounding sediments to enable effective penetration.

The portability and simplicity of this equipment facilitates rapid deployment at an alternate location should the previous location provide a poor return.

The aim was to collect 3 cores in total across the site, of at least 1.5m in length, from sample points indicated on Figure 1. Each sample core was split into sections and samples for analysis collected from the upper, middle and lower sections as a minimum.

Upper Section – 0.0 – 0.5m below seabed
Middle Section – 0.5-1.0m below seabed
Bottom Section – 1.0-1.5m below seabed

The vessel was manoeuvred to each of the locations in turn and secured fore and aft to avoid swinging during the sampling operation.

FIGURE 2 - VIBROCORE ON COMPLETION OF CORE

All vibrocore locations were sampled on 30th September 2019 at the following locations:

VIBROCORE POINT	SAMPLED EASTING	SAMPLED NORTHING	CORE LENGTH
Core 1	311897.56	678746.24	1.5
Core 2	311937.38	678808.78	1.5
Core 3	311932.11	678875.85	1.5

6. EQUIPMENT USED FOR SAMPLING

A Speciality Devices Incorporated D-4 vibrocorer was used for all samples. A 76mm diameter, 3m long core was fitted for all sample attempts and each core tube was constructed of aluminium.

The sediment was pushed out of the core tube and carefully sampled to prevent taking material that had come into contact with the tube wall.

FIGURE 3 - SDI D-4 VIBROCORER AND CORE BEING RECOVERED TO DECK OFSHORE SENSOR

7. SAMPLE ANALYSIS

The laboratory analysis was carried out by SOCOTEC in Burton on Trent. The intention was that all vibrocore samples would be sub sampled at 0.5m intervals at the top middle and bottom of the length of the core and each sub sample analysed for Particle Size, Heavy Metals, TOC, Specific Gravity, PAHs, TBT and DBT.

Soil / water	Test	Method (method code in bold)	Accreditation U=UKAS M=MCERTS	Method Reporting Limit, ppm unless stated otherwise
	Marine Scotland Suite (Table 2)			
	CRM &/Or In-House Reference Material to be run with each batch and data included in report			
sediment	Moisture content	Documented in-house method, oven drying @ 105°C, **PAHSED**		0.2%
sediment	**Sieving < 63 um** (samples for trace metals analysis should be sieved to <63 um) Selve size used to be noted on report	IHM		
sediment	**Metals Suite including low level Mercury at 0.01 mg/kg** *As(0.5), Cd(0.04), Cr(0.5),Cu(0.5), Pb(0.5), Hg(0.015), Ni(0.5), Zn(2)*	Documented in-house method using aqua regia extraction and ICPMS, **ICPMSS**	U (Hg UKAS accredited at 0.015mg/kg)	Detection Limits in brackets (mg/kg)
sediment	Low Level TBT & DBT	In house method: OGSNSED		1 ug/kg
sediment	PCBs, ICES 7 Congeners (PCB: 28, 52, 101, 118, 138, 153, 180)	Documented in-house method Triple Quad, **PCBMSSQ (marine sedS)**		0.1µg/kg
sediment	PAHs: 2 to 6 ring aromatics by GC-MS and/or + 16 USEPA (as required)	Documented in-house method using DTI specification by GC-MS, **PAHSED**	U (16 USEPA + Dibenzthiophene & Benzo(e)pyrene only)	0.001
sediment	Particle size distribution by wet and dry sieving to **BS 1377** and Laser Diffraction	Subcontracted to **Kenneth Pye Associates**		

FIGURE 4 - MARINE SCOTLAND SEDIMENT ANALYSIS SUITE & WAC ANALYSIS

SAMPLE LOCATION	SAMPLE ACHIEVED	ANALYSIS ORDERED	FIELD ANALYSIS SEDIMENT DESCRIPTOR	LAB ANALYSIS SEDIMENT DESCRIPTOR
Core 1	1.5m	Sampled for PSD, TOC, Specific Gravity, PAHs, TBT and DBT, Heavy metals.	0.0 - 0.5m 10YR2/2 becoming 10YR2/1 @ 0.42m Dark Brown / Black Silt	**SILT**

The samples have been analysed against the Action Levels quoted by Marine Scotland and are presented in the standard Marine Scotland spreadsheet format: *A7167_Marine Scotland - Results Template MAR00427.xlsx* referenced in Appendix B of this document.

Details on the analysis of individual items are also provided in the accompanying laboratory records for each sample.

8. SURVEY VESSEL

FIGURE 5 - SURVEY VESSEL: OFFSHORE SENSOR

Offshore Sensor is a 22m aluminium hulled catamaran with a deck crane suitable for vibrocore operations.

9. SURVEY PERSONNEL

The following personnel were involved in the survey:

NAME	POSITION
Colin Thomson	QA and Reporting
Jason Hunter	Hydrographic Surveyor
Andrew McCormick	Survey Coxswain

All staff have marine survey experience, and adhered to Health & Safety instructions, including the wearing of life jackets at all times.

For full analyte name see method summaries

~ Indicates result is for an In-house Reference Material as no Certified Reference Materials are avaliable.

As the method uses surrogate standards to correct for losses, the RM results are reported as percentage trueness, not recovery.

REPORT NOTES

Method Code	Sample ID	The following information should be taken into consideration when using the data contained within this report
SOCOTEC Env Chem*	MAR00427.001-009	Analysis was conducted by an internal SOCOTEC laboratory. UKAS accredited analysis by this laboratory is under UKAS number 1252.
SOCOTEC Doncaster*	MAR00427.001-009	Analysis was conducted by an internal SOCOTEC laboratory.
SUB_01*	MAR00427.001-009	Analysis was conducted by an approved subcontracted laboratory.
SUB_02*	MAR00427.001-009	Analysis was conducted by an approved subcontracted laboratory.
ASC/SOP/301	MAR00427.001-009	The matrix of this sample has been found to interfere with the result for this test. The sample has therefore been diluted, but in doing so, the detection limit for this test has been elevated.
ASC/SOP/303/304	MAR00427.001-009	Chrysene is known to coelute with Triphenylene and these peaks can not be resolved. It is believed Triphenylene is present in these samples therefore it is suggested that the Chrysene results should be taken as a Chrysene (inc. Triphenylene).This should be taken into consideration when utilising the data.

DEVIATING SAMPLE STATEMENT

Deviation Code	Deviation Definition	Sample ID	Deviation Details. The following information should be taken into consideration when using the data contained within this report
D1	Holding Time Exceeded	N/A	N/A
D2	Handling Time Exceeded	N/A	N/A
D3	Sample Contaminated through Damaged Packaging	N/A	N/A
D4	Sample Contaminated through Sampling	N/A	N/A
D5	Inappropriate Container/Packaging	N/A	N/A
D6	Damaged in Transit	N/A	N/A
D7	Insufficient Quantity of Sample	N/A	N/A
D8	Inappropriate Headspace	N/A	N/A
D9	Retained at Incorrect Temperature	N/A	N/A
D10	Lack of Date & Time of Sampling	N/A	N/A
D11	Insufficient Sample Details	N/A	N/A
D12	Sample integrity compromised or not suitable for analysis	N/A	N/A

Certificate of Analysis

Test Report ID	MAR00427
Issue Version	1
Customer Reference	A1767

Method	Sample and Fraction Size	Method Summary
Total Solids	Wet Sediment	Calculation (100%-Moisture Content).Moisture content determined by drying a portion of the sample at 105°C to constant weight.
Particle Size Analysis	Wet Sediment	Wet and dry sieving followed by laser diffraction analysis.
Total Organic Carbon (TOC)	Wet Sediment	Carbonate removal and sulphurous acid/combustion at 800°C/NDIR.
Metals	Air dried and seived to <63µm	Aqua-regia extraction followed by ICP analysis.
Organotins	Wet Sediment	Solvent extraction and derivatisation followed by GC-MS analysis.
Polychlorinated Biphenyls (PCBs)	Air dried and seived to <2mm	Solvent extraction and clean up followed by GC-MS-MS analysis.
Organochlorine Pesticides (OCPs)	Air dried and seived to <2mm	Solvent extraction and clean up followed by GC-MS-MS analysis.
Polyaromatic Hydrocarbons (PAH)	Wet Sediment	Solvent extraction and clean up followed by GC-MS analysis.
Total Hydrocarbon Content (THC)	Wet Sediment	Solvent extraction and clean up followed by GC-FID analysis.

Analyte Definitions

Analyte Abbreviation	Full Analyte name	Analyte Abbreviation	Full Analyte name	Analyte Abbreviation	Full Analyte name
ACENAPTH	Acenaphthene	C2N	C2-naphthalenes	THC	Total Hydrocarbon Content
ACENAPHY	Acenaphthylene	C3N	C3-naphthalenes	AHCH	alpha-Hexachlorcyclohexane
ANTHRACN	Anthracene	CHRYSENE	Chrysene	BHCH	beta-Hexachlorcyclohexane
BAA	Benzo[a]anthracene	DBENZAH	Diben[ah]anthracene	GHCH	gamma-Hexachlorcyclohexane
BAP	Benzo[a]pyrene	FLUORANT	Fluoranthene	DIELDRIN	Dieldrin
BBF	Benzo[b]fluoranthene	FLUORENE	Fluorene	HCB	Hexachlorobenzene
BEP	Benzo[e]pyrene	INDPYR	Indeno[1,2,3-cd]pyrene	DDE	p,p'-Dichorodiphenyldicloroethylene
BENZGHIP	Benzo[ghi]perylene	NAPTH	Naphthalene	DDT	p,p'-Dichorodiphenyltrichloroethane
BKF	Benzo[k]fluoranthene	PERYLENE	Perylene		
C1N	C1-naphthalenes	PHENANT	Phenanthrene		
C1PHEN	C1-phenanthrene	PYRENE	Pyrene		

Annex C
Standard Disclaimer

A7167

1. All client-supplied data is taken on trust as being accurate and correct, and the subcontractor cannot be held responsible for the quality and accuracy of that data set.

2. Geophysical interpretation of bathymetry and sonar is based on an informed opinion of the supplied data, and is subject to inherent errors out with the control of the interpretational hydrographer or geophysicist, which include but are not limited to GPS positioning errors, navigation busts, data quality, assumed speed velocity sediment profiles in the absence of Geotechnical data, sub bottom profile pulse width, and induced scaling errors therein associated with seismic signature. Seabed geomorphology and sub-seabed geology should be further investigated by visual or intrusive methods.

3. The limits of this survey are defined by the data set; out with the survey limits are not covered at any level by the subcontractor.

4. The data is accurate at the time of data acquisition, the subcontractor cannot be held responsible for environmental changes, and the client by accepting this report accepts that the environment of the seabed is subject to continuous change, that items of debris, hard contacts etc. may move, appear, be relocated or removed, thickness of surficial sediment change out with the knowledge of the subcontractor and they will not be held responsible for such actions at any level.

REPORT NOTES

Method Code	Sample ID	The following information should be taken into consideration when using the data contained within this report
SOCOTEC Env Chem*	MAR00427.001-009	Analysis was conducted by an internal SOCOTEC laboratory. UKAS accredited analysis by this laboratory is under UKAS number 1252.
SOCOTEC Doncaster*	MAR00427.001-009	Analysis was conducted by an internal SOCOTEC laboratory.
SUB_01*	MAR00427.001-009	Analysis was conducted by an approved subcontracted laboratory.
SUB_02*	MAR00427.001-009	Analysis was conducted by an approved subcontracted laboratory.
ASC/SOP/301	MAR00427.001-009	The matrix of this sample has been found to interfere with the result for this test. The sample has therefore been diluted, but in doing so, the detection limit for this test has been elevated.
ASC/SOP/303/304	MAR00427.001-009	Chrysene is known to coelute with Triphenylene and these peaks can not be resolved. It is believed Triphenylene is present in these samples therefore it is suggested that the Chrysene results should be taken as a Chrysene (inc. Triphenylene).This should be taken into consideration when utilising the data.

Contents

1 Introduction

1.1 Background to application

The report has been prepared to set out the Best Practice Environmental Option (BPEO) for the treatment of dredge arisings as a result of the need to carry out maintenance dredging within the boundary of Port Edgar Marina. The dredging is required to maintain a suitable dredge depth for operation of the marina.

Port Edgar Marina currently have a licence in place to allow plough dredging within the marina boundaries up to a volume of 2000m^3 less any volume dredged under previous licences.

Port Edgar Marina undertakes regular (annual) dredging as a result of sedimentation within the confines of the protected area, which has increased as a result of the construction of nearby bridge piers in recent years.

The current dredging licence is valid until July 2018; the operator is seeking to obtain an extension of time and volume. Due to the previous test samples having been obtained and reviewed over three years ago, this BPEO has been prepared to review the current sample test results. It is not intended to amend the method of dredging which has been reviewed and reported on in the previous BPEO which supported the current dredging licence application (Port Edgar Marina, Best Practicable Environmental Option Assessment: Sea Disposal of Solid Materials, Black & Veatch, Revised Feb 2015, see Appendix E). It is considered that plough dredging remains the most suitable option, due to the relative proximity of the disposal site which results in minimal impact due to adverse effects of transportation.

1.2 Source of Materials

The material to be relocated via plough dredging is from the area surrounding the pontoons within the marina. Drawing 122592/7004 in Appendix A shows the area to be dredged, and the location to which the sediment will be moved.

1.3 Description of Materials

1.3.1 Volume of Material

The licence application covers a period of three years, up to 10,000 wet tonnes. The volume of dredging to be carried out per year may vary, depending on the amount of sedimentation which occurs.

1.3.2 Nature of Material

The material to be removed is predominantly soft silty material.

The sediment has been tested in accordance with the guidelines set out in the Marine Scotland pre-disposal sampling guidance document.

A summary of the results of the sampling is provided in table 1 below, with the full results contained in Appendix B. Drawing 122592/7004 in Appendix A shows the locations at which the samples were obtained.

Photographs of each grab sample are contained within Appendix C.

Table 1: Grab Sample Descriptions

Sample	Material Description
Grab 1	Soft brown silt with a colour change at around 10mm below surface to a grey/brown colour. No noticeable odour and no anthropogenic inputs noted.
Grab 2	Soft brown silt with a colour change at around 20mm below surface to a grey/brown colour. No noticeable odour and no anthropogenic inputs noted.
Grab 3	Soft brown silt with a colour change at around 5mm below surface to a grey/brown colour. No noticeable odour and no anthropogenic inputs noted.

1.4 Test Results

The test results suggest that a number of trace metals and organotins, and PAHs fall between the suggested Marine Scotland action level 1 and 2 thresholds.

Samples with contaminants identified between action levels 1 and 2 may incur constraints such as restriction on disposal at sea, monitoring of dredge material and disposal site or treatment / mitigation measures.

Those contaminants which are greater than the Marine Scotland action level 1 are displayed for each sample in tables 2 - 4 below:

Table 2: Grab Sample 1 Contaminants Exceeding AL1.

Sample : Grab 1				
Contaminant of concern	**AL1 threshold** mg/kg dry weight (ppm)	**Result** mg/kg dry weight (ppm)	**Exceedance of AL1** mg/kg dry weight (ppm)	**Percentage exceedance** (%)

Pyrene	0.1	0.2574	0.1574	157

In accordance with Marine Scotland Pre-disposal Sampling Guidance (version 2), Figure 1 step (5), suitability of these samples for disposal will have to be determined ultimately by Marine Scotland through expert judgement based on evaluation of evidence including historical information, disposal site characteristics and physical characteristics of the material. Historical testing records for samples taken in 2013 are compared against 2017 chemical testing results, comparison of these results and those that exceed AL1 (highlighted in blue) are provided in table 5.

Table 5: 2013 & 2017 Comparison of Contaminants Exceeding AL1.

Contaminant of concern	**2013 Results** (3 samples) mg/kg dry weight (ppm)		**2017 Results** (3 samples) mg/kg dry weight (ppm)		AL1 threshold mg/kg dry weight (ppm)
	Minimum	Maximum	Minimum	Maximum

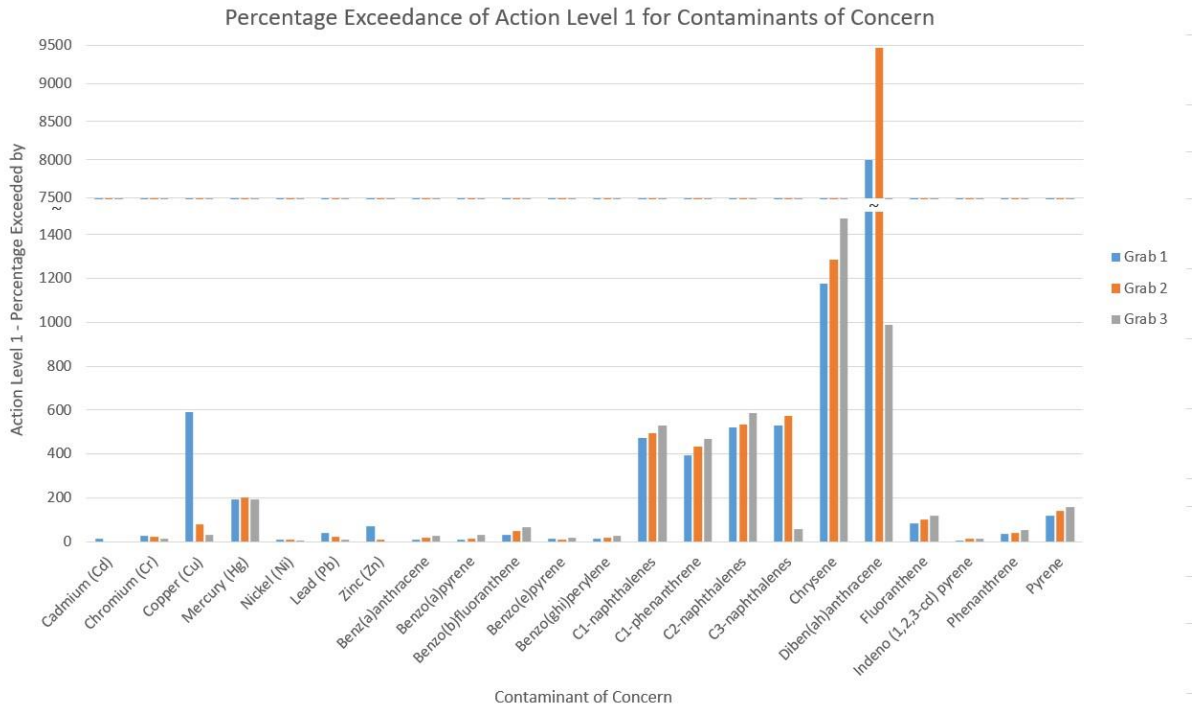
Note: samples highlighted in blue are above AL(1) but below AL(2)

The most proximal of the three samples to the proposed disposal area is Grab 1. The disposal area lies approximately 210m from the boundary of the dredge area as seen on drawing 122592/7004.

With respect to the contaminants of concern, 75% of those above AL(1) in 2017 were also above AL(1) in 2013, indicating that few 'new' contaminants have been introduced into the environment. Graph 1, below, shows that the exceedances seen in the three 2017 samples follow similar exceedance trends, suggesting that there is unlikely to be a large variation in contamination levels elsewhere in the site, including within the proposed disposal area.

Graph 1: Percentage Exceedance of AL1 for Contaminants of Concern



As the dredge material in question is not to be moved out of the site of origin, but moved to a nearby location within the site, the possible risk of cross contamination could be considered low, however, as previously mentioned, suitability of this material for disposal in the proposed area will ultimately be determined by Marine Scotland.

1.5 Details of Previous Dredging Operations

Port Edgar Marina has held dredging licences as follows in table 6:

Table 6: Port Edgar Marina Dredging Licences

Licence Ref	Dates Valid	Allowable Quantity	Description
05048/14/0	10/2/14 – 9/2/15	24,000m3	Capital dredging – sea disposal
05048/15/0	18/2/15 – 28/2/15	23,000m3 sea disposal 1,000m3 plough	Revision to above
05577/15/0	14/7/15 – 13/7/18	2,000m3	3 year plough dredging licence
05577/17/0	14/7/15 – 13/7/18	2,000m3 (less any arisings from above licence)	Revision to above
05577/17/1	31/1/17 – 13/7/18	2,000m3 (less any arisings from above licence)	Revision to above
05577/17/2	1/2/17 – 13/7/18	2,000m3 (less any arisings from above licence)	Revision to above

A programme of capital dredging was carried out in 2015 and thereafter maintenance dredging has been carried out annually to ensure operability of the marina.

2 Options for Relocation of Dredge Spoil

The material to be dredged from the vicinity of the marina berths will not be removed off site; plough dredging will be carried out to move the material from the high spots at the marina to an area at the north east corner of the area for which Port Edgar Marina is responsible. This is in line with current practice in place at the marina, following a previous exercise being undertaken to look at the options

for dredging, and is considered to represent the most appropriate option for the continuation of dredging operations, taking account of the proximity of the disposal site resulting in minimal environmental impact due to transportation.

Drawing 122592/7003 in Appendix A shows the layout of the pontoons and the area which requires maintenance dredging to be carried out. The area to which the dredge arisings will be removed is shown on drawing 122592/7004 in relation to the dredge area, with the dredge spoil being relocated approximately 210m from the boundary of the dredge area.

3 Removal of Invasive Species

An invasive species of seaweed, Japanese Wakame, was noted to be present in the marina. Subsequent investigations by Marine Scotland noted that while the seaweed does not seem to have spread to nearby areas, it would be prudent for the seaweed to be removed. Port Edgar Marina has been in discussion with Marine Scotland's Marine Planning department in order to resolve this issue.

A letter issued by Marine Scotland's Planning and Policy department on 27th November 2017 confirms that the meeting was undertaken and that means of removal of the seaweed were agreed (letter contain in Appendix D). The seaweed has now been removed; therefore there is no outstanding issue relating to the presence of this invasive species.

In line with current good practice, regular inspections will be carried out in order to identify any invasive species as soon as is reasonably possible and minimise the risk of further spread of non-native species, alongside a cleaning regime and the development of a biosecurity plan which is to be followed in the event that non-native species are discovered. This biosecurity plan will be developed and managed in line with the guidance published by SNH within the document "Marine Biosecurity Planning – Guidance for producing site and operation-based plans for preventing the introduction of non-native species" (Payne, R.D., Cook, E.J. and Macleod, A. (2014)), and as directed by SEPA https://www.nature.scot/sites/default/files/2017-06/A1294630.pdf.

A monthly inspection around the waterline of the pontoons, moorings, and piles will be carried out, while annually an underwater inspection will be undertaken. Annual cleaning of marine fouling will be undertaken, taking cognisance of the safe collection and disposal of arisings to minimise the risk of a spread of non-native species. In addition to the actions which can be taken by Port Edgar Marina operators, visiting vessel owners will be encouraged to adhere to the SEPA good practice biosecurity measures as described in their "Check Clean Dry" campaign.

4 Special Protection Area

The foreshore at Port Edgar is part of a designated Special Protection area (SNH site code 8499, Firth of Forth), due to the area supporting a number of overwintering bird populations and some migrating species.

The dredge area however covers an area of the marina basin which is outwith the SPA boundary and does not include the foreshore; therefore it is considered that plough dredging will have minimal effect on the habitat and feeding grounds of these birds. The timing of plough dredging will be determined to minimise the overall impact.

5 Discussion and Conclusions

5.1 Disposal

The material to be dredged will be disposed of within the boundaries of Port Edgar Marina, as depicted on drawing 122952/7004.

5.2 Environmental Impact

Samples collected within the proposed dredge area have been compared to the previous set of tests from 2013, which has shown limited variation in the characteristics of contaminants within the material. In accordance with MS Pre-disposal sampling guidance v2, fig 1 step 5, the final decision for disposal of the material rests with Marine Scotland. However, we note that there is likely to be limited environmental impact in relation to the disposal of the dredge material as it is being kept within the confines of the marina limits. Therefore there are limited issues related to the environmental impact of transportation, which will be minimal due to the proximity of the disposal site under the plough dredging regime compared to taking the arisings offsite.

5.3 Conclusion

This BPEO report has been prepared to support the application being made to undertake plough dredging within Port Edgar marina, with the dredge arisings being moved to an area immediately adjacent to the marina breakwater on the north east boundary of the marina.

Sample Test Results

Pre-disposal Sampling Results Form

Version 2 - June 2017

This form should be used to submit the results from your pre-disposal sampling plan.
Full information must be provided in all relevant sheets of this workbook. The blue cells in each worksheet indicate where information can be entered.
Where information cannot be provided, or where there are more than 30 samples required, please contact the Marine Scotland - Licensing Operations Team (MS-LOT) using the contact details below.

Once you have completed this form, send it (including any reference number for the dredging and sea disposal marine licence application in the subject header of your email) to the following email address:
ms.marinelicensing@gov.scot

If you have any questions in relation to this form contact MS-LOT:

Marine Scotland - Licensing Operations Team

Applicant Information

Applicant:	Port Edgar Marina
Description of dredging:	Plough dredging
Total amount to be dredged (wet tonnes)	10,000 over 3 years

Sample Details & Physical Properties

Explanatory Notes:
An example of a 'Dredge area' is: 'Dock A, Harbour X'
Provide description of the dredge area and the latitude and longitude co-oridnates (WGS84) for each sample location. Co-ordinates taken from GPS equipment should be set to WGS84.
Note for sample depth that the seabed is 0 metres.
Gravel is defined as >2mm, **Sand** is defined as >63um<2mm, **Silt** is deinfed as <63um).

Sample information:

Comments:

Laboratory Details

Explanatory Notes:
Please complete a separate worksheet for each laboratory (e.g. complete 'Laboartory_1' worksheet for 1 laboratory and complete 'Laboartory_2' worksheet for a second laboratory). If there are more than 3 laboratories then please contact MS-LOT.

Laboratory 1 Details:

Laboratory name:	Socotec
Year:	2018

LabRefMat	**Q1**	Does the laboratory carrying out the analyses undertake the analysis of blank samples and laboratory reference materials with each batch of samples of waste and other material dumped in the maritime area that is analysed by that laboratory?	Yes
CompAnal	**Q2**	Does the laboratory carrying out the analyses undertake periodic comparative analysis of laboratory reference materials and certified reference materials?	Yes
QAQC	**Q3**	Does the laboratory carrying out the analyses undertake the compilation of quality control charts based upon the data resulting from the analyses of the laboratory reference materials and certified reference materials, and the use of those quality control charts to monitor analytical performance in relation to all samples of dumped wastes or other materials?	Yes
InterlabCaleb	**Q4**	Does the laboratory carrying out the analyses undertake periodic participation in interlaboratory comparison exercises, including, where possible, international comparison exercises?	Yes
InternatCaleb	**Q5**	Does the laboratory carrying out the analyses undertake periodic participation in national and, where possible, international laboratory proficiency schemes?	Yes
SpikedSamples	**Q6**	If the answer to questions 4 or 5 is 'Yes' then does the laboratory analyse samples of substances which are provided by the organisers of the scheme?	Yes
BlindSamples	**Q7**	If the answer to questions 4 or 5 is 'Yes' then does the laboratory confirm that the composition of those samples is not disclosed in advance?	Yes
Ranking	**Q8**	If the answer to questions 4 or 5 is 'Yes' then does the laboratory confirm that the results of the scheme for each participating laboratory are made available to all participating laboratories?	Yes
FracAnal	**Q9**	Enter the size fraction that is analysed i.e. Whole or less than 63µm etc.	<63um(metals)
GranMeth	**Q10**	PSA method	NMBAQC
OCMeth	**Q11**	Organic Carbon method	carbonate removal and sulfurous acid/combustion at 800°C/NDIR,
MetExtrType	**Q12**	Method of extraction used for metal analysis	Aquaregia
MethOfDetMetals	**Q13**	Method of detection used for metal analysis	ICP-MS
PAHExtrType	**Q14**	Method of extraction used for poly aromatic hydrocarbon analysis	Methanol/DCM solvent extraction with silica clean up and copper clean up stages
MethOfDetPAH	**Q15**	Method of detection used for poly aromatic hydrocarbons analysis	GCMS
OHExtrType	**Q16**	Method of extraction used for organohalogens inc PCBs, pesticides, flame retardants etc analysis	Ultrasonic acetone/hexane solvent extraction
MethOfDetOH	**Q17**	Method of detection used for organohalogens inc PCBs, pesticides, flame retardants etc analysis	GCMSMS
OTExtrType	**Q18**	Method of extraction used for organotin analysis	derivatisation and solvent extraction
MethOfDetOT	**Q19**	Method of detection used for organotin analysis	GCMS

Additional Report Notes

Method Code	Sample ID	The following information should be taken into consideration when using the data contained within this report
PAHSED	CL1787802 to CL1787804	The Primary process control data associated with this Test has not wholly met the requirements of the Laboratory Quality Management System QMS with one or more target analytes falling outside acceptable limits. However the remaining data gives the Laboratory confidence that the test has performed satisfactorily and that the validity of the data may not have been significantly affected. However in line with our QMS policy we have removed accreditation, where applicable, from the affected analytes (Naphthalene) . These circumstances should be taken into consideration when utilising the data.
PAHSED	CL1787802 to CL1787804	Chrysene is known to coelute with Triphenylene and these peaks can not be resolved. It is believed Triphenylene is present in these samples therefore it is suggested that the Chrysene results should be taken as a Chrysene (inc. Triphenylene).This should be taken into consideration when utilising the data.

Fraser Sturgeon
Port Edgar Marina
Shore Road
South Queensferry
EH30 9SQ

27 November 2017

Dear Fraser,

***Undaria pinnatifida* (Japanese Wakame) found at Port Edgar Marina**

Thank you for meeting myself and David Pratt at Port Edgar on the November 01 to discuss the removal of Japanese Wakame from the marina in order to help control and contain it. In order to determine the spread of wakame, Marine Scotland and Scottish Natural Heritage have surveyed a number of locations along the Firth of Forth where access was possible. No wakame was found leading to the conclusion there is still merit in seeking to control it at Port Edgar.

We discussed methods for its removal and agreed that there were a number of actions the marina could undertake to help contain it. These include

- the removal of wakame as part of the marina's regular programme of removing biofouling from the pontoons but that the method is adapted to catch dislodged material and dispose of it on land rather than release it into the marine area

- opportunistic cleaning when possible of areas otherwise difficult to access as part of the regular cleaning programme, such as cross supports of the floating pontoons and the barrage

You have since confirmed to us via telephone that the biofouling has been removed.

You made us aware of an application for a licence to dredge the marina that your agents would be submitting to Marine Scotland Licensing Operations Team. MSLOT have confirmed to us that this has been received. Presence of an invasive non-native species and the risk of spread that accompanies a marine activity is one which is considered as part of routine licensing considerations. Unless a species has been eradicated there may still be a risk of spread from specific activities, and this will be factored into the consideration of licence applications. Should MSLOT require information in relation to wakame or the actions we have recommended, we will of course liaise with them as necessary.

An outstanding action on us has been to provide advice in relation to the disposal of the biofouling which you have removed. I have received confirmation from SEPA that it can be disposed of as organic waste, meaning that it can be sent to landfill or used as composting. Should you wish to satisfy yourself of this your local SEPA area office can be contacted. I have included a link to authorised landfill sites in the email which accompanies this letter. I have also attached a list of organic waste processors. This information has been sourced from a third party and I have not contacted the companies directly. It does not confer a recommendation to use these companies and other operators may be available.

I am of course happy to discuss the wakame and its removal/ disposal further if this would be helpful to you.

Yours sincerely,

Lorna King

BEST PRACTICABLE ENVIRONMENTAL OPTION (BPEO) ASSESSMENT: SEA DISPOSAL OF SOLID MATERIALS

1. INTRODUCTION

1.1 Background to application

This report is the Best Practicable Environmental Option (BPEO) for the Application for Dredging and Deposit of Solid Waste in the Territorial Sea and UK Controlled Waters Adjacent to Scotland, relating to dredging works required at Port Edgar, Edinburgh, Scotland.

This report is part of the requirement for the application for the sea disposal of solid materials at sea. Part 4, Section 27(2) of the Marine (Scotland) Act 2010 states that the Licensing Authority has an obligation to consider the availability of practical alternatives when considering applications involving disposal of material at sea.

This report will outline the available alternative options that have been considered, and the reasons that have led to depositing the materials at sea.

1.2 Source of materials

The source of the material that is being considered for disposal at sea is the dredged material from Port Edgar Marina. The site location is shown on Drawing 121937-DL-002 in Appendix A. The dredging areas (the shaded areas) where the materials will be sourced are shown in Drawing 121937-DL-005 in the same appendix.

A sketch has been added to Appendix A showing a small area adjacent to an existing slipway that it is proposed to dredge using a plough in February 2015.

1.3 Description of materials

1.3.1 Volume of materials

The volume of dredged materials to be disposed in the sea is approximately 20,000m^3 to 25,000m^3, of which approximately 1,000m^3 will be from the plough dredging of the slipway.

1.3.2 Nature of Materials

The material for disposal at sea consists mostly of soft silty material. The results from sample analysis of the material are shown in Appendix A.

The sediment has been tested for PCBs, PAHs and heavy metals. The results are provided in the Analytical Report, and Sediment Sampling Results Summary enclosed with the licence application.

Some of the results suggest a risk to public health, and any options for disposal of the material that could result in an increase in this risk will therefore not be considered.

The material from the area to be plough dredged has been deposited within the past five years having been regularly plough dredged by the previous owners of the marina (Edinburgh Leisure) at a time when plough dredging did not require licensing.

1.4 Details of previous, related operations

Anecdotal evidence exists to suggest that some dredging was carried out either in the late 1980's or early 1990s, but it has not been possible to confirm this.

Since that time only plough dredging (within the limits of the marina) has been carried out to level the channel beds and remove high spots, but this process provides only a short term measure and is not sufficient to maintain the required navigational depths in the long term.

2. INITIAL OPTIONS FOR RELOCATION/REMOVAL OF MATERIALS

A long list of eight options was considered for the relocation or removal of the material.

The options considered are:

- Spreading on agricultural land, or for soil conditioning of reclaimed land
- Beach nourishment
- Onshore construction
- Concrete manufacture
- Reclamation
- Sacrificial landfill
- Land incineration and subsequent disposal of residue
- Sea disposal

Each of the above options was considered first in broad terms to determine what options should be short listed for more detailed consideration. The options were examined using the criteria of strategic, environmental and cost consideration. Table 2.1 discusses the criteria in relation to the eight options for the disposal of the material.

Table 1.1: Criteria for the Assessed Options for the Disposal of the Dredged Material

Option	Criteria	Positive	Negative
Spreading on agricultural Land, or for soil conditioning of reclaimed land	**Strategic**		Identification of sites for agricultural use would be required, but timing of the work makes it unlikely that a suitable site could be found. Similar issue with use in reclaimed land. Land reclamation sites unlikely to be within reasonable transport distances. Agricultural use would require pretreatment to remove salt, followed by dewatering.
	Environmental		Contamination in the disposal material presents a risk to the health and safety of the public. There is a risk of PCB and PAH entering the food chain if used for spreading on agricultural land. PCB and PAH could also spread via skin contact.
	Cost		High cost due to rehandling and transportation.
Beach nourishment	**Strategic**		The disposal material is classified as soft silty material. Smaller grains are less stable as beach nourishment material because it is prone to accelerated erosion. The material is therefore unsuitable for use in beach recharge. Thus this option is eliminated from further consideration.
	Environmental		The materials to be disposed is contaminated (PCB and PAH) and it is highly unlikely that it would be acceptable as beach recharge material.
	Cost		High cost due to rehandling (transhipment to vessels capable of placing recharge material)
Onshore construction	**Strategic**		The material is classified as soft silty material and is unlikely to be suitable for construction.
	Environmental		The materials to be disposed is contaminated (PAH and PCB) and would pose a health risk if used in construction.
	Cost		High cost due to rehandling and transportation.

Option	Criteria	Positive	Negative
Concrete manufacture	**Strategic**		The material is classified as soft silty material and is not suitable for concrete manufacture.
	Environmental		The materials to be disposed is contaminated (PAH and PCB) and could post a health risk if used in construction.
	Cost		High cost due to rehandling and transportation.
Reclamation	**Strategic**		The material is classified as soft silty material and is unlikely to be suitable for reclamation. Engineering properties are unsuitable without post placement treatment (dewatering and soil stabilisation)
	Environmental		The materials to be disposed is contaminated (PCB and PAH). PCB and PAH can spread via skin contact.
	Cost		
Sacrificial landfill	**Strategic**	A facility has been identified. Avondale Hazardous Landfill Site only 17 km away from Port Edgar.	
	Environmental		The number of round trips need to be made by the truck to transport the material to the landfill is in the region of 1,000, with significant associated environmental impact. There is a potential risk of air pollution from the vehicles, as well as the risk of spillage from the trucks transporting the material. Noise and increased traffic would be other concerns. High energy cost.
	Cost		High transportation and labour costs due to the number of trips needed to be made by the truck to and from the Port to the landfill.

Option	Criteria	Positive	Negative
Land incineration and subsequent disposal of residue	**Strategic**	There are facilities in the UK suitable for incineration of PCBs.	The facilities are limited to three sites only. None of these sites are in Scotland. The closest site would be Pontypool, 630 km from Port Edgar.
	Environmental	This method would disposed of the PCB and PAH, eliminating any risk in the future of contamination and pollution from the residue.	The number of round trips need to be made by the truck to transport the material to the incinerator is in the region of 1,000, with a 1,260km round trip. Shipment by sea would require considerable rehandling.
	Cost		PCB and PAH needs to be combusted under extreme and carefully controlled conditions. Improper combustion of PCB would lead the formation of other toxins and incomplete destruction of PCB. Such specific conditions mean that it is extremely expensive to destroy PCB in a huge scale. High energy, transportation and labour costs due to the number of trips needed to be made by the truck to and from the port to the incinerator location.
Sea Disposal (1)	**Strategic**	A site location (Oxcars Spoil Ground) has been identified for sea disposal less than 10km east of Port Edgar.	
	Environmental	Material originates from the sediment load of the Firth of Forth. The material is considered suitable for disposal at sea because the amount of PCB, PAH, TBT and other Heavy Metals adheres to the Cefas guideline for Environmental Action Levels (EALs) for the disposal of dredge material.	Some of the contaminants are slightly higher than the EAL1 levels, although they are still well below the EAL2 levels.
	Cost	The costs and the number of trips required to transport the materials to the disposal site is affordable as no double handling is needed as the materials are loaded from the dredger to the split hopper barge, which would dispose it at sea.	

Sea Disposal (2)	**Strategic**	Plough dredging of the slipway and marina fairways has been undertaken regularly over the past 10 years with the material being dragged into the main channel of the Forth with no observed adverse effect.	
	Environmental	Material originates from the sediment load of the Firth of Forth.	Some of the contaminants are slightly higher than the EAL1 levels, although they are still well below the EAL2 levels.
	Cost	The costs and the number of trips required to transport the materials to the disposal site is affordable as no double handling is needed. The material is dragged directly to the disposal area without leaving the seabed.	

The materials to be disposed are contaminated with a number of compounds. Several options for the disposal of the dredged material, which could potentially cause direct effects to public health and safety, have been eliminated from further consideration. All of these options are also likely to be prohibitively expensive due to the requirement for rehandling of the material and transportation costs.

The options that have been eliminated from further consideration at this stage are:

- Spreading on agricultural Land, or for soil conditioning of reclaimed land
- Beach nourishment
- Onshore construction
- Concrete manufacture
- Reclamation

The remaining options take forward for further (more detailed) consideration are:

- Sacrificial landfill
- Land incineration and subsequent disposal of residue
- Sea disposal

3. SHORTLISTED OPTIONS FOR RELOCATION/REMOVAL OF MATERIALS

The shortlisted options were examined based on the strategic, environmental and cost consideration. This chapter would further evaluate the shortlisted options.

3.1 Sacrificial Landfill

a) Strategic Considerations

A facility has been identified suitable for the disposal of the dredged material, near to Port Edgar, which is the Avondale Hazardous Landfill. Figure 3.1 shows the location of the facility and the possible routes to transport the material from the port to the landfill.

Figure 3.1: Location of the Facility and Possible Transport Routes

The address of the facility is:

Avondale Environmental Limited
Avondale Quarry
Polmont
Falkirk
Stirlingshire FK2 0YG

There are two possible routes identified to transport the material from Port Edgar to Avondale Hazardous Landfill. The first route is via land all the way from Port Edgar to the landfill, which is identified via the blue line on Figure 3.1. The distance of this route is approximately 24.5km. The second route is via transporting the waste from Port Edgar to Grangemouth Dock by sea, and then transporting it to the landfill by land. The distance between Grangemouth Dock and Port Edgar is 18km and the distance by land from Grangemouth Dock to the landfill is 7.3km.

b) Environmental Consideration

The total number of round trips needed to transport the material from Port Edgar or Grangeworth dock is in the region of 1,000, assuming that the truck would be carrying approximately 20$m^3$of waste per trip.

This poses a risk of pollution to the environment from the vehicle emissions and further contamination to the environment as the risk of spillage is high and unlikely to be accepted by the local population.

There is a very high risk of spillage of material when transporting by land, as each of the vehicle would need to carefully transport this contaminated spoil without spillage, using routes that are frequently used by the public, along a number of parks and residential areas. This would not be a viable option, as the risk of spillage is high and the local resident are unlikely to accept such a high number of trucks carrying contaminated materials passing through their residential area.

Some form of stilling basin would also be required to allow the sediment to settle out of the water column before transportation. Frequent rehandling of the material would increase the risk of spillage and contamination.

c) Cost considerations

The transportation cost would be very high, as this involves 1,000 round trips to and from the port or dock to the landfill. Labour costs would also increase as more supervisors would be needed at the dock or port during the loading of the contaminated dredge material to supervise and make sure that the material is securely loaded on the truck to the landfill all the time.

3.2 Land Incineration and subsequent disposal of residue

a) Strategic Considerations

Three facilities have been identified in the UK suitable for the disposal of the dredged material. These incinerators have the facilities for incineration of PCBs and equipment. None of these sites are in Scotland. The incinerators are Cleanaway Ltd and two run by Shanks Chemical Services Ltd. The three sites are:

Cleanaway Ltd
Bridges Road
Ellesmere Port
South Wirral
Merseyside
L65 4EQ

Shanks Chemical Services Ltd
Pontyvelin Industrial Estate
Panteg
Pontypool
NP4 5DQ

Shanks Chemical Services Ltd
Charleston Road
Hardley
Hythe
SO45 3NX

Figure 3.2 shows the locations of the facilities, and the routes and distances to transport the material from the port to each of the facilities. Figure 3.2 shows that the nearest Incinerator from Port Edgar is Shanks (Facility 1) and the furthest would be Shanks (Facility 2).

Figure 1.2: Location of the Incinerators and Distance from Port Edgar

b) Environmental Consideration

The total number of trips needed to transport the material from Port Edgar or Grangeworth dock is approximately 1,000, assuming that the truck would be carrying

approximately 20m^3 of wastes per trip. The minimum distance each truck would need to travel to transport the waste per round trip is 1,260km.

This would post a risk of pollution to the environment from the emissions of the vehicles transporting the material.

There is also a very high risk of spillage of material when transporting by land, as each of the vehicle would need to carefully transport this contaminated spoil, sharing routes with the public going through residential and public areas before the trucks could get on the motorway. This would not be a viable option, as the risk of spillage is high and the local resident are unlikely to accept such a high number of trucks carrying contaminated materials passing through their residential area.

Some form of stilling basin would also be required to allow the sediment to settle out of the water column before transportation. Frequent rehandling of the material would increase the risk of spillage and contamination.

c) Cost considerations

The transportation cost would be very high, as this involves 1,000 round trips to and from the port to the incinerator. Labour costs would also increase as supervisors would need to be at the port during the loading of the contaminated dredge material to supervise and make sure that the material is securely loaded on the truck to the landfill all the time.

The cost to destroy PCB at a huge scale is extremely costly. This is because PCB and PAH needs to be combusted under extreme and carefully controlled conditions. Improper combustion of PCB would lead the formation of other toxins and incomplete destruction of PCB. Such specific conditions mean that it is extremely expensive to destroy PCB in a huge scale.

Costs from both transportation and the disposal of the material itself would deem it too costly for this option to be viable

3.3 Sea Disposal

a) Strategic Considerations

A site that has been identified as the nearest acceptable site for sea disposal is the Oxcars Spoil Ground which is less than 10km east of Port Edgar. Early consultation with Marine Scotland suggests that the material should be suitable for disposal at sea. A copy of the correspondence with Marine Scotland is included in Appendix B.

Figure 3.3 shows the location of the Oxcars Spoilground and the distance from Port Edgar.

Figure 3.3: Location of the Oxcars Spoilground and the Distance from Port Edgar

b) Environmental Consideration

The amount of round trips needed to transport the material from Port Edgar to the Oxcars spoilground is approximately 80, assuming that the barge would be carrying approximately 300m^3 of material per trip. The distance each barge would need to travel to transport the waste per round trip is less than 20km.

This would reduce double handling as the dredged material would be securely loaded on a barge and brought to Oxcars for direct disposal.

Early consultation with Marine Scotland suggests that the material should be suitable for disposal at sea. A copy of the correspondence with Marine Scotland is included in Appendix B.

c) Cost considerations

The transportation cost would be affordable as the material would only need to be transported less than10km away from the site with only around 80 round trips. This would also eliminate double handling, as the dredged material would be loaded onto split hopper barges.

d) Plough Dredging

Plough dredging will be used to move recently deposited material to a deepwater location in the Forth, adjacent to the marina. It is anticipated that the locally based vessel "Forth Boxer" will be able to complete the ploughing operation of approximately 1,000m^3 in four days. It is a cost effective way of returning to the estuary environment sediment that has been recently deposited by tidal action in the marina. The fine material will be weakened by the ploughing operation and is expected to be resuspended when deposited by the plough and spread by tidal action. The quantity is small in relation to the natural suspended sediment load of the estuary.

4. CONCLUSION

4.1 Summary of the Assessment

Eight options to dispose the waste material based on strategic, environmental and cost consideration, shows that several options could have direct potential effects on public health and safety due to the contaminants found in the material. These options were spreading on agricultural land, or for soil conditioning of reclaimed land, beach nourishment, onshore construction, concrete manufacture and reclamation. These options were eliminated from further consideration as the negative implications to public health are too high.

Hence three other options were then discussed in more detail before coming to a conclusion on why the disposal method at sea was the most favourable. These options were sacrificial landfill, land incineration and sea disposal.

In terms of Strategic consideration, there are suitable facilities for all the remaining options. However, in terms of transportation, handling, and acceptability to the public, both landfill and incineration are considered unacceptable.

In terms of Environmental consideration, the potential benefits of incineration are considered to be wiped out by energy costs and transportation impacts. Both sacrificial landfill and the incineration facility would need 1,000 round trips from the port to the disposal facilities, with the distance being as short as 7.3km for the sacrificial landfill and 630km for the incineration facility. There is a real risk of air pollution, traffic disruption, and local residents disapproving this option as the routes to the disposal sites would pass along public and residential areas. However, the sea disposal site (Oxcars) would only need 80 round trips for a distance of less than 10km. This would greatly reduce the potential for air pollution, traffic disruption and the need to go through roads near public areas.

In terms of costs, the sea disposal is the most favourable as this option would provide low energy, transportation and labour costs. This is because it reduces the amount of double handling as the dredged material that has been loaded on the barge could be brought to site immediately to be disposed of.

4.2 BPEO: Sea Disposal

Disposal at sea is the Best Practicable Environmental Option. It is strategically and financially viable, and poses the lowest risk in terms of environmental impact. Whilst capital dredging should be taken to the licensed disposal ground, dredging by ploughing techniques to the deep channel immediately beyond the marina is the BPEO for small maintenance dredging campaigns.

To: Rebecca Martin
Subject: RE: 122592: Port Edgar - Notice of Intention to Carry Out an Exempted Activity
Attachments: ATT00001.txt

Dear Rebecca,

We have approved the plans for pre-dredge sampling in Port Edgar. The samples (3) will need to be core samples as you are dredging between 1m-1.5m cd and tested for the top, middle and bottom of the core sample. Also, please note all of these samples should be retained for the duration of the dredge campaign in case further analysis is required at any point.

If you have any further questions please get in touch.

Kind regards,
Fiona Munro

Subject: RE: 122592: Port Edgar - Notice of Intention to Carry Out an Exempted Activity

Hi Fiona,

The depth will be 1m – 1.5m below chart datum and the volume will be 10,000m3 annually.

Thanks
Becca

Subject: RE: 122592: Port Edgar - Notice of Intention to Carry Out an Exempted Activity

Dear Ms. Martin,

Thank you for the notice of intention to carry out an exempted activity for pre-dredge sampling in Port Edgar. Could you please confirm the planned dredge volume and depth?

Kind regards,
Fiona Munro

Subject: 122592: Port Edgar - Notice of Intention to Carry Out an Exempted Activity

Good afternoon,

Attached is a notice of intention to carry out an exempted activity, this is for taking three samples within Port Edgar for pre-dredge sampling. Also attached is the pre-dredge sampling plan and correspondence from SNH confirming they have no concerns with the sampling proposal.

Kind Regards
Becca

Subject: RE: Port Edgar Pre-Dredge Sampling Confirmation

Rebecca –

Thank you for contacting us regarding the proposed pre-dredge sampling at Port Edgar.

I note the outline method statement that you have provided in your email below, alongside the sample point locations in the attached PDF. It is clear from this that the sampling activity represents one additional boat active for a brief period, in an already busy marina, during higher tidal state. I confirm that the effects of this activity upon the SSSI/ SPA/ Ramsar site will be minimal and do not require any further assessment. In Natura terms this activity will not generate 'likely significant effects' upon the SPA.

Please use this email as confirmation to Marine Scotland that we have no issues to raise with the sampling proposal.

Please contact SNH at the appropriate time regarding the subsequent proposal to carry out a capital dredge – as on a first reading this looks like it will lead to a loss of SPA habitat.

All the best.

Subject: Port Edgar Pre-Dredge Sampling Confirmation

Good morning,

I am writing on behalf of a client who is applying for a capital dredging marine licence within Port Edgar. The location of the proposed dredging site (see attached drawing attached drawing 122592A/WS/0002) is within the Firth of Forth SSSI, SPA and is close to a RAMSAR site.

As part of the process we are required to carry out pre-dredge sampling under a 'Notice of intention to carry out an exempted activity', and within this we require written confirmation from SNH that the proposed sampling will not have a likely significant effect on the SSSI, SPA or RAMSAR. Is this something that can be provided at this stage?

We are planning on taking three samples, using a locations seen on the attached drawing 122592A/WS/0002, within the proposed dredging area.

Below is the method statement on how the sampling is carried out;

- The site is accessed at high tide using a small displacement work boat (6 meter boat powered by an air cooled diesel engine)
- The grab used is a small scale stainless steel bucket grab.

- The boat is positioned using a handheld GPS over the pre-determined site for sampling.
- The grab is lowered to the sea bed by hand over the side of the boat using a length of rope.
- Once the grab is on the sea bed it is activated so the two sides can come together to collect the sample.
- The grab is recovered onto the boat where the samples is removed and placed into the collection pots.
- The grab is cleaned over the side of the boat to avoid contamination at the next site.
- The process is completed at each site as required.

Within the main marine licence application we will be consulting with SNH regarding the dredging and also consulting with a marine ecologist to ensure there is no significant effect on the protected areas.

If there is any more information required please contact me.

If there is someone more specific I should contact can you please let me know.

Kind regards
Becca

1. Project background

Out of over 90 marine non-native species (NNS) in the UK and Ireland (Payne *et al*. 2014) 23 are established in Scotland (Nall 2015), with their spread primarily due to shipping (ballast water, biofouling of hulls) and imported consignments of cultured species (Nall *et al.* 2016; Cook *et al.* 2016). Recently, the NNS, *Undaria pinnatifida* (Japanese wakame) has been found in Port Edgar Marina but further surveys of locations along the Firth of Forth found no other occurrences of wakame and therefore Marine Scotland conclude that there is merit in seeking to control the NNS at Port Edgar. Whilst the non-native seaweed has been removed from the hard structures in the marina, full eradication of marine NNS is difficult and a precautionary approach should be adopted so that control and containment measures are considered for all activities and sites (Scottish Government 2012)[1], including prevention of new introductions of other NNS. As such, the Scottish Government requires a Biosecurity Plan to risk assess the routine dredging operations at the marina to avoid further spread of existing NNS or introduction of new NNS as part of its precautionary approach to biosecurity.

Within this approach there are two types of biosecurity plans: 'Site' and 'Operations'.

- A site biosecurity plan covers the long-term, on-going activities at a single location such as a marina (e.g. routine anti-fouling or routine dredging activities).
- The operation biosecurity plan is for a particular activity or set of activities which are time-limited (e.g. construction of a new jetty or one-off dredging activities) (Payne *et al.* 2014). Site biosecurity plans are likely to be in place for a longer period of time and suited to periodic monitoring and review.

There are three levels of biosecurity plan, two of which are described in detail in the Scottish Natural Heritage guidance (Payne *et al.* 2014); a simple approach and a more in-depth approach (using a simplified Hazard Analysis and Critical Control Point (HACCP) technique). The third approach is a full HACCP technique and is not included in the guidelines. The simple approach for this project would list the activities which make up the dredging operation that may carry a risk of introducing or spreading NNS and control measures are proposed for each activity. Following liaison with Marine Scotland in September 2018 the simple approach was deemed suitable to accompany the dredge license application at Port Edgar Marina, with the primary aim of the Biosecurity Plan being to identify best practice for the control of spread of wakame.

[1] Scottish Government non-native species code of practice: https://www.gov.scot/Publications/2012/08/7367

2. Methodology

The preparation of the Port Edgar Biosecurity Plan following the simple approach outlined by Scottish Natural Heritage Biosecurity Planning Guidance (Payne *et al.* 2014) involves the following aspects:

- Defining the dredging operations to be undertaken – frequency, size of operation, location, methods etc.
- Site description – description of physical site components (e.g. permanent hard structures) and environmental description (water flow, salinity etc.) and how these affect the risk of new NNS introductions and the spread of NNS.
- Review of current status of NNS in the marina.
- Review of proposed dredging activities (e.g. arrival, activity, disposal, leaving site).
- Assigning a risk level for each activity (High, Medium, Low).
- Proposing biosecurity control measures for the medium and high risk tasks associated with the dredging activity along with instructions for staff and contractors.
- Proposing contingency plan e.g. rapid response and containment measures if monitoring detects high risk incidents or new NNS.

3. Marine Biosecurity Plan

3.1 Introduction

This operation biosecurity plan has been prepared to assess the biosecurity risks associated with routine dredging operations within Port Edgar Marina.

3.1.1 Description of operation

The scope of the dredging operation is defined in the dredging Marine Licence Application submitted to Marine Scotland as:

“Port Edgar Marina undertakes regular (annual) dredging as a result of sedimentation within the confines of the protected area, which has increased as a result of the construction of nearby bridge piers in recent years. The material to be dredged from the vicinity of the marina berths will not be removed off site; plough dredging will be carried out to move the material from the high spots at the marina to an area at the north east corner of the area for which Port Edgar Marina is responsible”

.

3.1.2 Site Description

Location

Port Edgar is situated on the southern shore of the Firth of Forth on the east coast of Scotland, between the Queensferry Crossing Bridge and the new Forth Road Bridge (please refer to Figure 1). The Firth of Forth is a busy industrial estuary with large commercial dockyards at Rosyth and Leith, which are located approximately XXX km from Port Edgar (both receive substantial shipping traffic from Europe and around the world). Furthermore, the oil refinery at Grangemouth receives boat traffic from around the world. The Firth of Forth is fed by the River Forth and flows into the North Sea along the coasts of Fife and East Lothian. The estuary is considered to be well-mixed to partially mixed, depending on the river flow and tidal range (Webb & Metcalfe 1987). The salinity varies from 18-31[2] at the surface to 26-32 at the bottom in the wider estuary (Webb & Metcalfe 1987). Salinity intrusion into the Forth estuary is highly dependent on river flow and tidal range (Webb & Metcalfe 1987). The Firth of Forth has a moderate but variable current speed of between 2.5 and 4.5 knots at peak flow depending on location (Admiralty Chart 734).

Port Edgar Marina

The marina at Port Edgar consists of three main structural components (the outer breakwaters, floating pontoons and the piers) and each should be considered separately (see Figure 1). Each structural component is subjected to similar environmental conditions, however, the habitats associated with them and the physical characteristics of the structures are different. Therefore, each of the three structures will have different risk factors and control measures associated with them specific to their physical characteristics.

Outer breakwaters

The outer breakwater sections are the oldest part of the marina and a remnant of the original naval base. The breakwaters are solid structures extending from the seabed to above the surface and are approximately 450 metres (m) long on each side of the marina with a further 150 m stretch at the front of the marina. The breakwaters are constructed from caissons and rubble and provide a large subtidal and intertidal area with high levels of structural complexity. The structural complexity created by the outer breakwater provides large areas of habitat suitable for colonisation by marine organisms.

[2] Salinity values determined by conductivity measurement are calculated as a ratio of measured conductivity to standard KCl conductivity. Since Salinity is a ratio, the value is actually dimensionless (no units)

Floating pontoons

The floating pontoons are the newest addition to the harbour and consist of seven floating arms, comprising of 3 x 150 m, 2 x 200 m and 2 x100 m sections, supporting 300 floating berths. The floating platforms have various designs and provide large areas of subtidal habitat that can be colonised by marine organisms.[3]

Piers

The two piers are also remnants of the original naval base. The piers comprise one 230 m and one 350 m section supported by numerous piles. The piles create a large subtidal and intertidal area with high habitat complexity, capable of supporting diverse intertidal and subtidal communities.

Dredge site

The proposed dredging operation will take place within the marina, between the pontoons and piers within the confines of the breakwaters Figure 1. The actual dredged extent will likely be a smaller section within the dredge area outlined in Figure 1 which will be informed by depth conditions at the site and the needs of the marina berth holders. The seabed within the marina is predominantly soft sediment and described as SS.SMu.CSaMu 'Circalittoral sandy mud' under the EUNIS classification system (EmodNET)[4]. The mud habitats are not considered to provide suitable substrate for colonisation by the NNS currently found in Port Edgar Marina (see Section 3.2.4). However, debris and other hard substrata amongst the mud could provide potential settlement habitats and a precautionary approach requires the assumption that NNS could be present in the sediment.

3.1.3 Plan period

Proposed dredging operations are planned between 1st January 2019 and 31st January 2022 on an annual or biannual (twice yearly) basis. It is anticipated that the dredger (provided by Briggs Marine) will be able to carry out the required volume of dredging within approximately ten – twelve days.

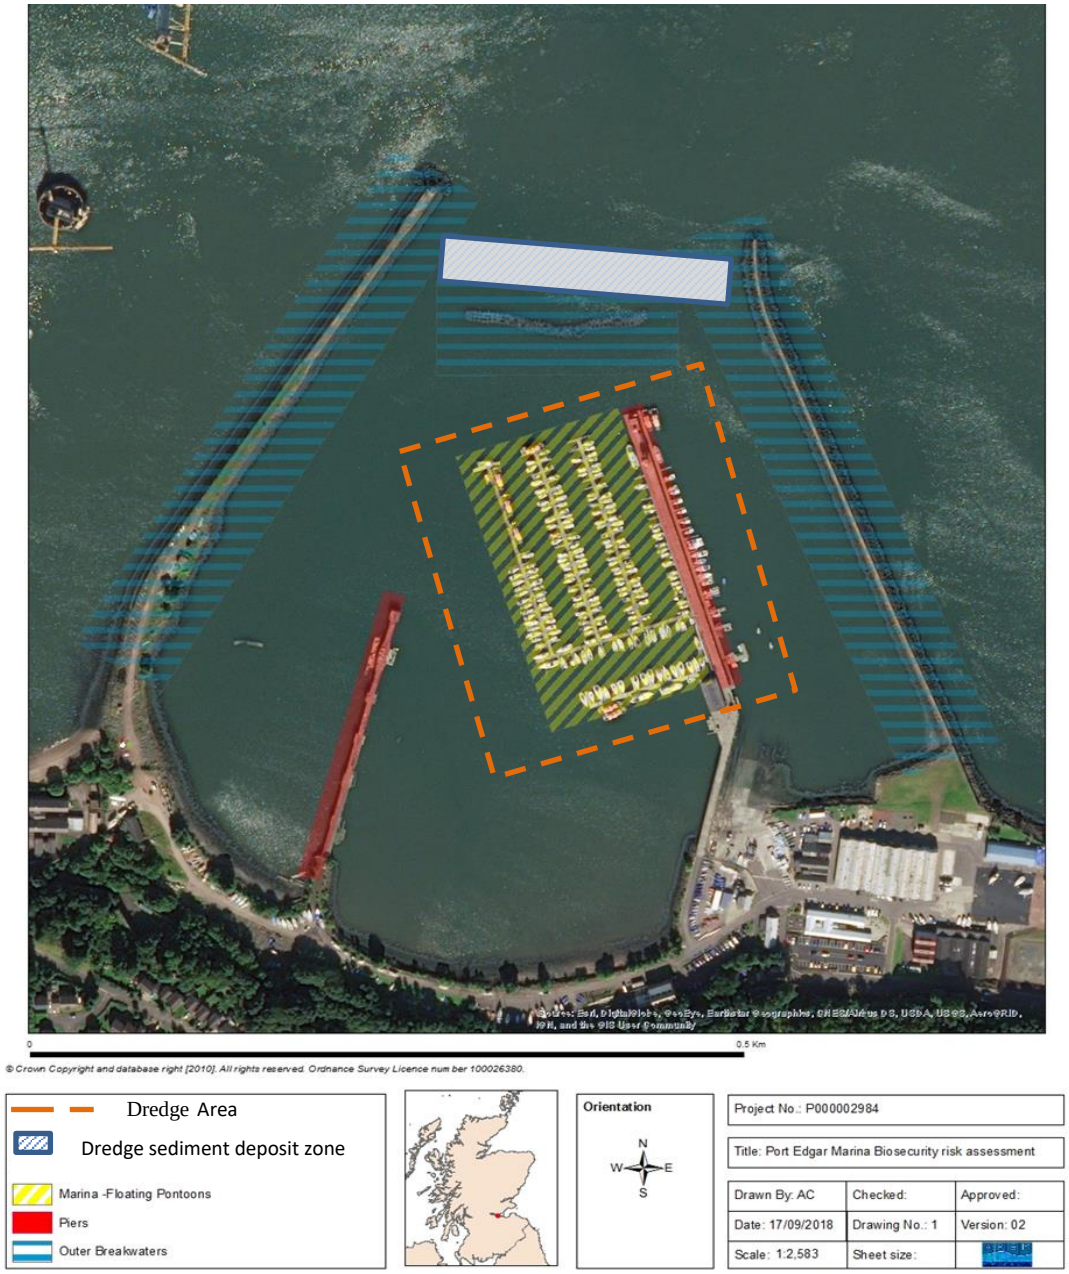

Figure 1 Plan view of Port Edgar indicating the location of the outer breakwaters, marina, piers and dredge area.

3.2 Information related to the environmental conditions affecting biosecurity

3.2.1 Salinity, temperature, tidal flow

Port Edgar can be considered a fully marine site, with a salinity regime capable of supporting fully marine species. The effects of any freshwater inputs are not evident within Port Edgar, which has a salinity of between 31 and 33 (Catarino *et al*. 2018). In addition, the temperature range within Port Edgar is favourable for most European-habituated NNS with an annual variation of between 15.7 °C in the summer and 5.6 °C in the winter (Catarino *et al.* 2018). The tidal flow within the marina is also minimal, making larval retention times high but possible dispersal potential is low. Due to the fully marine environment, favourable temperature and tidal conditions the marina is categorised as high risk for the colonisation of NNS according to the Scottish Natural Heritage Non-Native Species guidelines (Payne *et al*. 2014).

3.2.2 Submerged structures

Port Edgar has a variety of different submerged structures without anti-fouling coating, that are submerged for longer than 6 months at a time and that can only be cleaned *in situ*. Therefore these submerged structures all present a high-risk under the Scottish Natural Heritage Non-Native Species guidelines (Payne *et al*. 2014).

Breakwaters

The breakwaters present the greatest risk to biosecurity, because of their age, structural complexity, lack of antifouling measures and limited cleaning / eradication potential. As such, they provide a large area of colonisable habitat suitable for most NNS present in Scottish waters.

Floating pontoons

The pontoons provide a submerged hard-structure for NNS settlement and are in close proximity to recreational boating traffic (which is a primary transportation vector for NNS). However, the pontoons can be cleaned *in situ* and can be removed and treated further if necessary. The marina carries out biannual scraping and removal of seaweed using a method approved by Marine Scotland for containment of the NNS seaweed Japanese wakame. During this removal the wakame is gathered into a large net on a pole prior to scraping, the weed is then scraped off into the net, removed from the water, dried on the breakwater and disposed of in landfill or used for composting. The pontoons are therefore considered low risk due to the ongoing biosecurity management routine already in place.

Piers

The piers present a high risk settlement structure, because of their age, structural complexity, lack of antifouling measures and limited cleaning / eradication potential. Furthermore, the piers are in close proximity to high risk areas of NNS transportation such as recreational boating and the fuel berth.

3.2.3 Dredge site

The dredging site (Figure 1) can be considered low risk in terms the spread of NNS that are already present due to the dominance of sandy mud substrate which is not favourable for the NNS recorded at the site (see Section 3.2.4), particularly wakame.

3.2.4 Non-native species at Port Edgar

There are currently 23 known non-native species (NNS) in Scotland (Nall *et al*. 2015). Their distribution is uneven and available data are mainly restricted to that obtained from marinas (Nall *et al*. 2015). Currently three non-native species have previously been recorded within Port Edgar (Table 1). Two species (Green fingers seaweed *Codium fragile* subsp. *tomentosoides* and the Japanese skeleton shrimp *Caprella mutica*) were recorded in Port Edgar in 2006 during a survey of the ten largest marinas in Scotland to determine the presence of the seven marine non-native species highlighted in the Marine Aliens programme[5] (Ashton *et al.* 2006). The Japanese brown kelp known as wakame *Undaria pinnatifida* was not found in 2006 but has subsequently been identified on the floating pontoons in Port Edgar with containment measures introduced in collaboration with Marine Scotland. These consist of twice annual removal of biofouling seaweed from the floating pontoons as described above. Wakame has not been found to be growing on the piers.

Although only three NNS have been reported in Port Edgar, many other NNS are widespread and common across the UK. The Scottish Government advocates a precautionary approach with the Marine Biosecurity Planning document (Payne *et al*. 2014) recommending that biosecurity plans and measures assume the presence of potential NNS as well as those recorded, and that operations should be planned and biosecurity measures identified accordingly. This approach has been followed for the biosecurity assessment for the dredging operations at Port Edgar Marina.

[5] (http://www.marlin.ac.uk/marine_aliens/)

Table 1: Non-native species recorded within Port Edgar (as recorded in Ashton *et al*. 2006 and by Port Edgar Marina and Marine Scotland).

Species	Description	Habitat and ecology
Undaria pinnatifida	Japanese wakame, a brown kelp which can out compete native species[6].	A fouling species which attaches to hard substrate and is often found on man-made structures such as floating marina pontoons. Reproduction occurs in late spring or early summer[5].
Codium. fragile subsp. tomentosoides	Green sea-fingers, a spongy green seaweed which can displace native seaweeds, considered invasive by Scottish Natural Heritage[7]	Occurs on rock and coralline algae in pools and on open rock, often found on man-made structures[5]. Reproduction likely occurs towards the end of the summer / beginning of autumn[5].
Caprella mutica	Japanese skelton shrimp, which is considered invasive by Scottish Natural Heritage[5]	Often found on biogenic reefs and in areas of human activity on natural and artificial substrate such as hydroids, mooring ropes and buoys[5]. Fully benthic lifecycle with limited dispersal potential although can disperse along coasts on drifting algae[5].

4. Dredge activities which have a significant risk of introducing or spreading non-native species

The dredge operation has been broken down into three main activities: vessel arrival, dredging and vessel departure. Within each of these activities the biosecurity risks for each task have been identified and the risk assessed using the Marine Biosecurity Planning guidelines (Payne *et al*. 2014), to aid expert judgement. As a precautionary approach the overall activity risk was categorised at the highest risk level of any of the component tasks. Internal quality control for the risk categorisation consisted of review of the risk table by a senior marine taxonomist with expertise in non-native species.

[6] GB Non Native Secretariat species factsheets (http://www.nonnativespecies.org/home/index.cfm).
[7]https://www.nature.scot/professional-advice/land-and-sea-management/managing-coasts-and-seas/marine-non-native-species

Table 2 Risk assessment of introduction and spread of NNS during dredge operations. Risk categories were assigned using guidelines in Payne *et al.* (2014), additional scientific literature and expert judgement.

Activity	Biosecurity risk	Risk factor assessment	Task risk (High/ Medium /Low)	Overall activity risk (High/Medium /Low)
Arrival of dredge vessel.	Introduction of new NNS.	The vessel will be provided by Briggs Marine which are located locally in the Forth of Firth (north shore). Movements for commercial purposes will be unknown but will likely consist of regular movements between different ports along the east coast of Scotland.	Medium	Medium
		The vessel "Forth Sentinel" has a running speed of 9.5 knots and is therefore not considered slow moving.	Low	
		The biofouling removal regime is unknown at present.	Medium	
Dredging	Spreading on NNS via fragmentation or dispersal of NNS into the water column from hard structures due to physical disturbance or propwash	The dredge vessel will be operated by a very experienced company (Briggs Marine) minimising the risk of contact with hard structures.	Low	High
		The floating pontoons will be removed from the piers and rafted together providing opportunity for fragmentation, especially wakame which has been found on the pontoons.	High	
		Propwash from the dredge vessel could fragment NNS from hard structures.	Low	
	Dispersal of NNS from dredged sediment	The sandy-mud sediment that is to be dredged is not a favourable habitat of any of the NNS known to be present in Port Edgar, however using the precautionary approach it is assumed that some soft sediment NNS may be present. Hard debris such as shells and rocks can provide substrate for wakame and green sea fingers[1].	Medium	Medium

Activity	Biosecurity risk	Risk factor assessment	Task risk (High/ Medium/ Low)	Overall activity risk (High/Medium /Low)
Departure of vessel.	Spread of NNS from Port Edgar Marina on the hull of the dredge vessel.	The dredge vessel is expected to be present for approximately ten - twelve days in January or February each year and it is expected that the planktonic dispersal phase of most NNS will occur outside this timeframe. For example wakame releases zoospores in late spring or early summer[1], after the anticipated dredging. Japanese skeleton shrimp spend their entire lifecycle on substrate and lack a free swimming planktonic stage, dispersal can occur on drifting algae[1]. Green sea fingers are thought to have reproduction peaks in late summer / early autumn[2].	Low	Low

[1]GB non-native species secretariat: http://www.nonnativespecies.org/factsheet/index.cfm.

[2]Watanabe *et al.* (2009)

5 Biosecurity Control Measures

5.1 Existing measure

Port Edgar already adopts best practice biosecurity measures for the removal of wakame under an agreement with Marine Scotland. Pontoons are regularly checked by Port Edgar Marina for biofouling and cleaned twice annually to remove wakame and other bio-fouling organisms as described above.

5.2 Additional proposed measures

Additional biosecurity control measures have been identified for the specific medium and high risk activities indicated in Table 3. Consideration has also been given to using any movement of the floating pontoons to scrape wakame and other fouling biota from areas of the hard structure that would otherwise be inaccessible. Whilst it is not anticipated that access will be changed, any opportunities observed during operation will be taken. The control measures in Table 3 will be listed in a biosecurity log and the date when each control measure is carried out will be recorded in the log. This process will allow the identification of any breaches in control measures. If such a breach occurs it will be recorded in the biosecurity log and the contingency plan triggered.

Table 3 Biosecurity control measures proposed for Port Edgar dredging activity

Activity and biosecurity risk	Risk	Control measure	Where	When
Arrival of dredger - introduction of new NNS.	Dredge vessel is a commercial vessel with regular movement between unknown ports, biofouling removal regime is unknown.	Briggs Marine is a large respected marine services company and their boats are used by the Environment Agency who require stringent biosecurity measures and carry out inspections regularly.	NA	Ongoing
		Request anti-fouling treatment and bio-fouling removal record from Briggs Marine. If biofouling removal does not occur at intervals appropriate for the type of antifoul applied then refuse entry until bio-foul is removed.	Port Edgar Marina	Prior to dredge activity
		Use the rapid visual inspection scheme (see Table 5) on vessel arrival. If vessel is ranked at level 3 or higher the vessel should be refused entry.	Port Edgar Marina	On vessel arrival
Dredging - Fragmentation and dispersal of NNS.	Fragmentation of NNS especially wakame when floating pontoons are moved and rafted together.	Port Edgar Marina already carries out twice annual removal of bio-foul, including wakame from the floating pontoons. This procedure will be carried out no earlier than six weeks prior to the dredging activities.	Floating pontoons, Port Edgar Marina	Within 6 weeks prior to dredging
	Dispersal of NNS from dredged sediment.	All dredged material will be disposed of inside the marina breakwater to avoid any NNS being transported outside of the marina.	Port Edgar Marina	During dredge activities
		Any larger rock dredged and spotted by the dredge workers will be inspected for NNS including wakame, which will be removed and disposed of in landfill or composting.	Port Edgar Marina	During dredge activities
All	All	Training will be given to key staff at Port Edgar in the identification of NNS (e.g. see Firth of Clyde Forum Marine Invasive Non-Native Species Identification Guide[1]) and using the visual inspection scheme (Table 5). These references should be printed off and placed in the biosecurity plan folder along with this plan.	Port Edgar Marina	Prior to dredge activity

6. Contingency Plan

In the event of any of any control measures being breached or the detection of a new NNS all necessary steps should be made to control the spread and dispersal of the NNS. Contingency plans for specific scenarios are provided in Table 4.

Table 4 Port Edgar Contingency Plan

Issue	Action	Responsibility	Equipment
Fragmentation or dispersal of NNS into the water column.	Remove debris from the water column and dispose to landfill. Use the same procedures in place for routine cleaning.	Port Edgar should instruct dredge operatives to inform management of any observed fragmentation.	Hand nets
Dredge vessel is ranked at class 3 or above in the visual inspection (see Table 5).	The vessel is not allowed entry to port Edgar. Remove from water at home port, clean and antifoul. Inspect surrounding berths.	Port Edgar staff to carry out visual inspection prior to entry. Port Edgar Marina to refuse entry if required.	Laminated copy of visual inspection table to be available in marina office.
Debris with NNS are dredged off the seabed.	Remove from water and allow to air dry or dispose to landfill.	Port Edgar	NA
New non-native species found.	Inform Marine Scotland. Follow Marine Scotland and SNH instructions.	Port Edgar	Copy of Marine Scotland contact available in marina office.

7. Site surveillance and reporting procedure

The Marine Biosecurity Planning guidelines (Payne *et al*. 2014) require the use of a biosecurity logbook to record training, surveillance, control measures carried out and any other activities or concern regarding the biosecurity of the operation. The pontoons will be routinely scraped of bio-foul which will occur twice a year with one scraping occurring within six weeks prior to the dredging operation. This should be recorded in the biosecurity logbook. In addition, a visual inspection of the hard structures (using the visual inspection method in Table 5) within the marina should take place at Port Edgar prior to any dredging operation. This is to determine the presence and extent of any biofouling (specifically NNS), so that any adjustment can be made to procedure or biosecurity action plans.

Surveillance and biosecurity procedures should be assessed annually to ensure they are still relevant and up to date. In addition, procedure should be revised if any significant changes occur to the structure of the marina or if new NNS are recorded.

Following the guidance given by the Scottish Government under the Marine Scotland Act, any new NNS or a significant increase of existing NNS should be reported to Marine Scotland and Scottish Natural Heritage. The Marine Scotland contact for reporting invasive non-native species is the Scottish Environment and Rural Services telephone number: 08452 30 20 50 and email: info@sears.scotland.gov.uk

The GB Non-native Species Secretariat should also be informed so they can update species distribution and abundance databases for NNS.Relevant details are located on their website:

http://www.nonnativespecies.org

Table 5 Biofouling visual assessment (Payne *et al.* 2014)

Rank	Description	Visual estimate of biofouling cover
0	No visible fouling. Hull entirely clean, no biofilm on visible submerged parts of the hull.	Nil
1	Slime fouling only. Submerged hull areas partially or entirely covered in biofilm, but the absence of any plants or animals.	Nil
2	Light fouling. Hull covered in biofilm and one to two very small patches of one type of plant or animal.	1–5 % of visible submerged surfaces
3	Considerable fouling. Presence of biofilm, and fouling still patchy, but clearly visible and comprised of either one or more types of plant and/or animal.	6–15 % of visible submerged surfaces
4	Extensive fouling. Presence of biofilm and abundant fouling assemblages consisting of more than one type of plant or animal.	16–40 % of visible submerged surfaces
5	Very heavy fouling. Many different types of plant and / or animal covering most of visible hull surfaces.	41–100 % of visible submerged surfaces

9 Annex: Glossary

Biofouling: Biological growth which develops on manmade structures in the aquatic environment.

Biosecurity: Taking action in order to minimise the introduction or spread of invasive non-native species or disease.

Biosecurity Plan: A written document which details site / operation activities and actions that will be undertaken to minimise the introduction or spread of a specified threat (i.e. invasive non-native species).

Control Measures: Refers to actions which are undertaken in order to prevent the introduction or spread of an invasive non-native species.

Establishment: Refers to the process of a non-native species in a new location successfully producing viable offspring with the likelihood of continued survival.

EUNIS: The European Nature Information System (EUNIS) habitat classification is a pan-European system, which was developed between 1996 and 2001 by the European Environment Agency (EEA) in collaboration with experts from throughout Europe. It covers all types of natural and artificial habitats, both aquatic and terrestrial.

Introduction: Refers to the movement by human means, indirect or direct, of a species outside its natural range. This movement can be within a country or between countries.

Native Species: Also known as indigenous species, means a species occurring within its natural range (past or present) and dispersal potential, i.e. within the range it occupies naturally or could occupy without direct or indirect introduction or intervention by humans.

Non-Native Species: Non-native species (also known as alien, non-indigenous, foreign or exotic) means a species or subspecies occurring outside its native range i.e. the range it occupies naturally without the intervention of human activity. This includes any part of the species that might survive and subsequently reproduce.

Prop Wash: An aviation and nautical term used to define a mass of air or water pushed aft or fore by the propeller of an aircraft or propeller-driven watercraft. This term is synonymous with any water disturbance created by a vessel's propulsion systems.
