Figure 4-25: peak numbers of velvet scoter recorded at Blackdog between 1998 and 2007.

Passage of velvet scoter past Peterhead occurs during spring and autumn with peak counts of up to 300 birds occurring in October and evidence of a small spring passage when up to 150 birds were recorded during April (Innes 1996).

Boat-based surveys

Four sightings of velvet scoter were made from boat-based surveys totalling 14 birds. Two singles in February, a flock of five in July and seven in November (IECS 2008).

Vantage Point surveys

In Aberdeen Bay low numbers of velvet scoter were recorded during the winter months with an increase in numbers during the year and a peak passage of velvet scoter of usually less than one bird per hour during June. Results from all the Vantage Point counts undertaken recorded only two velvet scoter flying above 30 m. Most birds were recorded between 1 km and 3 km from shore (EnviroCentre 2007a, 2007b, Alba Ecology 2008b).

Bird Detection Radar

A total of 28 velvet scoter were recorded during radar surveys in October 2005. Numbers were split fairly evenly between the two sites at which surveys were undertaken with 13 at Drums and 15 at Easter Hatton. All sightings were within 2.5 km from shore and all birds recorded in flight were flying below 10 m (Walls *et al* 2005).

Six velvet scoter were recorded at Blackdog within 1 km of the coast between 11 and 26 April 2007 (Simms *et al.* 2007).

4.12.3 Summary of Results

Velvet scoter were only occasionally recorded throughout the year during surveys undertaken across Aberdeen Bay. A total of fourteen velvet scoter were recorded from boat-based surveys and a peak from shore-based counts occurred in June. Most velvet scoter were recorded between 1 km and 3 km off the coast

Of those recorded in flight all but one were recorded flying below 30 m.

Although no counts during surveys undertaken across Aberdeen Bay were of national importance peak counts from Blackdog have, in the past, been of national importance.

4.12.4 Initial Assessment of Significance

Velvet scoter	Overall sensitivity	Magnitude	Significance
Collision	Medium	Negligible	Negligible
Barrier	High	Medium	Moderate
Displacement	Very High	High	Major

4.12.5 Species Sensitivities

Qualifying species

There are two SPAs in the region for which velvet scoter is a qualifying species as part of waterfowl assemblages: Firth of Forth SPA and Firth of Tay and Eden Estuary SPA.

Flight height

The small number of flight heights obtained from boat-based surveys undertaken in Aberdeen Bay reported all flights as flying below 25 m and therefore not at risk of collision. There was one record of a velvet scoter flying above 30 m.

Elsewhere in the UK small numbers (<20) of velvet scoter have been recorded all of which have been flying below rotor height with a mean flight height of less than 1 m.

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that velvet scoter are generally uncommon in Aberdeen Bay, occurring within the larger common scoter flocks. They occur mainly within 3 km of the coast and in waters less than 20 metres.

Evidence from elsewhere indicates that velvet scoter detour around wind farms and are at low risk of collision. A total of nearly 1,600 velvet scoters were recorded in the Kalmar Sound and no collisions were recorded (Petterrson 2006).

Consequently, the risk of an impact arising due to collisions is low and significance should it occur negligible.

The two SPAs in the region for which velvet scoter is a qualifying species as part of an assemblage are both over 90 km away. The probability of birds from these SPA populations flying through the proposed development area at turbine height is low and consequently the risk of collision is also very low. Therefore there will not be an adverse effect on the population due to collision.

Barrier effect

Studies undertaken in Sweden and Denmark have shown that there is the potential for a barrier effect on velvet scoter with changes in flight directions of up to 1 km from offshore wind turbines and birds seen flying around wind farms. Therefore, it is predicted that the proposed development may cause a barrier effect to common scoter in Aberdeen Bay.

There is no evidence of regular daily movements of velvet scoter within Aberdeen Bay to and from feeding or roosting areas. However, velvet scoter frequently mix in flocks of common scoter and should a barrier effect occur for common scoter then it may also do so for velvet scoter. As with common scoter, the potential additional increase in daily energy expenditure due to possible displacement may be between 2.2% and 2.6% (Speakman, Gray & Furness 2009). This is a relatively small increase in daily energy expenditure and is unlikely to have an adverse effect or significant impact on velvet scoter in Aberdeen Bay.

The incremental increase in the distance migrating velvet scoter from their breeding grounds in Scandinavia or Russia may incur should they be displaced during their migration to or from the Firth of Forth or Firth Tay & Eden Estuary SPAs will be negligible and not cause an adverse effect.

Displacement

Based on the results from the monitoring data, the worst-case scenario is that, should displacement occur, there will be 100% displacement of velvet scoter within the proposed development area and out to a distance of 1 km. A further 50% decrease in abundance occurs out to 2 km from the wind farm. However, very few velvet scoter were recorded during site specific surveys undertaken within the bay and peak counts from Blackdog have, in recent years, been below 200 individuals (Figure 4-25). There are no reports on whether velvet scoter are displaced by offshore wind farms but evidence of little or no displacement to the closely related common scoter indicate that displacement is unlikely to occur. Based on this assumption then it is predicted that there will not be an adverse effect or significant impact from the proposed development on velvet scoter.

Disturbance

Disturbance effects on velvet scoter will be similar to those identified for common scoter and they may be disturbed by vessels, both during the construction phase and during operations from maintenance vessels. The numbers of velvet scoter recorded within the proposed development area were very low and it is therefore predicted that disturbance from either construction or service vessels will have a negligible impact and not cause an adverse effect.

Cumulative and in-combination

Aside from the historical and on-going levels of shipping, there are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on velvet scoter present within Aberdeen Bay. There is not predicted to be any cumulative or in-combination impacts arising at other planned developments as their locations offshore and their water depths indicate that velvet scoter may not regularly occur in these areas. No velvet scoter were reported during studies undertaken at the Beatrice demonstrator wind farm (Talisman 2005). Consequently there are unlikely to be any cumulative or in-combination impacts.

4.12.6 Conclusions

Habitats Appraisal

Based on the evidence from existing offshore wind farms indicating a very low collision risk, potentially little or no displacement and no significant barrier effects; it is predicted that there will not be any adverse effects on the SPAs for which velvet scoter is a qualifying species.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on velvet scoter.

4.13 Common goldeneye (*Bucephala clangula*)

4.13.1 Protection & Conservation Status

The (Common) goldeneye is listed in Appendix II of the Bonn Convention, Appendix III of the Bern Convention and is on the Green List of Species of Conservation Concern.

4.13.2 Background

Goldeneye		
GB population	Breeding – 200 pairs Winter – 25,000 ind	BTO 2011
Scottish population	Breeding: 120 - 150 prs Winter: 10,000 – 12,000 ind.	Holling *et al*. 2010 Forrester *et al.* 2007
International threshold	11,500 ind.	Calbrade *et al*. 2010
GB threshold	249 ind.	Calbrade *et al*. 2010

European population estimate	Breeding 490 – 590,000 prs Wintering – >310,000 ind	Birdlife 2004
European population trend	Status 'secure' Trend 'small increase'	Birdlife 2004
World population	2,5 – 4,600,000 'adults'	Birdlife 2011

Goldeneye breed beside freshwater habitats across northern Europe with a total breeding population of up to 590,000 pairs primarily in Sweden, Finland and Russia. There is a small and localised breeding population in the UK with approximately 120 to 150 pairs nesting in Scotland (Holling *et al.* 2010).

During the winter goldeneye move away from the breeding sites and move onto both fresh and salt water bodies. In eastern Scotland the Firth of Forth holds the largest wintering population in the UK with a peak mean of 581 over the last five years. This is considerably lower than recent historical counts at the site where over 2,000 goldeneye used to be regularly recorded (Cork Ecology 2004a).

In North-east Scotland goldeneye has only recently colonised the region as a scarce breeding bird with a small but increasing population of about 30 nests, inland with relatively small numbers wintering along the coasts and inland freshwater. The main areas are Loch of Skene and Loch of Strathbeg where peak numbers of up to 100 to 200 birds may occur (Buckland, Bell & Picozzi 1990; NESBR).

On the coast goldeneye are rarely recorded between June and September with birds present from October onwards when numbers passing Peterhead peak with up to 2 birds per hour between November and January (Innes 1996). All sightings of goldeneye at Peterhead were of birds within 1 km of the shore.

Boat-based surveys

Five goldeneye were recorded from boat-based surveys with three in April and two in November.

Vantage Point surveys

Small numbers of goldeneye were recorded passing through Aberdeen Bay with a total of 41 records between November and April over the three years of data collection.

Five goldeneye were recorded from boat-based surveys with three in April and two in November.

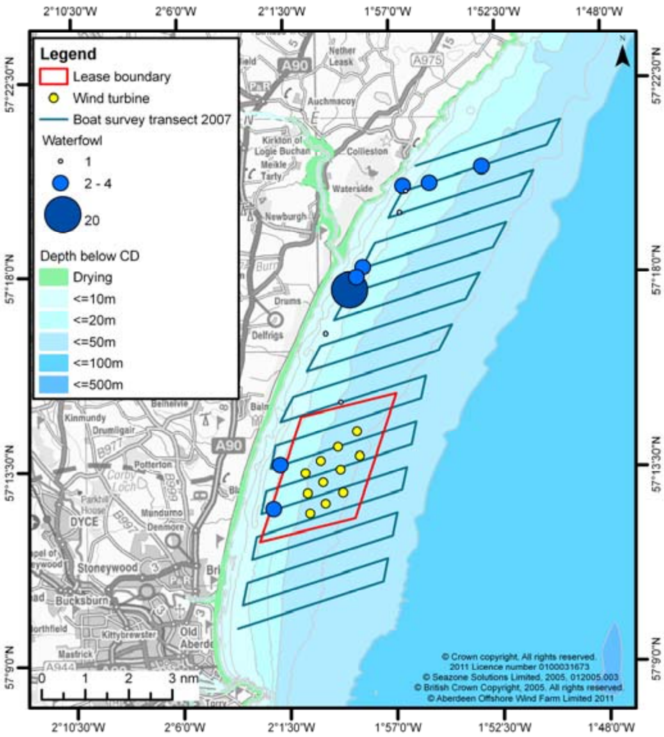

Figure 4-26: Waterfowl distribution in Aberdeen Bay - February 2007 to April 2008 (all sightings).

Bird Detection Radar

No goldeneye were recorded during the radar studies undertaken at Easter Hatton and Drums during October 2005 but three were recorded at Blackdog during the additional radar surveys undertaken at Blackdog during April 2007 (Simms *et al.* 2007).

4.13.3 Summary of Results

Goldeneye were infrequently recorded in Aberdeen Bay with most sightings from Vantage Point surveys between November and April.

4.13.4 Initial Assessment of Significance

Goldeneye	Overall sensitivity	Magnitude	Significance
Collision	Medium	Negligible	Negligible
Barrier	High	Negligible	Negligible
Displacement	Medium	Negligible	Negligible

4.13.5 Species Sensitivities

Qualifying species

There are two SPAs for which goldeneye are part of the qualifying assemblages: Firth of Forth SPA and Firth of Tay & Eden Estuary SPA. Goldeneye was also listed as part of the qualifying assemblages in original citation for the Loch of Strathbeg but is not so for subsequently updated ones.

Flight height

Very few records of goldeneye were made from site specific boat-based or land-based surveys and only two records of their of flight altitudes were made. Both were of birds flying below 25 m.

Elsewhere there is very limited data from other offshore wind farms on flight heights for goldeneye.

Collision risk

Evidence from site specific monitoring indicated that goldeneye are scarce in Aberdeen Bay and primarily occur in near-shore waters. Evidence from other offshore wind farms indicated that goldeneye are at low risk of collision from offshore wind farms. A total of nearly 3,100 goldeneye were recorded during studies undertaken in Kalmar Sound and no collisions were recorded (Pettersson 2005). Based on the relatively low numbers of goldeneye recorded and evidence from other wildfowl of a potentially high avoidance rate it is predicted that the risk of an adverse or significant environmental effect on goldeneye from collision mortalities arising from the proposed development is negligible.

Barrier effect

Evidence from studies undertaken at Kalmar Sound suggests that there is the potential for some barrier effects as goldeneye may avoid flying through offshore wind farms. Should a barrier effect occur then goldeneye will fly around the proposed development. This may incur an overall increase in flying distance of approximately 3.2 km. There is no evidence of any regular feeding or roosting flights by goldeneye across Aberdeen Bay nor any regular usage of the site itself. Any additional distance flown should goldeneye fly around the proposed development will be small compared to the total distance of their migration and will not be significant nor have an adverse effect.

Displacement

Goldeneye do not use Aberdeen Bay for feeding or roosting and therefore no displacement effects will occur.

Cumulative and in-combination

The low level of usage of the site by goldeneye and the relatively few recorded from other UK developments indicate that there will not be any cumulative or in-combination impacts.

4.13.6 Conclusions

Habitats Appraisal

There are no SPAs for which goldeneye is a qualifying species that will be effected by the proposed development.

Environmental Impact Assessment

Based on the relatively low numbers of goldeneye recorded and their known behaviour it is predicted that there will not be a significant environmental impact arising from the proposed development on goldeneye.

4.14 Red-breasted merganser (*Mergus serrator*)

4.14.1 Protection & Conservation Status

Red-breasted merganser is listed in Appendix II of the Bonn Convention, Appendix III of the Bern Convention and is on the Green List of Species of Conservation Concern.

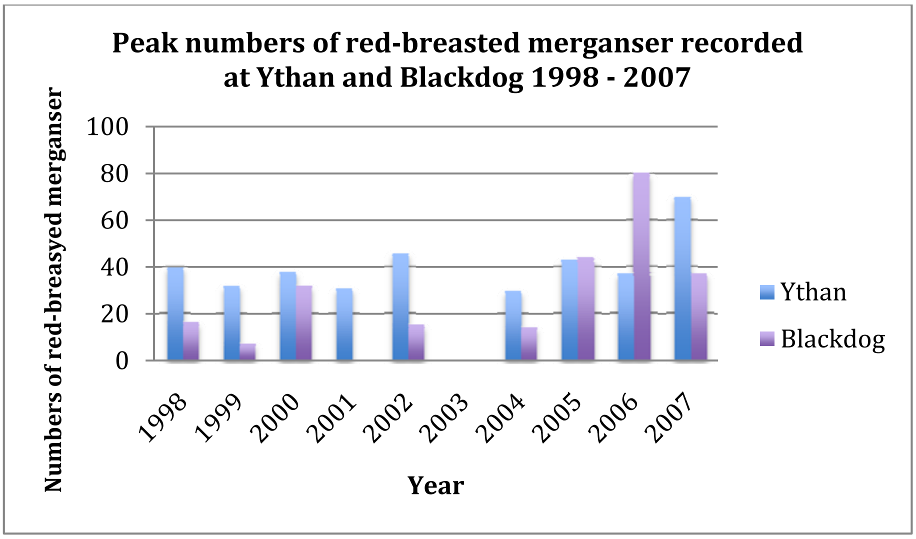
4.14.2 Background

Red-breasted merganser		
GB Population	Breeding: 2,400 prs. Winter: 10,200 ind.	Birdlife 2004
Scottish population	Breeding: 2,000 prs Winter: 8,500 ind	Forrester *et al*. 2007.
International threshold	1,700 ind.	Calbrade *et al.* 2010
GB threshold	98 ind	Calbrade *et al.* 2010
Designated east coast sites where species is a noted feature	Firth of Forth	SNH 2011
European population estimate	Breeding 59,818 – 84,484 pairs Wintering – 89,000 ind.	Hagemeijer & Blair 1997 Birdlife 2004
European population trend	Status 'secure' Trend 'small decline'	Birdlife 2004
World population	510,000 – 610,000	Birdlife 2011

Red-breasted merganser breed across northern Europe with the largest populations occurring in Scandinavia. In Scotland there is an estimated 2,000 pairs. The UK wintering population is estimated to 10,200 individuals, of which 8,500 occur in Scotland; dispersed around the coasts with the main wintering areas in the Moray Firth, Firth of Forth, St Cyrus and Montrose Basin and the Scottish west coast. During August and September adult red-breasted mergansers undergo a wing moult and become flightless for a period. During this period they congregate in flocks in regular areas including the Cromarty Firth, Inner Moray Firth and in Aberdeen Bay. There is evidence of migration during the spring and autumn with peak passage during March/April and October (Forrester *et al*. 2007).

Outwith the breeding season between 85% and 90% of red-breasted merganser occur along coasts and estuaries feeding on a variety of fish species (Cork Ecology 2004a).

In North-east Scotland red-breasted merganser is a scarce and possibly irregular breeder but is widespread in generally low numbers along the coasts during the winter. Peak numbers occur at Loch of Strathbeg, Ythan Estuary and in Aberdeen Bay primarily between November and February.



(Source NESBR)

Figure 4-27: Peak numbers of red-breasted merganser in Aberdeen Bay between 1998 and 2007.

Peak numbers pass Peterhead throughout the year but highest numbers occur during March and April with up to 2.4 birds per hour with most sightings within a few hundred metres from shore and nearly all sightings within 1 km from shore (Innes 1995).

Boat-based surveys

During boat-based surveys, one red-breasted merganser was recorded in March at the Donmouth (IECS 2008).

Vantage Point surveys

Data from Vantage Point Counts undertaken between March 2005 and March 2008 recorded peak numbers of red-breasted merganser in October and November when up to four birds per hour were recorded passing the Donmouth in October 2007. Up to nineteen birds were recorded in April 2006 and ten off the Promenade during March 2005 (EnviroCentre 2007a).

Out of the 84 sightings of birds in flight there was only one record of a bird flying above 30 metres. At Blackdog most sightings were of birds between 1–2 km from the shore, whereas at the Donmouth birds were recorded out to 3 km (Alba Ecology 2008b).

Bird Detection Radar

A total of 51 red-breasted merganser were recorded during five days of surveys at Drums and Easter Hatton in October 2005. Fourteen were at Drums and 37 at Easter Hatton. Birds were recorded out to 3 km from shore but the majority were within 2 km, with peak numbers within 500 m of the coast. The mean flight height was 14 m with one record of birds at 40 m (Walls *et al.* 2006).

Red-breasted mergansers were frequently recorded during the 17 days of radar surveys undertaken at Blackdog in April 2007. A total of 31 records of 76 individuals were recorded with a mean flock size of two and a peak count of seven birds (Simms *et al.* 2007). All birds were seen flying below 30 m above sea surface and the majority, 60, of sightings were of birds flying south.

4.14.3 Summary of Results

There was one sighting of red-breasted merganser from the boat-based surveys but they were regularly recorded from land-based studies with peak numbers in October and November. The majority of birds were within 2 km of the coast with most within 500 m.

Of those recorded in flight all but two were recorded flying below 30 m.

No counts during any surveys undertaken across Aberdeen Bay were of national importance.

4.14.4 Initial Assessment of Significance

Red-breasted merganser	Overall sensitivity	Magnitude	Significance
Collision	Medium	Negligible	Negligible
Barrier	High	Low	Negligible
Displacement	High	Medium	Moderate

4.14.5 Species Sensitivities

Qualifying species

Red-breasted Merganser is a qualifying species as part of waterfowl assemblages: Firth of Forth SPA, a site with a 5 year mean peak count of 410 individuals (Calbrade *et al*. 2010).

Flight height

No flight heights were obtained from boat-based surveys undertaken in Aberdeen Bay. One was recorded as flying above 30 m from Vantage Point surveys and one from radar surveys. However, the mean flight height was recorded as being 14 m.

Elsewhere in the UK 10% of all flights have been recorded at rotor height (n=71).

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that red-breasted merganser are widespread in Aberdeen Bay and occur out to 3 km from shore. Consequently they are at risk of interacting with the proposed development.

At other offshore wind farms, over 9,000 red-breasted mergansers were recorded in the Kalmar Sound and although birds were recorded flying through the wind farms there were no recorded collisions. There was also clear evidence of avoidance behaviour with a four-fold decrease in the number of mergansers flying through zone post-construction (Petterson 2006).

The majority of red-breasted mergansers were within 2 km of the shore and therefore not at risk of collision. Furthermore most sightings were of birds flying below 25 m and evidence from operating wind farms has indicated a very high avoidance rate. Therefore, the risk of a significant impact arising due to collisions is low and the significance of any impact, should it occur, would be negligible.

The only SPA in the region for which red-breasted merganser is a qualifying species is over 130 km away. The probability of birds from this SPA flying through the proposed development area at turbine height is low and consequently the risk of collision is also very low. Therefore there will not be an adverse effect on the population due to collision.

Barrier effect

Studies undertaken in Sweden and Denmark have shown that there is the potential for a barrier effect on red-breasted merganser with changes in flight directions up to 1 km from offshore wind turbines and birds seen flying around wind farms. Therefore, it is predicted that the proposed development may cause a barrier effect to red-breasted merganser in Aberdeen Bay.

There was no evidence from Vantage Point surveys or radar studies of any regular daily movements of red-breasted merganser within Aberdeen Bay to and from feeding or roosting areas. Should a barrier effect occur it is likely to be on an occasional *Ad hoc* basis and If so then it is predicted on the occasions that it occurs the increase in flight distance will cause an increase of between 1% and 1.5% of daily energy expenditure. This is a relatively small increase in daily energy expenditure and is unlikely to have an adverse effect on or significant impact on red-breasted merganser in Aberdeen Bay.

The incremental increase in the distance migrating red-breasted merganser from their breeding grounds will incur on their way to or from the Firth of Forth SPA, should they be displaced, will be negligible and not cause an adverse effect.

Displacement

Based on the results from the monitoring data, the worst-case scenario is that should 100% displacement occur, then no red-breasted merganser will be within the proposed development area out to a distance of 1 km. There may be a gradual in the number of birds present with a further 50% decrease in abundance out to 2 km from the wind farm. Very few red-breasted merganser were recorded from the site specific surveys undertaken within the bay and peak counts from Blackdog are below 80 individuals (Figure 4-27). Evidence from Sweden also suggest that operating wind farms cause little or no displacement (Pettersson 2006). Studies undertaken at Nysted offshore wind farm recorded more red-breasted mergansers during post-construction surveys than during pre-construction including in the wider area.

Based on the distribution of red-breasted mergansers in Aberdeen Bay and evidence from other sites then it is predicted that there will not be an adverse effect or significant impact from the proposed development on red-breasted merganser due to displacement.

Disturbance

Studies undertaken in Sweden concluded that although red-breasted mergansers could be disturbed by vessels they returned to areas once the vessels departed. There will be both construction traffic and maintenance vessels associated with the proposed development. These may cause some disturbance to red-breasted mergansers when on site but this will be temporary. The numbers of red-breasted merganser recorded within the proposed development area were very low and it is therefore predicted that disturbance from either construction or service vessel will have a negligible impact and not cause an adverse effect.

Cumulative and in-combination

Aside from the historical and on-going levels of shipping, there are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on red-breasted merganser present within Aberdeen Bay. There is not predicted to be any cumulative or in-combination impacts arising at other planned developments as their locations offshore and their water depths indicate that red-breasted merganser may not regularly occur in these areas. No red-breasted mergansers were reported during studies undertaken at the Beatrice demonstrator wind farm (Talisman 2005). Consequently, there are unlikely to be any cumulative or in-combination impacts.

4.14.6 Conclusions

Habitats Appraisal

Based on the evidence from existing offshore wind farms indicating a very low collision risk potentially little or no displacement and no significant barrier effects, it is predicted that there will not be any adverse effects on the SPAs for which red-breasted merganser is a qualifying species.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on red-breasted merganser.

4.15 Red-throated diver (*Gavia stellata*)

4.15.1 Protection & Conservation Status

The red-throated diver is listed in Annex I of the Birds Directive, Appendix II of the Bern Convention, Appendix II of the Bonn Convention, Schedule 1 under the Wildlife and Countryside Act, 1981 and is on the Amber List of Species of Conservation Concern.

4.15.2 Background

Red-throated diver		
GB Population	Breeding: 1,014 – 1,551 prs. Winter: 17,000 ind.	Calbrade *et al*. 2010
Scotland	Breeding: 1,000 – 1,500 prs. Winter: 2,270 ind.	Forrester *et al.* 2007
International threshold	3,000 ind.	Calbrade *et al*. 2010
GB threshold	170 ind.	Calbrade *et al*. 2010
Designated east coast sites where species is a noted feature	Firth of Forth SPA 317 ind.	SNH 2011 JNCC 2011a Calbrade *et al*. 2010
European population estimate	Breeding 32,000 – 92,000 Wintering >51,000	Birdlife 2004
European population trend	Status: 'Depleted' Trend: 'stable'	Birdlife 2004
World population	200 – 590,000 'adults'	Birdlife 2011

Red-throated divers are relatively common around the Scottish coasts and spend much of the year at sea only coming onto fresh water during the breeding season. The species is entirely coastal in its wintering distribution, often being associated with shallow coastal inshore sandy bays during the winter months (Lack, 1986). The major prey items are crustaceans, sand eels, sprat, herring, flatfish and codling and, as the name of the species suggests, these items are obtained by diving. The majority of wintering individuals are located down the east coast of Britain. Recent findings from aerial survey data have estimated the UK wintering population of this species to be now in the region of 17,000 birds (O`Brien *et al.* 2008).

Red-throated divers are a very rare breeding species in North-east Scotland but are a common wintering and passage species around all coasts.

Historically peak numbers of red-throated diver occurred during the late autumn and early winter periods with a peak count of 1,470 birds between Don Mouth and Collieston in October 1979 (Buckland, Bell & Picozzi 1990). In more recent years Aberdeen Bay has held up to 400 red-throated divers during a peak spring period between March and May. However, numbers recorded appear to have decreased (Figure 4-28). Outwith the peak spring period, red-throated diver occur in lower numbers throughout the year particularly during the summer months. There is also an increase in numbers during the autumn with birds returning from their more northerly breeding grounds. Counts of up to nearly 180 birds have been recorded in the bay during September (Lewis *et al.* 2008). Evidence from studies undertaken by JNCC in 2005/06 indicated that the distributions of red-throated diver within the bay may vary slightly across the year. However, peak counts are most frequent between the Donmouth and Balmedie and at the Newburgh Bar at the mouth of the Ythan Estuary. There are very few records of any red-throated divers in water depths of greater than 20 m (Söhle *et al.* 2006; Lewis *et al*. 2008).

Three aerial surveys undertaken by the JNCC in Aberdeen Bay between December 2005, January 2006 and May 2006 recorded a maximum of 39 red-throated divers in May (Söhle *et al.* 2006).

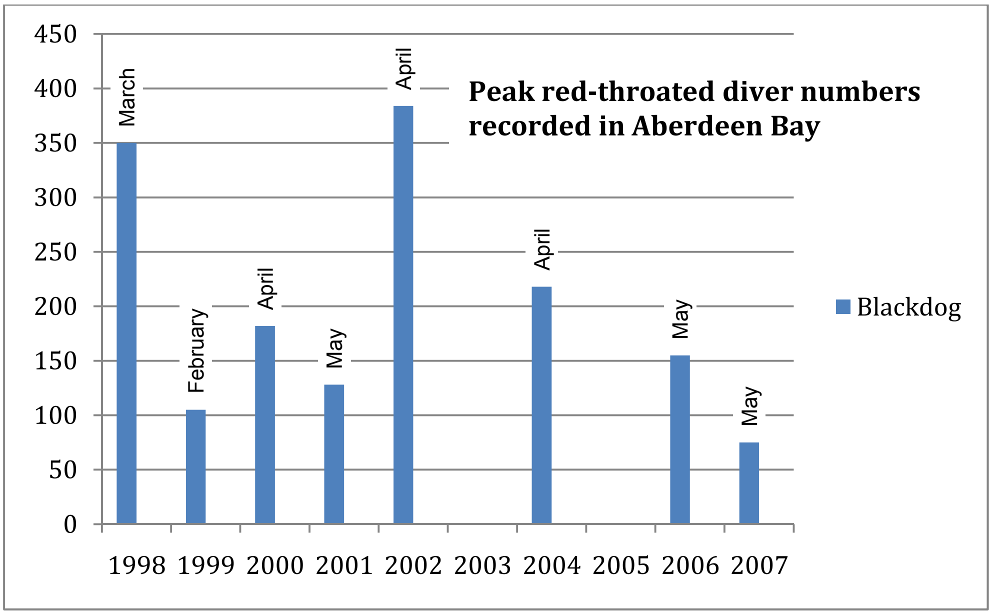


Figure 4-28: Peak numbers of red-throated diver recorded in Aberdeen Bay between 1998 and 2007. (Source NESBR).

4.15.3 Survey Results

Boat-based surveys

Boat-based surveys were undertaken on a monthly basis between February 2007 and April 2008 and from August 2010 to present. The surveys recorded red-throated divers throughout the year in Aberdeen Bay with the majority of sightings during the spring and autumn and relatively few between June, July and August. The majority of sightings were in waters less than 10 m and within 1 – 2 km of the coast. There were very few records of red-throated diver within the proposed development area. The peak in May probably reflected movement of divers heading to northern Scottish breeding sites or back across to Scandinavia, whilst the increase in winter months indicated the presence of a wintering population in Aberdeen Bay.

Based on extrapolation of overall density, including birds recorded in short-transect lengths, a total of 93 birds were estimated to be using the proposed EOWDC survey area during the passage period in May 2007. Numbers were estimated to be lower for the rest of the year with an estimated 55 birds present in December (Table 4-11). Population estimates were lower in the 'control' area, particularly during the winter months (Table 4-12).

Table 4-11: Red-throated diver monthly population estimate within the proposed EOWDC area.

Month	On water estimate	In flight estimate	Total estimate
February 2007	16	0	16
March 2007	11	3	14
April 2007	34	0	34
May 2007	88	5	93
June 2007	26	0	26
July 2007	9	0	9
August 2007	22	0	22
September 2007	7	5	13
October 2007	16	0	16
November 2007	26	0	26
December 2007	52	3	55
January 2008	33	0	33

Table 4-12: Red-throated diver monthly population estimate within the 'control' survey area.

Month	On water estimate	In flight estimate	Total estimate
February 2007	4	0	4
March 2007	29	0	29
April 2007	7	0	7
May 2007	0	0	0

October 2007	13	0	13
November 2007	7	0	7
December 2007	9	3	11
January 2008	10	0	10

Further analysis of the data collected between February 2007 and January 2008, undertaken by the Sea Mammal research Unit (SMRU) using Distance Sampling techniques, recorded peak estimated abundance during the winter months with an estimated abundance within the proposed EOWDC survey area of 38 birds in December and January and 47 birds in February and relatively lower numbers of less than 30 birds in spring. Densities were also higher in the winter with up to 0.9 birds/km^2 in the proposed EOWDC area (Table 4-13, Figure 4-30) (SMRU 2011a).

Table 4-13: Monthly estimates of density and abundance of Red-throated diver in the proposed EOWDC and 'control' areas (using Distance sampling).

Month	Location	Density Estimate (km^2)	SE	Estimated Abundance	SE	No. Observations
January	EOWDC	0.744	0.354	38	18.0	15
	Control	0.134	0.072	7	3.6	3

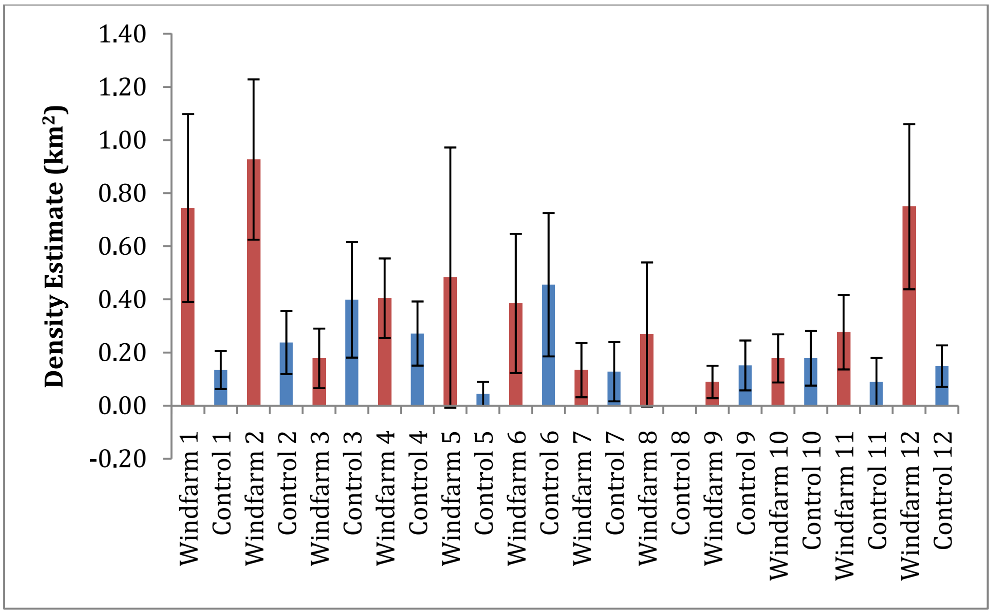

Figure 4-29: Monthly estimates (+/- SE) of density of red-throated divers in the proposed EOWDC and 'control' Areas. February 2007 – January 2008 (Wind farm 1-12 and 'control' 1-12 refers to months).

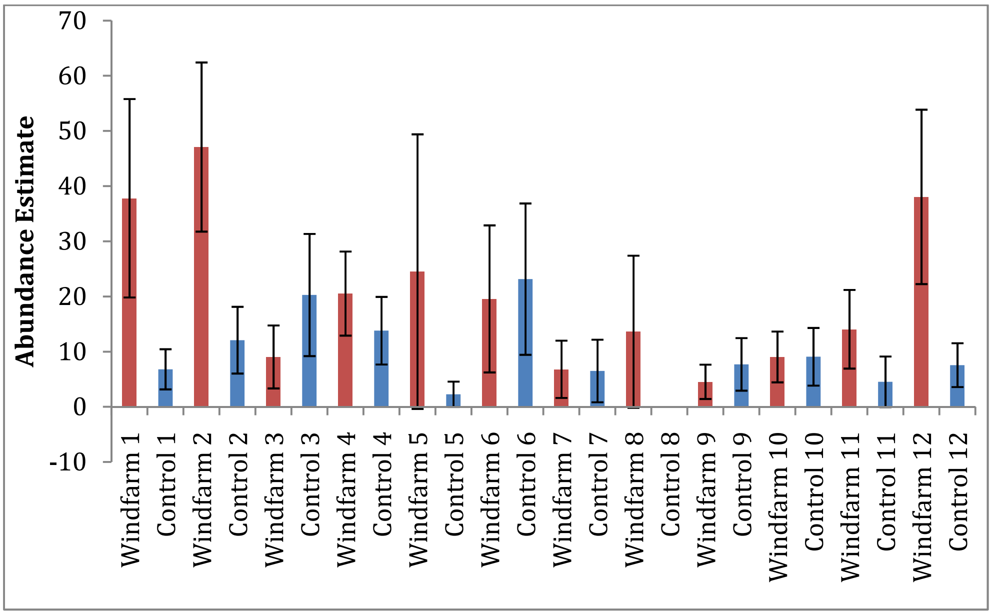

Figure 4-30: Monthly estimates (+/- SE) of abundance of red-throated Divers in the proposed EOWDC and 'control' Areas; February 2007 – January 2008 (Wind farm 1-12 and 'control' 1-12 refers to months).

Distribution maps from boat-based surveys indicate that red-throated divers exhibit a preference for water shallower than 20 m, but with concentrations observed on the 'short legs' of the survey, around the 5 m to 10 m depth contour line (Figure 4-31, Figure 4-32, Figure 4-33).

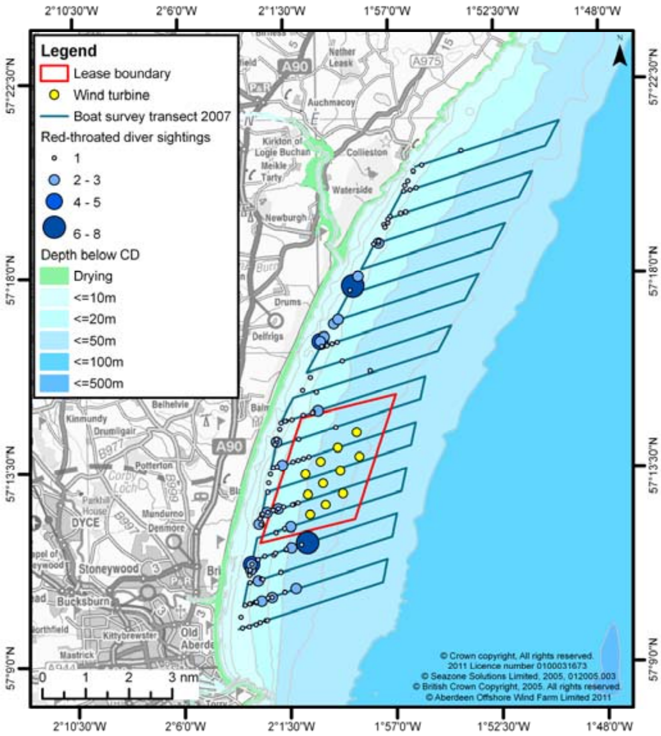

Figure 4-31: Red-throated diver distribution during winter period: November to March; 2007 – 2008 (all sightings).

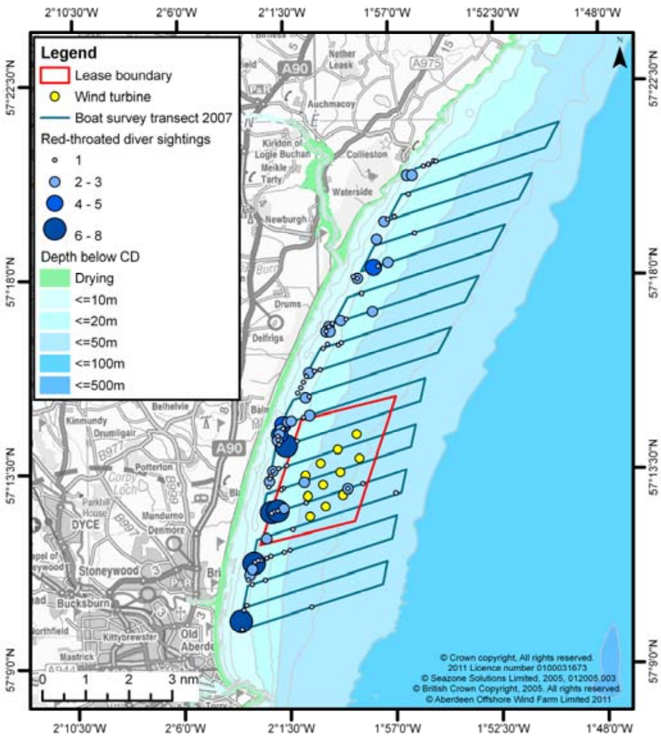

Figure 4-32: red-throated diver distribution during passage: April, May and September, October; 2007 (all sightings).

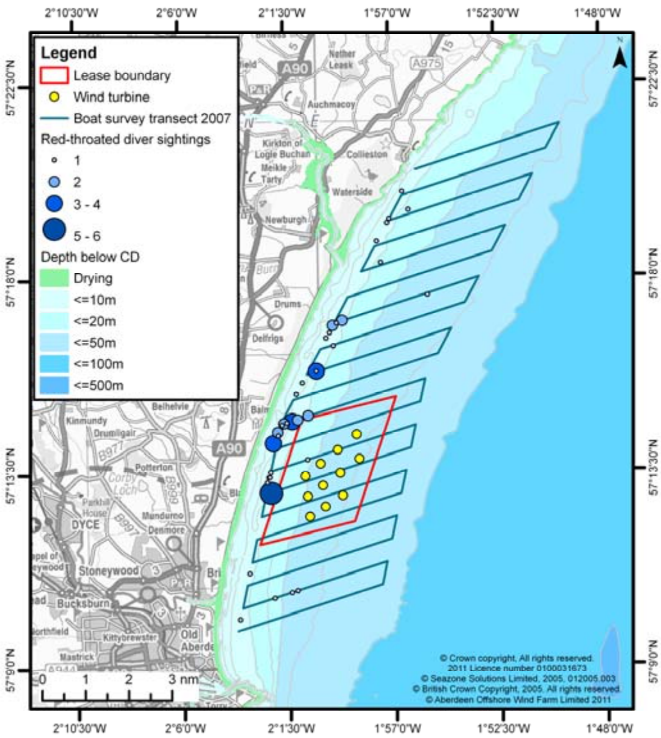

Figure 4-33: red-throated diver distribution during summer period: June, July and August 2007- (all sightings).

Additional boat-based data collected between August 2010 and January 2011 recorded a peak abundance estimate using *Distance* sampling techniques of 697 red-throated diver at a density of 4.9 birds/km^2 in the northern survey area during November 2010 with very low abundances to the south or offshore (Figure 4-34, Figure 4-35) (SMRU 2011b).

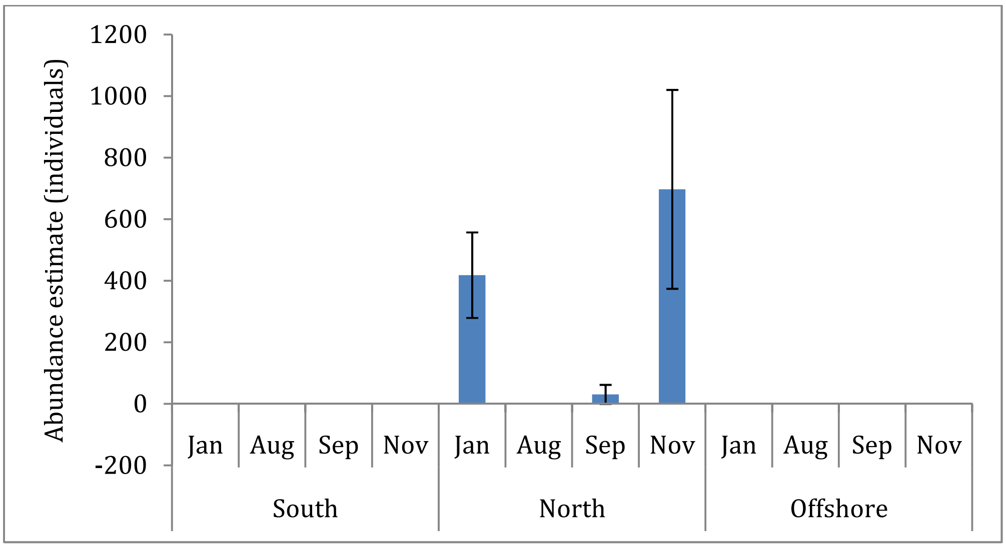

Figure 4-34: Abundance estimates for red-throated diver between August 2010 and January 2011.

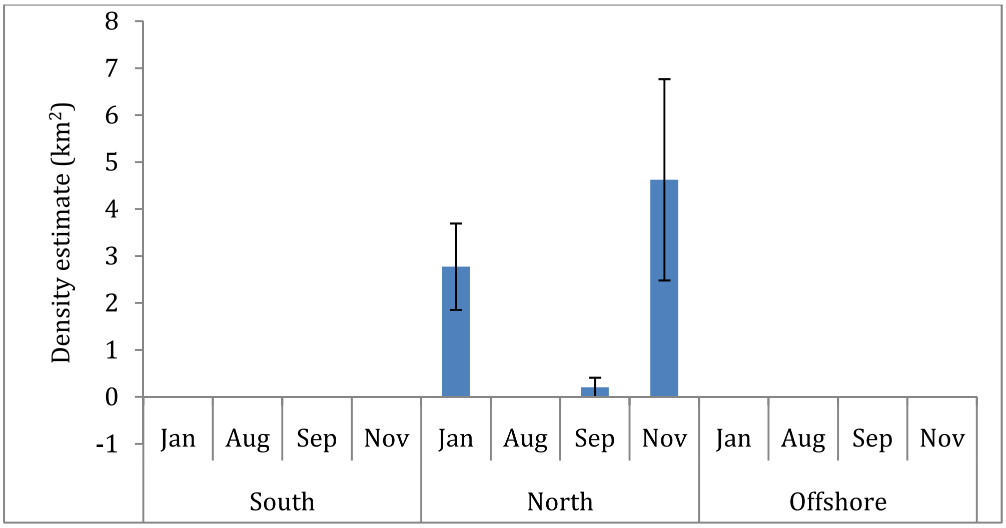

Figure 4-35: Density estimates for red-throated diver between August 2010 and January 2011.

Most sightings during this period were to the north of the proposed development area with less than five red-throated diver recorded from all surveys within the footprint of the proposed development (Figure 4-36).

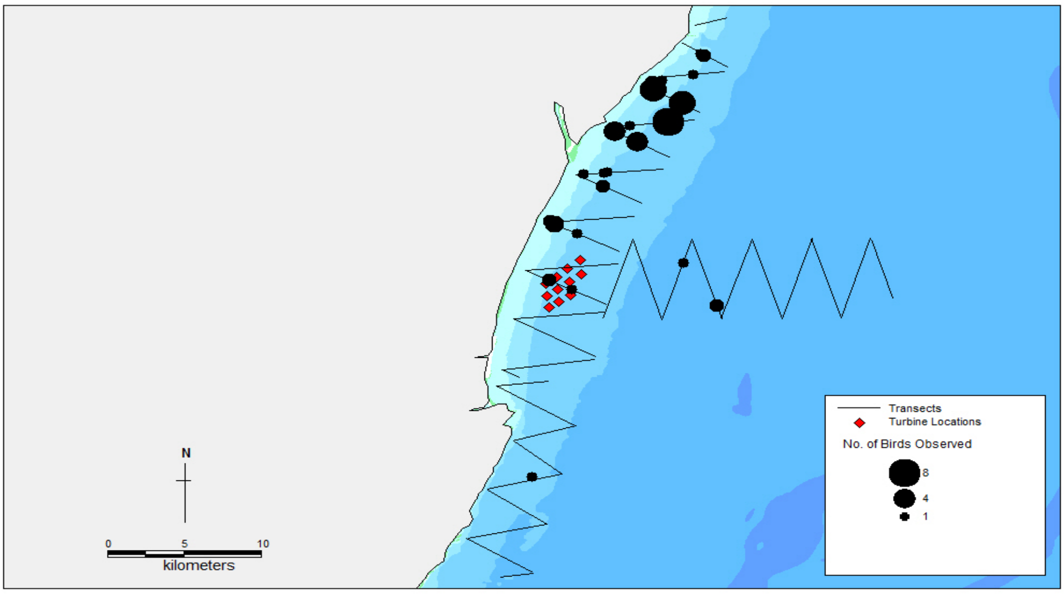

Figure 4-36: On-effort observations of all Diver species (Red-throated and Unidentified Diver species) along transects during August, September and November 2010 and January 2011

Vantage Point surveys

Data from vantage point surveys were collected in Aberdeen Bay between March 2005 and October 2005 and also from April 2006 to March 2008.

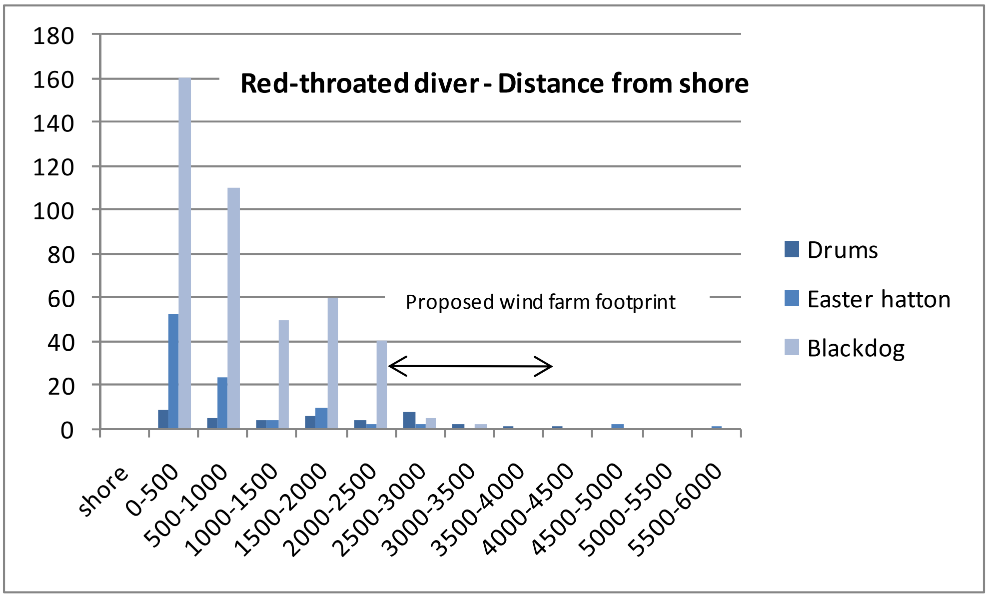
The results indicate a strong seasonal variation across the year with peak numbers occurring in the bay during April and May with a mean of up to 40 birds/hour passing in April 2007 and peak counts of 28 birds off Murcar, over four hours of observation, during May 2005 (Alba Ecology 2008a). Red-throated divers were seen at all vantage point locations, mainly within 1 km or out to 2 km from shore with most records from Murcar, Drums and Balmedie and generally lower numbers at Blackdog and Donmouth.

Of those recorded in flight between 3% and 16% were between 30 to 150 metres above the sea suface, i.e at potential rotor height.

Bird Detection Radar

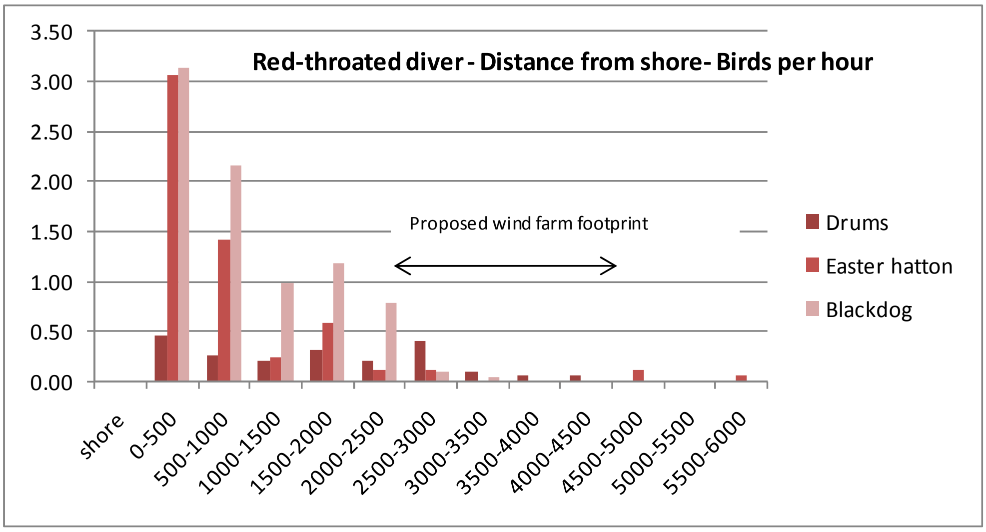
During radar studies undertaken in October 2005 a total of 157 red-throated divers were recorded, of which 65 were at Drums and 95 were at Easter Hatton (Walls *et al* 2005). Peak numbers were recorded within 500 m from shore although small numbers were recorded out to 5.5 km. Of those recorded in flight the mean height was 5 m with a maximum height of 40 m (Walls *et al.* 2006).

In April 2007, further Bird Detection Radar surveys were undertaken at Blackdog for a period of 17 days. During this time a total of 427 birds were recorded usually as singles with a maximum flock size of four birds (Simms *et al.* 2007). The majority of sightings were of birds within 1.5 km of the coast, although birds further offshore may have been missed (Figure 4-37, Figure 4-38).



(Adapted from Walls *et al.* 2006, Simms *et al.* 2007)

Figure 4-37: Distances from shore for red-throated diver from three locations in Aberdeen Bay during surveys undertaken in October 2005 (Drums & Hatton) and April 2007 (Blackdog).



(Adapted from Walls *et al.* 2006, Simms *et al.* 2007)

Figure 4-38: Number of red-throated diver per hour and distance from shore from three locations in Aberdeen Bay during surveys undertaken in October 2005 (Drums & Hatton) and April 2007 (Blackdog).

4.15.4 Summary of Results

Red-throated diver occur throughout the year in Aberdeen Bay with peak numbers occurring during the winter and spring periods. Peak numbers of red-throated diver recorded within the proposed EOWDC survey area was 93 in May 2007 and peak density of 0.9 birds/km^2 in February 2007. Further surveys identified potentially main areas for red-throated diver to the north of the proposed development where densities of up to 4.9 birds/km^2 were recorded during November 2010. Evidence from boat-based surveys supports the findings from the Vantage Point and radar studies that most red-throated diver occur within 2 km of the shore and in water depths of less than ten metres. Estimated numbers of red-throated diver recorded in Aberdeen Bay were below the threshold for a site of international importance but the bay may, on occasions, hold nationally important numbers.

The number of red-throated diver flying above 30 m and therefore at risk of potential collision varied from between 0% and 16%.

4.15.5 Initial Assessment of Significance

Red-throated diver	Overall sensitivity	Magnitude	Significance
Collision	High	Negligible	Negligible
Barrier	Very High	Medium	Major
Displacement	Very High	Medium	Major

4.15.6 Species Sensitivities

Qualify species

There are no SPAs for red-throated diver that are within the area of potential impact from the proposed development. It is recognised that currently Aberdeen Bay is an area of search with respect to becoming a potential SPA and could include red-throated diver as a qualifying species. However, it is understood that it is currently unlikely to become an SPA in the foreseeable future.

Flight height

Red-throated diver typically fly low and just above wave height. Site specific data obtained from boat-based surveys recorded 55 red-throated divers in flight all of which were recorded as flying below 25 m. Evidence from other locations have recorded 99.6% of red-throated divers as flying below 30 m (LAL 2005, RBA 2005).

Collision risk

Evidence from site specific monitoring from boat-based and land-based surveys and other data sources indicate that red-throated diver are widespread and frequent within Aberdeen Bay.

In order to determine potential effects of collision mortality on red-throated diver a collision risk assessment has been undertaken based on a collision probability of 9% and over a range of possible avoidance rates of 98%, 99% and 99.5%.

In order to determine whether any potential increase in mortality is significant the assessment is based on the precautionary figure of 1% of the baseline mortality rate for the population as has previously been considered for other offshore developments and based on EC Guidance (EC 2000).

The peak population estimate for red-throated diver recorded in Aberdeen Bay from any source is an estimated 697 individuals in November 2010 at a density of 4.9 birds/km^2. (SMRU 2011).

The annual mortality rate for red-throated diver is 16% (BTO 2011).

Consequently, out of a population of 697 individuals in Aberdeen Bay an annual mortality of 111 red-throated divers may be predicted. Therefore, 1% of the baseline mortality is 1.1 birds per year, i.e. an increase in mortality rate of more than 1 bird per year caused by collisions may be considered significant.

The Firth of Forth SPA has a wintering population of 317 individuals and therefore an annual mortality rate of 51 birds per year and a baseline mortality rate of 0.5 birds per year.

Table 4-14: Predicted number of collisions for various avoidance rates for red-throated diver

Collision probability	Avoidance rate (%)		
	98	99	99.5
9%	0.08	0.04	0.02

Based on the various scenarios and using a precautionary avoidance rate of 98% it is predicted that a total of 0.08 collisions per year may occur (Table 4-14) this is lower than the 1% baseline mortality rate of 1.1 birds per year for Aberdeen Bay and 0.5 birds per year for the Firth of Forth SPA.

Evidence from other offshore wind farms indicates that red-throated diver are at low risk of collision. Studies undertaken at Horns rev and Nysted offshore wind farms in Denmark indicate that red-throated divers avoid wind farms. Sixty-one Divers were tracked using radar none of which were recorded flying into the wind farm. Instead they were recorded as being deflected westward and flying around the wind farm (Petersen *et al*. 2006). Red-throated divers are therefore unlikely to come into direct contact with them (Petersen *et al*. 2006).

Based on the results from the Collision Risk Modelling and evidence from other sites it is concluded that the potential impact of collision risk is negligible.

Barrier effect

Evidence from studies undertaken in Denmark indicate that red-throated divers may avoid flying through wind farms; consequently, there may be a barrier effect on red-throated divers within Aberdeen Bay. Should a barrier effect occur out to a distance of 1km from the proposed development then a Diver may detour around the wind turbines causing it to increase its flight by a total of 3.2 km. Energetics modelling predicts that by flying around the proposed development the additional 3.2 km will cause an increase in energy usage of 8.5 Kj or 1% of daily energy expenditure (Speakman, Gray & Furness 2009).

There is no evidence of any regular daily movement in the form of feeding or roosting movements across Aberdeen Bay by red-throated diver and so any increase in energy expenditure due to the avoidance of the wind turbines should it occur is not predicted to be on daily basis and consequently any incremental increase in energy expenditure is likely to be *Ad hoc* and not a regular event. An increase in potential daily energy expenditure of 1% is small and likely to within the range of natural daily variations and it is therefore not considered to be significant and consequently based on current evidence the likely predicted effects from potential barrier impacts are considered to be negligible.

Displacement

Evidence from post-construction monitoring undertaken in the UK and Denmark suggests that red-throated divers may avoid wind farms (Ecology Consulting 2009, 2010; Petersen *et al.* 2006). The results from the monitoring undertaken at the Kentish Flats Offshore Wind Farm do not show 100% avoidance but do indicate a reduced usage of the site out to 1 km. Based on the results from the monitoring data, the worst-case scenario is that there is a 100% displacement of red-throated divers from the proposed development out to 1 km and a further 50% decrease out to 2 km from the area.

Based on the peak density of 4.9 birds/km^2, should there be a total displacement of red-throated diver from within the proposed development then it is predicted that up to 21 red-throated diver may be displaced during periods of peak density. Based on a 100% displacement out to 1 km (a total surface area of 12.3 km^2) from the proposed development then it is predicted that up to 60 red-throated diver may be displaced and a further 50 out to 2 km should there be 50% displacement between 1 km and 2 km from the proposed development. Therefore, the maximum number of red-throated diver potentially displaced is up to 131 birds based on the highest densities recorded from any survey within Aberdeen Bay and displacement out to 2 km.

Evidence from boat based surveys suggest that peak densities occur to the north of the proposed development area and outwith the immediate zone of displacement effect (Figure 4-31, Figure 4-32, Figure 4-33, Figure 4-36) and that densities within the vicinity of the development are typically much lower at below 1 bird/km^2 (Figure 4-29, Figure 4-30). Consequently, it is predicted that should displacement occur, the number of Divers typically displaced will be between 16 individuals (with 1 km of displacement) and 26 birds (with up to 2 km of displacement). Furthermore, the distribution of divers across Aberdeen Bay is largely within 3 km of the shore and therefore densities to the east of the proposed development, i.e. within the proposed development area, will be lower than has been used for this assessment which has not taken this decrease in offshore red-throated diver density into account.

Based on the maximum estimated population of 697 birds at a density of 4.9 birds/km^2, it is predicted that up to 19% of the red-throated diver population of Aberdeen Bay may be displaced. Based on site specific numbers from the proposed development area 4% may be displaced. Should red-throated divers be displaced then they are predicted to relocate to other suitable foraging areas. Evidence from surveys indicates that areas to the north of the proposed development area are preferred over areas within the vicinity of the proposed development.

Red-throated diver numbers within Aberdeen Bay vary across seasons and years and there is no evidence of the population of red-throated divers within Aberdeen Bay being at carrying capacity as numbers fluctuate considerably across years. Consequently, should displacement occur it is not predicted to, nor is there any evidence for, any increase in the mortality rate of red-throated diver.

Based on site specific data and results from other sites it is concluded that the potential impact of displacement is at worst moderate and most likely minor.

Calculations used for displacement		
Area	*Peak density of red-throated diver – 4.9 birds/km^2*	*Typical density of red-throated diver – 1 bird/km^2*
Area of EOWDC – 4.3 km^2	4.3 * 4.9 = 21	4.3 * 1 = 4
Area of 1 km buffer = 12.3 km^2 (100% displacement)	(12.3 * 4.9) =60	12.3 * 1 = 12
Area of 2 km buffer – 20.3 km^2 (50% displacement)	(20.3 * 4.9)*0.5 = 50	(20.3 * 1)/2 = 10
Total number potentially displaced	21 + 60 + 50 = 131	4+ 12 + 10 = 26

Disturbance

Red-throated divers are predicted to be disturbed by vessels both during construction and during operation from maintenance vessels. Previous studies have indicated that there may be total displacement from within 100 m of a vessel and varying degrees of displacement at distances up to 1,000 m. Some displacement may occur beyond 1,000 m but this is not reliably quantified or attributed to the survey vessel. The average displacement recorded is 82% of all birds within 1 km (Norman & Ellis 2005). When disturbed divers respond to approaching vessels by low, direct flights usually perpendicular to the line of approach and that these flights are generally below 15 m (Norman and Ellis 2005)

During construction there may be a number of vessels operating within the area but will likely be focussed around a single point where the turbine is being installed. Consequently, up to 82% of the Divers may be displaced from within 1 km radius of the installation; an area of 3 km^2. Based on the highest recorded density of 4.9 birds/km^2, it is therefore predicted that up to 15 red-throated diver may be displaced from the vicinity during construction. This equates to approximately 2% of the red-throated diver population within Aberdeen Bay based on the peak estimated figure of 697 individuals recorded in November 2010. The construction period will be of short duration and the impacts of construction vessels temporary. Consequently, any potential impact is predicted to be negligible.

Displacement by service boats within the EOWDC area assumes that red-throated divers are not already deterred by the turbines. If that is the case, then the presence of service boats may diminish the re-population of the site. It is not known how many service vessels may be required but based on the scale of the proposed development it is unlikely to be more than one vessel on any one occasion. The presence of the proposed development in the vicinity of the intensively used Aberdeen Harbour means that the potential increase of one vessel movement on a regular basis will not have any noticeable difference to the number of vessels already using Aberdeen Bay. Any specific displacement caused by the service boats will be temporary as Divers will be able to move into the area once the vessels leave. In addition the wide distribution of Divers is such that there are alternative suitable sites that displaced Divers could utilise.

It is concluded that the effect of service boats is much smaller than assuming total displacement from the EOWDC area and the potential impact from disturbance is minor.

Cumulative Impacts

There is the potential for cumulative impacts with other offshore wind farms, planned or proposed and other activities such as shipping.

With respect to other wind farms, three occur in the Firth of Forth (Inch Cape, Neart na Gaoithe and Firth of Forth) in an area not known to hold significant numbers of red-throated diver. Consequently there is not predicted to be any cumulative impact from these three wind farms.

Evidence from aerial surveys and site specific data at Beatrice indicate that the two wind farms planned in the Moray Firth (Beatrice and Moray Firth Offshore Wind Farms) are also in areas where red-throated diver may not occur (Söhle *et al*. 2006; Lewis *et al.* 2008; Brookes 2009). Consequently, the likelihood of a cumulative impact arising is considered to be low.

There is the potential for a cumulative impact with respect to disturbance arising from other activities, notably vessel activities in the area. Although there will be an increase in vessel movements during the construction period, post-construction it is likely that there will be less than one vessel per day. This increase is within the day-to-day variation in the number of vessels operating in and out of Aberdeen Harbour and is therefore unlikely to be noticeable.

The potential future Ocean Pod will require additional vessel movements within the proposed development area during its construction and operation. Should this occur then there is the potential for a cumulative effect on red-throated diver. It is not yet known what type of structure the Ocean Pod may be or how it will be installed or the number of vessel movements will be required. However, it is a single structure and it is predicted that the level of disturbance will be no greater than that arising from the installation of a single wind turbine. The scale of disturbance is therefore predicted to be localised and of short duration.

It is concluded that the cumulative effect of service boats is much smaller than assuming total displacement from the proposed development area and the potential cumulative impact is negligible.

4.15.7 Conclusions

Habitats Appraisal

No designated sites for which red-throated diver is a qualifying species have been identified as being at risk of a potential adverse effect.

Environmental Impact Assessment

Red-throated divers are widely distributed in Aberdeen Bay and in varying numbers. The assessment has been based on the peak densities and maximum counts recorded within the bay and is based on a series of worst-case assumptions.

Based on the low numbers of Divers recorded flying at turbine height, either within Aberdeen Bay or at other offshore wind farms, the collision risk for red-throated diver is very low and there is not likely to be a significant effect on the population arising from collision mortality rates.

There is the potential for up to 19% of the red-throated diver population within Aberdeen Bay to be displaced based on there being total avoidance of the EOWDC site out to 1 km and a further 50% decrease out to as far as 2 km. However, evidence from post construction monitoring at other offshore wind farms indicates that following construction total displacement will not occur. Furthermore, evidence from boat-based and land-based surveys indicate that the proposed development is not a major area for red-throated divers in Aberdeen Bay and alternative areas to the north are favoured. Therefore, the percentage of the population potentially displaced will be lower than has been used in this assessment. There is no evidence to suggest that, should displacement occur that any displaced red-throated divers will be at increased risk of mortality.

Disturbance from construction and maintenance vessels will occur but the impact will be localised and temporary. The number of predicted vessel movements associated with the proposed development are within the variable range of vessel activity associated with the intensively used Aberdeen harbour and unlikely to be noticed above the existing activities.

It is predicted that, although there may be some displacement of red-throated divers away from the proposed EOWDC area, there will not be a significant environmental impact arising from the proposed development on red-throated diver.

4.16 Northern Fulmar (*Fulmaris glacialis*)

4.16.1 Protection & Conservation Status

The (northern) fulmar is listed in Appendix II of the Bonn Convention, Schedule 1 under the Wildlife and Countryside Act, 1981 and is on the Amber List of Species of Conservation Concern.

4.16.2 Background

Fulmar		
GB Population	538,000 nests	Mitchell *et al* 2004
Scottish population	486,000 AoS	Forrester *et al.* 2007
International threshold	Unknown	-
GB threshold	5,000	1% of GB Pop[n]
Designated east coast sites where species is a noted feature	Fowlsheugh: 246 prs Buchan Ness to Collieston: 1,370 prs Troup Pennan and Lion's Heads: 636 prs Forth Islands: 402 prs	JNCC (2011)
European population estimate	Breeding: 2.8 – 4.400,000 Wintering: 1,500,000	Birdlife 2004
European population trend	Status 'secure' Trend 'large increase'	Birdlife 2004
World population	15 – 30,000,000 'adults'	Birdlife 2011

Fulmars are one of the most abundant pelagic birds in the North Atlantic with a global population of up to 30 million individuals and a UK breeding population of over 500,000 individuals. The fulmar population has increased dramatically during the last couple of centuries and numbers in Britain doubled between 1969 – 1970 and 1985 – 1987 (Wernham *et al.* 2002).

After fledging, young fulmars spend up to four years at sea, during which time they are thought to disperse widely and rarely visit land (Wernham *et al*. 2002). They feed at sea often scavenging behind fishing vessels.

The UK population is estimated to be 538,000 apparently occupied nests (AoN) and therefore in excess of a million birds, of which approximately 80% are in Scotland (Mitchell *et al*. 2004).

In North-east Scotland the fulmar population has increased with over a 118% increase in the number of breeding bird in Moray, 136% increase between Banff and Buchan and 167% increase in Kincardine and Deeside (Mitchell *et al*. 2004).

During a ten year study of seabird movements at Peterhead, fulmars passed along the north-east coast throughout the year but were scarcest in winter, with a general pattern of a modest southward movement. In spring numbers increase with the majority of birds heading north. In the autumn numbers of fulmars passing Peterhead decreased with the majority of birds still heading north (Innes 1992). During periods of poor weather the number of fulmars passing along the coast can be large with regular counts of over a 1,000 birds per hour during these periods (Buckland, Bell & Picozzi 1990).

4.16.3 Survey Results

Boat-based surveys

Fulmars were recorded widely across Aberdeen Bay throughout the year from boat-based surveys. However, population estimates were relatively low, particularly in the proposed EOWDC survey area where there were no records of fulmars in transect between October 2006 and January 2007. Peak numbers were recorded within the 'control' survey area to the north where up to 45 birds were recorded during December (Figure 4-41, Table 4-15). Numbers of fulmar within Aberdeen Bay were lowest from August through to November with no fulmars recorded within transect during October and November (IECS 2008) (Figure 4-39). There were very few records of fulmar recorded in proposed development area throughout the year.

Table 4-15: Fulmar monthly population estimates in Aberdeen Bay: Boat-based surveys 2007 – 2008.

Month	On water estimate	In flight estimate	Total estimate
	No.	No.	No.
February	8	24	32
March	3	3	6
April	9	10	19
May	0	21	21
June	6	6	12
July	8	6	14
August	6	3	9
September	6	0	6
October	0	0	0
November	0	0	0
December	3	42	45
January	0	8	8

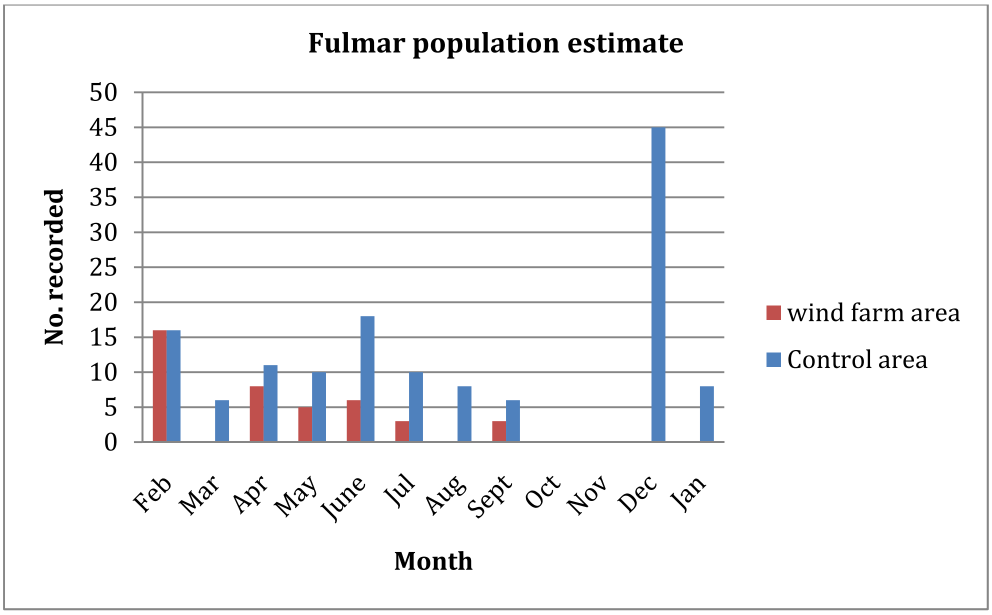


Figure 4-39: Fulmar monthly population estimates in proposed EOWDC and 'control' areas: Boat-based surveys 2007 – 2008.

Additional data collected between August 2010 and January 2011 recorded a total of 178 fulmars in September 2010 and lower numbers less than 50 individuals, during the rest of the period (Figure 4-40) (SMRU 2011b). There was insufficient detections to undertake *Distance* sampling analysis on any of the fulmar data.

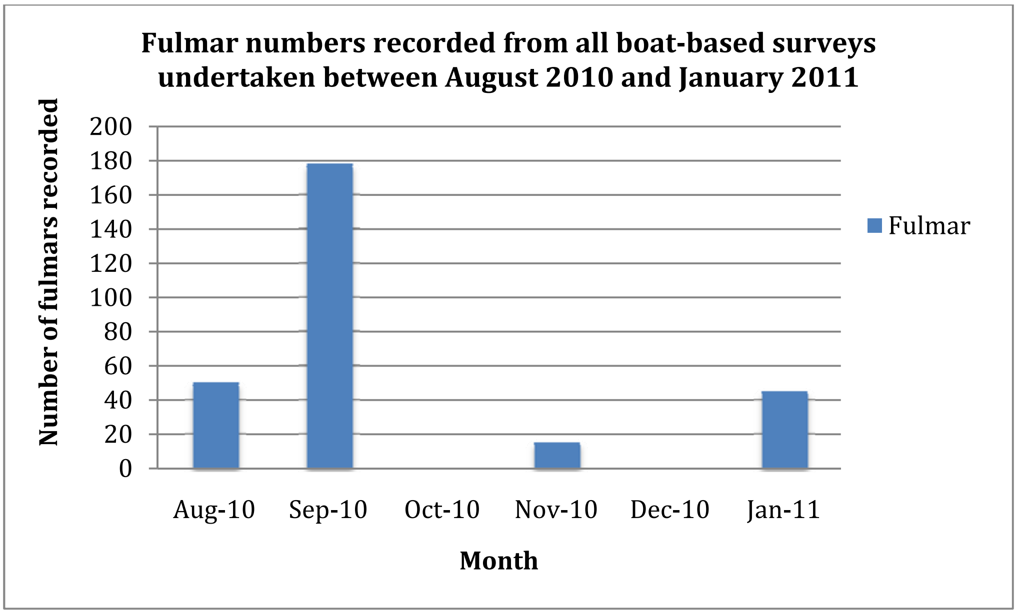

Figure 4-40: Numbers of fulmar recorded from boat-based surveys undertaken in Aberdeen Bay between August and January 2011. (Note no counts were made in October or December 2010).

Fulmar distribution within Aberdeen Bay was widespread, particularly during the breeding season. During the winter period there were fewer records and a cluster of observations to the north of the survey area near to breeding colonies. During post-breeding season the majority of fulmar sightings were further offshore with relatively few recorded in nearshore waters. (Figure 4-41, Figure 4-42, Figure 4-43, Figure 4-44). Flight height data from boat-based surveys recorded <0.5% of flights below 15 m.

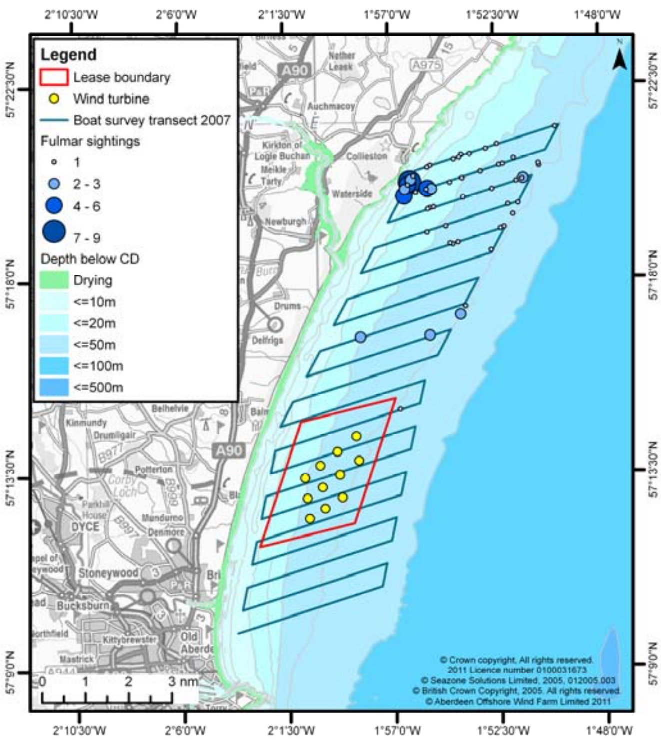

Figure 4-41: Fulmar distribution during winter period: November to February (all sightings).

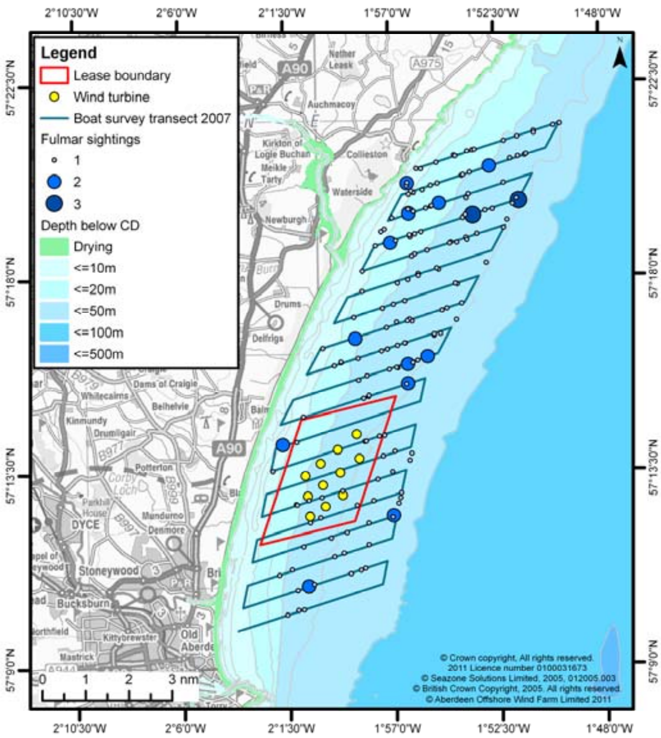

Figure 4-42: Fulmar distribution during breeding season: March to August (all sightings).

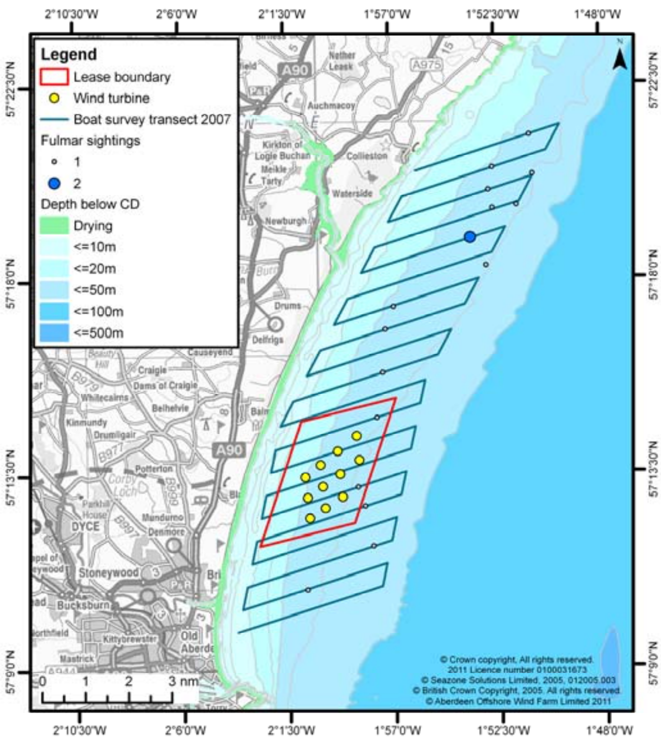

Figure 4-43: Fulmar distribution during post-breeding: September and October (all sightings).

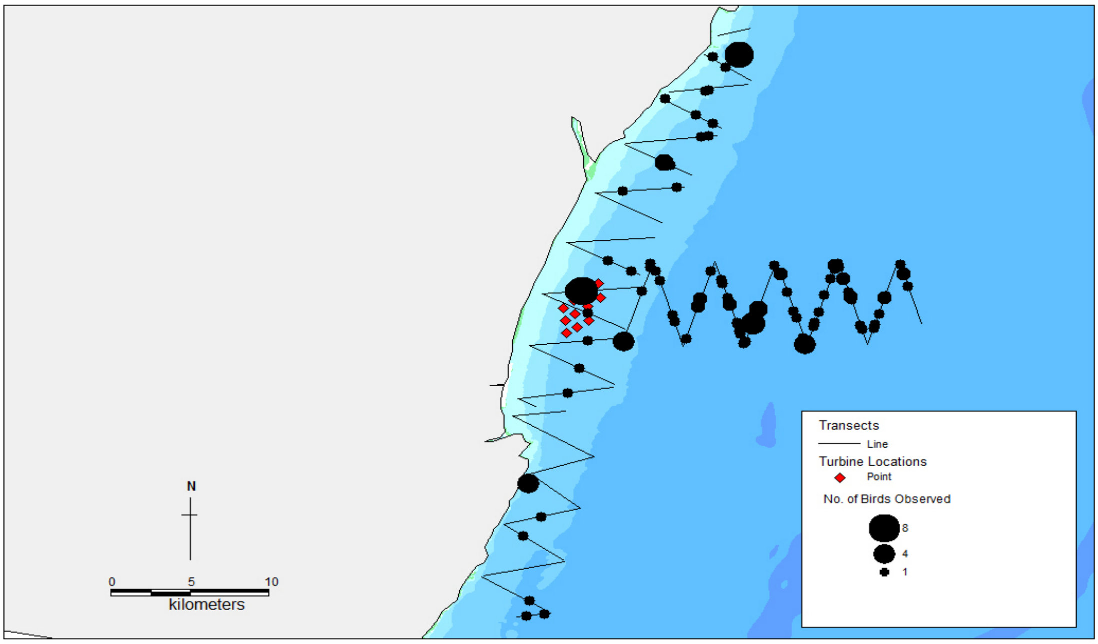

Figure 4-44: On-effort observations of Fulmar along transects during August, September and November 2010 and January 2011.

Vantage Point surveys

In Aberdeen Bay fulmars were present during peak dawn and dusk activity periods between April and September in numbers generally less than 20 birds per hour but occasionally up to 75 birds per hour during peak periods in June (Alba Ecology 2008a). This is considerably lower than the number of birds recorded at Peterhead during the same seasonal period where between 300 to 400 birds per hour were recorded (Innes 1992).

Numbers of fulmar sighted within Aberdeen Bay decreased during the winter months with less than three birds per hour passing through any one Vantage Point site in Aberdeen Bay between October 2006 and March 2007. Twenty-five fulmars were recorded during a hundred hours of observations between October 2006 and March 2007 (EnviroCentre 2007b) and twenty-four between October 2007 and March 2008 (Alba Ecology 2008b).

Most records during the winter months were of birds at least 1 km from the shore, with the majority being between 2 km and 3 km offshore. Of those recorded in flight at least 80% of all flights were below 30 m.

Bird Detection Radar

No fulmars were recorded during five days of observations undertaken at Easter Hatton and Drums during October 2005. Further radar studies undertaken at Blackdog over a seventeen day period in April 2007 recorded 158 fulmars at a rate of three birds per hour during April (Simms *et al.* 2007).

4.16.4 Summary of Results

Fulmars occur throughout the year in Aberdeen Bay with peak numbers during the late summer, late winter and spring periods. Very few fulmars were recorded in nearshore waters during the post-breeding and early winter periods. Fulmars were more frequently recorded within the ‘control’ survey to the north and in offshore waters than within the proposed offshore EOWDC survey area, where there was a peak count of sixteen birds in February 2006. Results from the Vantage Point and radar studies suggest that the majority of fulmars occur between 2–3 km offshore and between 0.5% and 20% of all flights were below 30 m. The numbers recorded from boat-based and Vantage Point land based surveys were lower than the peak counts reported for Aberdeen Bay from other land based counts.

Numbers of fulmar recorded in Aberdeen Bay were below the threshold for a site of international importance.

4.16.5 Initial Assessment of Significance

Fulmar	Overall sensitivity	Magnitude	Significance
Collision	Very High	Negligible	Minor
Barrier	Medium	Medium	Minor
Displacement	Medium	Negligible	Negligible

4.16.6 Species Sensitivities

Qualify species

There are twenty-five SPAs for which fulmar is a qualifying species all of which are within the potential foraging range from the proposed development of 664 km. However, for the purposes of this assessment four colonies have been identified as being within close enough proximity for there to be a potential significant effect:

- Buchan Ness - Collieston SPA (9.5 km).
- Fowlsheugh SPA (31.1 km).
- Forth Islands SPA (124.4 km).
- Troup, Pennan and Lion’s Heads SPA (74.3 km).

Fulmar populations at the time of designation or at the time of last review at each of the sites were:

- Buchan Ness to Collieston SPA held 1,765 apparently occupied nest (AoN). Recent counts indicate a slight decline to 1,370 AoN;
- Fowlsheugh SPA held 1,170 AoN. Recent counts indicate a decline to 246 AoN.
- Forth Islands held 1,600 AoN. Recent counts indicate a decline to 402 AoN.
- Troup, Pennan and Lion’s Head SPA held 4,400 AoN.

  Note – the ‘recent counts’ may not be complete and therefore the declines suggested may not be genuine decreases.

Flight height

Data obtained from boat-based surveys did not record any fulmars flying above 25 m and less than 0.5% were flying above 15 m (n=214).

Elsewhere data from other offshore wind farms have recorded less than 1% at rotor height and a mean flight height 17 metres (n=1,734).

Collision risk

Evidence from site specific monitoring from boat-based and land-based surveys indicate that fulmars are widespread across Aberdeen Bay with increasing numbers offshore including within the proposed development area (Figure 4-41 to Figure 4-44). All sightings within Aberdeen Bay were of birds flying below 25 m and therefore not at risk of collision.

There is only one record of a fulmar collision with an offshore wind farm with one recorded at Blyth (Zucco *et al*. 2006). Evidence from other offshore wind farms indicate that fulmars fly predominantly below turbine height and are therefore not at significant risk of collision.

Based on the evidence from existing offshore wind farms and site specific data indicating a very low level of flight height, predominantly below turbine height, it is concluded that the risk of any significant impact or adverse affect on fulmars from collision is negligible.

Collision Risk Modelling undertaken for fulmar is based on:

- Body length of 52 cm
- Wingspan of 117 cm
- Flight speed of 13 $m.s^{-1}$

Modelling has been undertaken based on a collision probability of 9.8% and over a range of possible avoidance rates of 98%, 99% and 99.5%.

Table 4-16: Predicted number of collisions for various avoidance rates for fulmar.

Collision probability	Avoidance rate (%)		
	98	99	99.5
9.8%	0.08	0.04	0.02

Based on the various scenarios and using a precautionary avoidance rate of 98% it is predicted that a total of 0.08 collisions per year may occur (Table 4-16). The current SPA population across all four SPAs is 6,418 AoN; approximately 12,836 adults.

The annual mortality rate for fulmar is 3% (BTO 2011). Consequently, out of a population of 12,836 individuals an annual mortality of 385 fulmars may be predicted. Therefore, 1% of the baseline mortality is 3.8 birds per year, i.e. an increase in mortality rate of more than 3 birds per year caused by collisions may be considered significant.

For the individual SPAs the increase in mortality which could cause an adverse effect is lower.

- Fowlsheugh has the lowest currently reported population for a SPA of 246 AoN (492 individuals) then an increase in mortality of more than 0.1 bird per year could be adverse.

- Buchan Ness to Collieston SPA has a current population of 2,740 individuals (1,370 AoN) and an annual mortality of 82 birds per year. Therefore 1% of baseline mortality is 0.8 birds per year.
- Recent counts at the Forth Islands SPA are of 804 individuals (402 AoN). An annual mortality of 24 birds per year. 1% of baseline mortality is therefore 0.2 birds per year.
- Troup, Pennan and Lion's Head SPA held 4,400 AoN, 8,800 individuals. An annual mortality of 264 birds per year. 1% of baseline mortality is therefore 3 birds per year.

Site specific data and results from other offshore wind farm locations indicate that less than 1.0% of fulmars fly at above 20 – 25 m and consequently the risk of collision is very remote. The results from the collision risk modelling also indicate that the risk of a collision is very low and that it is predicted that 0.08 fulmar per year may collide with the wind turbines when 1% of flights are at rotor height. This is lower than 1% baseline mortality rates for any of the SPAs identified as being at potential risk from the proposed development.

Based on the site specific evidence and the results from collision risk modelling it is concluded that the risk of a significant environmental impact is negligible and an adverse effect minor.

Barrier effect

The number of fulmars reported at operating wind farms is very low consequently there is little or no evidence of any barrier effect. The few records from Danish studies suggest that fulmars may avoid flying through the operating wind farm and consequently there may be a barrier effect.

In order to avoid the turbines the birds may incur additional energetic expenditure. The proposed EOWDC is at its longest point approximately 4 km and at its widest 2 km. Assuming birds avoid the proposed development area at 1,000 m then they may incur an overall increase in flight distance of 3.2 km.

Fulmars are extremely efficient fliers and during the breeding season can travel many hundreds of kilometres in single feeding trips up to 580 km (Roos *et al.* 2010) and outwith the breeding season forage widely across the North Sea and North Atlantic. Consequently, any additional increase in foraging distance due to avoidance of flying through the proposed development and its significance will be minor.

Displacement

Fulmars are primarily an aerial species spending relatively little time on the sea surface and do so primarily when preening or feeding or during periods of calm weather. There are no data available from constructed wind farms to determine whether fulmars are displaced from wind farms.

Data from boat-based surveys undertaken between 2007 and 2008 recorded a peak count of 16 fulmars in the proposed EOWDC survey area during February (Figure 4-39). This is less than 0.3% of the SPA fulmar population. There is no evidence from the surveys that the area is used extensively by fulmars and should there be total displacement that the displaced fulmars will not find other suitable areas. Fulmars forage over a wide area in search of small fish (sandeels), crustaceans and squid. They also scavenge extensively around fishing vessels (Phillips *et al*. 2009). Consequently, it is predicted that should displacement occur the magnitude of the effect and its significance will be negligible.

Cumulative and in-combination

The very large range that fulmars can fly suggest that any individual fulmar may interact with any of the proposed offshore wind farms in Scottish waters and elsewhere. Consequently, there is the potential for cumulative and in-combination effects. The closest constructed offshore wind farm is the Beatrice demonstrator project in the Moray Firth. Collision Risk Modelling undertaken for that project suggested that one fulmar every three years may collide with the turbines (Talisman 2005). However, there is no evidence to suggest any likely significant impact on fulmar from collision risks; nor any impact from barrier effect or displacement. The relatively low level of usage of the site indicates the potential for a cumulative or in-combination effect to be low and the magnitude negligible.

4.16.7 Conclusions

Habitats Appraisal

Based on the available evidence from site specific surveys undertaken at the proposed development area, in particular the relatively low usage of the site along with evidence from existing wind farms it is concluded that the proposed development will not have an adverse effect on fulmars as qualifying features for Buchan Ness - Collieston SPA, Fowlsheugh SPA, Forth Islands SPA, Troup, Pennan and Lion’s Heads SPA.

Environmental Impact Assessment

Based on the very low usage of the site and the known behaviour of fulmar it is predicted that there will not be a significant environment impact arising from the proposed development on fulmars.

4.17 Northern Gannet (*Morus bassanus*)

4.17.1 Protection & Conservation Status

The (Northern) gannet is listed in Appendix III of the Bern Convention, and is on the Amber List of Species of Conservation Concern.

4.17.2 Background

Gannet		
GB population	Breeding: 230,000 prs	Mitchell *et al* 2004
Scottish population	Breeding: 182,511 AoS Winter: 'a few thousand'	Forrester *et al.* 2007
International threshold	Unknown	-
GB threshold	4,600 ind.	1% of GB Pop[n]
Designated east coast sites where species is a noted feature	Forth Islands: 44,000 prs	JNCC
European population estimate	Breeding 300,000 – 310,000 prs Wintering – unknown	Birdlife 2004
European population trend	Status 'secure' Trend 'large increase'	Birdlife 2004
World population	950,000 – 1,200,000 'adults'	Birdlife 2011

Gannets are widespread across the whole of the North Sea but breed at relatively few but typically large colonies. They have a prolonged breeding season with adults attending colonies from January through to November with chicks fledging from August to October. During the breeding season adults will forage up to 500 km from the breeding colony, although more typically it is within 100 km from the colony. Gannets recorded in Aberdeen Bay during the breeding season are likely to be from the colony at Troup head or potentially Bass Rock as opposed to those from Fair Isle or further afield.

Once fledged, chicks move predominantly southwards wintering between the Bay of Biscay and Senegal. However, many gannets may also spend at least part of the winter in the North Sea.

The gannet population has increased in recent decades with up to 230,000 pairs recorded during the Seabird 2000 censuses (Mitchell *et al*. 2004).

In North-east Scotland gannets occur throughout the year in variable numbers. During a ten year study of seabird movements at Peterhead, gannets were scarcest during the winter, but numbers increased in the spring from April onwards, peaking in May. During the summer and early autumn numbers recorded passing Peterhead remained relatively high before decreasing from October onwards (Buckland, Bell & Picozzi 1990; Innes 1991).

Boat-based surveys

Gannets were recorded throughout Aberdeen Bay from boat-based surveys with no areas identified as being of particular importance but with the majority of sightings in water depths of between 20 m and 50 m (Figure 4-45, Figure 4-46, Figure 4-47). Numbers of gannets recorded were lowest between November and March and highest during the breeding season from April to August when gannets were widespread throughout the area.

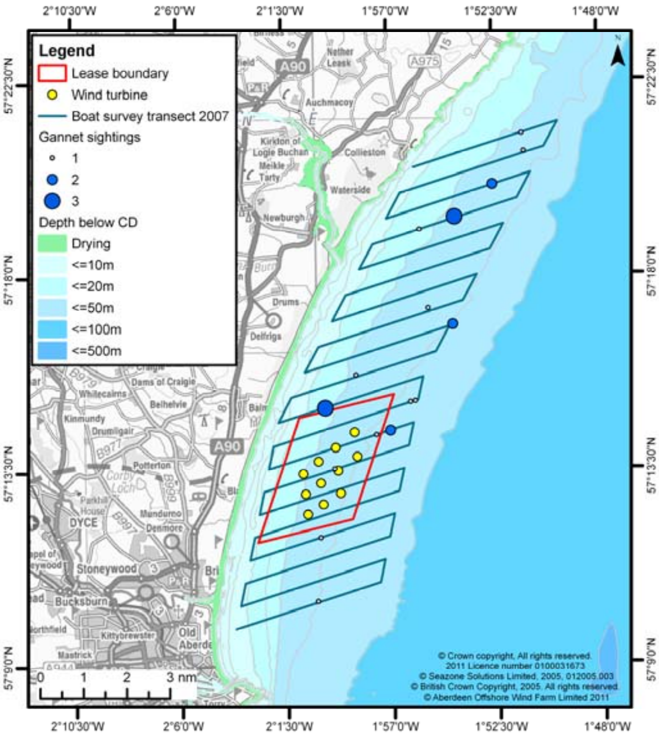

Figure 4-45: Gannet distribution during winter period: November to March (all sightings)

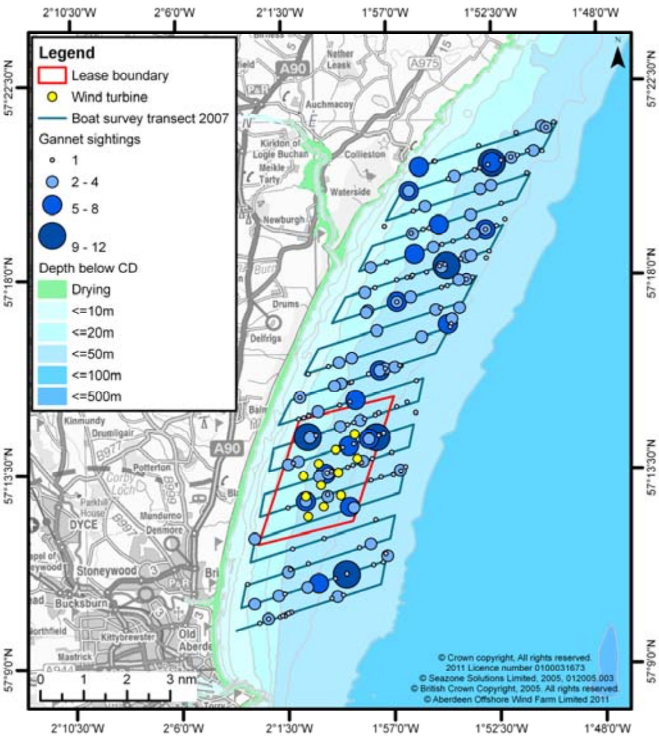

Figure 4-46: Gannet distribution during breeding season: April to August (all sightings).

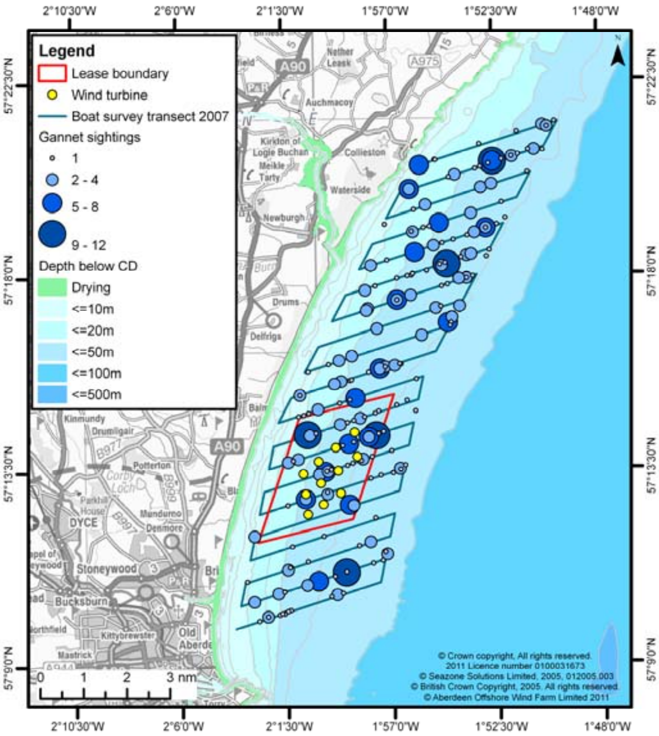

Figure 4-47: Gannet distribution during post-breeding: September and October (all sightings).

Additional surveys undertaken between August 2010 and January 2011 recorded gannets in low numbers in offshore waters with clusters to the north of the Ythan Estuary and relatively few within the proposed development area (Figure 4-48).

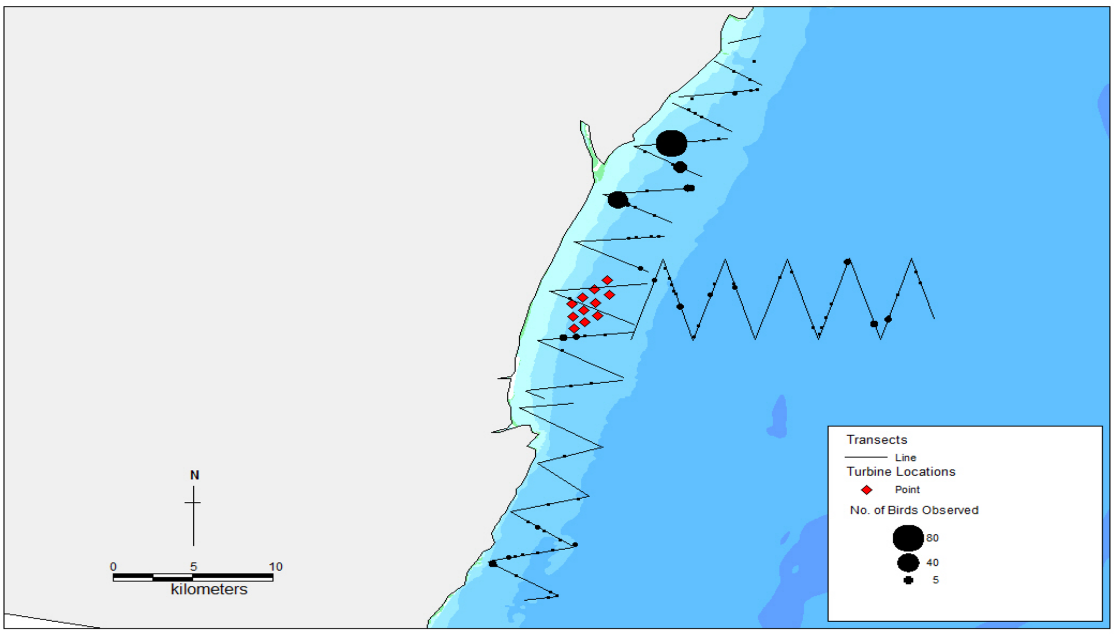

Figure 4-48: On-effort observations of Northern Gannet along transects during August, September and November 2010 and January 2011.

Relatively few gannets were recorded from boat-based surveys during the winter months with an increase in numbers in June and a peak in July, August and September (Figure 4-49).

Distance analysis of the first year's data estimated a peak density of 3.1 birds/km^2 during July within the 'control' area when none were recorded within the proposed EOWDC survey area. Within the EOWDC area peak numbers were estimated to be in June and August (Figure 4-50 Figure 4-52). Additional *Distance* sampling analysis undertaken on the data collected between August 2010 and January 2011 estimated significantly higher numbers during September primarily in areas that had not previously been surveyed to the north of the proposed development area, with an abundance estimate of 642 birds in September and a density of 4.26 birds/km^2 (Figure 4-51, Figure 4-53).

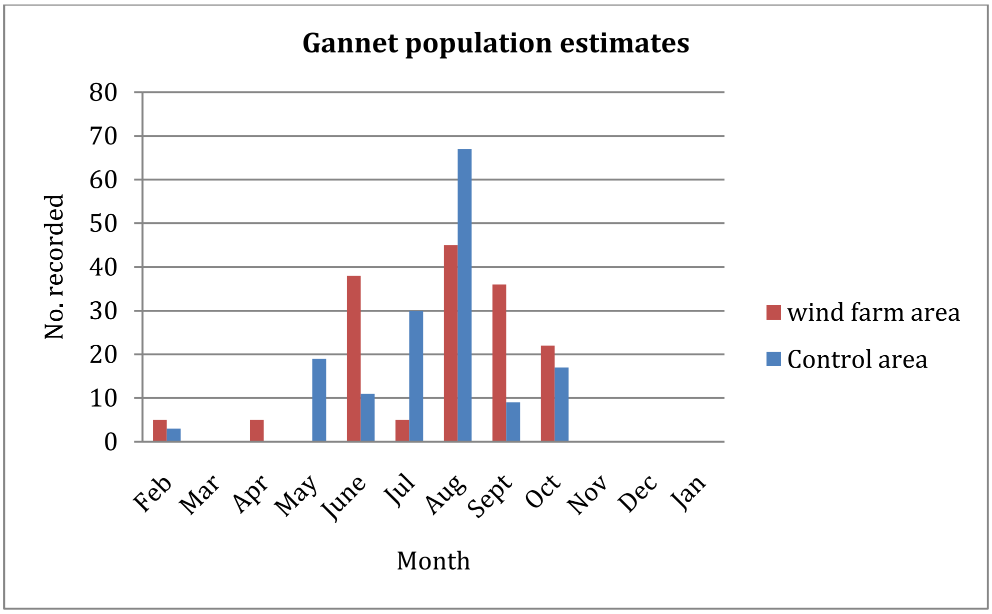

Figure 4-49: Gannet monthly population estimates in proposed EOWDC and 'control' areas: Boat-based surveys 2007 – 2008.

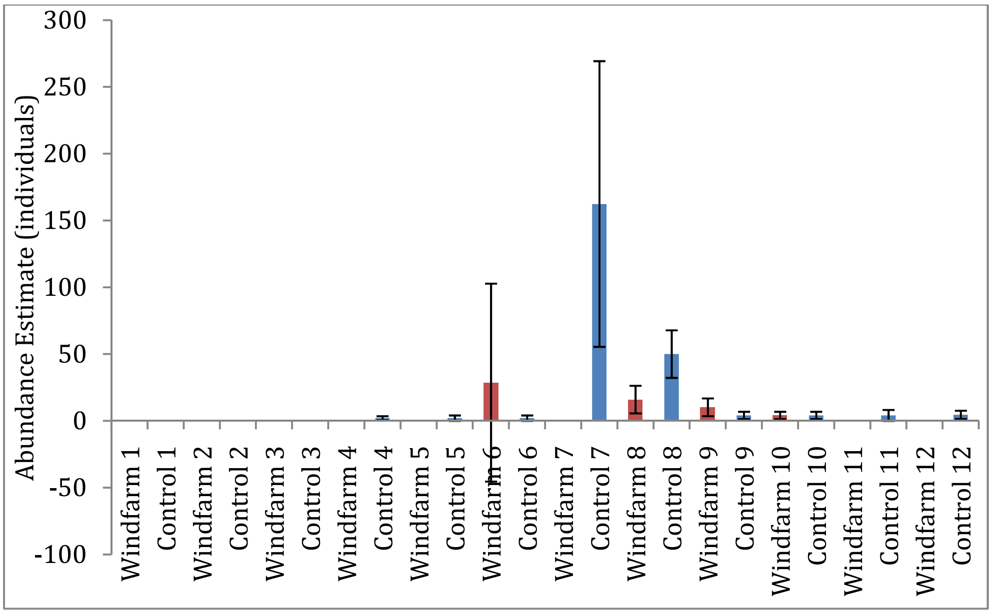

Figure 4-50: Monthly estimates (+/- SE) of abundance of gannets in the wind farm and 'control' Areas; February 2007 – January 2008 ('windfarm' 1-12 and 'control' 1-12 refers to months).

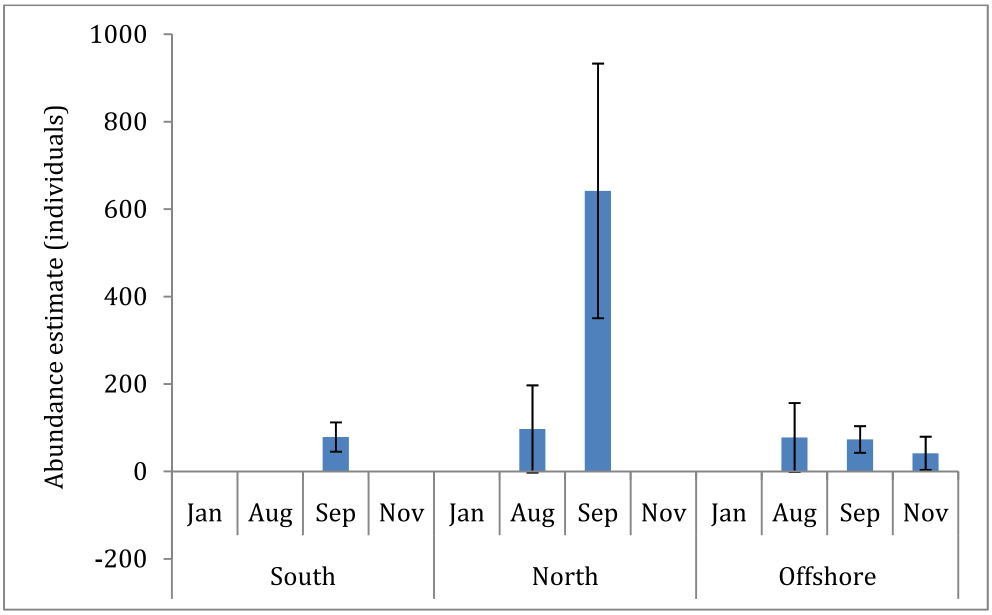

Figure 4-51: Monthly estimates (+/- SE) of abundance of gannet in the South, North and Offshore Strata between August 2010 and January 2011.

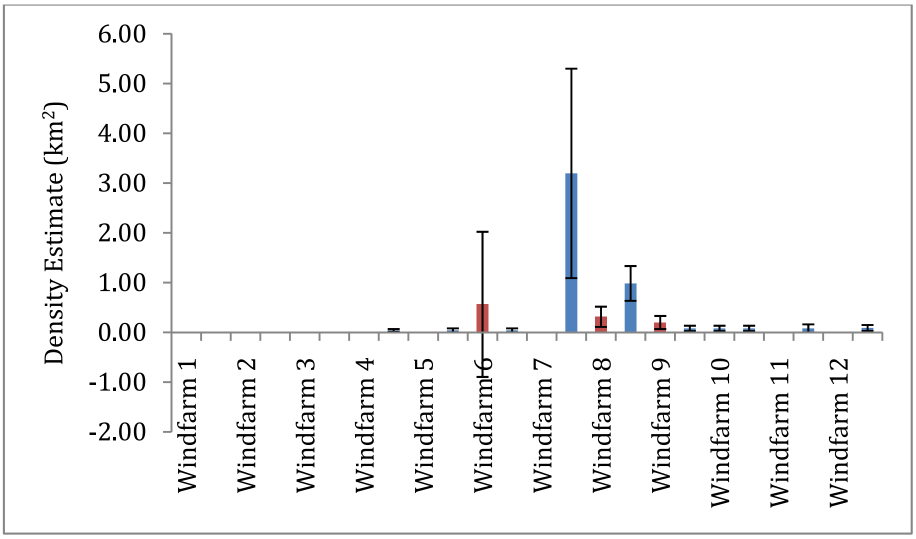

Figure 4-52: Monthly estimates (+/- SE) of density of gannets in the proposed EOWDC and 'control' Areas (wind farm 1-12 and 'control' 1-12 refers to months).

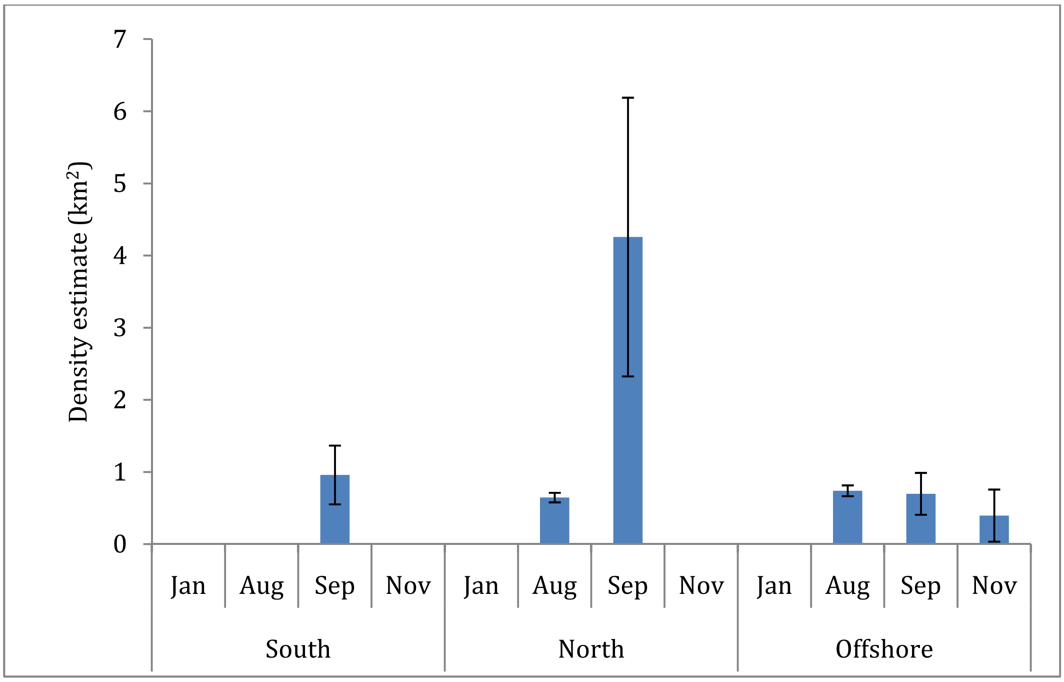

Figure 4-53: Monthly estimates (+/- SE) of density of gannet in the South, North and Offshore Strata between August 2010 and January 2011.

Flight heights of gannets recorded during the boat-based surveys indicated that 29% of all flights were above 15 m and 17% were above 25 m.

Vantage Point surveys

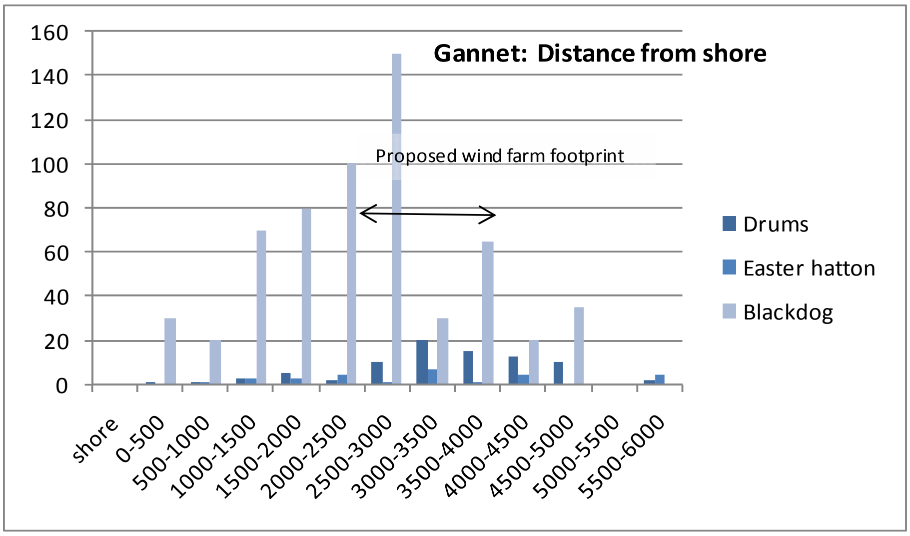
Gannets were observed from all Vantage Point sites, with a peak count of up to 120 birds per hour in July 2007 and 90 birds per hour in September 2006 (Alba Ecology 2008a, EnviroCentre 2007a) which is similar to the numbers recorded at

Peterhead during this period (Innes 1991). Numbers of gannets in Aberdeen Bay decreased after October with typically less than five birds per hour passing (EnviroCentre 2007b) and typically lower numbers during the winter with less than ten birds per hour between October and March (EnviroCentre 2007b, Alba Ecology 2008b).

Flight heights recorded between April and September 2006 from Vantage Point surveys recorded 25% of all gannets between 30–150 metre height across all Vantage Point Sites but between 40% and 50% were recorded within the same height bands between April to September 2007 (Alba Ecology 2008a). Gannets were recorded out to at least 3 km from shore with the majority of sightings between 2 and 3 km.

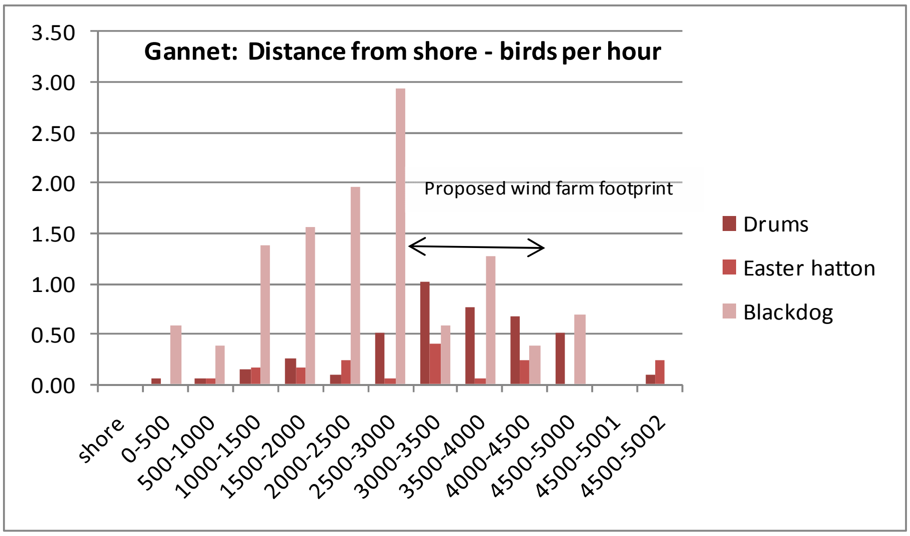
Bird Detection Radar

A total of 110 gannets were recorded during the radar studies undertaken in October 2005. Sightings were of birds out to 6 km from shore with peak numbers recorded at between 3 km and 5 km (Figure 4-54). Of those recorded in flight the mean height was 8 m above the sea surface with a maximum height of 30 m (Walls *et al.* 2006). A total of 633 gannets were recorded at a mean rate of 12.4 birds per hour at Blackdog during radar studies undertaken in April 2007. During this period the maximum flock size was of 64 birds but the mean flock size was of three (Simms *et al.* 2007). The majority of sightings were of birds flying between 1 km and 3 km offshore with a peak monthly rate of 2.9 birds per hour between 2.5 km and 3.0 km (Figure 4-55). All those recorded in flight were flying below 30 m.



(Adapted from Walls *et al.* 2006, Simms *et al.* 2007)

Figure 4-54: Distances from shore for gannet from three locations in Aberdeen Bay during surveys undertaken in October (Drums & Hatton) and April (Blackdog).



(Adapted from Walls *et al.* 2006, Simms *et al.* 2007)

Figure 4-55: Number of gannets per hour and distances from shore from three locations in Aberdeen Bay during surveys undertaken in October (Drums & Hatton) and April (Blackdog).

4.17.3 Summary of Results

Gannet occur throughout the year in Aberdeen Bay with peak numbers between June and September and relatively few records between November and April. Gannets were more frequently recorded within the 'control' area and to the north of the Ythan compared to the proposed development area where there was a peak estimated abundance of 45 birds in August compared to 642 birds in September 2010 to the north. Results from the Vantage Point and radar studies suggest that the majority of gannets occur between 2–3 km offshore. Of those recorded in flight 83% of all flights were below 25 m.

Numbers of gannet recorded in Aberdeen Bay were below the threshold for a site of national importance.

4.17.4 Initial Assessment of Significance

Gannet	Overall sensitivity	Magnitude	Significance
Collision	Very High	Low	Moderate
Barrier	Medium	Low	Minor
Displacement	Medium	Negligible	Negligible

4.17.5 Species Sensitivities

Qualify species

There are two SPAs for which gannet is a qualifying species both of which may be within foraging range from the proposed development

- Fair Isle SPA (*c*. 253 km)
- Forth Islands SPA (124.4 km).

Gannet populations at the time of designation or at the time of last review at each of the sites were:

- Fair Isle SPA held 1,166 apparently occupied nest (AoN). Recent counts indicate a an increase to 3,582 AoN (2009).
- Forth Islands SPA held 21,600 pairs. Recent counts indicate an increase of 48,065 AoN (2004).

Flight height

Data obtained from boat-based surveys recorded 404 gannets in flight of which 17% were recorded flying above 25 m.

Elsewhere published data from other offshore wind farms have recorded 14% of gannets flying at rotor height with a mean flight height of 10.25m (n=9,154).

Collision risk

Evidence from site specific monitoring from boat-based and land-based surveys indicate that gannets are widespread across Aberdeen Bay with peak numbers of passing birds between 1 km and 3 km from shore (Figure 4-45 to Figure 4-48). 17% of all sightings of flying birds were of birds flying greater than 25 m above sea surface. Consequently, gannets are at risk of collision with the proposed development.

Collision Risk Modelling undertaken for gannet is based on:

- Body length of 94 cm
- Wingspan of 180 cm
- Flight speed of 15 $m.s^{-1}$

The Collision Risk Modelling is based on a collision probability of 12% and a range of potential avoidance rates from 98%, 99% and 99.5% have been used.

Table 4-17: Predicted number of collisions for various avoidance rates for gannet.

Collision probability	Avoidance rate (%)		
	98	99	99.5
12%	1.66	0.83	0.41

Based on the various scenarios and using a precautionary avoidance rate of 98% it is predicted that a total of 1.6 collisions per year may occur. The current SPA population in the region is 51,647 pairs.

The annual mortality rate for gannet is 8.1% (BTO 2011). Consequently, out of a population of 51,647 pairs (103,294 adults) an annual mortality of 8,367 gannets may be predicted. Therefore, 1% of the baseline mortality is 84 birds per year, i.e. an increase in mortality rate of more than 84 birds per year caused by collisions may be considered significant.

For the two individual SPAs the increase in mortality that could cause an adverse effect is lower:

- Fair Isle SPA has a current population of 3,582 AoN (5,164 adults); therefore an annual mortality rate of 418 adults. 1% of baseline mortality is therefore 4 individuals.

- Forth Islands SPA has a current population of 48,065 AoN (96,130 adults); therefore an annual mortality rate of 7,786 adults. 1% of baseline mortality is therefore 78 individuals.

The results from the collision risk modelling indicate that between 1 and 2 gannets per year may collide with the proposed development. This is lower than either of the baseline mortality rates used to indicate whether the potential impact is will have an adverse effect.

There is no evidence that gannets from Fair Isle occur within the region during the breeding season. Foraging activity will likely remain within the waters around Shetland and therefore it is not predicted that there will be any impact on gannets associated with the Fair Isle SPA during the breeding season.

Tagging data of birds from the Bass Rock colony indicates that they forage widely and are potentially at collision risk with the proposed development (Hamer *et al.* 2000). Based on the collision risk modelling undertaken, should all the potential collisions be of birds arising from the Bass Rock colony in the Forth SPA, 124 km away, then there will be a very small increase in the baseline mortality rate and below the level that may be of concern.

The regional population of gannet include a colony at Troup Head to the north of the proposed development, where a total of 1,810 AoN were counted in 2007 (JNCC 2011a). Therefore, the breeding population is 3,620 individuals and will have an annual mortality of 434 birds. The 1% baseline mortality will therefore be 4 birds per year. Based on the collision risk modelling which predicts an annual collision mortality of between 1 and 2 birds per year it is predicted that even if all the gannets within the EOWDC development area are from Troup Head the potential impact will not be significant and its effects will be negligible.

Evidence from existing wind farms indicates that gannets avoid flying through wind farms and may have a significant far field avoidance rate; this behaviour will further reduce the risk of potential collision.

Barrier effect

The number of gannets reported at operating wind farms is low consequently there is limited evidence of any barrier effect. However, studies undertaken at Danish offshore wind farms indicates that gannets avoid flying through operating wind farms and consequently there may be a barrier effect (Zucco *et al*. 2006).

In order to avoid the turbines gannets may incur additional energetic expenditure. The proposed EOWDC is at its longest point approximately 4 km and at its widest 2 km. Assuming birds avoid the proposed development area at 1,000 m then they may incur an overall increase in flight distance of 3.2 km.

Gannets are extremely efficient fliers and during the breeding season can travel many hundreds of kilometres in single feeding trips up to 364 km from the colony and over 900 km in a single trip (Hamer *et al.* 2007). The additional distance of up to 3.2 km an individual gannet may have to fly in order to detour around the proposed development is therefore negligible. Furthermore, there is no evidence that the area is used as regular flyway or feeding location consequently the significance of any potential impact arising from a barrier effect is also negligible.

Displacement

Although gannets are primarily an aerial species evidence from tracking studies indicate that they may spend up to half their time away from colonies on the sea surface (Lewis *et al*. 2001). Consequently, gannets may be displaced from an area if they avoid entering wind farms.

Data from boat-based surveys undertaken between 2007 and 2008 recorded a peak count of 29 gannets in June at a density of 0.5 birds/km^2 in the proposed EOWDC survey area (SMRU 2011a); this is less than 0.02% of the SPA population. Gannet distribution was generally spread evenly across the bay with higher densities recorded to the north of the proposed development area. There is no evidence from the surveys that the area is used extensively by gannets and should there be total displacement that the displaced gannets will not find other suitable areas. Evidence from tracking studies indicate that gannets can forage across a very wide area and that the potential loss of 4 km^2 of sea surface is very small compared to the total area in which they forage. Consequently, it is concluded that any potential impact due to displacement, should it occur, will be negligible.

Cumulative and in-combination

The theoretical very large foraging range that gannets can fly suggest that any individual gannet may interact with a number of the proposed offshore wind farms in Scottish waters. Published data elsewhere indicates that gannets from colonies in Shetland or eastern England are unlikely to occur in Aberdeen Bay during the breeding season (Langston 2011), although they may occur during periods of passage.

Consequently, there is low potential for cumulative or in-combination effects with respect to gannets from Fair Isle SPA or Bempton Cliffs SPA. However, there is evidence to suggest that the gannets from the Forth Island SPA may occur within the Aberdeen Bay area. Populations from this SPA may also interact with potential offshore wind farm developments currently proposed the Firth of Forth area, namely: Neart na Gaoithe, Inch Cape and Firth of Forth offshore wind farms. There is currently very limited information on the proposed developments as decisions on the location, scale and numbers of turbines are still to be decided. Based on the scoping reports it is currently predicted that there may be an additional 526 turbines within the Firth of Forth area (Table 4-18). Information on the use of these areas by gannets is limited with no published information currently available from on-going studies being undertaken for the proposed wind farms. It is therefore not possible to undertake cumulative/in-combination collision risk assessment based on collision risk modelling or an assessment on possible cumulative displacement or barrier impacts.

Table 4-18: Predicted wind farms that may have an in-combination impact on gannets in the Firth of Forth.

Project	Estimated no. of turbines	Area (km^2)	Predicted Application date
Inch Cape	181	151	2012
Neart Na Gaoithe	130	105	2012
Firth of Forth (phase I)	215	597	2013

There is a magnitude difference in scale between the proposed development and those planned in the Firth of Forth area and it is a significantly greater distance from the Forth SPA. Any potential incremental increase arising from the proposed development will likely be minor by comparison and therefore not have a significant cumulative or in-combination impact.

Collision Risk Modelling undertaken for Beatrice offshore wind farm predicted a total of five gannets per year may collide with the Beatrice demonstrator project development based on a 98% avoidance rate (Talisman 2005). The additional mortality from the proposed development may increase this by one or two birds per year. Based on a population of 3,620 adults at Troup Head the potential increase in mortality will be above the 1% of baseline mortality. This increase in mortality is considered to be of moderate significance but does not take into account the reported far field avoidance rates.

There are two planned offshore wind farms within the Moray Firth that could potentially have a cumulative impact on the gannets at Troup head (Table 4-19). There is little information on the number or scale of turbines and there is no published information currently available from on-going studies being undertaken for the proposed wind farms. It is therefore not possible to undertake cumulative collision risk assessment based on collision risk modelling or an assessment on possible cumulative displacement or barrier impacts. The scale of the proposed development is significantly smaller than those proposed in the Moray Firth and consequently based on the current information on gannet distribution the scale of potential impact significantly lower.

Table 4-19: Predicted wind farms that may have a cumulative impact on gannets in the Moray Firth.

Project	Estimated no. of turbines	Area (km^2)	Predicted Application date
Moray Firth (phase 1)	200	296	2012
Beatrice	184	131	2012

4.17.6 Conclusions

Habitats Appraisal

Based on the available evidence from site specific surveys undertaken at the proposed development area, tagging studies undertaken at the relevant SPA and collision risk modelling it is concluded that the proposed development will not have an adverse effect on gannets as qualifying species for Fair Isle SPA or Forth Islands SPA. There is the potential for a cumulative impact but there are no data available to undertake such an assessment. However, the distance and scale of the proposed development from other projects is such that any in-combination impact will likely be relatively small and of minor or negligible significance.

Environmental Impact Assessment

Based on the site specific data and the known behaviour of gannets it is predicted that there will not be a significant environmental impact arising from the proposed development on gannets. However, there is the potential for a moderate cumulative impact with gannets associated with the Troup Head gannet colony and the existing Beatrice demonstrator project.

4.18 Manx shearwater (*Puffinus puffinus*)

4.18.1 Protection & Conservation Status

The Manx shearwater is listed in Appendix II of the Bern Convention, and is on the Amber List of Species of Conservation Concern.

4.18.2 Background

Manx shearwater		
GB Population	277,803 - 312,263 prs	Mitchell *et al* 2004
International threshold	Unknown	-
GB threshold	5,400 ind.	1% of GB Pop[n]
Designated east coast sites where species is a noted feature	None	JNCC
European population estimate	Breeding 350,000 – 390,000 Wintering – unknown	Birdlife 2004
European population trend	Status 'localised' Trend 'unknown'	Birdlife 2004
World population	340,000 – 410,000 ind.	JNCC 2011

Most of the world population of Manx shearwaters breed in Britain and Ireland. The world population is estimated to be between 338,000 and 411,000 pairs of which up to 374,000 pairs nest in Britain and Ireland (Mitchell *et al.* 2004).

There are no breeding colonies in the North Sea but outwith the breeding season Manx shearwaters disperse widely and migrate south to winter in waters off South America (Wernham *et al*. 2002).

In North-east Scotland Manx shearwaters occur in relatively low numbers from late spring through to the autumn. Studies undertaken off Peterhead identified a passage of Manx shearwaters from April through to November with peak numbers passing in June and July with up to ten birds per hour. The number of birds passing varies considerably with the majority of sightings occurring in periods of rain or sea mist and fewer records during periods of bright fine whether (Innes 1992).

Boat-based surveys

A total of 40 Manx shearwaters were recorded from all boat-based surveys between May and November with sightings scattered across Aberdeen Bay (Figure 4-56). Ninety percent of all records were of birds in flight with the majority heading north (IECS 2008).

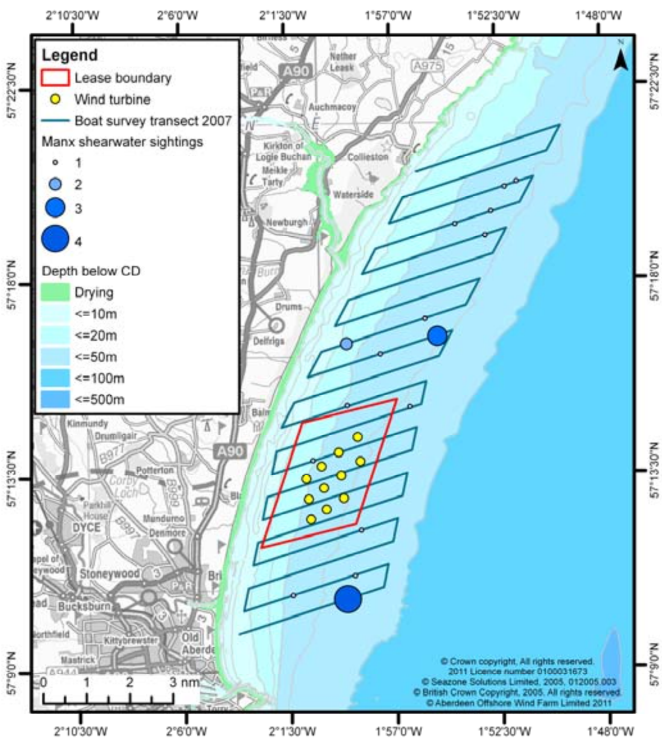


Figure 4-56. Shearwater distribution in Aberdeen Bay February 2007 to April 2008 (all sightings).

Vantage Point surveys

Manx shearwaters were observed in Aberdeen Bay from vantage point surveys between April and November with a peak of up to five birds per hour during June 2006 and one bird per hour during August 2005. Only one bird seen in October (EnviroCentre 2007a,b; Alba Ecology 2008a,b).

Bird Detection Radar

There were five sightings of Manx shearwaters during the seventeen days of observations undertaken in April 2007 (Simms *et al.* 2007).

4.18.3 Summary of Results

Manx shearwaters were recorded in low numbers from between April and November with a peak in June. Of those recorded in flight from boat based surveys all flights were below 30 m and most sightings were of birds approximately 1 km from shore.

Numbers of Manx shearwater recorded in Aberdeen Bay were below the threshold for a site of national importance.

4.18.4 Initial Assessment of Significance

Manx shearwater	Overall sensitivity	Magnitude	Significance
Collision	High	Negligible	Negligible
Barrier	Low	Negligible	Negligible
Displacement	Low	Negligible	Negligible

4.18.5 Species Sensitivities

Qualifying species

There are no SPAs in the North Sea for which Manx shearwater is a qualifying species. Of the four UK SPAs for which Manx shearwater is a qualifying species, two are in Wales and the other two are off western Scotland.

Flight height

Of those recorded in flight and for which flight heights were recorded all Manx shearwaters were flying below 15 m.

Elsewhere data from other offshore wind farms have recorded all Manx shearwater as flying below turbine height. Data from Walney offshore wind farm reported 5,999 sightings of which 99% were flying below 5 m (Dong 2006).

Collision risk

Evidence from site specific monitoring and elsewhere indicate that Manx shearwaters rarely fly at turbine height and therefore are not at risk of collision.

Barrier effect

The number of Manx shearwaters reported at operating wind farms is very low consequently there is little or no evidence of any barrier effect.

Should a barrier effect occur then the Manx shearwaters will fly around the proposed development. This would incur an overall increase in flying distance of approximately 3.2 km. Manx shearwaters are a highly pelagic species spending a significant proportion of their time in flight and travelling vast distances. The additional energetic cost that may be incurred if a barrier effect occurs will be negligible and not have any significant impact on Manx shearwaters.

Displacement

Relatively few Manx shearwaters were recorded from either the boat-based or the land-based surveys. Of those recorded over 90% were of birds in flight, indicating that Aberdeen Bay is not used as an area for birds to settle on the sea surface.

There are currently no constructed wind farms anywhere in the world where Manx shearwater regularly occur from which conclusions can be drawn to assess whether or not there may be a displacement effect. However, the relatively low usage of Aberdeen Bay by Manx shearwaters and the observation that over 90% of Manx shearwaters recorded were only in flight indicates that there will not be a significant impact should displacement occur and the significance of any potential impact will be negligible.

Cumulative and in-combination

The very low level of usage of the site by Manx shearwater indicates that there will not be any cumulative or in-combination impacts.

4.18.6 Conclusions

Habitats Appraisal

There are no SPAs for which Manx shearwater is a qualifying species that will be adversely affected by the proposed development.

Environmental Impact Assessment

Based on the relatively low numbers of Manx shearwaters recorded and their known behaviour it is predicted that there will not be a significant environmental impact arising from the proposed development on Manx shearwaters.

4.19 Great cormorant (*Phalacrocorax carbo*)

4.19.1 Protection & Conservation Status

The (great) cormorant is listed in Annex III of the Bern Convention and is on the Green List of Species of Conservation Concern.

4.19.2 Background

Cormorant		
GB population	Breeding: 8,400 prs Winter: 23,000 ind.	BTO 2011
Scottish population	Breeding: 3,600 AoN Winter: 9,000 – 11,000 ind.	Forrester *et al.* 2007
International threshold	1,200 ind.	Calbrade *et al.* 2010
GB threshold	230 ind	Calbrade *et al.* 2010

European population estimate	Breeding: 310 – 370,000 prs Wintering: unknown	Birdlife 2004
European population trend	Status 'secure' Trend 'large increase'	Birdlife 2004
World population	1,4 – 2,900,000 ind.	Birdlife 2011

Cormorants occur widely across the UK breeding and wintering on both freshwater bodies inland and also at coastal locations. Breeding occurs in colonies from April through to September when coastal breeding birds remain largely within nearshore waters. Following breeding, there is some dispersal away from the breeding areas with many birds moving south during the winter. The population of cormorant has increased across the whole of the UK but has decreased in certain localised areas. In North-east Scotland the number of breeding cormorants has recently increased with new colonies being formed to the north of Aberdeen Bay.

Results from ten years of observations undertaken at Peterhead indicate strong seasonal differences with peak numbers of cormorant occurring during the autumn and winter and relatively low numbers between May and August. Peak counts of up to 20 birds per hour were recorded in October with the majority of sightings shortly after dawn. Nearly all observations were within 500 metres of the coast (Innes 1991). Elsewhere cormorants occur widely along the coast with up 150 birds being recorded on the Ythan Estuary (NESBR).

Boat-based surveys

Cormorants were recorded in low numbers from boat-based surveys throughout the year. With the exception of one record of 25 birds nearly all sightings were of birds in nearshore waters and in water depths of less than 20 m. Concentrations were recorded in the shallow waters from the Ythan Estuary to Collieston (Figure 4-57) (IECS 2008). Peak numbers of cormorant were recorded during September and October with a population estimate of up to 20 birds in the 'control' area and 17 birds within the survey area for the proposed EOWDC during October (Figure 4-59). Data collected between August 2010 and January 2011 recorded low numbers of cormorants during August with a total of 8 birds seen throughout the surveyed area and peak numbers of cormorants during September when a total of 32 were recorded (Figure 4-58) (SMRU 2011b).

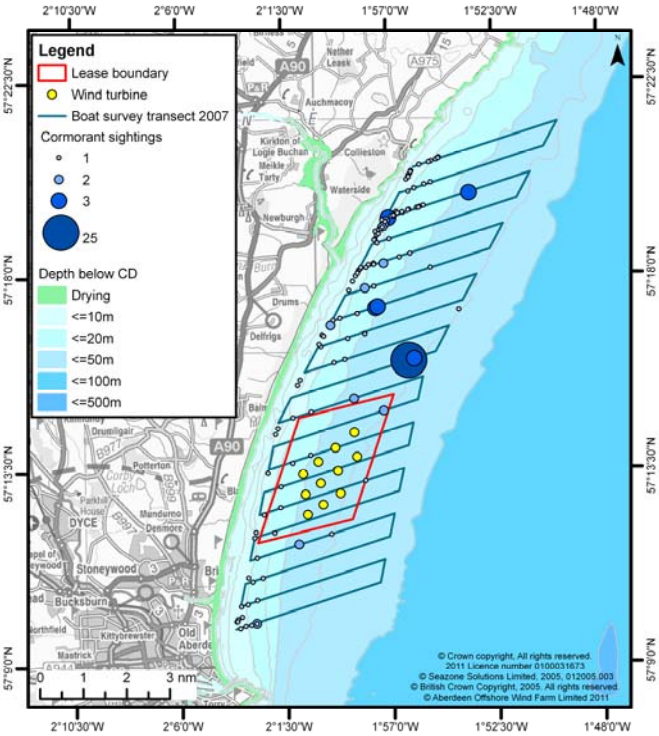

Figure 4-57: Cormorant distribution February 2007 to January 2008 (all sightings).

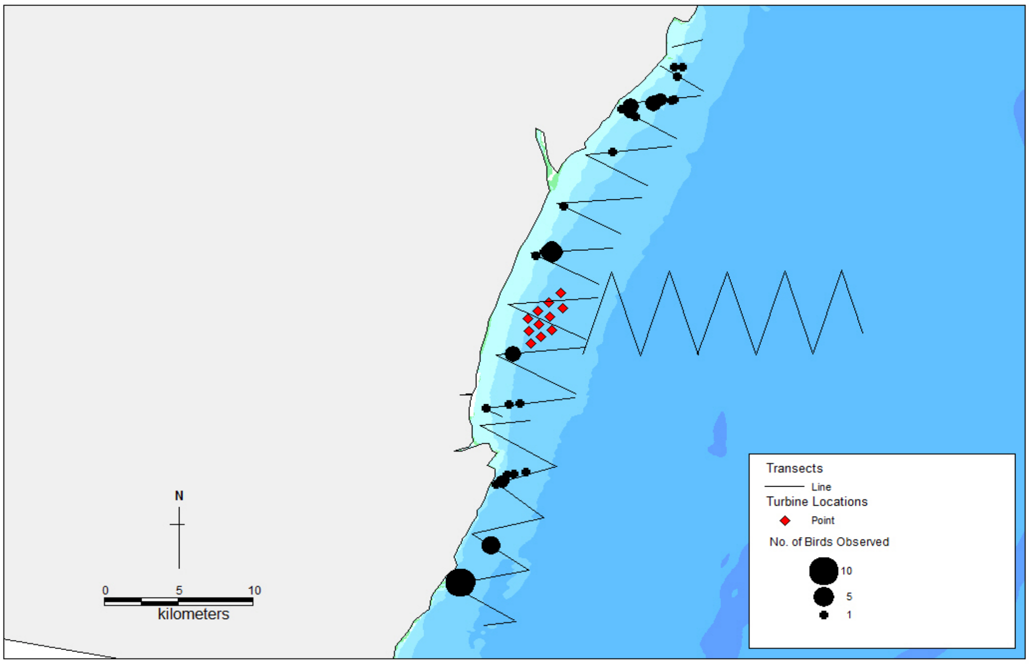

Figure 4-58: On-effort observations of all cormorant species (great cormorant and shag) along transects during August, September and November 2010 and January 2011.

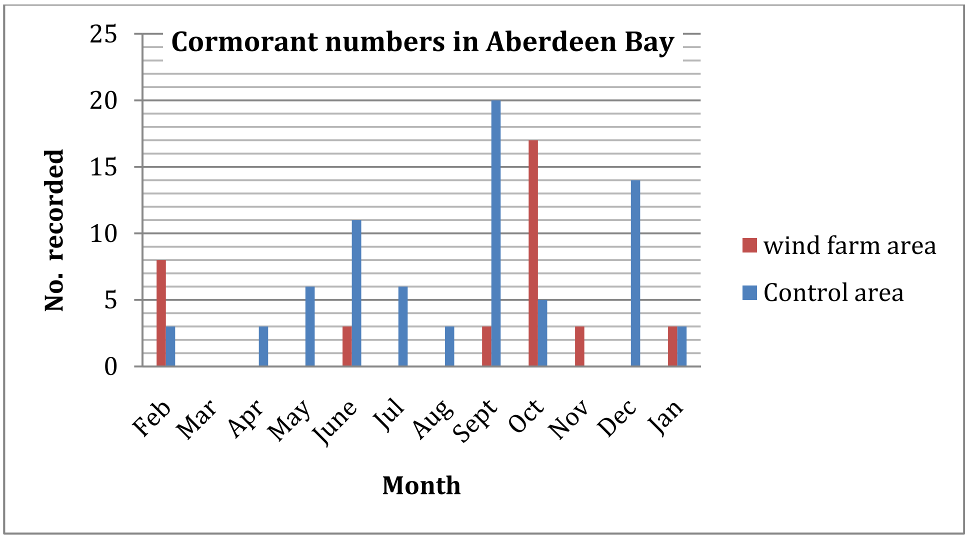

Figure 4-59: Cormorant monthly population estimates in proposed EOWDC and 'control' areas: Boat-based surveys 2007 – 2008.

There were not enough records to undertake *Distance* sampling on a monthly basis. However, *Distance* sampling was possible on seasonal data. Peak overall estimated abundances were during the spring and autumn periods with the majority of sightings within the 'control' area. Throughout the year, the numbers of cormorant estimated to be in the 'control' area were higher than within the proposed EOWDC area (Table 4-20, Figure 4-60, Figure 4-61).

Table 4-20: Seasonal estimates of density and abundance of cormorants in the proposed EOWDC and 'control' Areas

	Density Estimate (km^2)	SE	Estimated Abundance	SE	No. Observations
EOWDC- Winter	0.177	0.075	9	3.8	6

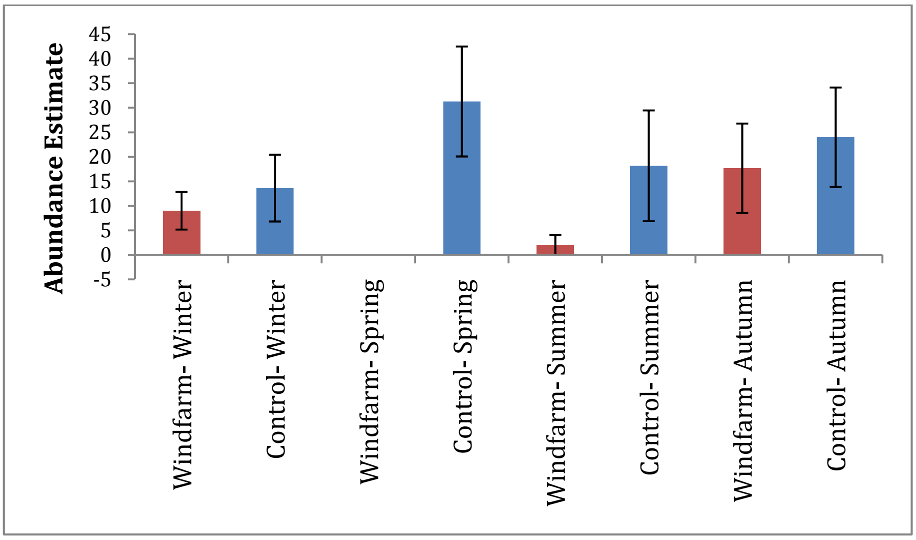

Figure 4-61: Seasonal estimates (+/- SE) of abundance of cormorants in the proposed EOWDC and 'control' Areas.

Vantage Point surveys

Cormorants were present during peak dawn and dusk activity periods in Aberdeen Bay throughout the year with peak numbers between June and September. Up to 15 birds per hour passed during peak periods. During the winter months the number of cormorants within Aberdeen Bay was lower with less than five birds per hour passing any one Vantage Point (EnviroCentre 2007b). Of those recorded in flight, 8% of cormorants were flying between 30 m and 150 m above sea surface with 0.5 birds per hour doing so during the winter months and up to one per hour during summer months (EnviroCentre 2007b). The majority of sightings were within 2 km of the coast (Alba Ecology 2008b).

Bird Detection Radar

A total of 96 cormorants were recorded during Bird Detection Radar studies undertaken during October 2005. The number of observations made between the two sites from which the surveys were undertaken was similar, with 47 cormorants recorded at Drums and 49 at Easter Hatton (Walls *et al*. 2006). Forty-three cormorants were recorded off Blackdog over a seventeen day period in April 2007. Most sightings were of single birds but a flock of three was recorded (Simms *et al.* 2007).

4.19.3 Summary of Results

Cormorants were regularly recorded in Aberdeen Bay throughout the year. Peak numbers occurred in the spring and autumn with most sightings within the 'control' area. Peak abundance of 31 birds and a density of 0.61 birds/km^2 occurred in the 'control' area during the spring. The majority of sightings were within 2 km of the coast and of those recorded in flight, 92% of all flights were below 30 m.

Numbers of cormorant recorded in Aberdeen Bay were below the threshold for a site of national importance.

4.19.4 Initial Assessment of Significance

Cormorant	Overall sensitivity	Magnitude	Significance
Collision	Very High	Negligible	Minor
Barrier	Medium	Low	Minor
Displacement	Very High	Low	Moderate

4.19.5 Species Sensitivities

Qualifying species

The nearest SPA to the proposed development for which cormorant is a qualifying breeding species is the Forth Islands SPA. The cormorant is also a qualifying species for the Firth of Forth SPA and Firth of Tay & Eden Estuary SPA for which the species is listed under Article 4.2 as part of wintering waterfowl assemblage (SNH 2011).

Flight height

Of those recorded in flight from boat-based surveys and for which flight heights were recorded all were flying below 25 m and 7% were flying between 15 m and 25 m. Data obtained from Vantage Point counts indicated that 8% were flying between 30 m and 150 m.

Data from other offshore wind farms have recorded overall 4% of cormorant as flying at rotor height with a mean flight height of 8.6 m (n=20,416).

Collision risk

Evidence from site specific monitoring from boat-based and land-based surveys indicate that cormorants are widespread in nearshore waters across Aberdeen Bay (Figure 4-57, Figure 4-58). There were no records of cormorants flying at rotor height from boat-based surveys and therefore a figure of 4% based on data from other offshore developments has been used for the Collision Risk Modelling.

Collision with offshore wind turbines have been reported (Zucco *et al.* 2006)

Collision Risk Modelling undertaken for cormorant is based on:

- Body length of 84 cm

- Wingspan of 160 cm
- Flight speed of 19.4 m.s^{-1}

(Koffijberg & Mennobart 1995; Gremillet, Schmid & Culik 1995)

Table 4-21: Predicted number of collisions for various avoidance rates for cormorant.

Collision probability	Avoidance rate (%)		
	98	99	99.5
8.9%	1.23	0.62	0.31

Based on the various scenarios and using a precautionary avoidance rate of 98% it is predicted that a total of 1.23 collisions per year may occur (Table 4-21).

The annual mortality rate for cormorant is 12% (BTO 2011). Consequently, out of a population of 198 pairs (396 individuals) at the Forth Islands SPA an annual mortality of 47 cormorants may be predicted. Therefore, 1% of the baseline mortality is 0.5 birds per year.

However, the Forth Islands SPA is 124 km away and the maximum reported foraging distance for breeding cormorants is 35 km (Roos 2010). Therefore, the proposed development is outwith the range of potential adverse effect on the breeding cormorants at the Forth Islands SPA.

Cormorants associated with the non-breeding wintering assemblages at the Firth of Forth and Firth of Tay & Eden Estuary SPA will remain within or in the vicinity of those sites during the non-breeding seasons. Both sites are in excess of 90 km away from the proposed development and therefore not at risk of an adverse effect from the proposed development.

Within North-east Scotland cormorants breed to the north of the proposed development with colonies on the Forvie National Nature reserve (NNR), Boddam area and Loch of Strathbeg. The majority of birds recorded from boat-based and land-based surveys were recorded in the ‘control’ area to the north and therefore are likely to be birds associated with these colonies. Based on an estimated breeding population of 150 pairs (300 individuals) an increase in mortality of 0.3 birds per year could be significant.

Results from collision risk modelling indicate that should all the cormorants at risk of collision be from colonies to the north of the proposed development, in order for less than 0.3 birds per year to collide with the turbines an avoidance rate of more than 99.5% is required. This is significantly lower than the precautionary 98% avoidance rate predicted.

Evidence from existing wind farms indicate that cormorants take avoidance behaviour and that up to 43% will do so before being at risk of collision. Furthermore studies undertaken at Ronland Offshore wind farm in Denmark recorded only one observation of cormorant at risk of collision after 560 hours of observations (Jensen 2006). Data from Sweden also indicates a significant reduction in the number of cormorants flying through the wind farm site once in operation compared to pre-construction (Zucco *et al.* 2006).

Based on the site specific evidence and the results from collision risk modelling it is concluded that risk of a significant environmental impact is minor and any possible adverse affect negligible.

Barrier effect

Although cormorants are regularly recorded within operating wind farms there is also evidence of a barrier effect with birds detouring around turbines (Petersen *et al*. 2006).

Should a barrier effect occur then cormorants will fly around the proposed development. By doing so this could cause an overall increase in flying distance of up to approximately 3.2 km. For a bird foraging at the maximum recorded foraging range from a colony of 35 km this additional distance would equate to an additional 10% of flight distance and add between 1% and 2% to the daily energy expenditure (Speakman, Gray & Furness 2009).

Foraging ranges of up to 35 km have been reported as unusual with only 5% of flights being of that distance and typical foraging range being of 5 km or less (Roos 2010). The additional 1 – 2% of daily energy expenditure that could be incurred by avoiding the proposed development area will not on an *ad hoc* basis have a significant effect and as foraging flights of that distance are unusual and not predicted to take place on a daily basis there will not be any detrimental cumulative impact caused by regular flights around the proposed development. Based on the evidence from existing offshore wind farms and site specific data it is concluded that the potential barrier effect will have a minor impact of cormorants

Displacement

Although cormorants may fly around wind farms they have also been regularly recorded within constructed offshore wind farms where they use the turbine structures for perches and have been recorded feeding within arrays of wind turbines (Petersen 2004). Consequently, although there may be an effect to flying birds cormorants do occur within wind farms and there is not total displacement and it is not predicted that there will be a significant effect arising from the proposed development on cormorants from displacement effects.

Cumulative and in-combination

The three closest SPAs for which cormorant is a qualifying species are all over 90 km away. The proposed offshore wind farms within the Firth of Forth area or the Moray Firth are all in waters largely in excess of 20 m water depth and therefore in areas where cormorants are unlikely to regularly occur. For example, only two cormorants were recorded over a year of surveys at the Beatrice Offshore wind farm demonstrator project (Talisman 2005). There is therefore no evidence of a likely adverse or significant effect on cormorants from either the proposed development on its own or in combination with other plans or programmes.

4.19.6 Conclusions

Habitats Appraisal

There are no SPAs for which cormorant is a qualifying species that will be adversely affected by the proposed development.

Environmental Impact Assessment

Based on the site specific data and data from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on cormorants.

4.20 European shag (*Phalacrocorax aristotelis*)

4.20.1 Protection & Conservation Status

The (European) shag is included in annex I of the Wild Birds Directive and Annex II of the Bern Convention. It is included on the Amber List of Species of Conservation Concern.

4.20.2 Background

Shag		
GB Population	Summer: 27,000 prs	BTO 2011
Scottish population	Summer: 21,500 – 30,000 prs Winter: 60,000 – 80,000 ind.	Forrester *et al.* 2007
International threshold	2,000 ind	Calbrade *et al.* 2010
GB threshold	540 ind	1% of GB population
Designated east coast sites where species is a noted feature	Buchan Ness – Collieston Coast: 331 prs Forth Islands: 480 prs	SNH 2011 JNCC 2011a
European population estimate	Breeding 75,000 – 81,000 pairs Wintering – >92,000	Birdlife 2004
European population trend	Status 'secure' Trend 'moderate decline'	Birdlife 2004
World population	230 – 240,000 'adults'	Birdlife 2011

The (European) shag occurs widely along rocky coastal areas of the UK where they breed in loose colonies along suitable rocky shores and forage typically within approximately 4 km of the shore. Outwith the breeding season, shags disperse locally up to 100 km away from their breeding colonies and are not strongly migratory. They remain within nearshore coastal waters often around rocky coasts or in large shallow sandy bays feeding, primarily, on a variety of fish species. The breeding population in the UK has increased substantially during the 20th century from 34,000 pairs in 1969/1970 to 43,000 pairs in 1985-1988.

In North-east Scotland, shags occur widely along all coasts and regular daily movements to and from roosting sites have been recorded at Peterhead. Peak counts at Peterhead occurred from October through to March where up to 1,200 birds per hour have been recorded flying north at dawn and counts of 3,000 to 4,000 birds have been recorded (Buckland, Bell & Picozzi 1990). During the breeding season the numbers of birds at Peterhead were considerably lower with less than 200 birds per hour passing (Innes 1991).

Boat-based surveys

Only fourteen shags were recorded 'in transect' during boat-based surveys with all but one within approximately 2 km of the coast and in water depths of less than 20 m Further records of birds detected but not in transect are included in Figure 4-62 and indicate that occasional records may occur further offshore.

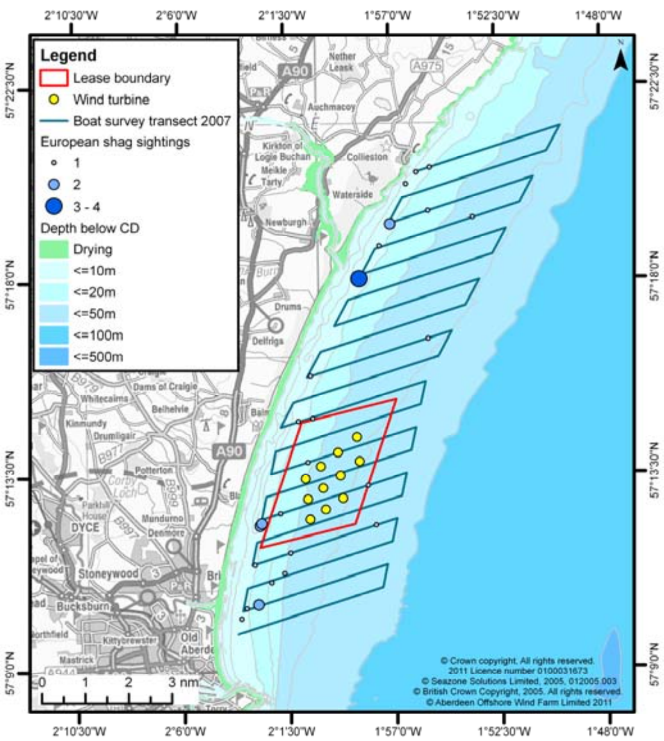

Figure 4-62: Shag distribution in Aberdeen Bay - February 2007 to April 2008 (all sightings).

Vantage Point surveys

In Aberdeen Bay shags were recorded in low numbers throughout the area. Peak numbers occurred in April with three birds per hour during April 2006 and eight birds per hour in April 2007 (EnviroCenrtre 2007a, Alba Ecology 2008a). Numbers decreased to less than one bird per hour during the winter months (EnviroCentre 2007b, Alba Ecology 2008b). Most shags were recorded between 1 km and 3 km from shore and at least 93% were flying below 30 m (EnviroCentre 2007a).

Bird Detection Radar

One shag was recorded at Easter Hatton during the five days of observations undertaken at both Drums and Easter Hatton in October 2005 (Walls *et al.* 2005). A further 14 birds were recorded during the 17 days of surveys undertaken in April 2007 (Simms *et al.* 2007).

4.20.3 Summary of Results

Although shags were recorded regularly in Aberdeen Bay throughout the year numbers were generally low. Peak numbers occurred in the spring and autumn with most sightings within 2 km from the shore. Of those recorded in flight, 93% of all flights were below 30 m.

Numbers of shag recorded in Aberdeen Bay were below the threshold for a site of national importance.

4.20.4 Initial Assessment of Significance

Shag	Overall sensitivity	Magnitude	Significance

Collision	Very High	Negligible	Minor
Barrier	Medium	Low	Minor
Displacement	Very High	Low	Moderate

4.20.5 Species Sensitivities

Qualifying species

The shag is a qualifying species for Buchan Ness to Collieston Coast SPA which lies approximately 9.5 km to the north of the proposed development and also the Forth Islands SPA which lies approximately 124 km to the south of the proposed development. (SNH 2011).

Flight height

Of those recorded in flight from boat-based surveys and for which flight heights were recorded all were flying below 15 m.

Data from other offshore wind farms have recorded 12% of shags as flying at rotor height (n=230).

Collision risk

Evidence from site specific monitoring from boat-based and land-based surveys indicate that shags are uncommon within the area of the proposed development. All sightings from boat-based surveys were of birds flying below rotor height and therefore not at risk from collision with the turbines. Further evidence from other offshore wind farms further indicates that shags flying at rotor height are unusual (ERM 2005).

Based on the relatively low numbers of shags recorded within the area of the proposed development and evidence indicating that shags rarely fly at rotor height it is predicted that very few collisions will occur and any impacts will be negligible and not cause an adverse effects on shag as qualifying species for either the Buchan Ness to Collieston Coast SPA and Forth Islands SPA.

Barrier effect

There is little or no evidence from existing offshore wind farms to determine whether or not a barrier effect may occur. However, should it do so then shags will fly around the proposed development. By doing so this could cause an overall increase in flying distance of up to approximately 3.2 km. For a bird foraging at the maximum recorded foraging range from a colony of 17 km (Roos 2010) this additional distance would equate to an additional 18% of flight distance and add between 1% and 2% to the daily energy expenditure (Speakman, Gray & Furness 2009).

Foraging ranges of up to 17 km are unusual and mean foraging ranges are less than 7 km from the colony consequently the majority of foraging being undertaken by shags associated with the SPA will be out with the proposed development area and there will not be a barrier effect. The additional 1 to 2% of daily energy expenditure that may be incurred on the occasions that shags do forage further and maybe avoid the proposed EOWDC area will not on an *ad hoc* basis have a significant effect and as foraging flights of that distance are unusual and not predicted to take place on a daily basis there will not be any detrimental cumulative impact caused by regular flights around the proposed development. Based on the evidence from existing offshore wind farms and site specific data it is concluded that the potential barrier effect will have a negligible impact on shags.

Displacement

There is limited data from existing offshore wind farms that shags occur within operating wind farms (Christensen & Hounisen 2005). However, should displacement occur then an area of approximately 4 km^2 may not be utilised by shags. Data from boat-based surveys indicate that shags are relatively uncommon within the vicinity of the proposed development and that the area is not an important location for shags. Even if displacement does occur the number of birds potentially displaced will be small and that their displacement into other areas will not have a detrimental effect. Based on the evidence from site specific surveys it is predicted that there will not be any significant environmental or adverse effects on shags from displacement impacts.

Cumulative and in-combination

Of the two SPAs for which shag is a qualifying species: the Forth Islands SPA is 124 km away and will not be impacted by the proposed development and the Buchan Ness to Collieston Coast SPA is 9.5 km away. No adverse effects are predicted upon either of these sites from the proposed development on its own. The proposed offshore wind farms within the Firth of Forth area and the Moray Firth are in deeper waters but may still be in areas where shags can forage. No data are available as to whether shags are being recorded at any of the planned wind farm locations. However, the distance from shore for all the planned Round 3 and Scottish Territorial Water wind farms locations indicate that they are unlikely to be frequently used as areas of importance for shags. The Beatrice demonstrator project recorded just 63 shags over a 12 month period indicating that the area is not extensively used by this species (Talisman 2005).

There is therefore no evidence of a likely adverse or significant effect on shags from either the proposed development on its own or in combination with other plans or programmes.

4.20.6 Conclusions

Habitats Appraisal

There are no SPAs for which the shag is a qualifying species that will be adversely effected by the proposed development.

Environmental Impact Assessment

Based on the site specific data and data from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on shags.

4.21 Great crested grebe (*podiceps cristatus*)

4.21.1 Protection & Conservation Status

The great crested grebe is listed in Annex I of the Birds Directive, Appendix II of the Bern Convention, Appendix II of the Bonn Convention, Schedule 1 under the Wildlife and Countryside Act, 1981 and is on the Green List of Species of Conservation Concern.

4.21.2 Background

The great-crested grebe is a widespread breeding species in the UK with an estimated breeding population of 8,000 pairs. They breed on freshwater habitats but can winter on along estuaries with an estimated 1,800 out of the UK wintering population of 16,000 doing so.

The main wintering area along the east coast of Scotland is the Firth of Forth where a mean peak of 156 great-crested grebe has been recorded over the last five years (Calbrade *et al*. 2010). In North-east Scotland great-crested grebes are an uncommon breeding and wintering species.

Great crested grebe		
GB population	Summer: 8,000 prs Winter: 16,000 ind.	BTO 2011
Scottish population	Summer: 240 – 365 prs Winter: 900 – 1,500 ind.	Forrester *et al*. 2007
International threshold	3,600 ind.	Calbrade *et al.* 2010
GB threshold	159 ind.	Calbrade *et al.* 2010
Designated east coast sites where species is a noted feature	Firth of Forth	SNH 2011 JNCC 2011a

World population	920,000 – 1,400,000 'adults'	Birdlife 2011

Vantage Point surveys

There was one record of a great-crested grebe from the Vantage Point surveys in October 2007 (Alba Ecology 2008b).

4.21.3 Initial Assessment of Significance

Great-crested grebe	Overall sensitivity	Magnitude	Significance
Collision	Medium	Negligible	Negligible
Barrier	High	Negligible	Negligible
Displacement	Very High	Negligible	Minor

4.21.4 Species Sensitivities

Qualify species

The nearest SPA for which great-crested grebe is a qualifying species is the Firth of Forth SPA, *c*134 km to the south of the proposed development. Great-crested grebe qualifies under Article 4.2 as part of a wintering waterfowl assemblage and the population at the time of citation was 720 individuals, 7% of GB population (SNH 2011).

Status

Great-crested grebes are rarely recorded within Aberdeen Bay and there was only one sighting from any of the project specific surveys. Records from other sources support the finding that great-crested grebes are infrequent in the bay (NESBR).

Cumulative

The very low level of usage of the site indicates that there will not be any cumulative or in-combination impact.

4.21.5 Conclusions

Habitats Appraisal

Based on the available evidence from site specific surveys undertaken at the proposed development area, in particular the very low usage of the site by great-crested grebes and the distance the site is from the Firth of Forth SPA, it is concluded that the proposed development will not have an adverse effect on great-crested grebe as qualifying species.

Environmental Impact Assessment

Based on the very low usage of the site it is predicted that there will not be a significant environment impact arising from the proposed development on great-crested grebe.

4.22 Great skua (*Stercorarius skua*)

4.22.1 Protection & Conservation Status

The great skua is listed in Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.22.2 Background

Great skua		
GB population	Breeding: 9,650 prs	Mitchell *et al* 2004
Scottish population	Breeding: 9,650 prs	Forrester *et al.* 2007
International threshold	Unknown	-
GB threshold	192 ind.	1% of GB Pop^{n}
Designated east coast sites where species is a noted feature	None	SNH 2011 JNCC 2011a
European population estimate	Breeding 16,000 pairs Wintering – unknown	Birdlife 2004
European population trend	Status 'secure' Trend 'Large increase'	Birdlife 2004
World population	16,000 pairs	Mitchell *et al* 2004

Approximately 60% of the world population of great skua nest in the UK, all of which nest in north and north-west Scotland. They are summer migrants to the UK arriving at their breeding colonies in April and May and departing primarily during August and September. During the breeding season non-breeding immature birds may also be present at the colonies. Following breeding, birds disperse into the North Sea and Atlantic and migrate southwards to their wintering grounds in the Bay of Biscay and West Africa. Autumn passage of great skuas is estimated to be between 2,000 to 10,000 birds when they remain largely offshore occurring in relatively low densities across the North Sea (Forrester *et al.* 2007).

During the breeding season they feed on fish, often following fishing vessels or by kleptoparasitising fish from other seabirds but they will also kill smaller seabirds.

In North-east Scotland great skuas occur between April and November with peak numbers in July and August with up 10 birds per hour past Peterhead (Innes 1993).

Boat-based surveys

Great skua were recorded from July to September with 27 sightings from the whole survey area. Sightings were recorded throughout the bay with no areas of significant concentrations recorded and very records were from within the proposed EOWDC development area (Figure 4-63).

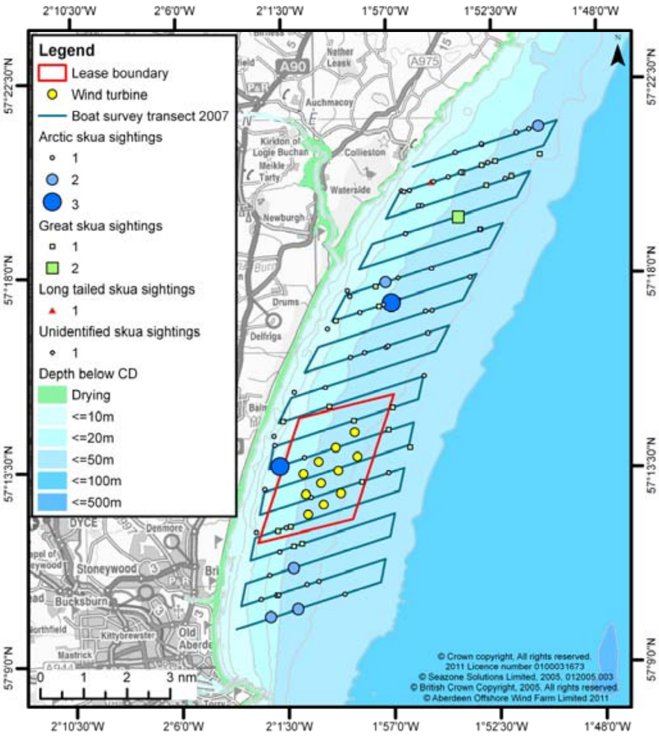

Figure 4-63: Skua distribution February 2007 to April 2008 (all sightings).

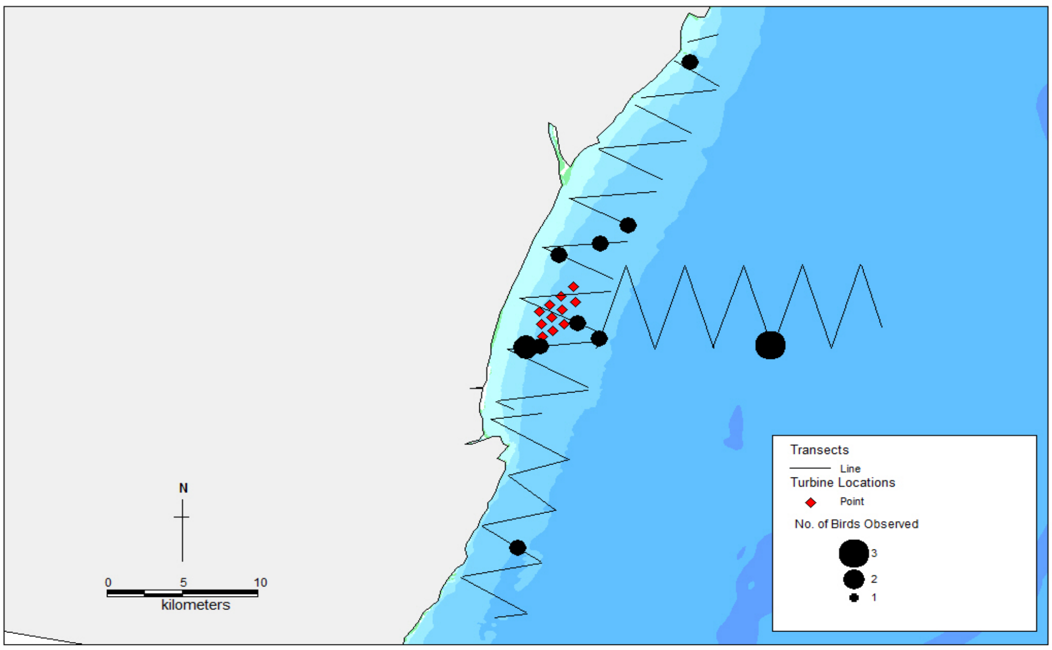

Figure 4-64: On-effort observations of all Skua species (great, Arctic and pomarine) along transects during August, September and November 2010 and January 2011.

Vantage Point surveys

Great skuas were recorded in relatively low numbers from Vantage Point counts from April and October with peak counts during August and September when up to three birds per hour were recorded. Most observations of birds were between 1–3 km from shore and between 84% and 87% were flying below 30 m.

Bird Detection Radar

Ten great skuas were recorded during the radar studies in October 2005 and seven during April 2007. All but one of the sightings was of single birds (Walls *et al* 2005, Simms *et al.* 2007).

4.22.3 Summary of Results

Great skuas were widely recorded across Aberdeen Bay in relatively low numbers from all surveys from between April and October. Peak counts were during the period of autumn migration when up to three birds per hour were recorded in August and September. There were also a smaller number of sightings during the spring migration with most records from April.

Of those recorded in flight, during boat-based surveys, 25% were recorded flying above 25 m and between 13% and 16% were recorded above 30 m from land-based surveys.

No counts of great skua from any of the surveys undertaken within Aberdeen Bay were of national importance.

4.22.4 Initial Assessment of Significance

Great skua	Overall sensitivity	Magnitude	Significance
Collision	High	Negligible	Negligible
Barrier	Low	Low	Negligible
Displacement	Low	Negligible	Negligible

4.22.5 Species Sensitivities

Qualifying species

There are no SPAs in the region for which the great skua is a qualifying species but over 73% of the UK breeding population of great skuas do occur in SPAs in northern Scotland.

Flight height

Observations from boat-based surveys undertaken in Aberdeen Bay reported two out of the eight great skuas for which flight heights were recorded as being above 25 m, i.e. 25% of flights were at rotor height..

Elsewhere in the UK out of 239 recorded flight heights of great skua obtained from boat-based surveys, 4% were recorded as being at rotor height.

Collision risk

Data obtained from boat-based and land-based surveys recorded great skuas across Aberdeen Bay in relatively low numbers particularly during the autumn passage periods. There is relatively little data from other constructed offshore wind farms to determine possible avoidance rates but these are assumed to be relatively high and 96% of flights are below rotor height.

Based on the relatively low usage of the site, the broad distribution of great skua across Aberdeen Bay and the high percentage of birds recorded as flying below rotor height it is concluded that there is a low risk of collision and that should it occur its significance on the species will be negligible.

Barrier effect

There are no data from any constructed wind farms to determine whether or not a barrier effect may occur. Should it do so, there will be an incremental increase in energy expenditure as the bird flies around the wind turbines. However, the increase in flight distance caused by doing so will be insignificant for a bird flying to or from its wintering grounds in the Bay of Biscay (or further south) and its breeding grounds in northern Scotland. The significance of any increase in energy expenditure will, if it occurs, be negligible.

Displacement

There are no data available to determine whether great skuas may be displaced from the proposed development area. Should they do so then they will forage elsewhere for their prey whether that is from scavenging behind fishing vessels, stealing it from other birds or catching it themselves. There is no indication that the proposed area is of any significant importance for great skua and therefore any displacement, should it occur, will be negligible.

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on great skuas.

Outwith Aberdeen Bay there are a number of planned offshore wind farms in the Firth of Forth and the Moray Firth. The only data available is that from the Beatrice Demonstrator Project which recorded 51 great skuas over a period of 12 months pre-construction surveys (Talisman 2005). The size, scale and exact locations of the Round 3 and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of great skuas that may be present in the planned development areas. Consequently, it is not possible to determine whether there will be a cumulative or in-combination impact arising from the proposed plans. However, although great skuas will be recorded within the area, the relatively far distance the proposed development is from the other planned offshore wind farms and its relatively small scale reduces the risk of a potentially significant cumulative or in-combination effect.

4.22.6 Conclusions

Habitats Appraisal

There are no SPAs in the region for which great skua is a qualifying species.

Environmental Impact Assessment

Based on the relatively low densities of great skuas recorded in Aberdeen Bay and their broad distribution it is predicted that there will not be a significant impact arising from the proposed development on great skuas.

4.23 Arctic skua (*Stercorarius parasiticius*)

4.23.1 Protection & Conservation Status

The Arctic skua is listed in Appendix III of the Bern Convention and is on the Red List of Species of Conservation Concern.

4.23.2 Background

Arctic skua		
GB Population	Breeding: 2,100 prs	Mitchell *et al* 2004
Scottish population	Breeding 2,100 prs	Forrester *et al*. 2007
International threshold	Unknown	-
GB threshold	50	Minimum
Designated east coast sites where species is a noted feature	None	SNH 2011 JNCC 2011a
European population estimate	Breeding 40,000 – 140,000 pairs Wintering – unknown	Birdlife 2004
European population trend	Status 'secure' Trend 'unknown'	Birdlife 2004
World population	85,000 – 340,000 pairs	Mitchell *et al* 2004

Within the UK Arctic skuas only nest in north and western Scotland where they are a summer migrant arriving on their breeding grounds during April and May and departing primarily in August and September. They feed on fish, primarily sandeels, that they often obtain from other seabirds as they enter the seabird colonies.

During migration from August to October Arctic skua occur widely offshore in low densities across the North Sea but may favour inshore waters where they can scavenge food from other seabirds, particularly Terns. In North-east Scotland peak passage occurs during August with a maximum of 326 Arctic skuas over a four hour period in August 1983 passing Peterhead (Buckland, Bell & Picozzi 1990).

Boat-based surveys

A total of 64 Arctic skuas were recorded from ship-based surveys undertaken between June and November 2007 and a further 16 were recorded between September and November 2010. Arctic skuas were recorded widely throughout the bay with no concentrations identified (Figure 4-63).

Vantage Point surveys

In Aberdeen Bay Arctic skuas were recorded between April and October with peak numbers of up to five birds per hour in July (EnviroCentre 2007a,b). Birds were recorded out to 3 km from shore with at least 78% of the sightings below turbine height.

Bird Detection Radar

Fourteen Arctic skuas were recorded by visual observations undertaken during Bird Detection radar studies in October 2005 and a further single observation was made at Blackdog in April 2007 (Walls *et al* 2006, Simms *et al.* 2007).

4.23.3 Summary of Results

Arctic skuas were widely recorded across Aberdeen Bay in relatively low numbers from all surveys from between April and October. Peak count numbers were during July when up to five birds per hour were recorded from land-based observations.

There was also a number of sightings during the spring and autumn migration periods.

Of those recorded in flight, 19% were recorded flying above 25 m from boat-based surveys and 22% above 30 m from land-based surveys.

No counts of Arctic skua from any of the surveys within Aberdeen Bay were of national importance.

4.23.4 Initial Assessment of Significance

Arctic skua	Overall sensitivity	Magnitude	Significance
Collision	High	Negligible	Negligible
Barrier	Low	Low	Negligible
Displacement	Low	Negligible	Negligible

4.23.5 Species Sensitivities

Qualifying species

There are no SPAs in the region for which the Arctic skua is a qualifying species but over 24% of the UK breeding population of Arctic skuas do occur in seven SPAs in Orkney and Shetland.

Flight height

Observations from boat-based surveys undertaken in Aberdeen Bay reported 16% of all flights above 25 m.

Elsewhere in the UK out of 50 recorded flight heights for Arctic skua four, i.e. 8%, were at rotor height.

Collision risk

Data obtained from boat-based and land-based surveys recorded Arctic skuas across Aberdeen Bay in relatively low numbers particularly during the autumn passage periods. There is relatively little data from other constructed offshore wind farms to determine possible avoidance rates but it is assumed to be relatively high and 92% of flights are below rotor height.

Based on the relatively low usage of the site, the broad distribution of Arctic skua across Aberdeen Bay and the high percentage of birds recorded as flying below rotor height it is concluded that there is a low risk of collision and that should it occur its significance on the species will be negligible.

Barrier effect

Data from post-construction monitoring studies undertaken in Denmark indicate that Arctic skua do not avoid entering wind farms consequently there is not thought to be a significant barrier effect (Zucco *et al*. 2006).

Displacement

There are no data available to determine whether Arctic skuas may be displaced from the proposed development area. However, they are known to follow Gulls, which may enter the proposed development area and Arctic skuas have been shown not to avoid wind farms. There is no indication any potential displacement effect but should it occur its significance is predicted to be negligible.

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on Arctic skuas.

Outwith Aberdeen Bay there are a number of planned offshore wind farms in the Firth of Forth and the Moray Firth. The only data available is that from the Beatrice Demonstrator Project which recorded 16 Arctic skuas over a period of 12 months pre-construction surveys (Talisman 2005). The size, scale and exact locations of the Round 3 and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of Arctic skuas that may be present in the planned development areas. Consequently, it is not possible to determine whether there will be a cumulative or in-combination impact arising from the proposed plans. However, although great skuas will be recorded within the area, the relatively far distance the proposed development is from the other planned offshore wind farms and its relatively small scale reduces the risk of a potentially significant cumulative or in-combination effect.

4.23.6 Conclusions

Habitats Appraisal

There are no SPAs in the region for which Arctic skua is a qualifying species.

Environmental Impact Assessment

Based on the relatively low numbers of Arctic skuas recorded in Aberdeen Bay and their broad distribution it is predicted that there will not be a significant impact arising from the proposed development on Arctic skuas.

4.24 Golden plover (*Pluvialis apricaria*)

4.24.1 Protection & Conservation Status

Golden plover is listed in Annex I of the Birds Directive, Schedule II of the Wildlife & Countryside Act, Appendix II of the Bonn Convention. Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.24.2 Background

Golden plover		
GB Population	Summer: 23,000 prs Winter: 250,000 nd.	BTO 2011
Scottish Population	Summer – 15,000 prs Autumn – 20,000 – 60,000 ind Winter: 25,000 – 35,000 ind.	Forrester *et al* 2007
International threshold	9,300 ind.	Calbrade *et al.* 2010
GB threshold	4,000 ind.	Calbrade *et al.* 2010

European population estimate	Breeding 436,000- 740,000 prs Wintering – 820,000 ind.	Birdlife 2004
European population trend	Status 'secure' Trend 'unknown breeding moderate increase wintering	Birdlife 2004
World population	640,000 to 1,200,000 ind.	Birdlife 2011

Golden plover breed on upland moorlands in northern Britain and Europe with the largest European populations in Iceland where up to 310,000 pairs (BirdLife 2004).

The UK holds 80% of the breeding population of the southern race of golden plover *P. apricaria apricaria* which has undergone a significant decline of 20% between the 1960's and 1980's (EC 2009). The breeding population occurs widely across the uplands of northern Britain and particularly Scotland where 15,000 pairs occur (Forrester *et al*. 2007).

In winter the UK population increases with birds arriving from Iceland and the Continent where they spend the winter on arable land, often winter crops, and open grassland. Birds return to the same areas and often same fields each year. Golden plover recorded in eastern Britain are thought to be predominantly birds from Scandinavia or further east whereas those from Iceland occur predominantly in western Britain and Ireland. Birds occurring in North-east Scotland are therefore most likely to be local breeding birds and from populations to the north and east (Wernham *et al*. 2002).

In North-east Scotland golden plover are a decreasing breeding species inland but occur widely during the winter at a few favoured locations near the coast each winter. Peak numbers in the region occur on the Ythan Estuary during the autumn as migrants. Maximum counts in recent years have been up to 9,000 birds but more often peak numbers are between 3,000 to 4,000 individuals (Buckland Bell & Picozzi

1990; NESBR). Birds forage and roost on the Ythan at low tide but move away as far as 10 km during high tides (Buckland Bell & Picozzi 1990).

Boat-based surveys

No golden plover were recorded from boat based surveys.

Vantage Point surveys

No golden plover were recorded from Vantage Point surveys

Bird Detection Radar

Golden plover were observed on three occasions but in large numbers during radar and visual surveys undertaken in October 2005. A total of 2,170 golden plover were recorded in three flocks along the shoreline and out to 3,300 m. Their mean flight height was 35 m and therefore at potential risk of collision (Walls *et al.* 2006)

Summary of Results

Golden plover were only recorded during land-based surveys undertaken on October 2005. The majority of sightings were of birds along the shore, although one flock occurred out as far as 3,300 metres offshore.

4.24.3 Initial Assessment of Significance

Golden plover	Overall sensitivity	Magnitude	Significance
Collision	Medium	Negligible	Negligible
Barrier	Medium	Low	Minor
Displacement	Low	Negligible	Negligible

4.24.4 Species Sensitivities

Qualifying species

Golden plover is a qualifying species as part of an assemblage for the Firth of Forth SPA.

Flight height

Flight heights recorded from land based surveys undertaken in October 2005 recorded a mean flight height of 35 m. Elsewhere very few golden plover have been recorded at offshore wind farms and all have been below turbine height.

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that golden plover are rarely recorded offshore in Aberdeen Bay. However, flocks of golden plover can occur. However, the only flock recorded offshore was to the north of the proposed development and were of birds likely associated with the Ythan Estuary also to the north, therefore golden plover are not at risk of collision. It is possible that golden plover may cross Aberdeen Bay during periods of passage. However, there is no indication that there are any regular movements across the bay nor that there is a flyway across the proposed development area.

Studies undertaken in Denmark have also indicated that golden plover fly above the turbine height during passage and are not at risk of collision and that other species of wader flying at rotor height demonstrated effective avoidance behaviour when near to offshore wind turbines (Petersen *et al.* 2006). Consequently, there is evidence to indicate that the risk of collision to golden plover in Aberdeen Bay is low and that the potential effect from collision is negligible.

Barrier effect

Data obtained from nearly three years of Vantage Point surveys plus additional radar studies and boat-based surveys did not detect any evidence to suggest that there are regular daily flights by golden plover across the proposed development area and so a regular barrier effect that may cause a long-term increase in daily energetic costs is not predicted. There is the potential for a relatively small *ad hoc* increase if golden plover cross the bay during migration but this would cause a very small incremental increase in energetic costs. It is predicted that the potential impacts arising from barrier effect will at worst be minor but most likely be negligible due to the relatively small incremental increase in flight distance compared to the likely total length of migration.

Displacement

No golden plover were recorded at the proposed development area and therefore no displacement effects will occur.

Cumulative and in-combination

It is possible that birds migrating long distances from Scandinavia or Russia may interact with one or more wind farm. However, it is not known where the golden plover recorded at the Ythan Estuary originate from or where they may migrate to and therefore it is not possible to undertake an evidence based cumulative or in-combination impact assessment.

The only data available that may be of relevance is from the Beatrice demonstrator project which did not record any golden plover during its surveys. Data from other proposed projects in the Moray Firth and the Firth of Forth are not currently available.

Habitats Appraisal

Based on the very low usage of the proposed development area by golden plover and some evidence from existing offshore wind farms indicating a low collision risk, it is predicted that there will not be any adverse effects on the Firth of Forth SPA for which golden plover is a qualifying species.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on golden plover.

4.25 Black-legged kittiwake (*Rissa tridactyla*)

4.25.1 Protection & Conservation Status

The (black-legged) kittiwake is listed in Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.25.2 Background

European population trend	Status 'depleted' Trend 'moderate increase'	Birdlife 2004
World population	97,000 – 270,000 'adults'	Birdlife 2011

Kittiwakes are the most numerous species of gull in the world and highly pelagic. It is the most abundant breeding gull in the UK nesting in often very large colonies on coastal cliffs. Kittiwakes start arriving back at their colonies during March and April and depart during August and September. During the breeding season they can forage widely with adults flying in excess of 100 km to suitable foraging sites.

Post-breeding, both adults and juveniles disperse across the North Sea and the north Atlantic with a greater proportion of unsuccessful breeders wintering off eastern Canada compared to those that have been successful that winter largely in the eastern Atlantic (Bogdanova *et al*. 2011).

In North-east Scotland kittiwakes are recorded throughout the year but with lowest numbers between November and March and peak numbers generally during July and August. On occasions there are records of exceptionally large movements of kittiwakes along Aberdeenshire coast. In April 1978 over 44,000 kittiwakes were recorded flying past Collieston and over 80,000 are estimated to have flown past Aberdeenshire on 29 October 1969 (Buckland, Bell & Picozzi 1990).

Observations off Peterhead occur out to 3 km with most records of birds closest to shore during poor weather (Innes 1991).

Boat-based surveys

Kittiwakes were the most frequently recorded Gull from boat-based surveys. They were recorded throughout Aberdeen Bay with the majority of sightings in water depths of between 10 m and 20 m and between 1 km and 3 km from the shore. Year 1 data indicated significantly more kittiwakes in to the north compared to those within the proposed EOWDC survey area. Relatively low numbers were recorded during the winter period and none within the footprint of the proposed development area (Figure 4-65)

Peak numbers occurred during the breeding season between April and July, with highest numbers to the north (Figure 4-66). Post-breeding, the numbers of kittiwake recorded decreased with low numbers recorded within the proposed development area (Figure 4-67).

Data collected from between August 2010 and January 2011 have indicated greater numbers within the vicinity of the proposed development compared to elsewhere (Figure 4-68).

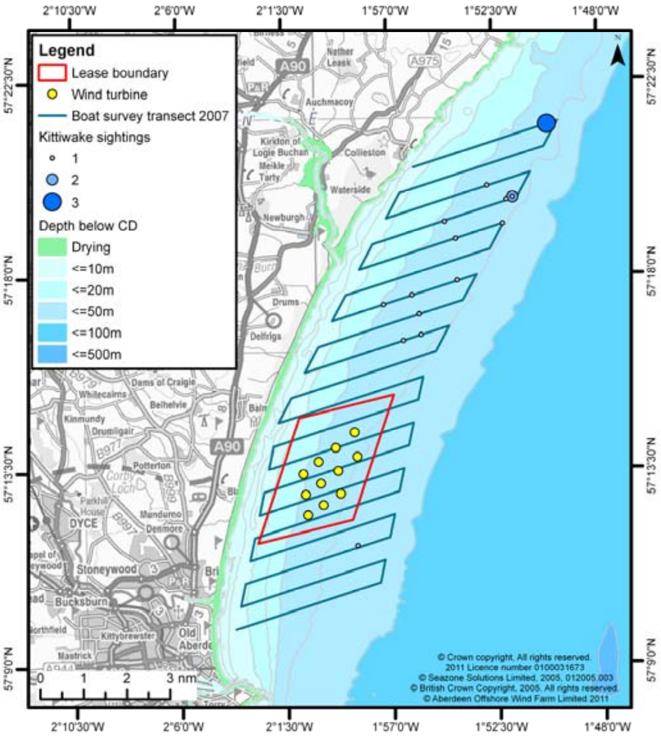

Figure 4-65: Kittiwake distribution in Aberdeen Bay during winter period: November to March (all sightings).

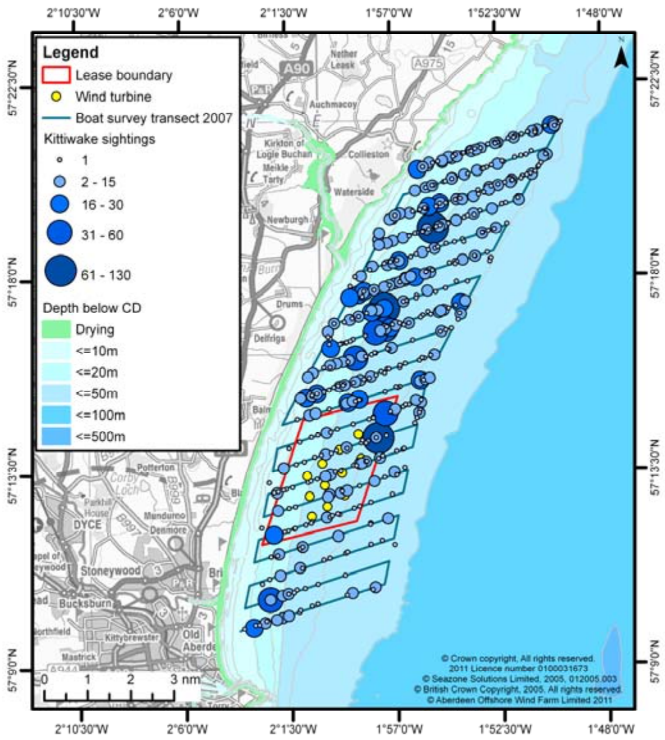

Figure 4-66: Kittiwake distribution in Aberdeen Bay during breeding season: April – July (all sightings).

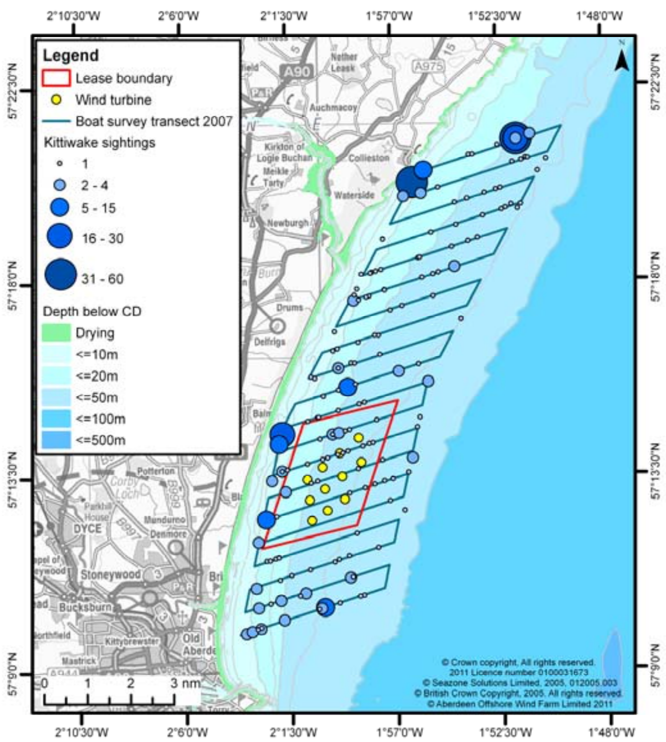

Figure 4-67: Kittiwake distribution in Aberdeen Bay during post-breeding: August - October (all sightings).

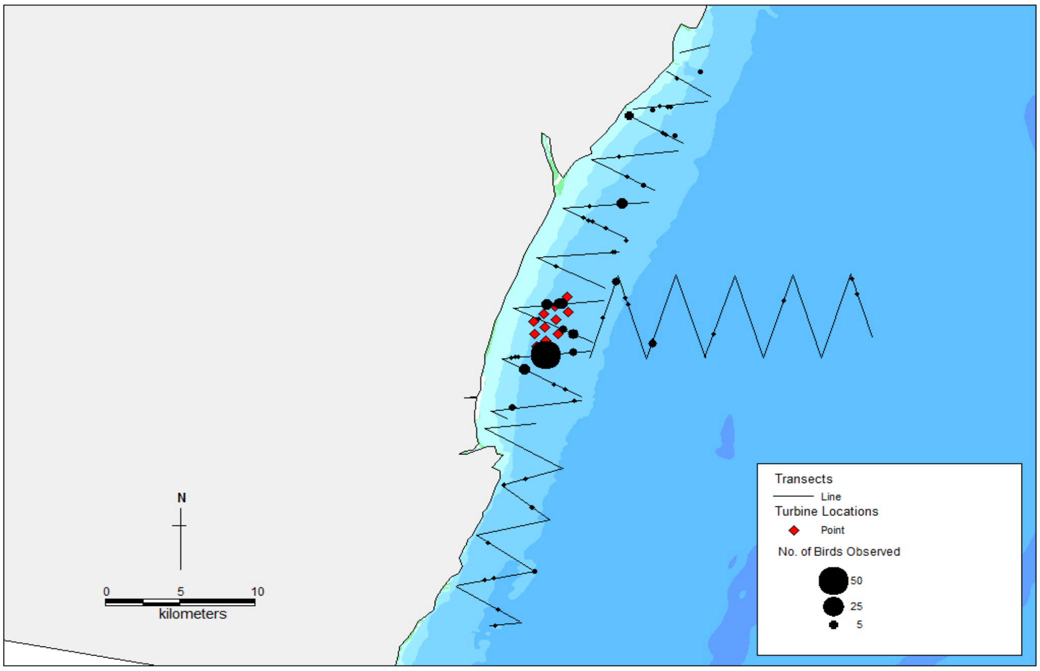

Figure 4-68: On-effort observations of kittiwake along transects during August, September and November 2010 and January 2011.

There was a strong seasonal variation in the frequency of sightings with relatively high numbers in June and July when there was a peak of *c.*2,300 kittiwakes within the surveyed area. Outwith the peak period numbers of kittiwakes recorded were relatively low with an estimated abundance of less than 14 birds in the proposed EOWDC development area during the autumn and only one bird during the winter period (

Table 4-22). Peak density estimates occurred during the spring and summer when up to 33 birds/km^2 were recorded.

Monthly data collected from between August 2010 and January 2011 recorded peak abundance estimate of 870 birds in the northerly survey area during September with relatively few birds to the south or offshore (Figure 4-71). Densities of kittiwakes during September were 5.7 birds/km^2 (Figure 4-72).

Table 4-22: Seasonal estimates of density and abundance of kittiwakes in the proposed EOWDC and 'control' areas.

Season	Density Estimate (km^2)	SE	Estimated Abundance	SE	No. Observations
EOWDC- Winter	0.025	0.025	1	1.3	1
Control- Winter	0.049	0.050	3	2.5	2
EOWDC- Spring	0.453	0.229	23	11.6	12

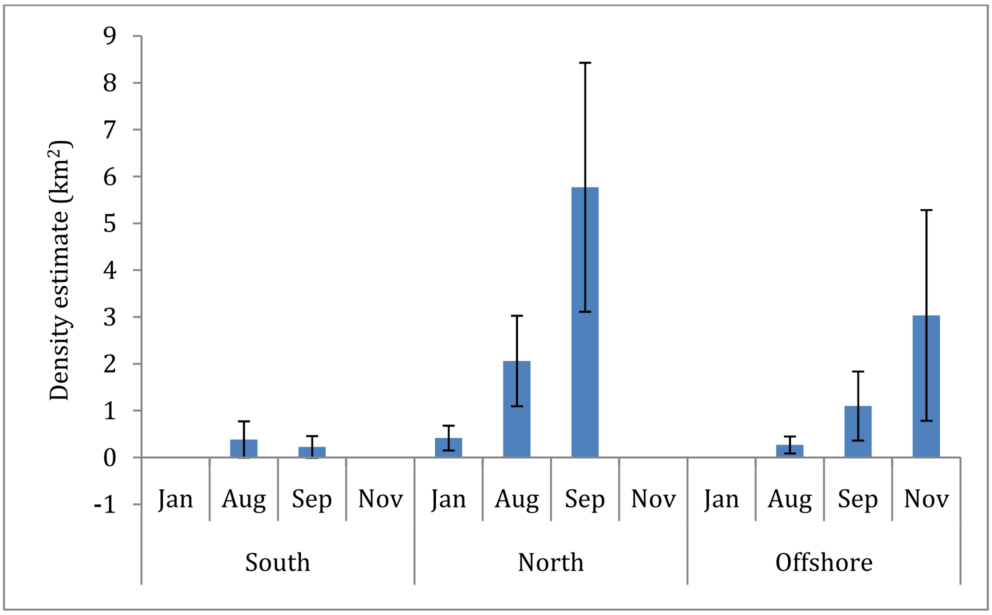

Figure 4-72: Monthly estimates (+/- SE) of density of Black-legged Kittiwake in the South, North and Offshore Strata; August 2010 to January 2011.

Vantage Point surveys

Vantage Point counts at four locations within Aberdeen Bay recorded kittiwakes throughout the year. Peak numbers were of up to 160 birds per hour during August 2005 and 200 birds per hour in July 2006 but numbers of passing birds were more frequently at <100 birds per hour (EnviroCentre 2007a, Alba Ecology 2008a). During the winter months there were considerably fewer kittiwakes present in Aberdeen Bay with less than 10 birds per hour recorded (Alba Ecology 2008b) Birds were recorded out to 3 km from shore with peak numbers within 1-3 km and at least 42% of sightings were of birds flying between 30-150 m from the sea surface.

Bird Detection Radar

One kittiwake was recorded at Easter Hatton during the Radar studies undertaken in October 2005 (Walls *et al*. 2005) and 26 were recorded during April 2007 radar surveys at a rate of 0.5 birds per hour (Simms *et al.* 2007).

4.25.3 Summary of Results

Kittiwakes were recorded throughout Aberdeen Bay in highly seasonally variable numbers. During the winter periods very few kittiwakes were recorded. However during the breeding season kittiwakes were frequently recorded with estimated populations within the 'control' area during this period of 1,676 birds and 663 birds in the proposed EOWDC development area. Peak densities of 33 birds/km^2 were recorded to the north of the proposed development during the summer months. Land-based observations also recorded peak numbers during the summer months with a peak in July. Of those for which flight height was recorded, 22% were greater than 25 m above the sea surface.

The majority of sightings were between 1 km and 3 km from the coast.

4.25.4 Initial Assessment of Significance

Kittiwake	Overall sensitivity	Magnitude	Significance
Collision	Medium	Medium	Minor
Barrier	Very High	Low	Minor
Displacement	Medium	Low	Negligible

4.25.5 Species Sensitivities

Qualifying species

Kittiwake is a qualifying species for four SPAs within the region: Buchan Ness to Collieston, Fowlsheugh, Troup, Pennan & Lion's Head and Forth Islands SPAs.

Flight height

Flight altitude data obtained from boat-based surveys reported 22% of flights at above 25 m.

Elsewhere out of over 14,000 recorded flight altitudes for kittiwake 13% were at rotor height.

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that kittiwakes are widespread and frequent within Aberdeen Bay and with a distinct seasonal peak during the summer months.

Collision Risk Modelling undertaken for kittiwake is based on:

- Body length of 39 cm
- Wingspan of 108 cm

- Flight speed of 10.5 $m.s^{-1}$

The Collision Risk Modelling is based on a collision probability of 11.9% and been undertaken over a range of avoidance rate from 98%, 99% and 99.5% have been used.

Table 4-23: Predicted number of collisions per year for kittiwake

Collision probability	Avoidance rate (%)		
	98	99	99.5
11.9%	3.6	1.8	0.9

Based on the precautionary avoidance rate of 98% it is predicted that a total of four collisions per year may occur (Table 4-23).

The annual mortality rate for kittiwake is 6% (BTO 2011). Consequently, out of a peak local population of 2,339 individuals in both the 'control' and EOWDC areas during summer 2007 an annual mortality of 140 kittiwakes may be predicted. Based on the regional SPA population of kittiwakes of 83,156 individuals, the annual mortality rate will be 4,989 individuals and therefore the 1% baseline mortality rate is 50 birds per year. The results from the Collision Risk Modelling predict a total of four kittiwakes per year may collide with the wind turbines.

The Buchan Ness to Collieston Coast SPA lies approximately 9.5 km away from the proposed development and holds approximately 25,000 breeding kittiwakes, based on the latest available counts in 2007. The colony will therefore have an annual mortality of 1,505 birds. It is likely that many of kittiwakes recorded within Aberdeen Bay during the breeding period are associated with this colony. The results from the collision risk modelling which predict a mortality of four kittiwakes per year, indicate that there will not be an adverse effect on the population of kittiwakes associated with the SPA based on the precautionary assumption that an increase of 1% above baseline mortality could be adverse, i.e. more than 15 kittiwakes a year collide with the turbines.

The Fowlsheugh SPA lies 31 km away from the proposed development and holds 11,140 breeding pairs of kittiwake based on latest counts. Therefore, the annual mortality rate from this colony is 1,337 birds per year. Based on the results from the collision risk modelling it is concluded that if all the kittiwakes at risk of collision are from Fowlsheugh then there is unlikely to be an adverse effect on the SPA population.

The Troup Pennan & Lion's Head SPA lies 74.3 km to the north of the proposed development and holds 29,792 breeding kittiwakes. The annual mortality is estimated to be 1,787 birds per year and consequently, based on a 1% of annual mortality threshold, an adverse effect on kittiwakes from this colony is not predicted.

The Forth Islands SPA is approximately 124 km to the south and holds 4,632 breeding kittiwakes. However, the maximum foraging range for kittiwakes reported is 83 km (Roos 2010) and therefore the SPA is outwith the maximum foraging range for breeding kittiwakes and there will not be an adverse effect on the population due to collision.

Based on the results of the Collision Risk Modelling and the current regional and SPA populations, it is predicted that that the potential population affect caused by collision impacts with the proposed development on kittiwakes is negligible.

Barrier effect

Data from post-construction monitoring studies undertaken in Denmark indicate that although kittiwakes may make some avoidance response they are generally not affected by offshore wind turbines and do not avoid entering wind farms.

Consequently, there is not thought to be a significant barrier effect on kittiwakes from the proposed development (Zucco *et al*. 2006).

Displacement

Although during periods of construction the number of kittiwakes present in the area may be reduced once in operation evidence to suggest that kittiwakes may be attracted to the area. Therefore no displacement is predicted.

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on kittiwakes.

Outwith Aberdeen Bay there are a number of planned offshore wind farms in the Firth of Forth and the Moray Firth all of which have the potential to contribute to a possible cumulative and in-combination effects. The only data available is that from the Beatrice Demonstrator Project which recorded 2,943 kittiwakes over a period of 12 months of pre-construction surveys (Talisman 2005). Collision Risk Modelling undertaken for the Beatrice Demonstrator Project predicted up to 9 kittiwakes per year may collide with the two turbines. The effect from the potential collisions was concluded not to be significant.

The size, scale and exact locations of the Round 3 wind farms and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of kittiwakes that may be present in the planned development areas. Consequently, it is not possible to determine whether there will be a cumulative or in-combination impact arising from the proposed plans. However, based on the known distribution and behaviour of kittiwakes it is predicted that they will be widespread across many of the possible areas at which wind farms may, in the future, be constructed.

4.25.6 Conclusions

Habitats Appraisal

There are four SPAs for which kittiwakes are a qualifying species in the region and based on the results from the Collision Risk Modelling which predicts an annual collision mortality rate of four birds per year and the likely foraging ranges kittiwakes it is predicted that there will not be an adverse effect on the SPAs.

Environmental Impact Assessment

Based on the results from Collision Risk Modelling undertaken and the potential number of kittiwakes, which may collide with the proposed development. It is predicted that there will not be a significant impact arising from the proposed development on regional population of kittiwakes.

4.26 Black-headed gull (*Larus ridibundus*)

4.26.1 Protection & Conservation Status

The black-headed gull is listed in Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.26.2 Background

Black-headed gull		
GB population	Breeding: 130,000 prs Wintering: 2.1 – 2,200,000 ind	Mitchell *et al* 2004 BTO 2011
Scottish population	Breeding: 43,200 AoN Wintering: 155,500 ind.	Forrester *et al*. 2007
International threshold	20,000 ind.	Calbrade *et al*. 2010
GB threshold	19,000 ind.	Calbrade *et al*. 2010
Designated east coast sites where species is a noted feature	None	SNH 2011 JNCC 2011a
European population estimate	Breeding 1.5 – 2,200,000 pairs Wintering – >3,200,000 individuals	Birdlife 2004
European population trend	Status 'secure' Trend 'moderate decline'	Birdlife 2004
World population	2.1 – 2,800,000 pairs	Mitchell *et al* 2004

Black-headed gulls are the most widespread seabird breeding in Britain and Ireland with similar numbers nesting inland as on the coast. The majority of the breeding population is semi-resident with the majority of the UK population undertaking only localised seasonal movements. However, the UK wintering population is bolstered by birds from northern and eastern Europe.

Outside the breeding season black-headed gulls occur in inshore tidal waters largely avoiding rocky or exposed coasts, preferring inlets, bays and estuaries with sandy or muddy beaches (Snow & Perrins 1998). Black-headed gulls are primarily a coastal species and are scarce offshore.

In North-east Scotland black-headed gulls occur throughout the year with peak numbers at Peterhead between July and February with nearly all sightings of birds passing Peterhead within 200 m of the coast (Innes 1994). The number of wintering black-headed gulls is 13,500 individuals of which nearly 12,000 are found along the coast (Forrester *et al*. 2007).

Boat-based surveys

Nine sightings of black-headed gulls were made from boat-based surveys undertaken between February 2007 and January 2008. Eight of the nine sightings were made in November and all were inshore (IECS 2008).

Vantage Point surveys

Black-headed gulls occur throughout the year in Aberdeen Bay but there were large variations in numbers between years. In 2006, peak numbers occurred in June with up to 5 birds per hour passing all within 2 km of the coast and the majority within 1 km (EnviroCentre 2007a). However, in 2007 peak counts occurred in July and August when up to 90 birds per hour passed the Donmouth (Alba Ecology 2008a). During the winter months numbers of black-headed gulls recorded were much lower with a peak count of less than 30 birds per hour in February 2008 (Alba Ecology 2008b). In 2006, 48% of sightings were within the 30-150 m height band across all vantage point sites and in 2007, 9% were within the same height band (Alba Ecology 2008a).

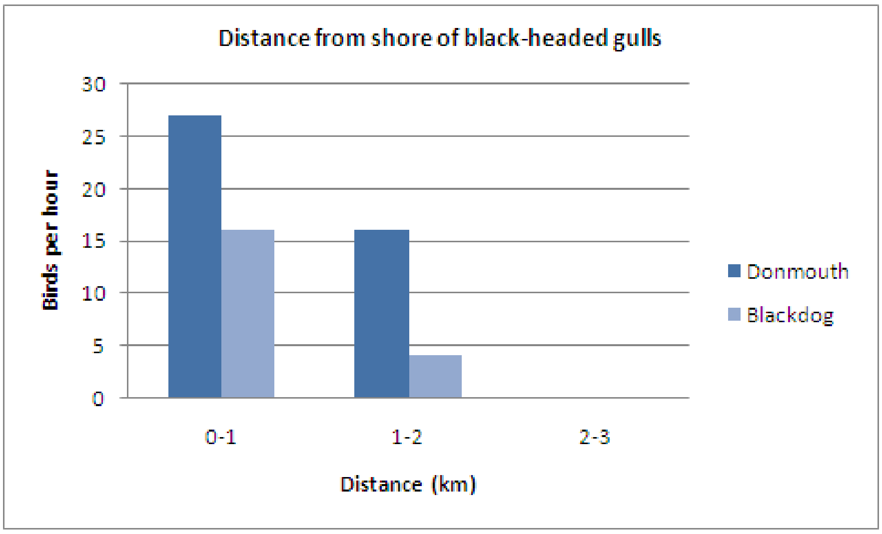

Figure 4-73: Number of black-headed gulls per hour recorded off Aberdeen Bay from Vantage Point Counts April 2006 – March 2008 and their distance from shore.

Bird detection Radar

One-hundred and forty-three black-headed gulls were recorded from observations undertaken during Bird Detection Radar surveys in October 2005 (Walls *et al.* 2006). Fourteen were recorded at Blackdog over a seventeen day period in April 2007 (Simms *et al.* 2007).

4.26.3 Summary of Results

Black-headed gulls were rarely recorded from boat-based surveys with most observations made from Vantage Point surveys. Numbers of black-headed gulls varied between years and across the seasons. Lowest numbers were during the winter months and peak counts from between June and August. Peak counts were of up to 90 birds per hour passing the Donmouth during July and August.

The majority of sightings were within 1 km of the coast there were very few records beyond 2 km from the shore. Of those recorded in flight up to 48% were recorded flying between 30 m and 150 m but numbers at these heights varied considerably.

No counts of black-headed gulls from any of the surveys were of national importance.

4.26.4 Initial Assessment of Significance

Black-headed gull	Overall sensitivity	Magnitude	Significance
Collision	High	Negligible	Negligible
Barrier	Low	Low	Negligible
Displacement	Low	Negligible	Negligible

4.26.5 Species Sensitivities

Qualifying species

There are no SPAs in the region for which black-headed gull is a qualifying species.

Flight height

Only four observations of flight altitudes were obtained from boat-based surveys. All were of birds flying below 25 m.

Elsewhere, out of 16,358 recorded flight altitudes for black-headed gull 13% were at rotor height.

Collision risk

Data obtained from boat-based and land-based surveys recorded black-headed gulls mainly within 1 km of the coast with most records during the summer months and lower numbers during the winter. Data from coastal wind farms have recorded relatively low avoidance behaviour towards wind turbines by black-headed gulls and they are known to collide with turbines. However, nearly all the sightings of black-headed gull were within 2 km of the coast and the majority were within 1 km (Figure 4-73). Boat-based surveys recorded very few black-headed gulls offshore.

Based on the very few records of black-headed gull in the vicinity of the proposed development there is considered to be a very low risk of collision and, should it occur, its significance on the species will be negligible.

Barrier effect

Data from post-construction monitoring studies undertaken in Denmark indicate that black-headed gulls are generally not affected by offshore wind turbines and do not avoid entering wind farms. Consequently, there is not thought to be a significant barrier effect (Zucco *et al*. 2006).

Displacement

Very few black-headed gulls were recorded within the area of the proposed development and black-headed gulls are not known to show any significant displacement effects. There is no indication of any potential displacement effect but should it occur its significance is predicted to be negligible.

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on black-headed gulls.

Outwith Aberdeen Bay there are a number of planned offshore wind farms in the Firth of Forth and the Moray Firth. The only data available is that from the Beatrice Demonstrator Project which recorded six black-headed gulls over a period of 12 months pre-construction surveys (Talisman 2005). The size, scale and exact locations of the Round 3 and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of black-headed gulls that may be present in the planned development areas. Consequently, it is not possible to determine whether there will be a cumulative or in-combination impact arising from the proposed plans. However, based on the known behaviour of black-headed gulls, in particular their coastal distribution it is predicted that the risk of any cumulative or in-combination effects is low and the consequences negligible.

4.26.6 Conclusions

Habitats Appraisal

There are no SPAs in the region for which black-headed gull is a qualifying species.

Environmental Impact Assessment

Based on the relatively low numbers of black-headed gulls recorded in Aberdeen Bay and that were not recorded in the proposed development area it is predicted that there will not be a significant impact arising from the proposed development on black-headed gulls.

4.27 Common gull (*Larus canus*)

4.27.1 Protection & Conservation Status

The common gull is listed in Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.27.2 Background

Common gull		
GB Population	Breeding: 48,000 prs Winter: 620 – 721,000 ind.	BTO 2011
Scottish population	Breeding: 48,100 AoN Winter: 79,700 ind.	Forrester *et al*. 2007
International threshold	20,000 ind.	Calbrade *et al*. 2010
GB threshold	9,000 ind.	Calbrade *et al*. 2010
Designated east coast sites where species is a noted feature	None	SNH 2011 JNCC 2011a
European population estimate	Breeding 590,000 – 1,500,000 pairs Wintering – >910,000	Birdlife 2004
European population trend	Status 'depleted' Trend 'unknown'	Birdlife 2004
World population	2,500,000 – 3,700,000 pairs	Birdlife 2011

Common gulls occur throughout much of Scotland breeding in colonies usually inland and foraging in fields, estuaries and nearshore waters. During the autumn the UK population is augmented by migrants from northern Europe that winter in the UK. In Scotland an estimated 100,000 to 200,000 common gulls occur during the spring and autumn passage (Forrester *et al.* 2007).

During the breeding season common gulls remain close to shore with relatively few sightings of common gulls from offshore waters. Outwith the breeding season common gulls disperse southward to southern Scotland and England but wintering birds remain largely in nearshore waters often occurring in large numbers in river estuaries where large roosts can occur. Spring passage occurs during March and April across a broad front.

In North-east Scotland peak numbers occur on the Ythan Estuary during October and November and there is some evidence of a spring and autumn passage of birds past Peterhead. Relatively few common gulls nest along the coast although an increasing population have nested on the flat roofs of nearby industrial estates since 1984. Historically there were large breeding colonies inland up Deeside where there were up to 17,000 pairs in the Coreen Hills up Deeside Up to 900 birds per month were recorded passing Peterhead during July and August (Buckland, Bell & Picozzi 1990).

Boat-based surveys

Common gulls were recorded throughout the year in Aberdeen Bay from boat-based surveys. Numbers were highest during the autumn, particularly November and February and March. Very few common gulls were recorded during June and July (Figure 4-77). Although common gulls were widely recorded throughout the surveyed area the majority of records during the winter were off Balmedie between 2 km and 3 km from shore and within the northern part of the proposed development area

During the breeding season significantly fewer common gulls were recorded and most records were in nearshore waters with few birds recorded within the footprint of the proposed development (Figure 4-75).

Post-breeding, the numbers of common gulls within Aberdeen Bay increased with widely scattered records in predominantly nearshore waters (Figure 4-76)

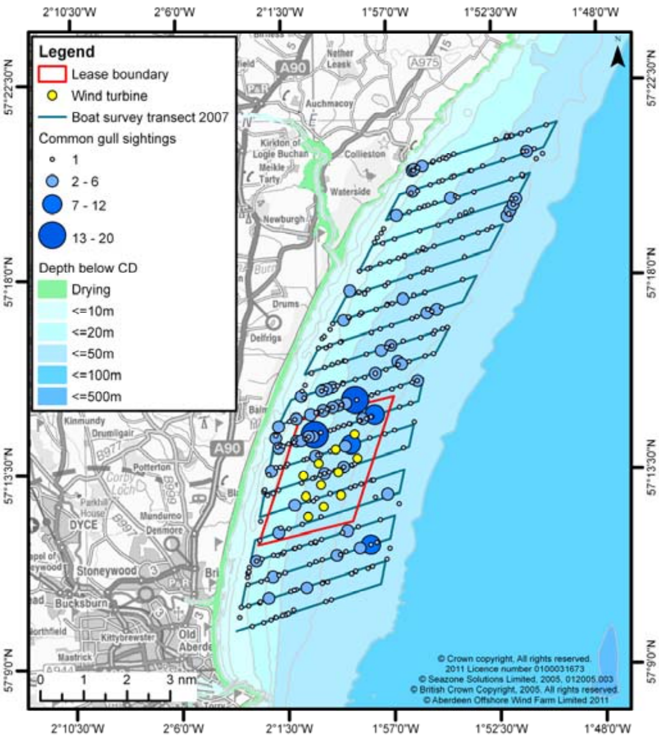

Figure 4-74: Common gull distribution in Aberdeen Bay during winter period: November to March (all sightings).

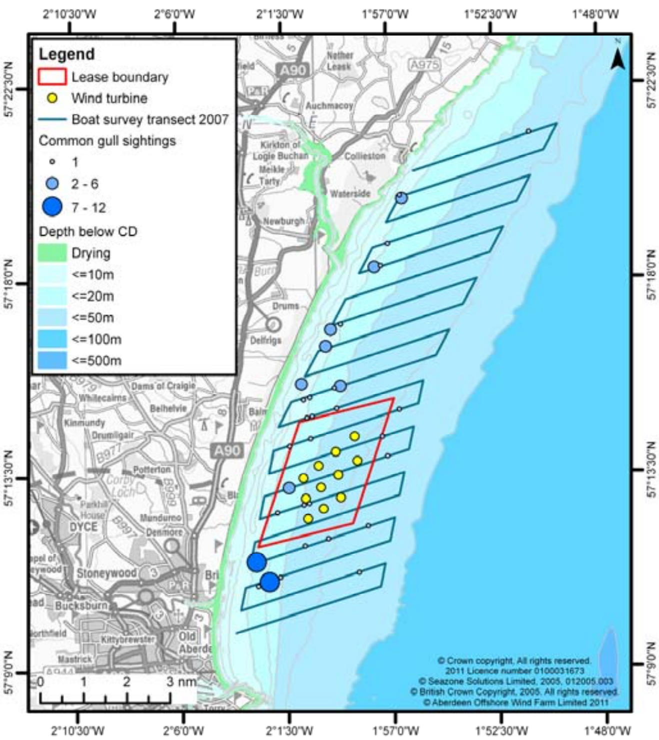

Figure 4-75: Common gull distribution during breeding season: April to July (all sightings).

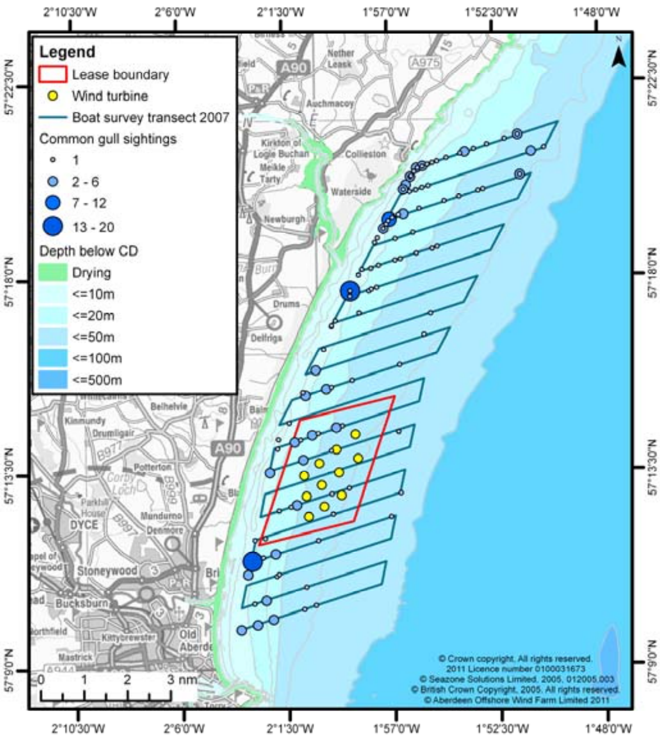

Figure 4-76: Common gull distribution during post-breeding: August to October (all sightings).

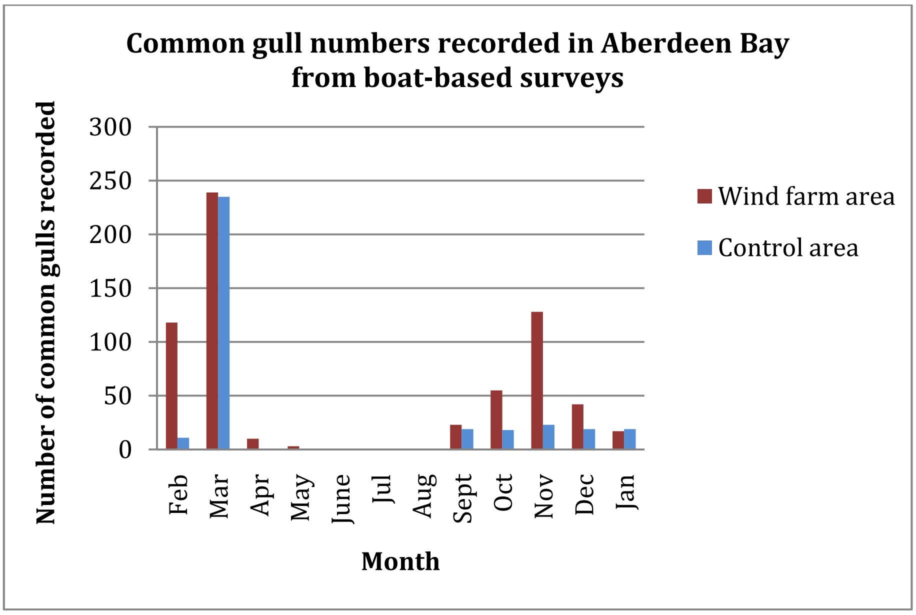

Figure 4-77: Common gull monthly population estimates in proposed EOWDC and 'control' areas: Boat-based surveys 2007 – 2008.

There were not enough sightings to undertake a monthly assessment using *Distance*. However, estimated densities on seasonal basis were able to be calculated and estimated peak autumn and spring abundances of 128 and 187 birds respectively. During the autumn and spring peak numbers occurred in the 'control' survey area whilst in the winter peak numbers occurred in the proposed development area (Table 4-24, Figure 4-78).

Table 4-24: Seasonal estimates of density and abundance of Common gulls in the proposed EOWDC and 'control' areas.

Season	Density Estimate (km^2)	SE	Estimated Abundance	SE	No. Observations
EOWDC - Winter	3.300	1.071	168	54.4	47
Control- Winter	0.832	0.239	42	12.1	24
EOWDC - Spring	0.535	0.529	27	26.9	9
Control- Spring	3.673	2.193	187	111.4	16
EOWDC - Summer	0.000	0.000	0	0.0	0
Control - Summer	0.000	0.000	0	0.0	0

Control - Autumn	2.510	1.772	128	90.0	9

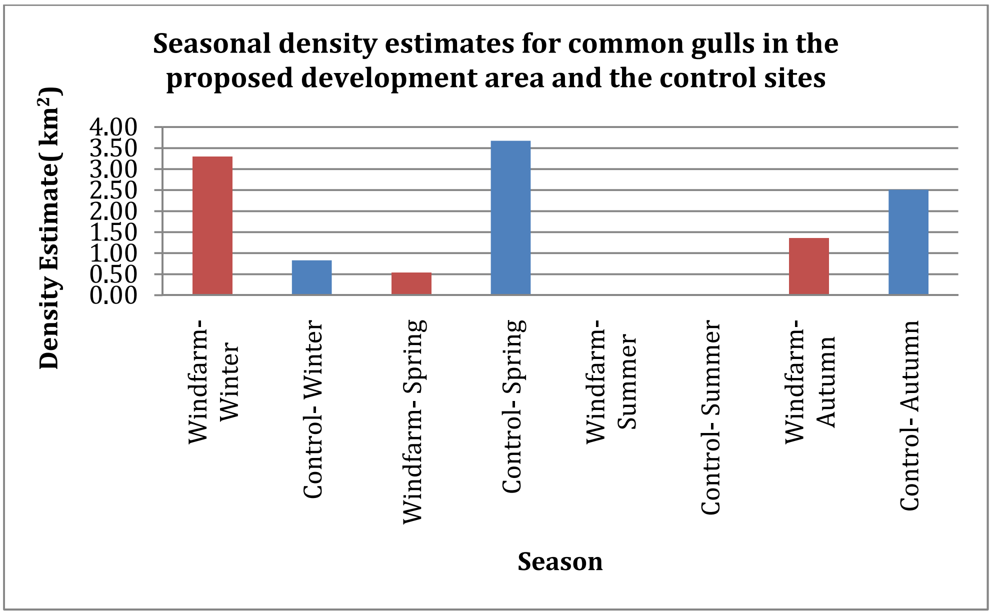

Figure 4-78: Seasonal estimates of density (+/- SE) of Common Gulls in the proposed EOWDC and 'control' areas

Vantage Point surveys

In Aberdeen Bay common gulls were recorded throughout the year with peak numbers during periods of passage when up to 130 birds per hour passed Balmedie in April 2007, 150 birds per hour in February 2008 and up to 60 birds per hour passing during August 2006 (Alba Ecology 2008a,b; EnviroCentre 2007a). The majority of sightings were within 0-2 km of the coast with up to 50% of birds flying between 30-150 m.

Bird Detection Radar

A total of 490 common gulls were recorded during the Bird Detection Radar studies undertaken at Drums and Easter Hatton during October 2005. Eighty per-cent of sightings were made at Drums (Walls *et al.* 2006).

In April 2007, 336 common gulls were recorded over a seventeen day period at Blackdog at a rate of 6.5 birds per hour. The mean flock size was of six birds but a maximum flock of 68 was recorded (Simms *et al.* 2007).

4.27.3 Summary of Results

Common gulls were recorded throughout the year with peak numbers during early spring and early autumn with peak counts of up to 150 birds per hour in February 2008. There were relatively few sightings during the breeding season and no sightings from boat-based surveys in August when up to 60 birds per hour were recorded from Vantage Point surveys.

The majority of sightings were within 2 km of the coast with relatively few records beyond 2 km from the shore. Of those recorded in flight up to 50% were recorded flying between 30 m and 150 m.

No counts of common gull from any of the surveys within Aberdeen Bay were of national importance.

4.27.4 Initial Assessment of Significance

Common gull	Overall sensitivity	Magnitude	Significance
Collision	Medium	Negligible	Negligible
Barrier	Low	Low	Negligible
Displacement	Low	Negligible	Negligible

4.27.5 Species Sensitivities

Qualifying species

There are no SPAs in the region for which common gull is a qualifying species.

Flight height

Observations from boat-based surveys recorded 33% of flight at above 25 m (n=494). Data from onshore surveys recorded up to 30% of flight heights as being above 30 m.

Elsewhere, out of 5,074 recorded flight altitudes for common gull, 21% were at rotor height.

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that common gulls are widespread throughout Aberdeen Bay, particularly between November and March (Figure 4-74).

Collision Risk Modelling undertaken for common gull is based on

- Body length of 41 cm
- Wingspan of 120 cm

- Flight speed of 13.4 $m.s^{-1}$

Collision Risk Modelling was undertaken based on a collision probability of 9.6% and across various avoidance rates of 98%, 99% and 99.5%.

Table 4-25: Predicted number of collisions per year for common gull.

Collision probability	Avoidance rate (%)		
	98	99	99.5
9.6%	4.9	2.4	1.2

Based on the precautionary avoidance rate of 98% it is predicted that a total of 4.9 collisions per year may occur (Table 4-25).

The annual mortality rate for common gull is 14% (BTO 2011). Consequently, out of a peak Aberdeen Bay population of 474 individuals in both the 'control' and potential development areas during March (Figure 4-77), an annual mortality of 66 common gulls may be predicted. Therefore, 1% of the baseline mortality is <1 bird per year. The regional coastal breeding population comprising of roof nesting birds in and around Aberdeen is estimated to be 1,240 breeding adults (Calladine *et al*. 2006) which will therefore have an annual mortality of 174 birds per year and a 1% baseline mortality of 2 birds. Should all the birds at risk of collision during the breeding season be from these colonies then it is predicted that at a 98% avoidance rate the effects from collision risk may be significant.

Based on the results from collision risk modelling, which predicts a total of nearly 5 collisions per year there may be a significant impact on common gull due to collisions.

However, studies relating to other species of gull have reported avoidance rates at greater than 99% and therefore it is predicted that the number of common gulls will be lower than has been indicated by the Collision Risk Modelling and is likely to be one to two birds per year.

Barrier effect

Evidence from existing offshore wind farms indicate that offshore wind farms do not have a significant barrier effect on Gulls and there is no evidence for any potential barrier effect to common gulls (Zucco *et al.* 2006). However, should it occur, the relatively short increase in distance, estimated to be at most 3.2 km, that common gulls may have to fly is predicted not to be significant in terms of increased energetic expenditure. Consequently, the potential impact from the barrier effect is predicted to be negligible.

Displacement

There is no evidence from any offshore wind farm that there will be any displacement effect on common gulls from offshore wind farms but should it occur its significance is predicted to be negligible.

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on black-headed gulls.

Outwith Aberdeen Bay there are a number of planned offshore wind farms in the Firth of Forth and the Moray Firth. The only data available is that from the Beatrice Demonstrator Project which did not record any common gulls over a period of 12 months pre-construction surveys (Talisman 2005). The size, scale and exact locations of the Round 3 and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of common gulls that may be present in the planned development areas. However, the location of the proposed developments are further offshore and common gulls are not predicted to occur in significant numbers within these areas. Consequently, it is predicted that the risk of any cumulative or in-combination effects is low and the consequences negligible.

4.27.6 Conclusions

Habitats Appraisal

There are no SPAs within the region for which common gulls are listed as a qualifying species.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on breeding common gulls.

4.28 Lesser black-backed gull (*Larus fuscus*)

4.28.1 Protection & Conservation Status

The Lesser-black backed gull is listed in Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.28.2 Background

Lesser black-backed gull		
GB population	Breeding: 110,000 prs Winter: 118 – 131,000 ind.	BTO 2011
Scottish population	Breeding: 25,000 AoN Winter: 200 – 600 ind.	Forrester *et al*. 2007
International threshold	5,500 ind.	Calbrade *et al*. 2008
GB threshold	500 ind.	Calbrade *et al* 2008
Designated east coast sites where species is a noted feature	Forth Islands 2,920 prs	JNCC 2011a
European population estimate	Breeding 300,000 – 350,000 pairs Wintering – >130,000	Birdlife 2004
European population trend	Status 'secure' Trend 'large increase'	Birdlife 2004
World population	910,000 – 1,100,000 'adults'	Birdlife 2011

The lesser black-backed gull breeds in colonies located around the UK coastline. There are approximately 110,000 breeding pairs in the UK, of which 21% occur in Scotland. In Scotland this species is principally a summer migrant with a small but increasing wintering population.

Lesser black-backed gulls occur in both inshore and offshore waters, often further offshore than many other species of gull during the breeding season. They are both scavengers and, offshore, fish often from fishing vessels.

In North-east Scotland the species is predominantly a summer migrant and is scarce during the winter months. At Peterhead passage of lesser black-backed gulls occurred between March and May with a peak in April with no records between October and February. The majority of sightings were within close proximity of the coast (Innes 1994).

Boat-based surveys

Only two sightings of lesser black-backed gulls were made during boat-based surveys undertaken between February 2007 and January 2008. Both were in June of birds within the proposed EOWDC survey area (IECS 2008).

A further 40 lesser black-backed gulls were recorded throughout the surveyed area during September 2010.

Vantage Point surveys

Lesser black-backed gulls were recorded in relatively low numbers at all Vantage Point sites between April and September. Peak counts occurred in June and July with up to two birds per hour recorded. Although lesser black-backed gulls were recorded out to 3 km from the shore, the vast majority were within 0-2 km from the shore. 40% of all flights were within the 30 -150 m height band. During the winter period, lesser black-backed gulls were scarce in Aberdeen Bay with nineteen records between October 2007 and March 2008 (Alba Ecology 2008b).

Bird Detection Radar

Six lesser black-backed gulls were recorded during the radar studies undertaken in October 2005 and three at Blackdog during April 2007 (Walls *et al.* 2005, Simms *et al.* 2007).

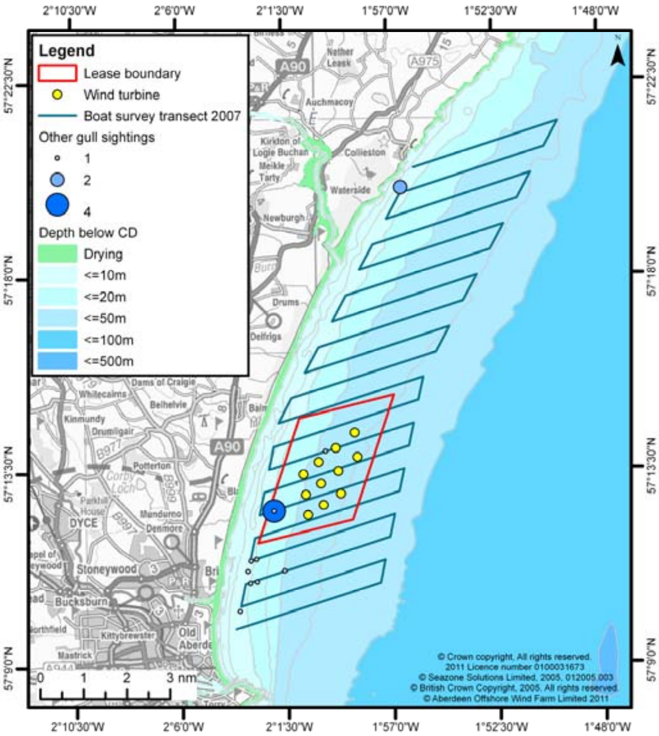

Figure 4-79: Other Gull distribution in Aberdeen Bay - February 2007 to April 2008 (all sightings).

4.28.3 Summary of Results

Lesser black-backed gulls were recorded in relatively low numbers between April and September with only two sightings from boat-based surveys and small numbers from land-based observations. Of those for which flight height was recorded, 40% were within 30 – 150 m of the sea surface.

The majority of sightings were within 2 km of the coast with relatively few records beyond 2 km from the shore.

No counts of lesser black-backed gull from any of the surveys within Aberdeen Bay were of national importance.

4.28.4 Initial Assessment of Significance

Lesser black-backed gull	Overall sensitivity	Magnitude	Significance
Collision	Very High	Low	Moderate
Barrier	Medium	Low	Minor
Displacement	Medium	Negligible	Negligible

4.28.5 Species Sensitivities

Qualifying species

The only SPA in the region for which lesser black-backed gull is a qualifying species is Forth Islands SPA where 2,920 pairs nest.

Flight height

Observations of flight altitudes were obtained from Vantage Point surveys which recorded 40% of lesser black-backed gulls as flying between 30 m and 150 m.

Elsewhere, out of 24,481 recorded flight altitudes for lesser black-backed gull, 22% were at rotor height.

Collision risk

Data obtained from boat-based and land-based surveys recorded relatively few lesser black-backed gulls nearly all within 2 km of the coast and all but one during the summer months. Data from coastal wind farms have recorded relatively low avoidance behaviour towards wind turbines by lesser black-backed gulls and they are known to collide with turbines. However, as nearly all the sightings of lesser black-backed gull were within 2 km of the coast and therefore not at risk of collision with the proposed development and there were relatively few sightings it is considered that there is a very low risk of collision and, should it occur, its significance on the species will be negligible.

Although lesser black-backed gulls are known to forage up to 300 km from their colonies and therefore those from the Forth Islands SPA may be at risk of collision with the proposed development. The majority of foraging trips are considerably smaller and therefore not at risk (Camphuysen 1995; Ens *et al.* 2008).

Barrier effect

Data from post-construction monitoring studies undertaken in Denmark and Sweden indicate that lesser black backed gulls are generally not affected by offshore wind turbines and do not avoid entering wind farms. Consequently, there is not thought to be a significant barrier effect (Zucco *et al*. 2006).

Displacement

Very few lesser black-backed gulls were recorded within the area of the proposed development and they are not known to show any significant displacement effects. There is no indication of any potential displacement effect but should it occur its significance is predicted to be negligible.

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on black-headed gulls.

Outwith Aberdeen Bay there are a number of planned offshore wind farms in the Firth of Forth and the Moray Firth. The only data available is that from the Beatrice Demonstrator Project which did not record any lesser black-backed gulls over a period of 12 months pre-construction surveys (Talisman 2005). The size, scale and exact locations of the Round 3 and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of gulls that may be present in the planned development areas. Consequently, it is not possible to determine whether there will be a cumulative or in-combination impact arising from the proposed plans. However, based on the known behaviour of lesser black-backed gulls they may occur in the areas of the proposed developments but are predicted to be in relatively low densities it is therefore predicted that the risk of any cumulative or in-combination effects is low and the consequences negligible.

4.28.6 Conclusions

Habitats Appraisal

The only SPA for which lesser black-backed gull is a qualifying species is the Forth Islands SPA, which is 124 km away. Although within the potential foraging range of lesser black-backed gull, the numbers recorded from boat-based and land-based surveys were low and consequently it is predicted that there not be an adverse effect on the SPA.

Environmental Impact Assessment

Based on the relatively low numbers of lesser black-backed gulls recorded in Aberdeen Bay it is predicted that there will not be a significant impact arising from the proposed development on lesser black-backed gulls.

4.29 Herring gull (*Larus argentatus*)

4.29.1 Protection & Conservation Status

The herring gull is listed in Appendix III of the Bern Convention and is on the Red List of Species of Conservation Concern.

4.29.2 Background

Herring gull		
GB Population	Breeding: 131,000 pairs	BTO 2011
Scottish population	Breeding: 72,000 AoN Wintering: 91,000 ind.	Forrester *et al* 2007
International threshold	5,900 ind	Calbrade *et al*. 2010
GB threshold	4,500 ind	Calbrade *et al*. 2010
Designated east coast sites where species is a noted feature	Buchan Ness to Collieston – 3,079 AoN (2007) Fowlsheugh – 122 AoN (2008) Forth Islands – 6,600 prs Troup Pennan & Lion's Heads – 4,200 prs	SNH 2011 JNCC 2011a
European population estimate	Breeding 764,000 – 1,400,000 prs Wintering – >800,000	Birdlife 2004
European population trend	Status 'secure' Trend 'overall increase'	Birdlife 2004
World population	2,700,000 – 5,700,000 'adults'	Birdlife 2011

Herring gulls are widespread around the British coasts with largest concentrations along rocky coastlines of northern and western Scotland and north-west England. Following breeding, there is a general southerly movement of herring gulls with breeding birds at any one area replaced by birds from more northerly colonies. They are opportunistic feeders, scavenging and predating a wide range of foods. At sea, herring gulls forage extensively around fishing vessels.

In North-east Scotland the breeding population has decreased since the 1960's when 42,500 apparently occupied nests were recorded to 15,000 in 2002. They occur throughout the year in North-east Scotland and a spring passage has been recorded past Peterhead between March and June and peak numbers occur from July and August (Innes 1994).

Boat-based survey

Herring gulls were recorded throughout the year within Aberdeen Bay but there was distinct seasonal variations in the numbers of herring gull present with relatively low numbers present between November and March (Figure 4-81), with a significant increase in the number of birds during the breeding season, particularly in June and July (Figure 4-82; Figure 4-80). Following breeding the number of herring gulls decreased with just a few birds recorded offshore (Figure 4-83). Peak population estimates within the wider proposed EOWDC development area occurred during June and July with up to 456 birds recorded during July. Of those recorded in flight 40% of herring gulls were flying above 25 m.

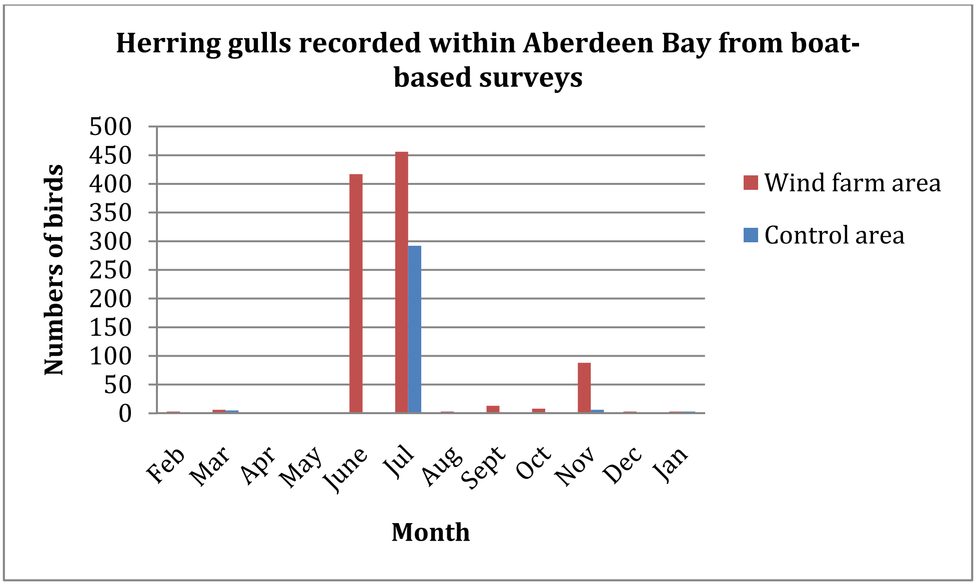

Figure 4-80: Herring gull monthly population estimates in proposed EOWDC and 'control' areas: Boat-based surveys 2007 – 2008.

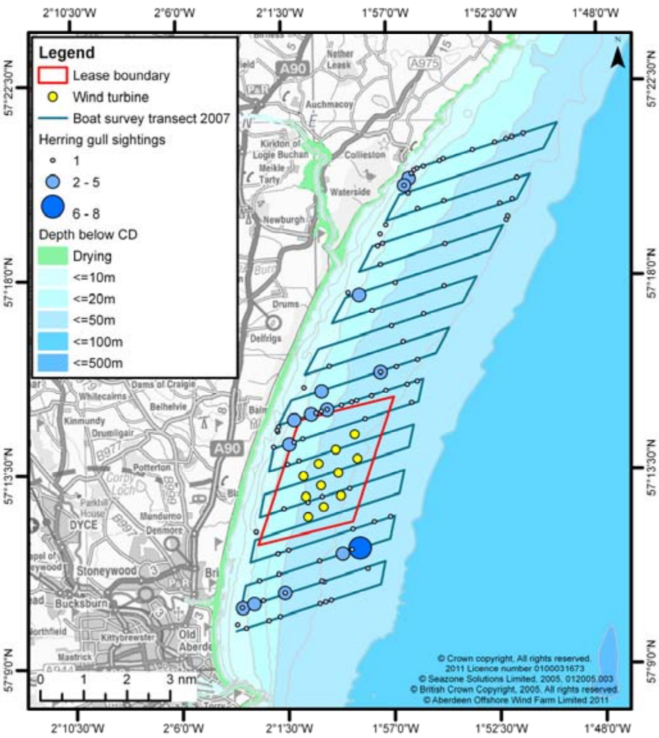

Figure 4-81: Herring gull distribution during winter period: November to March (all sightings).

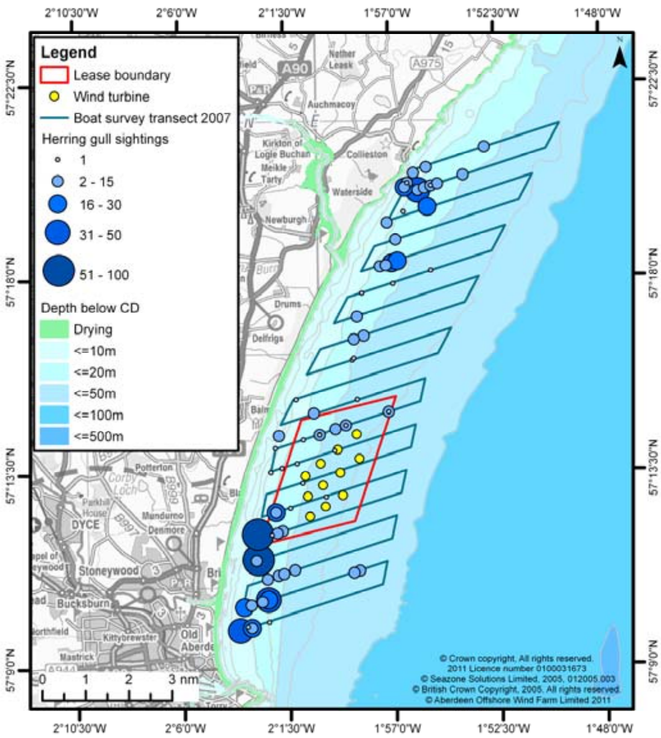

Figure 4-82: Herring gull distribution during breeding season: April, May, September and October (all sightings).

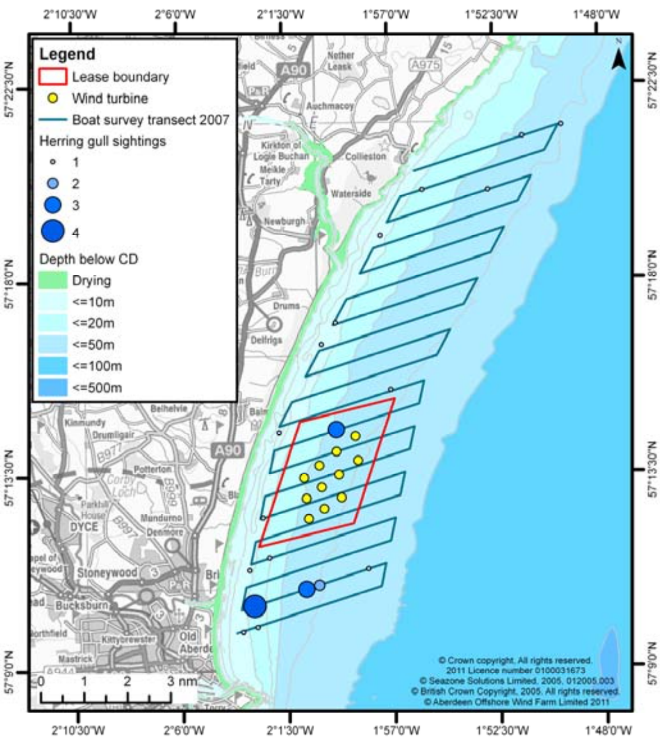

Figure 4-83: Herring gull distribution during post-breeding: June to August (all sightings).

Vantage Point surveys

Vantage point counts undertaken in Aberdeen Bay between March 2005 and October 2005 and again from April 2006 to March 2008 recorded herring gulls during every month and across all four survey sites. Peak numbers occurred during June when up to 240 birds per hour were recorded with 50% of all records within the 30-150 m height band (Alba Ecology 2008a, EnviroCentre 2007a). During the winter months herring gulls were still regularly recorded with generally less than 100 birds per hour, with a peak of 180 birds per hour at the Donmouth in March 2008 (Alba Ecology 2008b). The majority of all sightings were within 2 km of the coast with considerably fewer sightings beyond 2 km (Figure 4-84). Of those in flight 48% of herring gulls were recorded as flying between 30-150 m.

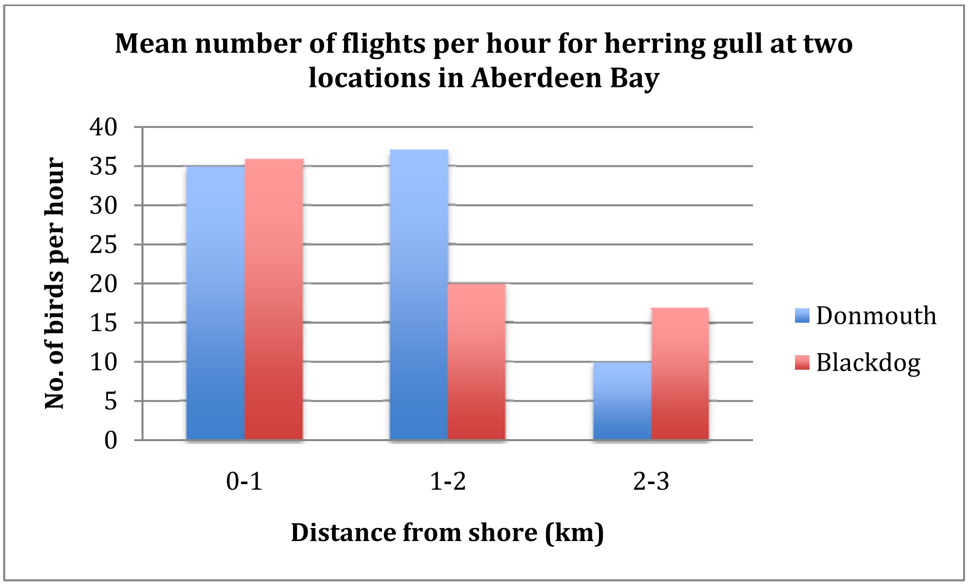

Figure 4-84: Mean number of herring gulls per hour passing two Vantage Points in Aberdeen Bay and their distance from shore.

Bird Detection Radar

Three hundred and eighty herring gulls were recorded during the Radar studies in October 2005. The majority of birds were recorded at Drums where 86% of all sightings occurred (Walls *et al.* 2005).

A total of 34 herring gulls were recorded during seventeen days of observations undertaken at Blackdog during April 2007 (Simms *et al.* 2007).

4.29.3 Summary of Results

Herring gulls were recorded throughout the year with peak numbers from boat-based surveys during June and July and relatively few records during other times of year. Land-based observations recorded higher numbers of herring gulls than the boat-based surveys in particular during the winter and spring periods when few if any were seen offshore.

The majority of sightings were within 2 km of the coast with relatively few records beyond 2 km from the shore. Of those recorded in flight up to 50% were recorded flying between 30 m and 150 m.

No counts of herring gull from any of the surveys within Aberdeen Bay were of national importance.

4.29.4 Initial Assessment of Significance

Herring gull	Overall sensitivity	Magnitude	Significance
Collision	Very High	Low	Moderate
Barrier	Medium	Medium	Minor
Displacement	Medium	Negligible	Negligible

4.29.5 Species Sensitivities

Qualifying species

Herring gull is a qualifying species for four SPAs that could potentially interact with the proposed development: Buchan Ness to Collieston, Fowlsheugh and Forth Islands SPAs, Troup Pennan & Lion's Heads.

Flight height

Flight altitude data obtained from boat-based surveys reported 40% of flights at above 25 m.

Elsewhere, out of nearly 15,000 recorded flight altitudes for herring gull 24% were at rotor height.

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that herring gulls are widespread and frequent within Aberdeen Bay and with a distinct seasonal peak during the summer months.

Collision Risk Modelling undertaken for herring gull is based on:

- Body length of 60 cm
- Wingspan of 144 cm
- Flight speed of 13.4 $m.s^{-1}$

The Collision Risk Modelling is based on a collision probability of 11% and been undertaken over a range of avoidance rate from 98%, 99% and 99.5% have been used.

Table 4-26: Predicted number of collisions per year for herring gull.

Collision probability	**Avoidance rate (%)**		
	98	99	99.5
11%	7.2	3.6	1.8

Based on the precautionary avoidance rate of 98% it is predicted that a total of 7.2 collisions per year may occur (Table 4-26).

Based on the regional SPA population of herring gulls of 19,562 individuals, the annual mortality rate will be 2,347 individuals and therefore the 1% baseline mortality rate will be 235 birds per year. The results from the Collision Risk Modelling predict a total of 7 herring gulls per year may collide with the turbines.

The Buchan Ness to Collieston Coast SPA lies approximately 9.5 km away from the proposed development and holds approximately 6,158 breeding herring gulls. Based on the latest available counts in 2007. The colony will therefore have an annual mortality of 739 birds. It is likely that many of herring gulls recorded within Aberdeen Bay during the breeding period are associated with this colony. The results from the collision risk modelling predict an annual mortality of 7 herring gulls per year indicating that there will not likely be an adverse effect on the population of herring gulls associated with the SPA based on the precautionary assumption that an increase of 1% above baseline mortality could be adverse, i.e. more than 8 herring gulls a year collide with the turbines. However, the predicted mortality of 7 birds per year is close but it is based on a series of precautionary figures that assume the peak numbers recorded within the development area are constant throughout the year. It is therefore predicted that the number estimated to collide each year is precautionary as is the avoidance rates which have been reported as being greater than 99%.

The Fowlsheugh SPA lies 31 km away from the proposed development and holds 122 breeding pairs of herring gull based on latest counts. Therefore, the annual mortality rate from this colony is 14 birds per year. Based on the results from the collision risk modelling it is concluded that if all the herring gulls at risk of collision are from Fowlsheugh then there is the potential for an adverse effect on the SPA population

The Forth Islands SPA is approximately 124 km away and holds 13,200 herring gulls. However, the SPA is too far away for breeding herring gulls from the SPA to occur regularly, if at all, within the proposed development area during the breeding season. Therefore, there will not be an adverse effect on the population due to collision.

The number of herring gulls recorded within the proposed development area was lower than elsewhere, with the majority of sightings within 2 km of the coast (Figure 4-84). Data from tagging studies confirms that although maximum foraging distances may mean that birds from the SPAs could occur within the proposed development area they also show that the majority of foraging is very coastal and within the tidal zones. Consequently, it is predicted that that the potential affect from collision risk on herring gulls is moderate to minor.

Barrier effect

Data from post-construction monitoring studies undertaken in Denmark and Sweden indicate that although herring gulls may make some avoidance response they are generally not affected by offshore wind turbines and do not avoid entering wind farms. Consequently, there is not thought to be a significant barrier effect on herring gulls from the proposed development (Zucco *et al*. 2006).

Displacement

There have been no reported displacement effects on herring gulls from offshore wind farms but some evidence of an increase in numbers within the constructed offshore wind farm areas. No displacement is predicted.

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on herring gulls.

Outwith Aberdeen Bay there are a number of planned offshore wind farms in the Firth of Forth and the Moray Firth. The only data available is that from the Beatrice

Demonstrator Project which recorded 193 herring gulls over a period of 12 months of pre-construction surveys (Talisman 2005). The size, scale and exact locations of the Round 3 and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of gulls that may be present in the planned development areas. Consequently, it is not possible to determine whether there will be a cumulative or in-combination impact arising from the proposed plans. However, based on the known behaviour of herring gulls and that they remain largely within coastal waters it is predicted that the risk of any cumulative or in-combination effects is low and the consequences negligible.

4.29.6 Conclusions

Habitats Appraisal

There are three SPAs for which herring gulls are a qualifying species in the region and based on the results from the Collision Risk Modelling which predicts an annual collision mortality rate of up to seven birds per year and the likely foraging ranges herring gulls it is predicted that there will not be an adverse effect on the Forth Islands SPA but may be one for Fowlsheugh SPA.

Environmental Impact Assessment

Based on the results from Collision Risk Modelling undertaken and the potential number of herring gulls, which may collide with the proposed development and the likely foraging ranges of the herring gulls present in the region it is predicted that there will not be a significant impact arising from the proposed development on regional population of herring gulls.

4.30 Great black-backed gull (*Larus marinus*)

4.30.1 Protection & Conservation Status

The great-black backed gull is listed in Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.30.2 Background

Great black-backed gull		
GB population	Breeding: 17,000 prs Winter: 71 – 81,000 ind	Mitchell *et al* 2004 BTO 2011
Scottish population	Breeding: 14,800 AoN Winter: 7,500 – 10,000 ind	Forrester *et al*. 2007
International threshold	4,400 ind.	Calbrade *et al 2010*
GB threshold	400 ind.	Calbrade *et al.* 2010
Designated east coast sites where species is a noted feature	None	SNH 2011 JNCC 2011a
European population estimate	Breeding 110,000 – 180,000 pairs Wintering – >150,000	Birdlife 2004
European population trend	Status 'secure' Trend 'large increase'	Birdlife 2004
World population	540 – 750,000 'adults'	Birdlife 2011

The great black-backed gull is Britain's largest breeding gull. It occurs widely around UK coast, particularly in areas of rocky coastlines. It is an opportunistic feeder being a predator, scavenger and food pirate and frequently occurs around fishing vessels.

The UK population is approximately 17,000 pairs of which 14,800 are in Scotland and of those, the majority are in the north and west of Scotland. In North-east Scotland the great black-backed gull is a scarce breeding species with 72 pairs in 2002 (Forrester *et al.* 2007). The UK population is largely sedentary with some localised winter movements and migrants from northern Europe arriving during the winter.

In North-east Scotland great black-backed gulls occur around all coasts with numbers increasing from July and August onwards. No obvious passage of birds was detected at Peterhead during the ten years of observations undertaken between 1978 and 1988 (Innes 1994).

Boat-based surveys

Great black-backed gulls were recorded widely across Aberdeen Bay, predominantly within 1 to 2 km form the coast, throughout the year in relatively low numbers (Figure 4-85). Peak counts from boat-based surveys were during June with 127 birds in transect with relatively lower numbers during other months. The peak count in June included 123 birds within the EOWDC area that were associated with a fishing vessel and therefore causing a potentially inflated number of birds in a localised area. Aside from the peak count in June there was a notable increase in numbers during the autumn from September to December (Figure 4-86). Additional surveys undertaken between August 2010 and January 2011 recorded only five birds in August and increased up 19 birds across the whole surveyed area during November and January (SMRU 2011b).

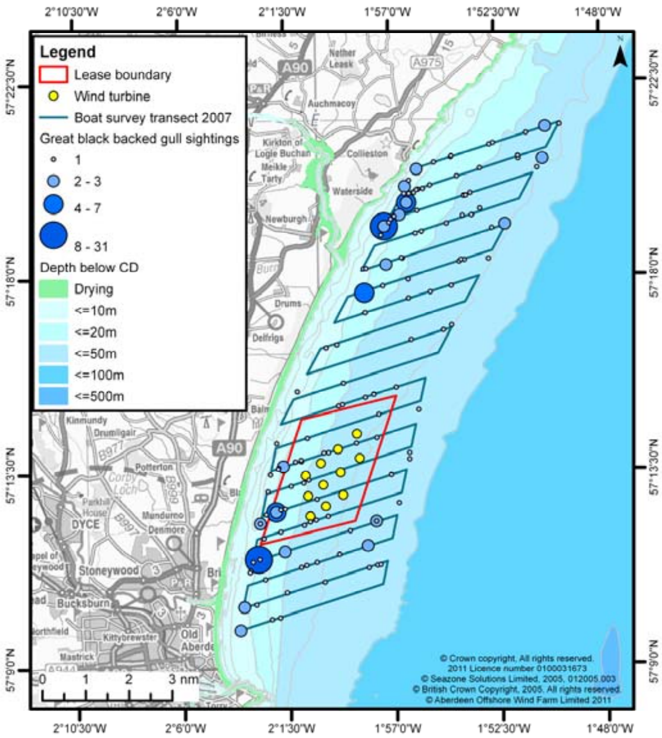

Figure 4-85: Great black-backed gull distribution in Aberdeen Bay February 2007 to January 2008 (all sightings).

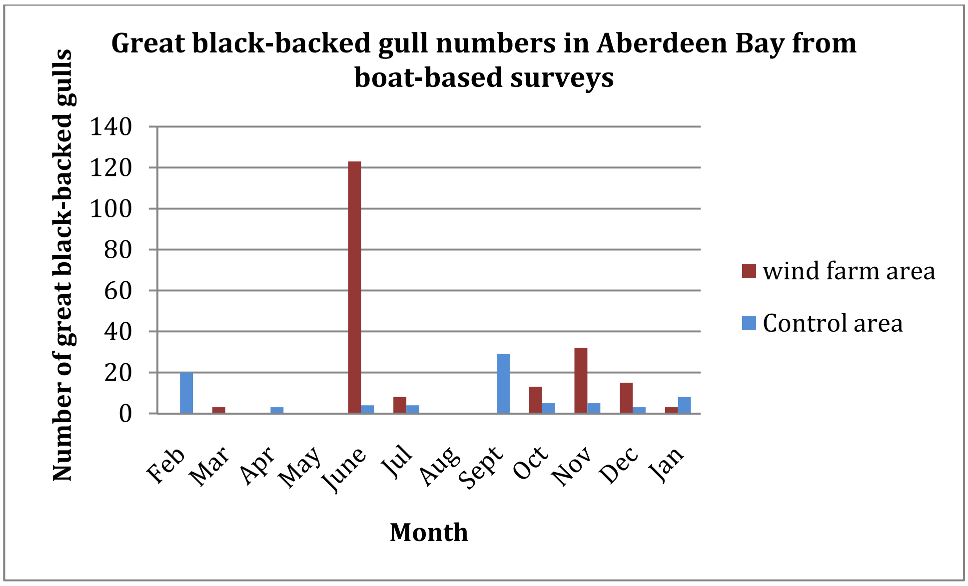

Figure 4-86: Great black-backed monthly population estimates in proposed EOWDC and 'control' areas: Boat-based surveys 2007 – 2008.

Vantage Point surveys

Great black-backed gulls were recorded in Aberdeen Bay throughout the year with peak counts of up to 15 birds per hour in June 2006 and eight birds per hour in August 2007 (Alba Ecology 2008a, EnviroCentre 2008a). Relatively low numbers of six or less birds per hour were recorded during the rest of the year (EnviroCenter

2007b, Alba Ecology 2008b). Recorded flight heights of 'black-backed gulls' (both lesser and great-black-backed) indicate that 40% of all flights occur within 30-150 m from sea surface and the majority of flights are within 1 km of the coast.

Bird Detection Radar

A total of 41 great-black-backed gulls were recorded during Bird Detection Radar studies in October 2005 (Walls *et al*. 2005) and one bird was recorded during 17 days of observations in April 2007 (Simms *et al.* 2007).

4.30.3 Summary of Results

Great black-backed gulls were recorded in relatively low numbers throughout the year. Peak counts occurred in June when a flock was recorded associating with a fishing vessel. Land-based observations also recorded peak numbers during June and August. Outwith the breeding season the numbers of great black-backed gulls were lower. Of those for which flight height was recorded, 40% were within 30 - 150 m of the sea surface.

The majority of sightings were within 1 km of the coast with relatively few records beyond 1 km from the shore.

No counts of great black-backed gull from any of the surveys within Aberdeen Bay were of national importance.

4.30.4 Initial Assessment of Significance

Great black-backed gull	Overall sensitivity	Magnitude	Significance
Collision	High	Low	Minor
Barrier	Low	Low	Negligible
Displacement	Low	Negligible	Negligible

4.30.5 Species Sensitivities

Qualifying species

There are no SPAs in the region for which great black-backed gull is a qualifying species.

Flight height

Observations of flight altitudes were obtained from boat-based Surveys recorded 60% of great black-backed gulls as flying above 25 m.

Elsewhere 28% of great black-backed gulls have been recorded at rotor height.

Collision risk

Data obtained from boat-based and land-based surveys recorded relatively few great black-backed gulls with nearly all sightings within 2 km of the coast. Consequently, it is considered that there is a very low risk of collision and, should it occur, its significance on the species will be negligible.

Barrier effect

Data from post-construction monitoring studies undertaken in Denmark indicate that there is no barrier effect on great black backed gulls from constructed wind farms (Zucco *et al*. 2006).

Displacement

Data from operating wind farms indicate that great black-backed gulls may be attracted to offshore wind farms and that there are no displacement effects.

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause a cumulative impact on black-headed gulls.

Outwith Aberdeen Bay there are a number of planned offshore wind farms in the Firth of Forth and the Moray Firth. The only data available is that from the Beatrice Demonstrator Project which recorded 424 great-black backed gulls and predicted six collisions per year (Talisman 2005). The size, scale and exact locations of the Round 3 and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of gulls that may be present in the planned development areas. Consequently, it is not possible to determine whether there will be a cumulative impact arising from the proposed plans. Based on the known behaviour of great black-backed gulls they may occur in the areas of the proposed developments and be at risk of collision. However, based on the location and scale of the proposed development any cumulative impact will be relatively small and predicted to be negligible.

4.30.6 Conclusions

Habitats Appraisal

There are no SPAs in the region for which great black-backed gull is a qualifying species.

Environmental Impact Assessment

Based on the low numbers of great black-backed gulls recorded and that most sightings were within 2 km from the coast it is predicted that there will not be a significant impact arising from the proposed development on great black-backed gulls.

4.31 Little tern (*Sterna albifrons*)

4.31.1 Protection & Conservation Status

The Little tern is listed in Annex I of the Birds Directive, Schedule I of the Wildlife and Countryside Act, Appendix II of the Bonn Convention, Appendix II of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.31.2 Background

Little tern		
GB population	Breeding: 1,900 prs	Mitchell *et al* 2004
Scottish population	Breeding: 331 AoN	Forrester *et al.* 2007
International threshold	490 ind.	Calbrade *et al*. 2010
GB threshold	50 ind	Calbrade *et al*. 2010
Designated east coast sites where species is a noted feature	Ythan Estuary Sands of Forvie and Meikle Loch – 36 pairs (2009) Firth of Tay & Eden Estuary (0 pairs)	SNH 2011 JNCC 2011a
European population estimate	Breeding 35,000 – 55,000 Wintering – none	Birdlife 2004
European population trend	Status 'declining' Trend 'moderate decline'	Birdlife 2004
World population	190,000 – 410,000	Birdlife 2011

The little tern is the smallest of Britain's terns, nesting in small colonies along sand and shingle beaches where they often suffer from disturbance and predation.

They arrive from their West African wintering grounds from April onwards and depart in August and September. They feed on small fish, foraging in close in-shore waters.

In North-east Scotland only sixteen little terns were recorded during ten years of observations at Peterhead. All were recorded between May and August and were within a few hundred metres of the shore. Little terns breed in the region at the Ythan Estuary where they return from their wintering grounds at the end of April. The numbers nesting varies considerably across years with many years having only a few pairs and others occasionally over 70 pairs nesting. The number of young fledged also varies considerably with most years producing only a few young due to predation and weather. During years where nests fail early on birds may leave the region by the end of June and early July but in years where nesting has been successful birds may remain in the area through to August or early September (Buckland, Bell & Picozzi 1990; NESBR).

Boat-based surveys

No little terns were recorded from any of the boat-based surveys.

Vantage Point surveys

Nine little terns were recorded during May 2005 but none from Vantage Point counts between May and August 2006 and only 11 during the same period in 2007 (Alba Ecology 2008a). The only sighting in 2006 was of six birds in September 2006 (EnviroCentre 2007a). All sightings were within 1 – 2 km of the coast and flying below 30 m.

Bird Detection Radar

There were no records of little tern from surveys undertaken during the radar studies.

4.31.3 Summary of Results

Very few little terns were recorded from any of the surveys undertaken during the study. There were no sightings from boat-based surveys and only 11 little terns over nearly three years of Vantage Point surveys undertaken between May and August 2006 and 2007. There were six birds in September 2006. All sightings were of birds flying below 30 m.

No counts of little tern from any of the surveys within Aberdeen Bay were of national importance.

4.31.4 Initial Assessment of Significance

Little tern	Overall sensitivity	Magnitude	Significance
Collision	Very High	Negligible	Moderate
Barrier	Medium	Low	Minor
Displacement	Medium	Negligible	Negligible

4.31.5 Species Sensitivities

Qualifying species

The little tern is a qualifying species for the Ythan Estuary, Sands of Forvie and Meikle Loch SPA where 36 pairs nested in 2009 and Firth of Tay and Eden Estuary where they last bred in 2007 and now no pairs breed.

Flight height

The only records of little tern were from Vantage Point surveys, which recorded a total of 18 little terns, all of which were flying below 30 m.

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that relatively few little terns occur in Aberdeen Bay and when they do they remain within 2 km of the coast and below turbine height. Consequently, it is predicted that the risk of a collision by little tern with the proposed development is extremely low.

Little terns typically forage between 3 m – 8 m above the surface and are therefore at low risk of collision (ECON 2006). Collisions of turbines by little terns have been reported from Zeebrugge harbour where an array of turbines are lined up along the harbour wall across which little terns fly to and from their colonies (Everaert & Stienen 2006). There have been no other collisions reported from other offshore wind farms where little terns occur.

Based on the small number of little terns potentially occurring within the proposed development area and the low flight heights it is predicted that the risk of collision is low.

Barrier effect

Studies undertaken in UK and Belgium have shown that there is unlikely to be a barrier effect with little terns recorded foraging within operating wind farms and no evidence of any strong avoidance behaviour. As little terns forage predominantly within 2 km of the coast there will not be a barrier effect.

Displacement

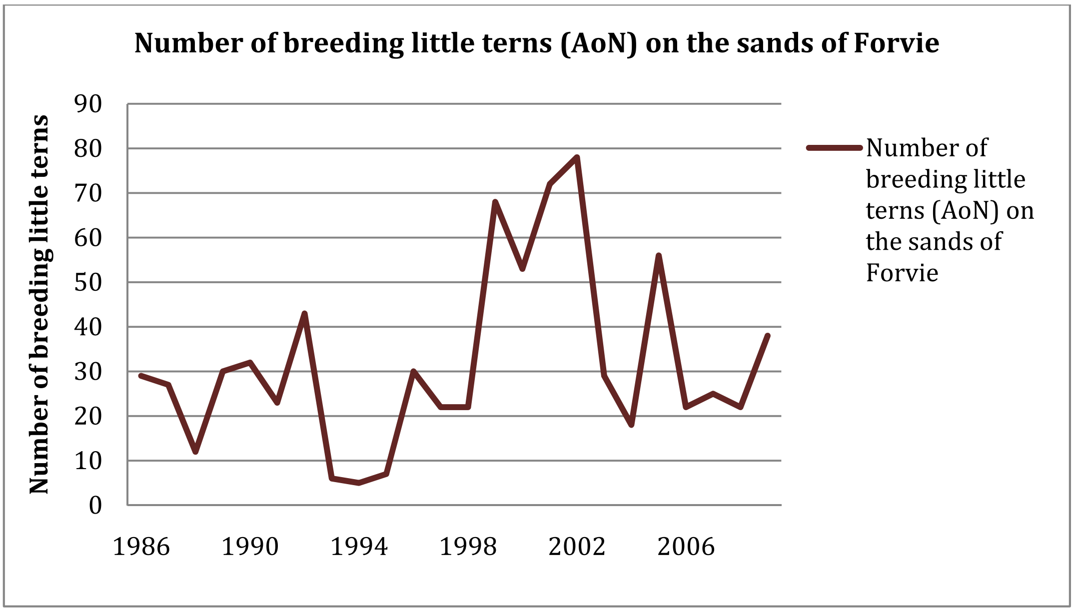
Evidence from studies undertaken in Belgium and the UK have not shown any evidence of a displacement effect. Four years of intensive studies undertaken at Scroby sands offshore wind farm reported that following construction there was a greater use of the area than there had been previously. This increase in use was thought to be due to the formation of a new sand bar within the wind farm thus providing better foraging opportunities (ECON 2008). Consequently, it is predicted that there will be no displacement effects on little terns due to potential development.

Disturbance

Little terns may not be impacted directly by activities associated with the proposed development. i.e. vessel movements, but evidence from monitoring undertaken at Scroby Sands indicates that there is the potential for a secondary impact should the prey of little terns be affected (ECON 2008). Little terns forage on small fish often, young clupeids. Monitoring undertaken at Scroby Sands recorded a reduction in the availability of young herring following the construction of a wind farm by pile-driving and a subsequent breeding failure of little terns (ECON 2008). The little terns were able to compensate for the reduction in available prey by foraging further afield and changing prey items and there has not been any evidence of an overall population decline in the number of little terns in the area but the locations where the terns foraged and the sizes of colonies have varied. Breeding success varies considerably across years and the size of the colonies may change significantly from one year to the next. Consequently, the link between the decline in young herring, and subsequent localised reduction in tern breeding success, being caused by the construction of the wind farm has not been confirmed. However an effect on little tern breeding success could not be discounted.

The significance of any potential effect depends on the scale of displacement and its duration. It also depends on whether other suitable foraging areas can be located. Although these are difficult to predict any potential impacts upon prey are expected to be relatively short-term as they should affect only one or two breeding seasons depending on whether significant pile-driving takes place and whether construction is undertaken over one or two years. Following cessation of construction new juvenile fish will be available the season following construction.

The numbers of breeding little terns breeding at the Sands of Forvie each year is highly variable as is their breeding success with many years where they fail to produce many, if any young (Figure 4-87).



AoN = Apparently Occupied Nest (Adapted from JNCC 2011b and NESBR)

Figure 4-87: Numbers of breeding little terns at the Sands of Forvie since 1986.

Based on the evidence from studies undertaken at Scroby Sands, there is the potential for a moderate effect on little terns should the construction of the proposed development cause a significant decline in potential prey items of little terns during the breeding season. However, should it occur it is predicted that the duration of impact would last no longer than one or two seasons as juvenile fish will be available the following season.

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts.

Although there are other planned offshore wind farms none are in areas where little terns will likely occur and therefore no cumulative or in-combination impacts are predicted.

Habitats Appraisal

Based on the evidence from existing offshore wind farms indicating both a very low collision risk, little or no displacement and that there are not expected to be any barrier effects; it is predicted that there will not be any adverse effects on the SPA for which little tern is a qualifying species. However, should pile-driving be undertaken, there is the potential for an impact on the prey of little terns during the construction period. If this occurs there is the potential for a localised adverse effect during the construction periods but thereafter breeding success would not be affected by the proposed development. Little terns regularly have unsuccessful breeding seasons and therefore the population can withstand one or two poor breeding seasons should they occur without having an adverse effect on the population.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on little tern. Although impacts arising from the potential reduction in the availability of suitable prey species during the breeding season could have a temporary impact.

4.32 Sandwich tern (*Sterna sandvicensis*)

4.32.1 Protection & Conservation Status

The Sandwich tern is listed in Annex I of the Birds Directive, Appendix II of the Bonn Convention, Appendix II of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.32.2 Background

Sandwich tern		
GB population	Breeding: 11,000 prs	Mitchell *et al* 2004
Scottish population	1,100 AoN	Forrester *et al*. 2007
International threshold	1,700 ind.	Calbrade *et al*. 2010
GB threshold	200 ind.	Calbrade *et al*. 2010
Designated east coast sites where species is a noted feature	Ythan Estuary, Sands of Forvie and Meikle Loch: 645 prs (2009) Loch of Strathbeg: 1 pr (2010) Firth of Forth: 1,617 ind. (passage) Forth Islands: 0 prs (2010)	SNH 2011 JNCC 2011a
European population estimate	Breeding 82 – 130,000 pairs Wintering – unknown	Birdlife 2004
European population trend	Status 'depleted' Trend 'small decline'	Birdlife 2004
World population	490 – 640,000 individuals	Birdlife 2011

Sandwich terns are regular summer migrants to UK waters and breed at coastal colonies on undisturbed beaches. They regularly move colonies and numbers at each colony can vary considerably across years.

Birds return to their breeding grounds during April and remain in the area until the autumn. The number of terns breeding is highly variable and their success depends on the availability of suitable prey, predation and weather. Sandwich terns forage offshore for small fish species, particularly sandeels and clupeids. The distance that they forage varies depending on prey availability with distances of up to 67 km reported.

The British breeding population is approximately 11,000 pairs of which 1,100 pairs breed in Scotland.

In North-east Scotland Sandwich terns breed at the Sands of Forvie where up to 1,800 pairs have bred although recent counts have been lower and occasionally at the Loch of Strathbeg where recently very small numbers have attempted to breed.

At Peterhead Sandwich terns have been recorded from March to October with peak numbers of up to three birds per hour in May and June.

Boat-based surveys

Although Sandwich terns are a common breeding species at the nearby Sands of Forvie, relatively few were recorded from boat-based surveys undertaken in the proposed development area. A total of five Sandwich terns were recorded within the proposed EOWDC survey area, all in May. Larger numbers were recorded in the area to the north of the proposed EOWDC area where a total of 43 birds were recorded between May and July (Figure 4-88; Figure 4-89). Nearly all sightings were of birds inshore and in water depths of less than 10 m (IECS 2008).

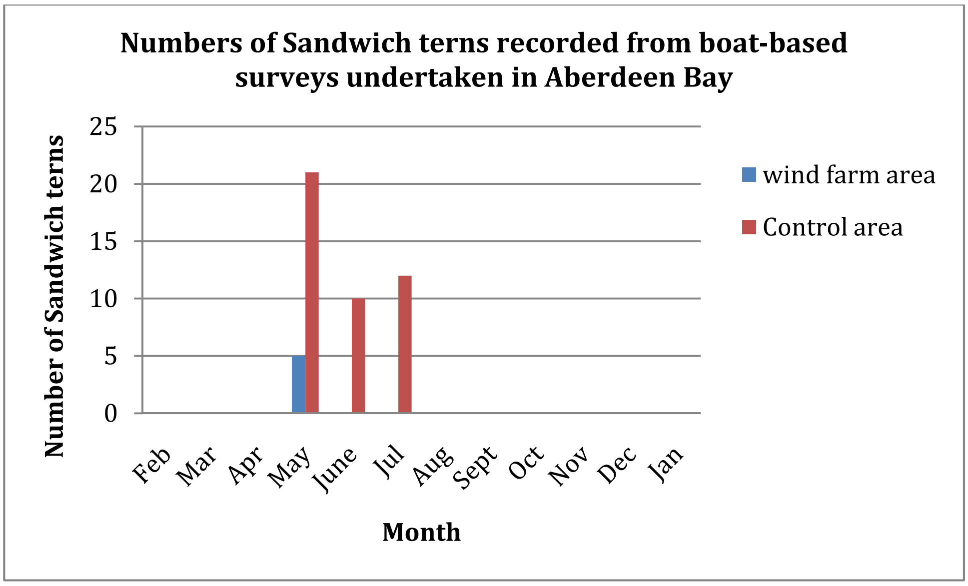


Figure 4-88: Sandwich tern monthly population estimates in proposed EOWDC and 'control' areas: Boat-based surveys 2007 – 2008.

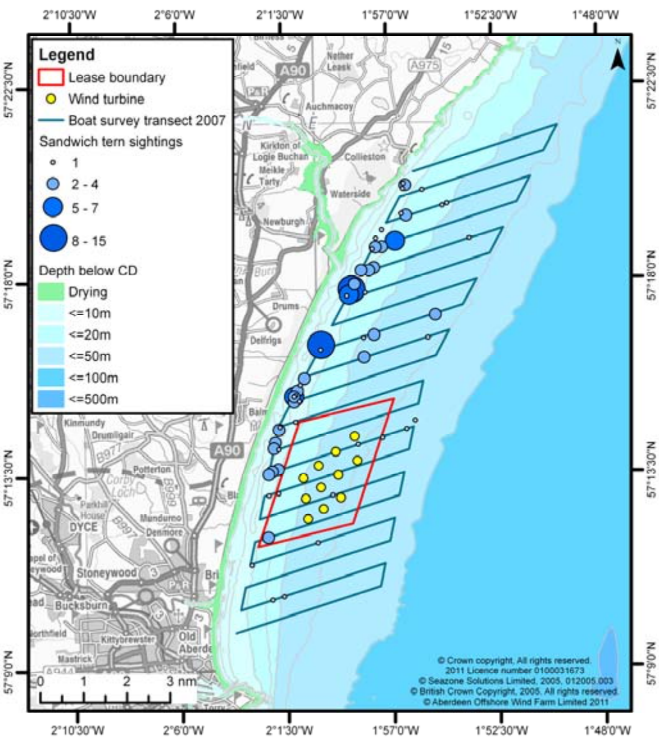

Figure 4-89: Sandwich tern distribution in Aberdeen Bay during breeding season: April – August (all sightings).

Vantage Point surveys

Sandwich terns occur in Aberdeen Bay from March through to October with peak counts in May when up 100 birds per hour were recorded, and August 2007 when up to 300 birds per hour were recorded (Alba Ecology 2008a). A significant decrease in the number of birds was recorded in Aberdeen Bay during the breeding season of June and July with generally less than 50 birds per hour passing. Birds were recorded predominantly within the 0-2 km of the shore with few records beyond 2 km

(Figure 4-90). Of those for which flight height was recorded at least 44% were recorded at between 30-150 m above the sea surface.

Bird Detection Radar

There were no sandwich terns recorded during the radar surveys undertaken at Drums and Easter Hatton during October 2005. In April 2007 a total of 298 Sandwich terns were recorded from Blackdog at a rate of nearly six birds per hour (Simms *et al*. 2007). All sightings were within 2 km from shore but this may in part be due to birds being missed further offshore.

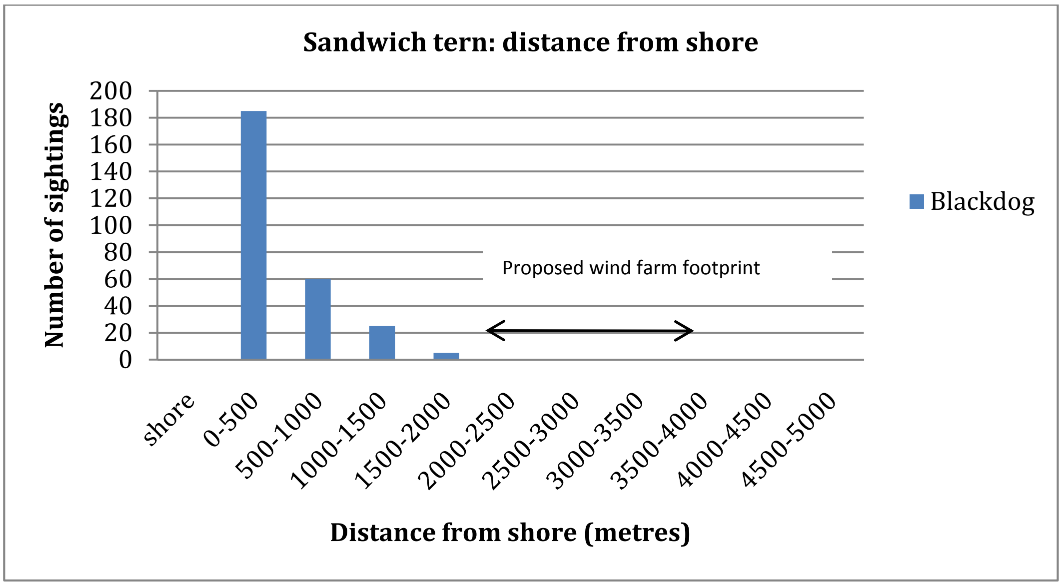

Figure 4-90: Distances from shore for Sandwich terns from Blackdog (April 2007).

4.32.3 Summary of Results

Relatively few Sandwich terns were recorded from boat-based surveys undertaken in Aberdeen Bay. Peak numbers were in May and August with lower numbers during the period of chick rearing in June and July. The majority of sightings were within 500 m from shore with few sightings of birds beyond 2 km. Of those recorded in flight, 44% of Sandwich terns were flying between 30 – 150 m.

No counts of Sandwich tern from any of the surveys within Aberdeen Bay were of national importance.

4.32.4 Initial Assessment of Significance

Sandwich tern	Overall sensitivity	Magnitude	Significance
Collision	Very High	Low	Moderate
Barrier	Medium	Medium	Minor
Displacement	Medium	Medium	Minor

4.32.5 Species Sensitivities

Qualifying species

The Sandwich tern is a qualifying species for the Ythan Estuary, Sands of Forvie and Meikle Loch SPA & Ramsar where 645 pairs nested in 2009; Loch of Strathbeg where 1 – 2 pairs nested in 2010, Forth Islands where no Sandwich terns now breed and the Firth of Forth which supports a post-breeding (passage) population of 1,617 individuals.

Flight height

Data from boat-based surveys recorded 4% of all flights at above 25 m, whereas 44% of those from Vantage Point Counts were reported as being at rotor height. Elsewhere, 12% of all flights have been reported as being at rotor height (n=5,080).

Collision risk

Collision Risk Modelling undertaken for sandwich tern is based on:

- Body length of 38 cm
- Wingspan of 100 cm
- Flight speed of 10.5 $m.s^{-1}$

The Collision Risk Modelling is based on a collision probability of 11.8% and been undertaken over a range of avoidance rate from 98%, 99% and 99.5% have been used.

Table 4-27: Predicted number of collisions per year for Sandwich tern.

Collision probability	Avoidance rate (%)		
	98	99	99.5
11.8%	0.4	0.2	0.1

Based on the precautionary avoidance rate of 98% it is predicted that a total of 0.4 collisions per year may occur (Table 4-27).

The annual mortality rate for Sandwich tern is 11% (BTO 2011).

Based on the regional SPA population of Sandwich tern of 645 breeding pairs the annual mortality rate will be 142 individuals and therefore the 1% baseline mortality rate is 1.4 birds per year. The results from the Collision Risk Modelling predict a total of less than 1 bird per year may collide with the wind turbines.

Collision Risk Modelling has been undertaken based on the higher 12% of all flights at rotor height as reported from other offshore wind farms. The results from the modelling indicate an annual mortality rate of 1.2 birds per year, which is similar to the 1% baseline mortality rate.

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that relatively few Sandwich terns occur in area of the proposed development with nearly all sightings within 2 km of the coast and the majority within 1 km.

Data from existing offshore wind farms have reported relatively high number of collisions of sandwich tern with wind turbines (e.g. Everaert & Stienen 2006). However they have also demonstrated high avoidance rates of more than 99%. The number of collisions recorded has been largely due to the high number of transits made by the Sandwich terns at the sites. Site specific data indicates a low usage of the proposed development area and low numbers of transits across the site consequently a low risk of collision.

Based on the small numbers of sandwich terns recorded within the proposed development area and the relatively high avoidance rates reported for Sandwich terns, it is predicted that the risk of collision is low and the significance negligible.

Barrier effect

Studies undertaken in UK and Belgium have shown that there is unlikely to be a barrier effect with sandwich terns recorded foraging within operating wind farms and no evidence of any strong avoidance behaviour. As the Sandwich terns in Aberdeen Bay forage predominantly within 2 km of the coast and there will not be a barrier effect.

Displacement

Evidence from studies undertaken in Belgium and the UK have not shown any evidence of a displacement affect on Sandwich terns with birds entering operating wind farms. Therefore, predicted that any potential impact from displacement will be negligible.

Disturbance

As with little terns, Sandwich terns are not predicted to be impacted directly by disturbance from construction or operating vessels. However, they could, in theory, be impacted indirectly if the construction of the proposed project has an impact on the availability of their prey. However, unlike with little terns this potential impact has not been reported from any offshore wind farm.

Sandwich terns feed predominantly on sandeels and clupeids (young herring) and should they be impacted by construction activities in the vicinity of the proposed development then Sandwich terns may have to either forage more widely or find alternative prey. It is not possible to determine whether either possible impacts are potentially likely but Sandwich terns do forage widely in the coastal waters of Aberdeen Bay and appear not to occur in the EOWDC area so those that are effected may be able to relocate should their be a localised effect.

There is no evidence of an indirect impact on breeding Sandwich terns from other constructed offshore wind farms but there is the potential for a temporary moderate effect on Sandwich terns should the construction of the proposed development cause a significant decline in the prey of Sandwich during the breeding season. If this effect occurs it is predicted that it would last no longer than a single season before fish numbers returned back to the population levels prior to construction.

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts.

Outwith Aberdeen Bay there are further planned wind farms in the Moray Firth and Firth of Forth areas. The exact locations, size and type of turbines are unknown and no site specific data are available to inform the cumulative or in-combination assessment.

Surveys undertaken at the Beatrice Demonstrator Project located in the Moray Firth did not record any Sandwich terns and there are no Sandwich tern colonies in the Moray Firth area. Therefore, Sandwich terns are unlikely to occur regularly in the Moray Firth. Sandwich tern is a qualifying species for its post-breeding passage population in the Firth of Forth SPA and as breeding species in the Forth Islands SPA. The SPA citation for the Forth Islands states 22 pairs of Sandwich tern but no pairs have nested there in recent years.

The detailed distribution of Sandwich terns in the Firth of Forth is unknown and there are no site specific data available to indicate whether Sandwich terns occur in the vicinity of the planned offshore wind farms. However, published seabirds at sea data indicate low densities occurring in the Firth of Forth area during the summer months with no records offshore during September or October (Stone *et al.* 1995). The Firth of Firth SPA is also approximately 124 km away from the proposed development and therefore the risk of any cumulative or in-combination impacts are low.

Habitats Appraisal

Based on the evidence from existing offshore wind farms indicating both a very low collision risk, little or no displacement and that there are not expected to be any barrier effects; it is predicted that there will not be any adverse effects on the SPA for which Sandwich tern is a qualifying species. However, should there be an impact on the prey items of Sandwich terns during the construction period then there is the potential for a short-term adverse effect for a single season but after which no adverse effects are predicted.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on sandwich tern. Although impacts arising from the potential reduction in the availability of suitable prey species during the breeding season could be possible.

4.33 Common tern (*Sterna hirundo*)

4.33.1 Protection & Conservation Status

The common tern is listed in Annex I of the Birds Directive, Appendix II of the Bonn Convention, Appendix II of the Bern Convention and is on the Green List of Species of Conservation Concern.

4.33.2 Background

Common tern		
GB population	10,000 prs	BTO 2011
Scottish population	4,800 AoN	Forrester *et al.* 2007
International threshold	1,900 ind	Calbrade *et al*. 2010
GB threshold	200 ind	Calbrade *et al*. 2010
Designated east coast sites where species is a noted feature	Ythan Estuary, Sands of Forvie and Meikle Loch – 6 pairs (2006). Forth Islands 378 prs	SNH 2011 JNCC 2011a
European population estimate	Breeding 270 – 570,000 pairs Wintering – unknown	Birdlife 2004
European population trend	Status 'secure' Trend 'stable'	Birdlife 2004
World population	1.6 – 4,600,000 individuals	Birdlife 2011

Common terns are a widespread summer visitor to the UK, arriving from their wintering grounds off West Africa during April and May and departing in August and September. They nest colonially along coasts and inland along rivers and freshwater bodies. Coastal breeders feed predominantly on small fish, which are caught by plunge diving in nearshore waters, shallow bays and lagoons. They have however been reported to forage up to 34 km from their breeding sites.

There are approximately 10,000 pairs in Britain of which approximately 4,800 nest in Scotland. In North-east Scotland common terns are found along all the region's coasts with the largest coastal breeding colonies at the Sands of Forvie. They also breed inland of Aberdeen and birds from these colonies may forage offshore. Peak numbers arrive during May and the birds remain in the region until August and September.

The identification of common and Arctic tern is difficult at any range and consequently records of distant passing birds are not assigned to either species and are recorded as 'commic' terns.

Passage of 'commic' terns past Peterhead occurs from April to September with peak numbers of up to 40 birds per month during July. Most records were of birds within several hundred metres from the shore.

Boat-based survey

Common terns were recorded from boat-based surveys between May and September. Peak counts occurred in June with a population estimate of 264 birds in the 'control' area and 55 birds in the proposed development area (IECS 2008). There were no records of common terns from boat-based surveys between October and March in the first year of data collection but eight were recorded during September 2010. There were no confirmed sightings of common tern within the proposed development area although two birds were recorded as either common or Arctic tern. The majority of sightings were to the north near the Ythan Estuary (Figure 4-92 and Figure 4-93).

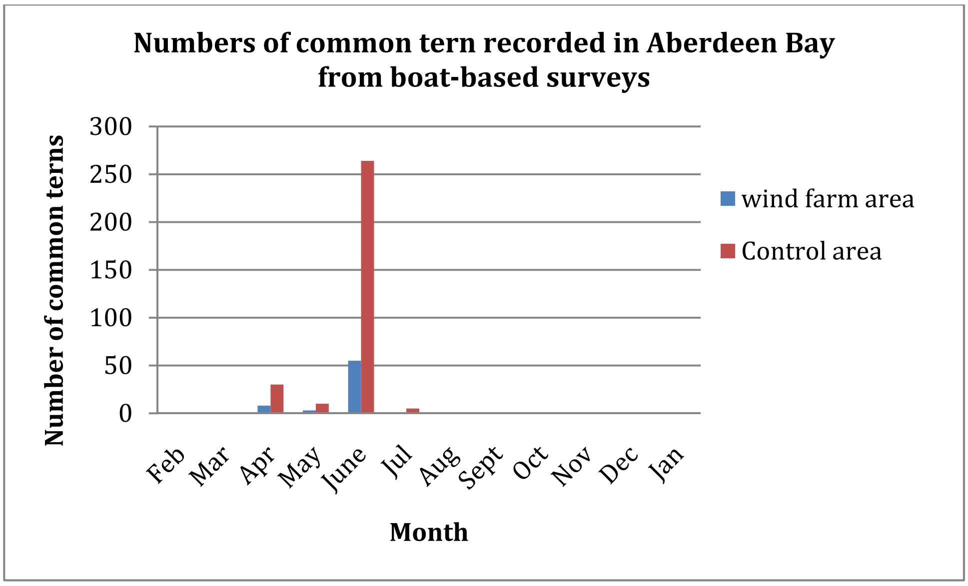

Figure 4-91: Common tern monthly population estimates in proposed EOWDC and 'control' areas: Boat-based surveys 2007 – 2008.

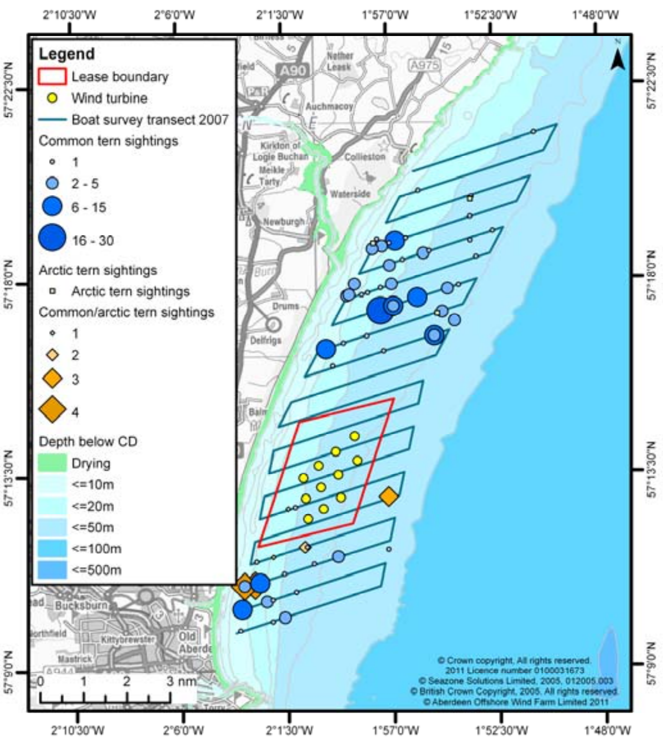

Figure 4-92: Common tern and Arctic tern distribution in Aberdeen Bay during breeding season: April – July (all sightings).

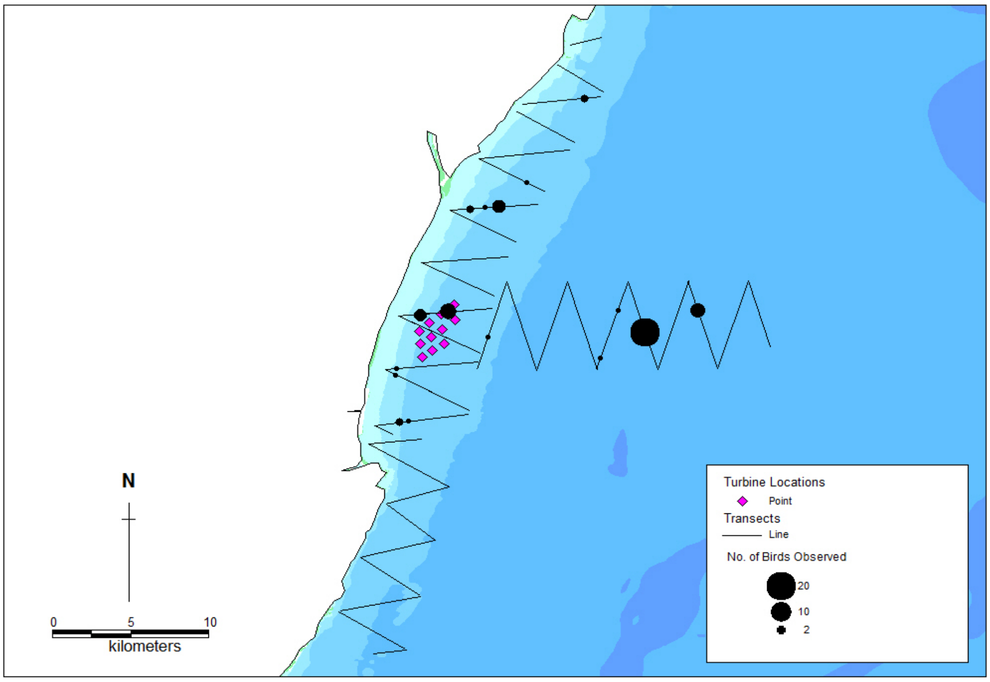

Figure 4-93: On-effort observations of Tern species (Common, Arctic Sandwich and Unidentified Tern species) along transects during August, September and November 2010 and January 2011.

Vantage Point surveys

In Aberdeen Bay common terns were recorded from April through to September with peak counts varying across years. In 2006 peak counts occurred during July and August when up to 50 birds per hour were recorded compared to a peak of less than 10 birds per hour in August 2005 and five birds per hour during the same period in 2007 (EnviroCentre 2007a, Alba Ecology 2008a). In 2008, the peak counts occurred in May when up to ten birds per hour passed the Donmouth. Relatively low numbers were recorded during June when birds were breeding.

The majority of sightings were of birds between 0–2 km from the coast and at least 83% of sightings were of birds flying below 30 m.

Bird Detection Radar

There were no common terns recorded during the radar surveys undertaken at Drums and Easter Hatton during October 2005. In April 2007 a total of 14 common terns were recorded from Blackdog at a rate of 0.27 birds per hour (Simms *et al*. 2007).

4.33.3 Summary of Results

Numbers of common terns from boat-based surveys peaked during June when up to 264 birds were present in the 'control' area. The timing of peak counts varied between years with some occurring in May and others in July and August when up to 50 birds per hour were recorded. The majority of sightings were within 2 km of the coast and at least 83 of sightings were of birds flying below 30 m.

The peak count of estimated abundance in June was greater than the threshold of national importance.

4.33.4 Initial Assessment of Significance

Common tern	Overall sensitivity	Magnitude	Significance
Collision	Very High	Low	Moderate
Barrier	Medium	Low	Minor
Displacement	Medium	Low	Minor

4.33.5 Species Sensitivities

Qualifying species

The common tern is a qualifying species for the Ythan Estuary, Sands of Forvie and Meikle Loch SPA where six pairs nested in 2009 and the Forth Islands SPA where 378 pairs nest.

Flight height

Out of 22 recorded flight heights for common tern obtained from site specific boat-based surveys, 14% of flights were above 25 m.

Elsewhere, out of 2,060 recorded flight heights, 11% have been recorded as being at rotor height.

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that common terns may occur within the proposed development area but in lower numbers than areas to the north. A peak estimated population of 55 birds occurred in the proposed EOWDC survey area during June when 264 birds were in the 'control' area to the north.

Collision Risk Modelling undertaken for common tern is based on:

- Body length of 33 cm
- Wingspan of 88 cm
- Flight speed of 10.9 $m.s^{-1}$

The Collision Risk Modelling is based on a collision probability of 11.8% and been undertaken over a range of avoidance rate from 98%, 99% and 99.5%.

Table 4-28: Predicted number of collisions per year for common tern

Collision probability	**Avoidance rate (%)**		
	98	99	99.5
11.8%	3.5	1.7	0.8

Based on the precautionary avoidance rate of 98% it is predicted that a total of 3.5 collisions per year may occur (Table 4-28).

The annual mortality rate for common tern is 10% (BTO 2011). Based on the regional SPA population of 768 breeding adults, the annual mortality rate will be 77 individuals and therefore the 1% baseline mortality rate is less than one bird per year. The results from the Collision Risk Modelling predict a total of 3.5 common terns per year may collide with the wind turbines.

Six pairs of common tern nest on the Sands of Forvie and consequently an increase in adult mortality could have an adverse effect. The Sands of Forvie lies approximately 7.2 km away from the proposed development and therefore may be within the potential foraging range of breeding common terns, which although have been estimated to forage less than 25 km away from their nests are more likely to be within 4 km and 6 km (Roos 2010).

A total of 378 pairs of common tern nest at the Firth of Forth, which lies approximately 124 km away and therefore outwith the maximum foraging range recorded for common terns.

Data obtained from Zeebrugge, where common terns frequently pass across an array of turbines, have reported relatively high collision mortalities although very low collision probabilities of 0.1% for birds flying at rotor height and 0.007% for birds at all altitudes (Everaert & Stienen 2006). Consequently the use of a 98% avoidance rate is very precautionary and it is predicted that avoidance of greater than 99% is likely. Based on this the number of potential collisions by common terns may be between one to two birds per year.

Based on the results from the collision risk modelling and the relatively small number of common terns potentially occurring within the proposed development area it is predicted that the risk of collision is low but the significance may be moderate or minor.

Barrier effect

Studies undertaken in UK, Belgium Denmark and Sweden have shown that there is unlikely to be a barrier effect, with common (or common/Arctic) terns recorded foraging within operating wind farms and no evidence of any strong avoidance behaviour. Post-construction monitoring undertaken at Kentish Flats have shown a potential barrier effect with fewer common terns flying through the operating wind farm than compared to prior construction (Gill *et al*. 2008). The location of the proposed development to the south of the tern colony on the Sands of Forvie and that site specific monitoring indicates that areas to the north of the proposed development are preferred indicates that there are unlikely to be any significant or adverse effects to common terns caused by the potential barrier effect.

Displacement

Evidence from studies undertaken in Denmark where common terns were seen to enter operating wind farms indicates that there may be little or no displacement. Should displacement occur, site specific data indicates that common terns may forage elsewhere, particularly to the north where then numbers of common terns present were higher.

Disturbance

Common terns may not be impacted directly by activities associated with the proposed development, i.e. vessel movements, but there is the potential for a secondary impact should the prey of common terns be affected by construction activities, particularly pile driving. Common terns forage on small fish, young clupeids, and crustaceans (shrimps). Should the construction of the proposed development cause a reduction in the availability of prey to breeding terns then this cause an adverse effect.

The location of nearest tern colonies 7 km away and that more common terns were recorded to the north of the development area indicate that should there be a reduction of suitable prey in the vicinity of the proposed development from pile driving, then there are other areas where common terns may forage, e.g. in the Ythan Estuary. Any potential impact will likely last for no more than the one or two seasons during construction as juvenile fish will be available as prey following cessation of construction.

The significance of any potential effect depends on the type of installation technique used the subsequent scale of disturbance and its duration. It also depends on whether other suitable foraging areas are available. Although these are difficult to predict any potential impacts upon prey are expected to be relatively short-term as they should only effect one or two breeding seasons, as new juvenile fish will become available the season following construction. Post construction monitoring undertaken at Kentish Flats did not record any reduction in the number of terns using the area and noted an increase in overall numbers indicating no significant effect from construction on Terns (Gill *et al*. 2008).

Based on the results from site specific surveys and evidence from studies undertaken at other constructed wind farms it is predicted that any potential impact may be of moderate significance.

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts.

Outwith Aberdeen Bay there are further planned wind farms in the Moray Firth and Firth of Forth areas. The exact locations, size and type of turbines are unknown and no site specific data are available to inform the cumulative or in-combination assessment.

Collision Risk Modelling undertaken for all species of tern recorded at the Beatrice Demonstrator Project located in the Moray Firth predicted an annual mortality rate of less than 1 bird per year. The additional mortality rate is therefore low and of minor significance.

The detailed distribution of common terns in the Firth of Forth is unknown and there are no site specific data available to indicate whether common terns occur in the vicinity of the planned offshore wind farms. However, published seabirds at sea data indicate low or very densities occurring in the Firth of Forth area with no records in the area where wind farms may in the future be developed (Stone *et al.* 1995). The Firth of Firth SPA is also approximately 124 km away from the proposed development and therefore the risk of any cumulative or in-combination impacts are low.

Habitats Appraisal

Based on the evidence from existing offshore wind farms indicating both a very low collision risk, little or no displacement or barrier effects; it is predicted that there will not be any adverse effects on the SPA for which common tern is a qualifying species. However, should there be an impact on the prey species for common tern during the construction period then there is the potential for a localised impact.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on common tern, although there may be a temporary moderate impact if the construction of the proposed development causes a displacement of fish species.

4.34 Arctic tern (*Sterna paradisaea*)

4.34.1 Protection & Conservation Status

The Arctic tern is listed in Annex I of the Birds Directive, Appendix II of the Bonn Convention, Appendix II of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.34.2 Background

Arctic tern		
GB Population	52,600 pairs	BTO 2011
Scottish population	47,300	Forrester *et al*. 2007
International threshold	Unknown	Calbrade *et al*. 2010

Designated east coast sites where species is a noted feature	Forth Islands: 908 prs	SNH 2011 JNCC 2011a
European population estimate	Breeding 500,000 – 900,000 pairs Wintering – none	Birdlife 2004
European population trend	Status 'secure' Trend 'unknown'	Birdlife 2004
World population	2,000,000 mature individuals	Birdlife 2011

Arctic terns are a summer migrant to the northern Europe and winter in the Antarctic. They arrive on their breeding grounds during April and May and depart during August and September. They breed in colonies on undisturbed beaches and islands and numbers in colonies varies considerably across years with birds regularly switching colonies. They forage in mainly coastal waters feeding predominantly on small fish by plunge diving to just below the surface.

An estimated passage of up to 200,000 Arctic terns may occur in Scotland. In North-east Scotland Arctic terns occur from April through to September with peak numbers in July when up to 40 birds per month were recorded past Peterhead (Innes 1994).

Boat-based surveys

Three Arctic terns were recorded in July 2007 from boat-based surveys (IECS 2008).

Vantage Point surveys

Arctic terns were regularly recorded in Aberdeen Bay from April through to October with a distinct peak in numbers between June and August. Peak numbers varied considerably across years with up to 150 birds per hour passing Drums in July 2008 but a peak of only up to ten birds per hour in June 2007 (EnviroCentre 2007a, Alba Ecology 2008a). Birds were recorded less than 2 km from shore and up to 36% of sightings were greater than 30 m above sea surface.

Bird Detection Radar

There were no Arctic terns recorded during the radar surveys undertaken at Drums and Easter Hatton during October 2005. In April 2007, 2 Arctic terns were recorded from Blackdog (Simms *et al*. 2007).

A further 23 common/Arctic terns were recorded during the April 2007 radar surveys (Simms *et al*. 2007). All terns recorded from the radar surveys were seen flying below 30 m.

4.34.3 Summary of Results

Numbers of Arctic terns recorded from boat-based surveys was very low but they were regularly recorded from land-based counts from April through to October with peak counts during July. Numbers recorded varied but were generally less than 10 birds per hour with one exceptional count of 150 birds per hour in July. The majority of sightings were within 2 km of the coast and 36% of all sightings were of birds flying above 30 m.

There is no UK threshold but the peak count of 150 birds per hour in July 2008 was less than the 1% of the national breeding population.

4.34.4 Initial Assessment of Significance

Arctic tern	Overall sensitivity	Magnitude	Significance
Collision	Very High	Low	Moderate
Barrier	Medium	Low	Minor
Displacement	Medium	Low	Minor

4.34.5 Species Sensitivities

Qualifying species

The Arctic tern is a qualifying species for the Forth Islands SPA where 908 pairs nest.

Flight height

There were no species specific flight heights recorded for Arctic terns from site specific boat-based surveys. Out of the 24 flights for 'commic' (common/Arctic) terns none were above 25 m.

Elsewhere, very few Arctic terns have been reported from other offshore wind farm surveys (n= 122) but for those that have, 24% have been recorded at rotor height.

Collision risk

Only three Arctic terns were recorded from site specific boat-based surveys undertaken in Aberdeen Bay but more were recorded from Vantage Point Counts with up to 36% of flight altitudes above 30 m. Nearly all sightings were of birds within 2 km of the coast, indicating that there is a low risk of collision with the proposed development. Avoidance rates for Arctic terns are unknown but based on the similar common tern results from Zeebrugge it is predicted that should Arctic terns occur in the vicinity of the proposed development they will have a high avoidance rate and the risk of collision low and any potential impacts negligible.

Barrier effect

Studies undertaken in Denmark and Sweden have shown that there is unlikely to be a barrier effect with common/Arctic terns recorded foraging within operating wind farms and no evidence of any strong avoidance behaviour. And there are unlikely to be any significant or adverse effects to Arctic terns caused by the potential barrier effect.

Displacement

Evidence from studies undertaken in Denmark where common/Arctic terns were seen to enter operating wind farms indicates that there may be little or no displacement. As very few Arctic terns were recorded beyond 2 km the use of the site by Arctic tern appears to be very low and therefore it is predicted that there will be little or no displacement effect.

Disturbance

Arctic terns may not be impacted directly by activities associated with the proposed development, i.e. vessel movements but there is the potential for a secondary impact should the prey of Arctic terns be affected by construction activities. Arctic terns are opportunistic feeders foraging on small fish and crustaceans. Should the construction of the proposed development cause a reduction in the availability of prey to Arctic terns then this could cause an adverse effect.

However, very few Arctic terns were recorded and there is no evidence to suggest that the proposed development area and the surrounds are particularly important for Arctic terns and that should their prey be displaced that they would not be able to find alternative areas to forage. Any potential impact will likely last for no more than one or two seasons as juvenile fish will be available as prey the following year.

Based on the results from site specific surveys and evidence from studies undertaken at other constructed wind farms it is predicted that any potential impact on Arctic tern will be low and of minor significance.

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts.

Outwith Aberdeen Bay there are further planned wind farms in the Moray Firth and Firth of Forth areas. The exact locations, size and type of turbines are unknown and no site specific data are available to inform the cumulative or in-combination assessment.

The detailed distribution of Arctic terns in the Firth of Forth is unknown and there are no site specific data available to indicate whether Arctic terns occur in the vicinity of the planned offshore wind farms. However, published seabirds at sea data indicate low or very densities occurring in the Firth of Forth area with no records in the area where wind farms may in the future be developed (Stone *et al.* 1995). The Forth Islands SPA is also approximately 124 km away from the proposed development and therefore the risk of any cumulative or in-combination impacts are low.

Habitats Appraisal

The only SPA in the region for which Arctic tern is listed as a qualifying species is the Forth Islands SPA, which is approximately 124 km to the south. The risk of an adverse effect on the qualifying species is therefore low and its significance should there be one, is negligible.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on Arctic tern. However, there may be a temporary minor impact if there is disturbance to prey during construction.

4.35 Common Guillemot (*Uria aalge*)

4.35.1 Protection & Conservation Status

The (common) guillemot is listed in Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.35.2 Background

Guillemot		
GB Population	Breeding: 1,300,000 ind.	BTO 2011
Scottish population	Breeding: 780,000 prs Winter: 750,000 ind.	Forrester *et al.* 2007

European population trend	Status 'secure' Trend 'large increase'	Birdlife 2004
World population	7,300,000 – 7,400,000	Mitchell *et al* 2004

The guillemot is one the most abundant seabirds in the northern hemisphere with a large population in the Atlantic. Numbers in Britain and Ireland have increased substantially during the last 30 years. Guillemots breed at most locations around the coast of Britain and Ireland where there is suitable cliff nesting habitat. The species is extremely gregarious, colonial nesting is the norm and colonies can contain tens of thousands of individuals (Wernham *et al*. 2002).

Birds may start to return to the colonies from their offshore wintering areas as early as October although many do not return until the spring. During the breeding season birds remain in proximity of their colonies but may forage in excess of 100 km from their breeding sites. The chick leaves the colony with the male when about three weeks old and still flightless. The male accompanies the chick for a further six to eight weeks while it develops and the adult undergoes a complete moult during which time it has a period that it becomes flightless.

Guillemots feed on a variety of small pelagic shoaling fish, especially lesser sandeels, sprats and members of the family Gadidae, which they catch by underwater pursuit after diving from the surface.

Guillemots feed mainly close offshore and are numerous around Britain and Ireland throughout the year. The species is dispersive, rather than migratory with many adults remaining within a few hundred kilometres of their colonies throughout the year. During late summer and early autumn the adults undergo a period of moult during which time they become flightless for a period. They are also accompanied by their flightless chicks during this period.

There is an estimated 1,000,000 pairs of guillemots nesting in Britain of which 75% are in Scotland, the majority in Shetland, Orkney, Caithness, Sutherland and Western Isles (Mitchell *et al*. 2004).

In North-east Scotland the guillemot occurs widely throughout the region and there are number of significant breeding colonies with a population of 150,000 individuals.

The region therefore holds approximately 10% of the UK and Scottish breeding populations.

A distinct passage of guillemots has been recorded off Peterhead with a northerly passage of birds in the spring when up to 24,000 birds per hour have been recorded. A smaller passage of birds occurs in the autumn with up to 400 birds per hour passing.

The passage of birds recorded past Peterhead extended from a few hundred metres from the shore to over 3 km (Innes 1990).

Boat-based surveys

Guillemot was the most frequently recorded species from boat-based surveys between February 2007 and January 2008. Guillemots were recorded throughout the year and throughout the surveyed area with birds recorded in shallow nearshore waters and further offshore in deeper waters of 30 m or more. Although the distribution of guillemots was fairly even across the surveyed area, more guillemots were recorded to the north and offshore of the proposed EOWDC area than within the proposed development area outwith the breeding season (Figure 4-94).

During the breeding season the numbers of guillemot present across the whole of the survey area were relatively low but evenly distributed in water depths of between 20 m and 50 m (Figure 4-95, Figure 4-96).

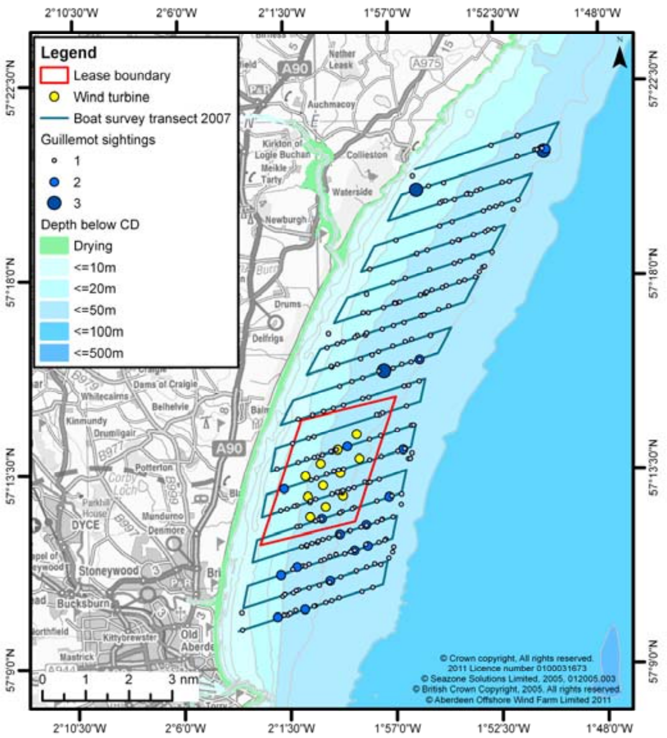

Figure 4-94: Guillemot distribution in Aberdeen Bay during winter period: November to February (all sightings).

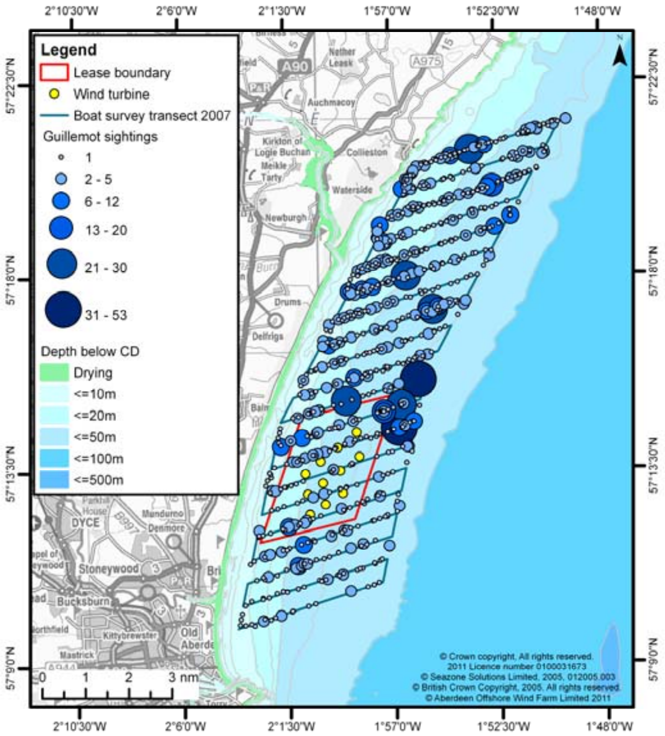

Figure 4-95: Guillemot distribution in Aberdeen Bay during breeding season: March to June (all sightings).

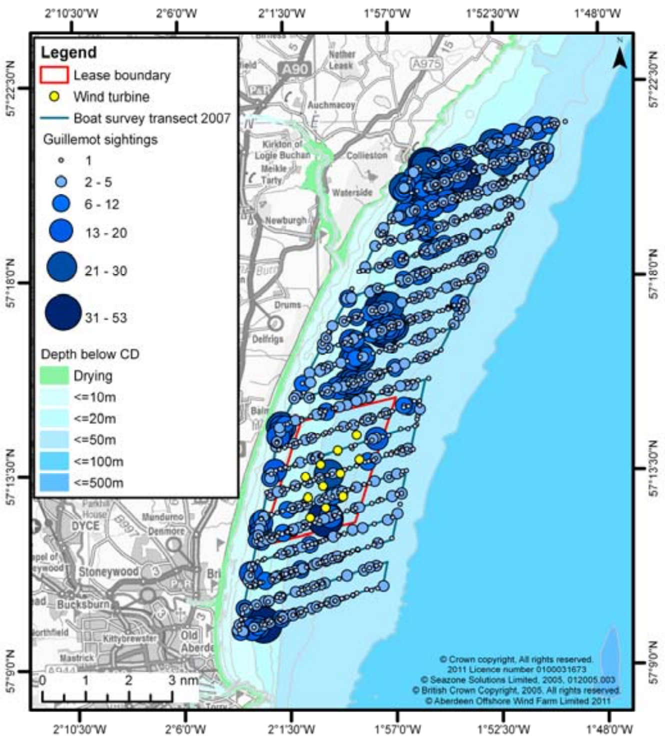

Figure 4-96: Guillemot distribution during post-breeding: July to October (all sightings).

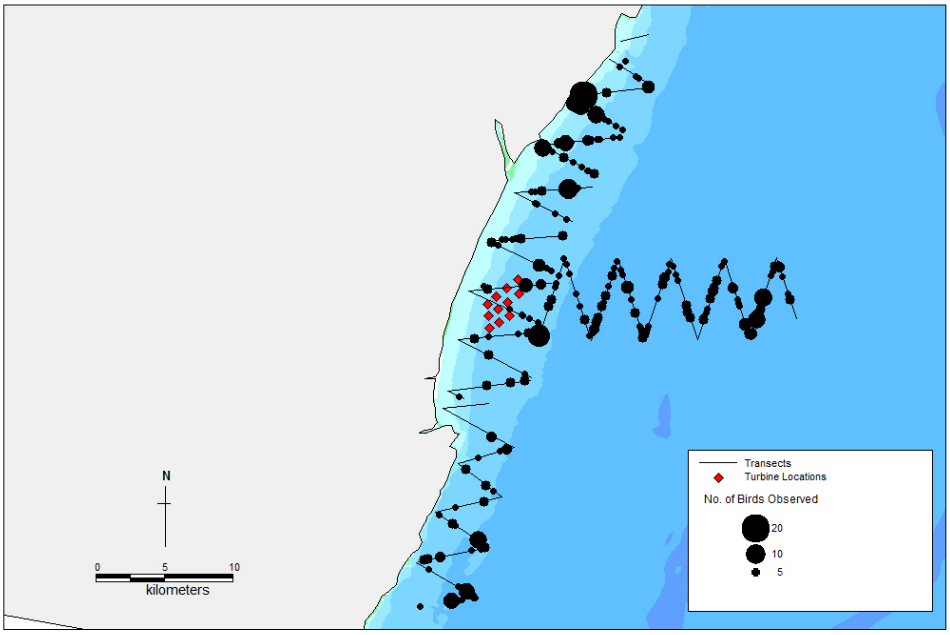

Figure 4-97: On-effort observations of Auk species (guillemot, razorbill and Puffin) along transects during August, September and November 2010 and January 2011.

Numbers of guillemot in the winter period were lower than during the summer months when numbers peaked in July (Figure 4-98). Estimated monthly numbers using *Distance* analysis indicate a population of up to 2,578 guillemots within the 'control' area during July and a further 1,511 in the proposed EOWDC survey area. Densities of up to 51 birds/km^2 and 30 birds/km^2 were estimated during this period (Figure 4-101, Figure 4-99). The highest abundance estimates were from the northern survey area with estimated abundances of nearly 5,500 individuals during September and a density of 36 birds/km^2 (SMRU 2011b).

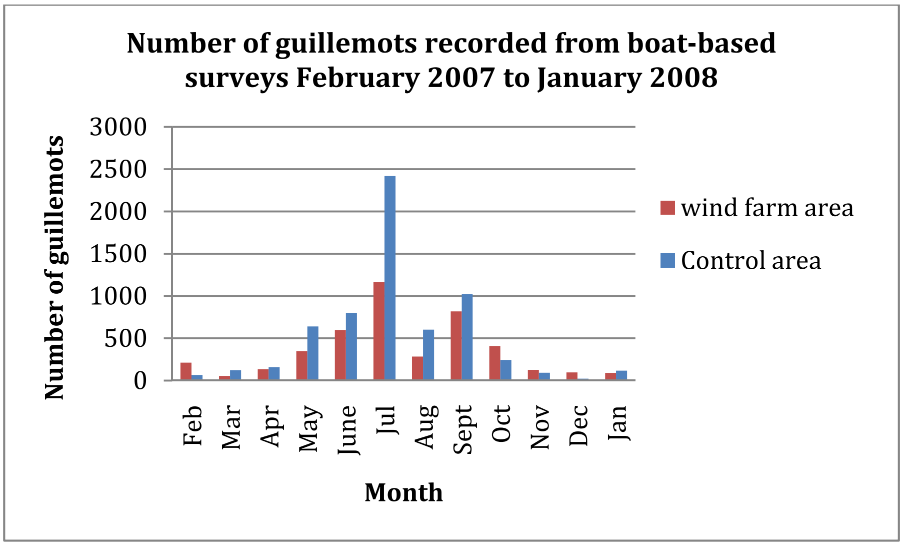

Figure 4-98: Guillemot monthly population estimates in proposed EOWDC and 'control' areas: Boat-based surveys 2007 – 2008.

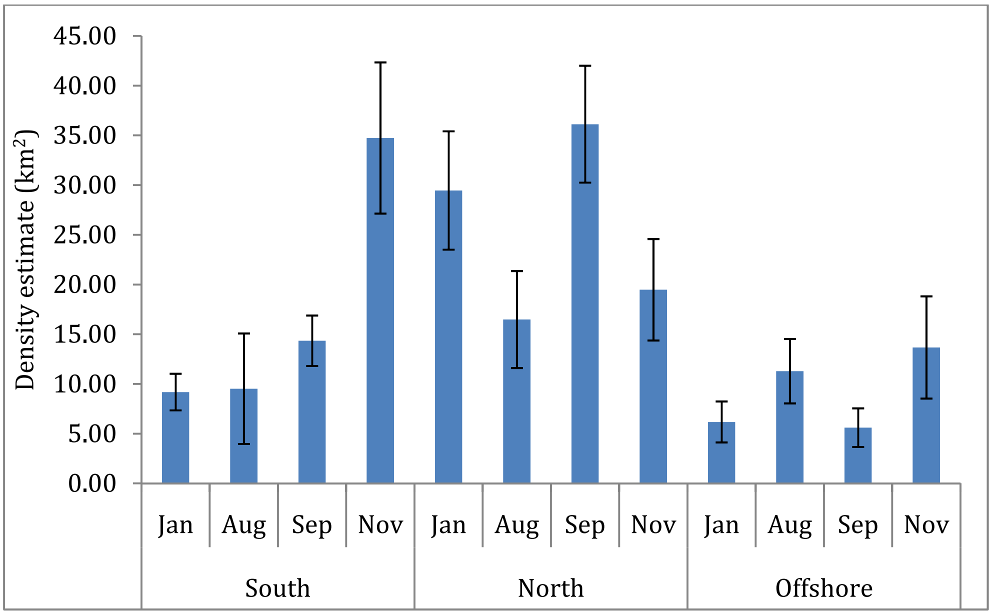

Figure 4-102: Monthly estimates (+/- SE) of density of Common Guillemot in the South, North and Offshore Strata.

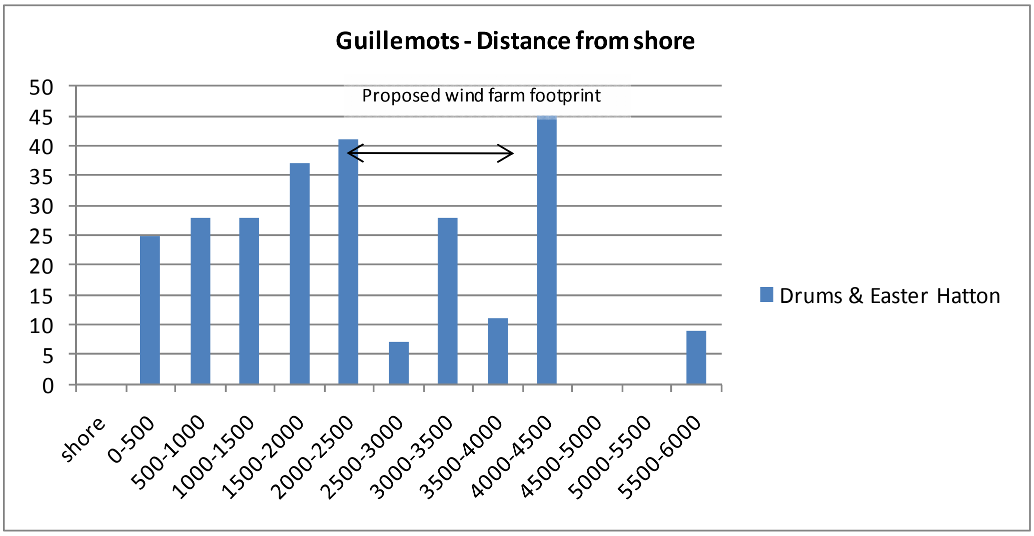
Vantage Point surveys

Guillemots were present in Aberdeen Bay throughout the year. Relatively low numbers were present between December and February with numbers increasing from March onwards. Up to 250 birds per hour were recorded flying past in March 2007, increasing to up to 400 birds per hour during April 2007. (EnviroCentre 2007a,b). At least 98% of all flights were below 30 m. Relatively few birds were recorded within 1 km of the coast with most between 1 km and 3 km; (Alba Ecology 2008a,b).

Bird Detection Radar

A total of 259 guillemots were recorded during the Bird Detection Radar studies undertaken in October 2005. The numbers recorded between the two survey sites were broadly similar with 108 at Drums and 151 at Easter Hatton. The distribution of guillemots was different between the two sites, with a larger proportion of birds at Easter Hatton recorded within 2.5 km from shore compared to Drums where a greater proportion were recorded out to 4.5 km. Combining observations from both sites suggests a generally broad distribution of guillemots (Walls *et al.* 2006).



(Adapted from Walls *et al.* 2006, Simms *et al.* 2007)

Figure 4-103: Guillemot distribution from shore from observation at Drums and Easter Hatton in October 2005.

4.35.3 Summary of Results

Guillemots were recorded widely across Aberdeen Bay from all surveys. Data from boat-based surveys indicate peak counts in the bay occur during the post-breeding period, particularly in July with more birds recorded within the 'control' site than within the proposed EOWDC development area. Relatively high numbers remain within the area until November after which numbers of guillemots in the area decrease. Land based observations recorded peak numbers during April. Data from boat-based surveys recorded guillemots widely across the surveyed areas and land-based observations recorded most guillemots from between 1.5 km and 4.5 km from the coast.

No counts during any surveys undertaken across Aberdeen Bay were of national importance.

4.35.4 Initial Assessment of Significance

Guillemot	Overall sensitivity	Magnitude	Significance
Collision	Very High	Negligible	Minor
Barrier	Medium	Medium	Minor
Displacement	High	Low	Minor

4.35.5 Species Sensitivities

Qualifying species

There are four SPAs in the region for which guillemot is a qualifying species: Buchan Ness to Collieston Coast, Fowlsheugh, Troup, Pennan and Lion's Head and Forth Islands SPA.

Flight height

Flight heights obtained from boat-based surveys undertaken in Aberdeen Bay recorded 271 guillemots in flight of which 1% were recorded as flying above 25 m and therefore at risk of collision.

Elsewhere in the UK out of over 6,000 guillemots for which flight heights have been recorded less than 1% have been recorded at rotor height.

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that guillemots are widespread and frequent within Aberdeen Bay and occur throughout the area.

Collision Risk Modelling undertaken for guillemot is based on:

- Body length of 40 cm
- Wingspan of 70 cm
- Flight speed of 16.5 $m.s^{-1}$

Collision Risk Mortality has been based on a collision probability of 7% and a range of avoidance rates of 98%, 99% and 99.5% have been used.

Table 4-29: Predicted number of collisions per year for guillemot.

Collision probability	**Avoidance rate (%)**		
	98	99	99.5
7%	0.04	0.02	0.01

Based on the precautionary avoidance rate of 98% it is predicted that a total of 0.04 collisions per year may occur (Table 4-29).

The annual mortality rate for guillemot is 5.4% (BTO 2011). Consequently, out of a peak regional population of 5,447 individuals (Figure 4-100) an annual mortality of 294 guillemot, may be predicted. Therefore, 1% of the baseline mortality is 3 birds per year.

Based on the results from collision risk modelling, which predicts a total of 0.04 collision per year there will not be a significant impact on the guillemot due to collisions.

The Buchan Ness to Collieston Coast SPA lies approximately 9.5 km away from the proposed development and holds 19,296 individual guillemots on the latest counts in 2007. The colony has an annual mortality of 1,041 guillemots. It is likely that the majority of guillemots within Aberdeen Bay during the breeding period are associated with this colony. The results from the collision risk modelling which predict an annual mortality of 0.04 guillemots per year indicate that there will not be an adverse effect on guillemot associated with the SPA based on the precautionary assumption that an increase of 1% above baseline mortality could be adverse, i.e. more than ten guillemots a year collide with the turbines.

The Fowlsheugh SPA lies 31 km away from the proposed development and holds 50,566 guillemots based on latest counts. Therefore, the annual mortality rate is 2,730 birds per year. Based on the results from the collision risk modelling it is concluded that even if all the guillemots at risk of collision are from Fowlsheugh there will not be an adverse effect.

Troup Pennan and Lion's Heads SPA is 74 km to the north of the proposed development and, based on the latest counts holds 16,325 guillemots and therefore an annual mortality rate of 881 guillemots. The results of the collision risk modelling indicate that there not be an adverse effect on guillemots associated with this SPA.

The Forth Islands SPA is approximately 124 km away and holds 16,888 guillemots therefore an annual mortality rate of 912 guillemots. Should the whole of the population in the Firth of Forth SPA fly through the proposed development area then the collision risk modelling predicts there will not be an adverse effect on the population due to collision.

Based on the results the very low risk of collision it is concluded that the potential effect from collision risk is negligible.

Barrier effect

Studies undertaken in Sweden and Denmark indicate that there is some potential for a barrier effect to occur with a reduced number of birds crossing the constructed wind farms.

During the breeding season it is predicted that there may be regular flights to and from colonies some of which will intersect the proposed development area. The distance guillemots forage varies depend upon the availability of suitable prey and at what stage during the breeding season they are. Maximum foraging ranges are up to 123 km but the median range is 38 km during incubation and 5 km during chick rearing (Roos 2010). Should a barrier effect occur with guillemots from either Fowlsheugh or Buchan Ness to Collieston Coast SPAs making daily movements from one location to another around the proposed development area then they may incur an additional flight distance of up 3.2 km each way, or a total of 6.4 km. This may increase the daily energy expenditure to between 2.0% and 2.5% (Speakman, Gray & Furness 2009).

The location and size of the proposed development is such that it will only occupy a relatively small zone through which birds may avoid flying. No significant concentrations of guillemots were recorded in the vicinity of the proposed development and therefore it is not considered to be a particularly favourable area for foraging. Regular daily movements by individual birds that could cause an incremental increase in distance of foraging flights on a daily basis is not predicted to occur, i.e. birds from colonies will forage over a wider area and will not need to detour around the proposed development on a regular daily basis.

Based on the above it is concluded that the potential incremental increases in foraging distances are unlikely to cause an adverse effect or significant impact on guillemots.

Displacement

Based on the results from the monitoring data, the worst-case scenario is that should displacement occur, no guillemots will be within the proposed development area out to a distance of 1 km and a 50% decrease in abundance occurs between 1 km and 2 km from the proposed development.

Based on the peak density obtained from boat-based surveys of 50.7 birds/km^2 in the 'control' area during July, should there be a total displacement of guillemot from within the proposed development area then it is predicted that up to 218 guillemot may be displaced during periods of peak density. Based on a 100% displacement out to 1 km (a total surface area of 12.3 km^2) from the proposed development area then it is predicted that up to 623 guillemot may be displaced and a further 515 out to 2 km should there be 50% displacement. Therefore, the maximum number of guillemot potentially displaced is up to 1,355 birds based on the highest densities recorded from any survey within Aberdeen Bay and displacement out to 2 km.

Based on the estimated total of 1,355 potentially displaced guillemots out of a peak reported count of 5,447 guillemot, it is predicted that up to 25% of the guillemots within Aberdeen Bay may be displaced. This is based on a peak density obtained from the 'control' area to the north, the peak density from within the EOWDC area was lower at 30 birds/km^2; consequently, the figure used in this assessment is therefore precautionary.

Based on the regional population estimate of 88,737 guillemots obtained from the regional SPA counts then approximately 1.5% of the regional population may be displaced.

Site specific surveys recorded guillemots throughout the survey area and no specific concentrations were detected, although densities tended to be higher to the north of the proposed development area. However, should there be a displacement effect there is no evidence to suggest that the loss of the area of the proposed development will be significant and that individuals displaced will not be able to find suitable foraging areas elsewhere. Therefore, there is no evidence to suggest that any displacement will have a negative impact on guillemots.

Post-construction monitoring undertaken at Horns Rev offshore wind farm has indicated that displacement of guillemots can occur. However, results from other operating wind farms have not shown a total displacement of guillemots. Guillemots have been recorded at the constructed Kentish Flats offshore wind farm but in reduced numbers (Gill *et al.* 2008). Counts from surveys undertaken during construction at Lynn and Inner Dowsing recorded on average more guillemots during construction than pre-construction but this also included the 'control' areas and more guillemots were also recorded during post-construction surveys at Egmond aan Zee offshore wind farm than were counted prior to construction. There is therefore some evidence to suggest that total displacement of guillemots from within the EOWDC area will not occur.

Based on the evidence from existing offshore wind farms it is predicted that the potential impact from displacement may be moderate.

Calculations used for displacement	
Area	*Peak density of guillemot – 50.7 birds/km^2*
Area of EOWDC – 4.3 km^2	4.3 * 50.7 = 218
Area of 1 km buffer – 12.3 km^2	12.3 * 50.7 = 623
Area of 2 km buffer – 20.3 km^2 at 50% displacement.	(20.3 * 50.7)/2 = 515
Total potentially displaced	218 + 623 + 515 = 1,355

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on guillemots.

Outwith Aberdeen Bay there are a number of planned offshore wind farms in the Firth of Forth and the Moray Firth. The only data available is that from the Beatrice Demonstrator Project which recorded 19 guillemots over a period of 12 months pre-construction surveys (Talisman 2005). The size, scale and exact locations of the Round 3 and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of guillemots that may be present in the planned development areas. Consequently, it is not possible to determine whether there will be a cumulative or in-combination impact arising from the proposed plans. However, although the developments are within the potential foraging ranges of guillemots from a number of SPAs the, relatively far, distance the proposed development is from the other planned offshore wind farms and its relatively small scale reduces the risk of a potentially significant cumulative or in-combination effect.

4.35.6 Conclusions

Habitats Appraisal

Based on site specific data and the broad distribution of guillemots in Aberdeen Bay plus evidence from existing offshore wind farms indicating a very low collision risk and recognising that there is potential for some but not total avoidance and potentially some displacement it is predicted that there will not be any adverse effects on the SPAs for which guillemot is a qualifying species.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on guillemots.

4.36 Razorbill (*Alca torda*)

4.36.1 Protection & Conservation Status

The razorbill is listed in Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.36.2 Background

Razorbill

GB threshold	2,200 ind	1% of GB Pop[n]
Designated east coast sites where species is a noted feature	Buchan Ness to Collieston Coast: 4,179 ind. (2007) Fowlsheugh: 4,632 ind. (2009) Firth of Forth: 3,464 ind Troup Pennan & Lion's Heads	SNH 2011 JNCC 2011a
European population estimate	Breeding 430,000 – 770,000 pairs Wintering – >500,000 individuals	Birdlife 2004
European population trend	Status 'secure' Trend 'unknown'	Birdlife 2004
World population	610 – 630,000	Mitchell *et al* 2004

The global distribution of razorbill is restricted to the North Atlantic and adjacent waters of the Arctic. In the breeding season, adult razorbills concentrate in shallow coastal waters at or near breeding colonies, which are usually situated on steep cliffs, often in the vicinity of guillemots. Relatively little is known about movements of razorbills away from their breeding colonies, although they are believed to be more southerly than guillemots (Wernham *et al*. 2002). During the winter razorbills can occur in Firths and larger estuaries and shallow marine areas such as St. Andrews Bay (Forrester *et al.* 2007). Razorbills feed chiefly on fish, with some invertebrates. Sandeel are a favoured prey item, which they catch by underwater pursuit after diving from the surface.

There is an estimated 110,000 pairs of razorbill nesting in Britain of which 93,000 pairs occur in Scotland and approximately 9,000 individuals within the two main colonies in North-east Scotland.

In North-east Scotland razorbills occur widely across the region, particularly during the breeding season. Peak passage occurs during April with a smaller autumn passage recorded.

Boat-based surveys

Razorbills were recorded throughout the year and across the whole of the surveyed area. Peak numbers occurred during post-breeding surveys between June and September, particularly to the north of the proposed development area. Relatively lower numbers were recorded between November and February (Figure 4-104, Figure 4-105, Figure 4-106). Razorbills were recorded within the footprint of the proposed development with peak numbers during the breeding season.

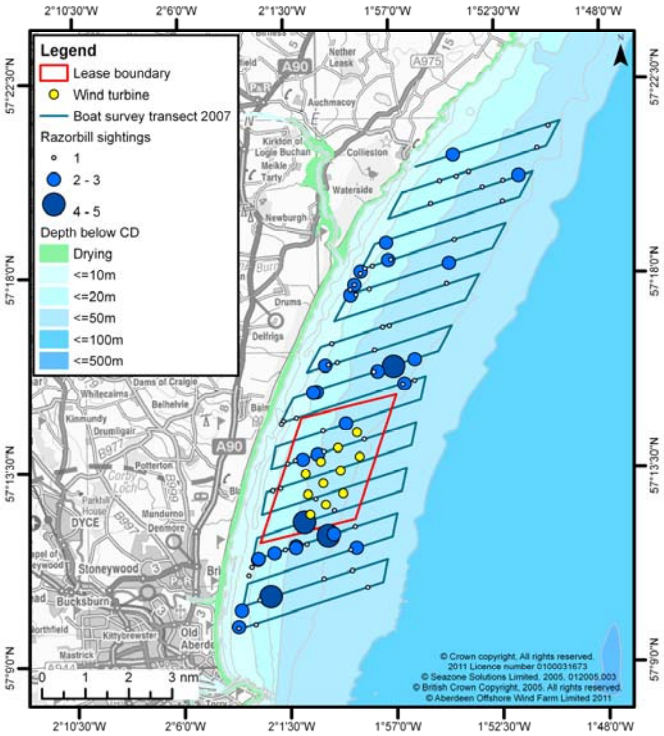

Figure 4-104: Razorbill distribution in Aberdeen Bay during winter period: November to February (all sightings).

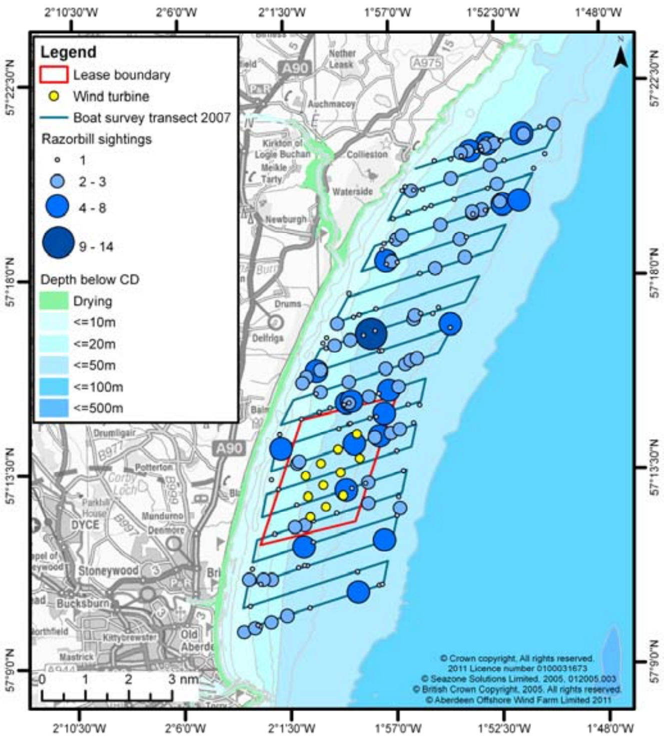

Figure 4-105: Razorbill distribution in Aberdeen Bay during breeding season: March to June (all sightings).

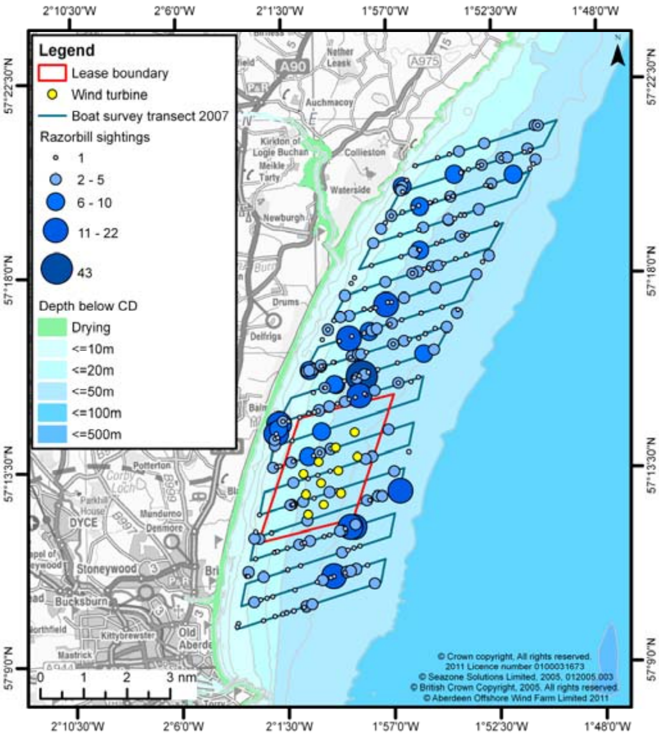

Figure 4-106: Razorbill distribution in Aberdeen Bay during post-breeding: July to October (all sightings).

Peak counts were of 378 birds in the ‘control’ area during July and 273 birds in the proposed EOWDC development area during in August (Figure 4-107).

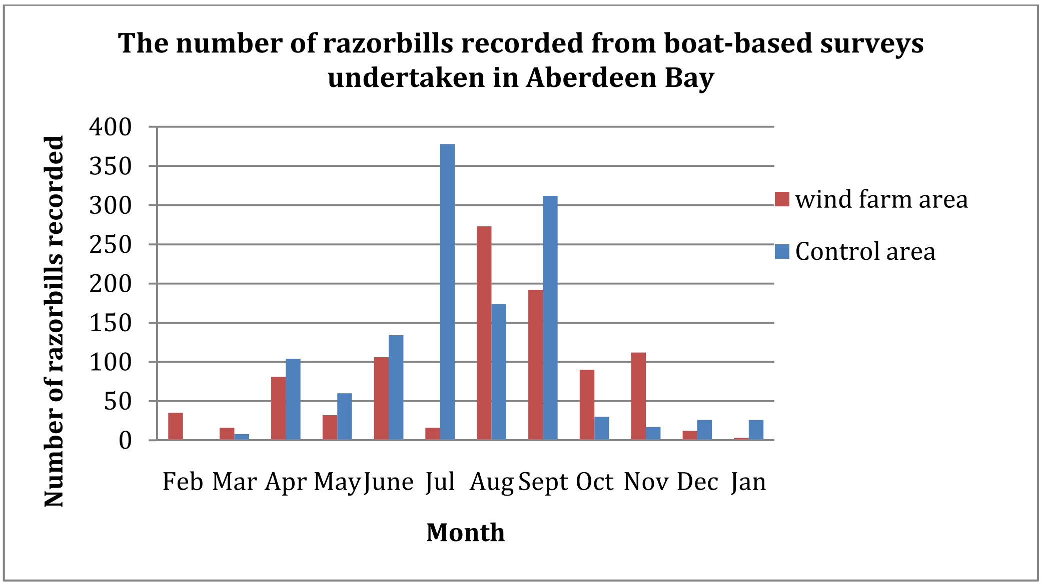

Figure 4-107: Razorbill monthly population estimates in proposed EOWDC and ‘control’ areas: Boat-based surveys 2007 – 2008.

Estimated abundances using *Distance* sampling on the first years of data, estimated peak abundance of razorbill within the proposed development during August with an estimated abundance of 359 birds. The highest abundance was within the ‘control’ area to the north with a total of 421 birds in October. Very low numbers were recorded throughout the area between January and March (Figure 4-108). Data obtained from between August 2010 and January 2011 recorded peak abundance in the northern survey area of 1,370 razorbills during August with decreasing numbers in most areas during the autumn and winter periods (Figure 4-109).

Peak densities of razorbills were 8.3 birds/km^2 within the ‘control’ area during October and 9 birds/km^2 in the southern and northern areas during August (Figure 4-109, Figure 4-110) (SMRU 2011b).

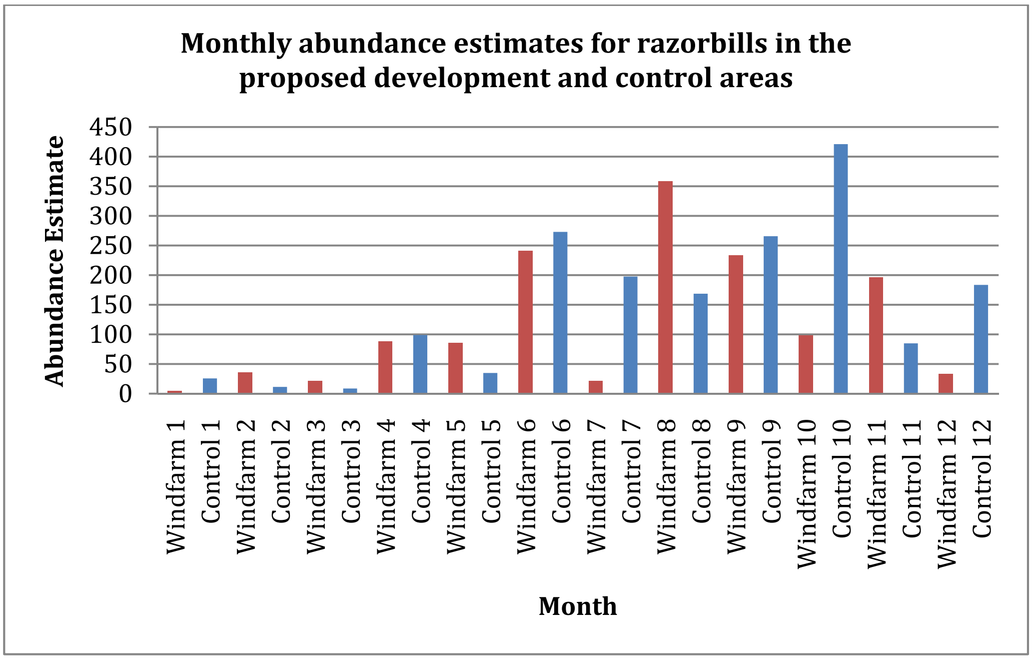

Figure 4-108: Monthly estimates (+/- SE) of abundance of razorbills in the proposed EOWDC and ‘control’ areas (Wind farm 1-12 and ‘control’ 1-12 refers to months).

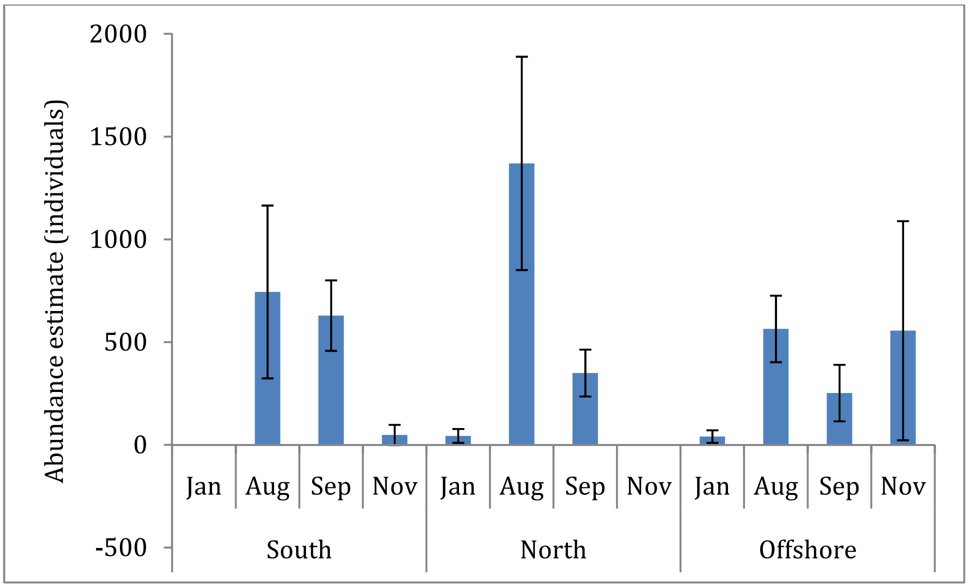

Figure 4-109: Monthly estimates (+/- SE) of abundance of Razorbill in the South, North and Offshore Strata.

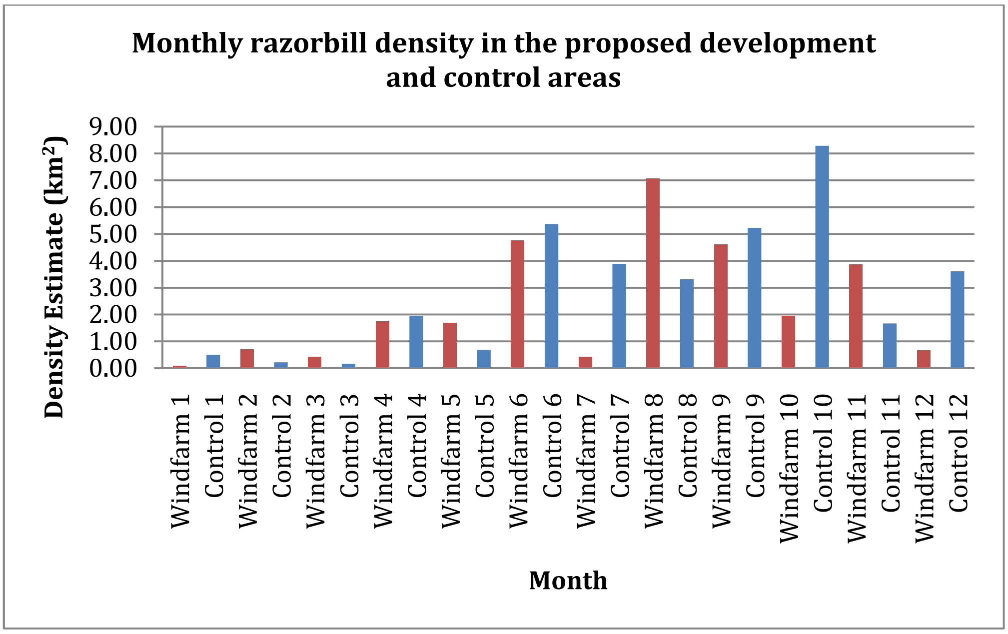

Figure 4-110: Monthly estimates (+/- SE) of density of razorbills in the proposed EOWDC and 'control' areas (Wind farm 1-12 and 'control' 1-12 refers to months).

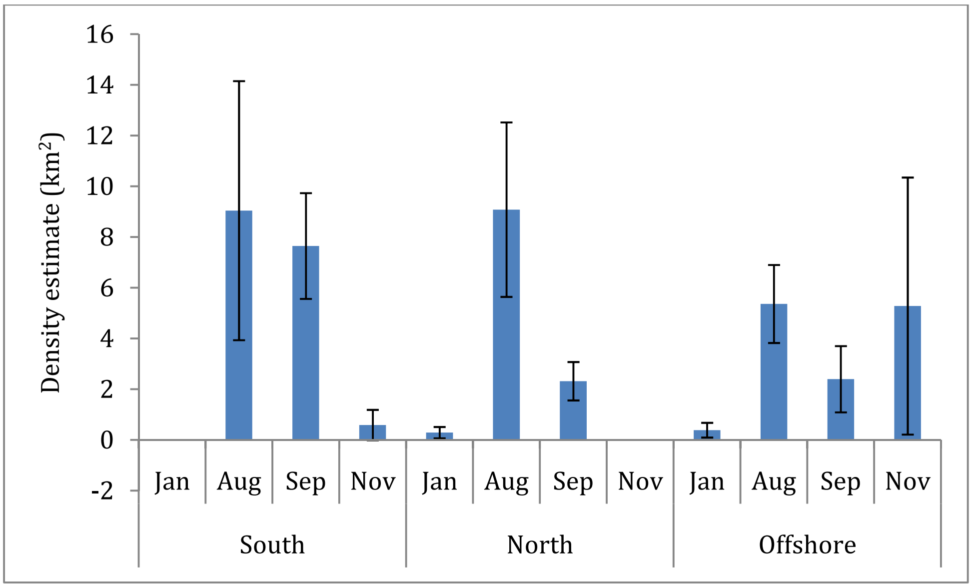

Figure 4-111: Monthly estimates (+/- SE) of density of Razorbill in the South, North and Offshore Strata.

Although birds were recorded in all water depths the majority of sightings were in areas where water depth was 20 m or below (IECS 2008). All those recorded in flight flew below 25 m.

Vantage Point surveys

Razorbills were recorded significantly less frequently in Aberdeen Bay than guillemots with a peak of up to seven birds per hour in March 2006 and five birds per hour during September 2007 (EnviroCentre 2007a,b; Alba Ecology 2008a). All birds recorded were flying below 30 m and unlike guillemot, most were flying between 1 and 2 km from shore.

Bird Detection Radar

There were no razorbills recorded during the radar surveys undertaken at Drums and Easter Hatton during October 2005. In April 2007 a total of 12 razorbills were recorded from Blackdog (Simms *et al*. 2007).

4.36.3 Summary of Results

Razorbills were widely recorded across Aberdeen Bay from all surveys. Low numbers were present at the beginning of the year but increased from April onwards. Data from boat-based surveys indicate peak counts in the bay between July and September but also a high count in October. Birds were recorded in relatively equal numbers across both the ‘control’ site and the proposed EOWDC survey area. Land based observations recorded peak numbers during April and September.

Data from boat-based surveys recorded razorbills widely across the surveyed areas and land-based observations recorded most birds from between 2.0 km and 4.0 km from the coast.

All those recorded in flight were seen to be flying below 25 m.

No counts during any surveys undertaken across Aberdeen Bay were of national importance.

4.36.4 Initial Assessment of Significance

Razorbill	Overall sensitivity	Magnitude	Significance
Collision	Very High	Negligible	Minor
Barrier	Medium	Medium	Minor
Displacement	High	Low	Minor

4.36.5 Species Sensitivities

Qualifying species

There are four SPAs in the region for which razorbill is a qualifying species: Buchan Ness to Collieston Coast, Fowlsheugh, Troup, Pennan and Lion's Head and Forth Islands SPA.

Flight height

Flight heights obtained from boat-based surveys undertaken in Aberdeen Bay recorded 354 razorbills in flight of which none were recorded as flying above 25 m and therefore at risk of collision.

Elsewhere out of 3,299 razorbills for which flight heights have been recorded 4% have been at rotor height.

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that razorbills are widespread and frequent within Aberdeen Bay and occur in relatively low densities throughout the area.

No razorbills have been reported as flying at rotor height within Aberdeen Bay or from other wind farms and no reports of collisions by razorbills have been found. Consequently, it is concluded that the risk of a collision with a turbine is very small and that collision mortality will not cause an adverse effect or significant impact to razorbills.

Barrier effect

As with guillemots, studies undertaken in Sweden and Denmark indicate that there is some potential for a barrier effect to occur with a reduced number of guillemots/razorbill crossing the constructed wind farms.

During the breeding season it is predicted that there may be regular flights to and from colonies some of which will intersect the proposed development area. The distance razorbills forage varies depending upon the availability of suitable prey and at what stage during the breeding season they are. Maximum foraging ranges are up to 150 km but most foraging occurs within 10 km of the colony (Roos 2010; Thaxter *et al*. 2010). Should a barrier effect occur with razorbills from either Fowlsheugh or Buchan Ness to Collieston Coast SPAs making daily movements from one location to another around the proposed development area then they may incur an additional flight distance of up 3.2 km each way, or a total of 6.4 km. This may increase the daily energy expenditure to between 2.0% and 2.5% (Speakman, Gray & Furness 2009).

The location and size of the proposed development is such that it will only occupy a relatively small zone through which birds may avoid flying. No significant concentrations of razorbills were recorded in the vicinity of the proposed development and therefore it is not considered to be a particularly favourable area for foraging. Regular daily movements by individual birds that could cause an incremental increase in distance of foraging flights on a daily basis is not predicted to occur, i.e. birds from colonies will forage over a wider area and will not need to detour around the proposed development on a regular daily basis.

Based on the above it concluded that the potential incremental increases in foraging distances are unlikely to cause an adverse effect or significant impact on razorbills.

Displacement

Based on the results from the monitoring data, the worst-case scenario is that should displacement occur, no razorbill will be within the proposed development area out to a distance of 1 km and a further 50% decrease in abundance occurs out to 2 km from the proposed development area.

Based on the peak density obtained from boat-based surveys of 9.0 birds/km^2 in the 'control' area during August, should there be a total displacement of razorbills from within the proposed development area it is predicted that up to 39 razorbills may be displaced during periods of peak density. Based on a 100% displacement out to 1 km from the proposed development area then it is predicted that up to 111 razorbills may be displaced and a further 91 out to 2 km should there be 50% displacement from between 1 km and 2 km. Therefore, the maximum number of razorbill potentially displaced is up to 241 birds based on the highest densities recorded from any survey within Aberdeen Bay and displacement out to 2 km.

Based on the estimated total of 241 razorbills potentially displaced out of a peak reported count of 1,369 razorbills (Figure 4-109), it is predicted that up to 18% of the razorbills within Aberdeen Bay may be displaced. This is based on a peak density obtained from surveys to the north of the development area and are therefore unlikely to be impacted by displacement effects; consequently the figure used is precautionary.

Based on the regional SPA population of 12,175 razorbills then approximately 1.9% of the regional population may be displaced.

Site-specific surveys recorded razorbills throughout the survey area and no specific concentrations were detected; although densities tended to be higher to the north of the proposed development area. However, should there be a displacement effect there is no evidence to suggest that the loss of the area of the proposed development will be significant and that individuals displaced will not be able to find suitable foraging areas elsewhere. Therefore, there is no evidence to suggest that any displacement will have a negative impact on razorbills.

Post-construction monitoring undertaken at Horns Rev offshore wind farm has indicated that displacement of razorbills occur. However, results from other operating wind farms suggest that this may not be the case and that total displacement from the are of the proposed development may not occur. Densities of razorbills within the area were not higher than elsewhere and consequently it is not thought that the proposed location is of particular importance, particularly as densities of razorbills tended to be higher to the north. Consequently, should displacement occur there are other areas where razorbills could relocate and it is predicted that any potential impact caused by displacement will be minor.

Calculations used for displacement	
Area	*Peak density of razorbill – 9.0 birds/km^2*
Area of EOWDC – 4.3 km^2	4.3 * 9.0 = 39
Area of 1 km buffer – 12.3 km^2	12.3 * 9 = 111
Area of 2 km buffer – 20.3 km^2 (50% displacement)	(20.3 * 9)/2 = 91
Total number at potential displacement	39+111+91 = 241

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on razorbills.

Outwith Aberdeen Bay there are a number of planned offshore wind farms in the Firth of Forth and the Moray Firth. The only data available is that from the Beatrice Demonstrator Project which recorded one razorbill over a period of 12 months pre-construction surveys (Talisman 2005). The size, scale and exact locations of the Round 3 and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of razorbills that may be present in the planned development areas. Consequently, it is not possible to determine whether there will be a cumulative or in-combination impact arising from the proposed plans. However, although the developments are within the potential foraging ranges of razorbills from a number of SPAs the relatively far distance the proposed development is from the other planned offshore wind farms and it's relatively small scale reduces the risk of a potentially significant cumulative or in-combination effect.

4.36.6 Conclusions

Habitats Appraisal

Based on site specific data and broad distribution of razorbills in Aberdeen Bay plus evidence from existing offshore wind farms indicating a very low collision risk and recognising that there is potential for some but not total avoidance and potentially some displacement it is predicted that there will not be any adverse effects on the SPA for which razorbill is a qualifying species.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on razorbills.

4.37 Guillemot/Razorbill (*Uria alage/Alca torda*)

4.37.1 Background

Guillemot and razorbill can be difficult to separate in the field and consequently a proportion of birds are not identified to either species but are instead recorded as either guillemot or razorbill.

Boat-based surveys

Data from boat-based surveys undertaken between February 2007 and January 2008 indicate a similar pattern of distribution for guillemot/razorbill as was found for each individual species. Peak numbers occurred during July with an estimated 4,058 birds recorded in the 'control' area to the north and 1,620 in the wider proposed development area. Outwith the peak post-breeding period there was an estimated density of less than 6 birds/km^2 from November through to March. Throughout the year densities and abundance were greater within the 'control' area than within the proposed development area (Table 4-30, Figure 4-110, Figure 4-108).

Within the footprint of the proposed development relatively low numbers of guillemots/razorbills were recorded particularly during the breeding and post-breeding seasons.

Table 4-30: Monthly estimates of density and abundance of guillemots, razorbills and individuals not identified to either species in the proposed EOWDC and 'control' areas.

Month	Location	Density Estimate (km^2)	SE	Estimated Abundance	SE	No. Observations
January	EOWDC	2.154	0.509	109	25.9	30

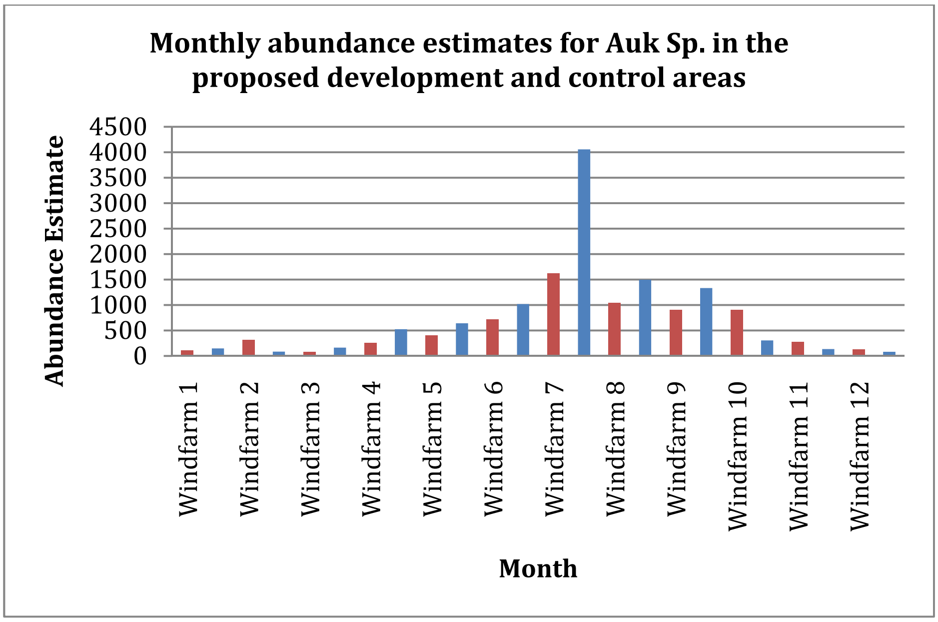

Figure 4-113: Monthly estimates (+/- SE) of abundance of guillemots, razorbills and individuals not identified to species in the 'wind farm' and 'Control' areas (Wind farm 1-12 and 'control' 1-12 refers to months).

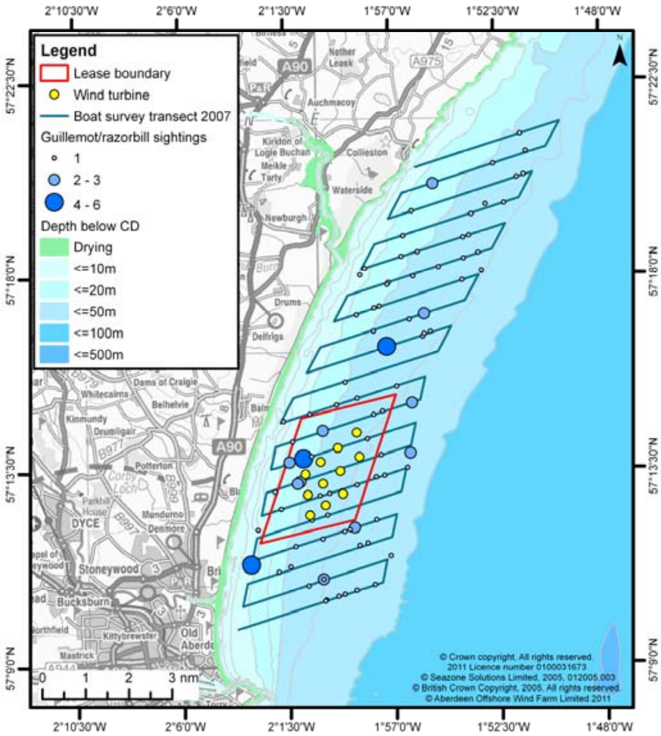

Figure 4-114: Guillemot/Razorbill distribution in Aberdeen Bay during winter period: November to February (all sightings).

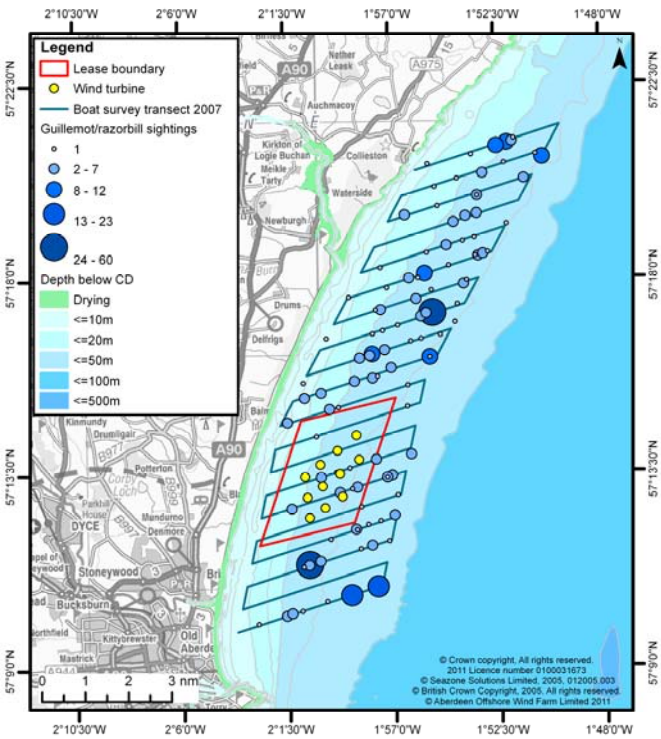

Figure 4-115: Guillemot/Razorbill distribution in Aberdeen Bay during breeding season: March to June (all sightings).

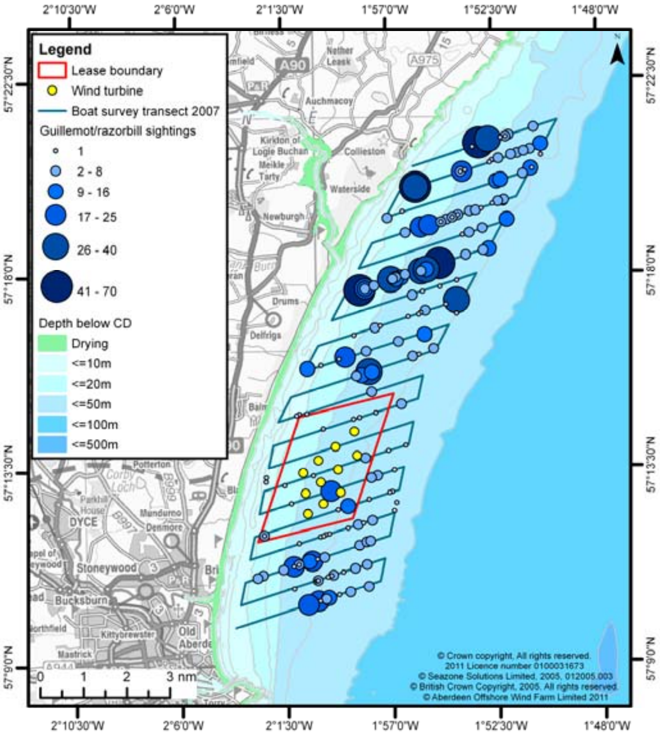

Figure 4-116: Guillemot/Razorbill distribution in Aberdeen Bay during post-breeding: July to October (all sightings).

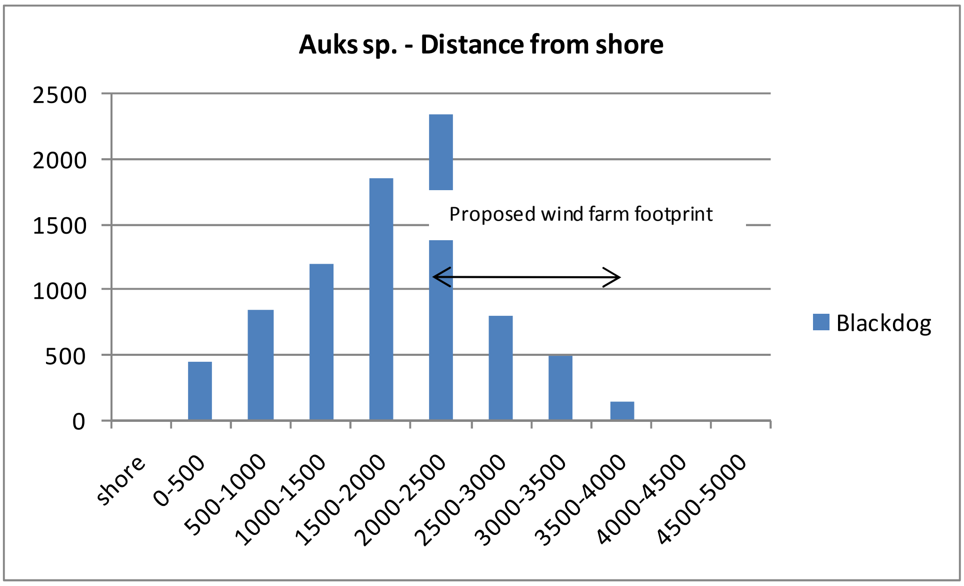
Vantage Point surveys

Unidentified Auks were recorded throughout the year during Vantage Point surveys. Peak numbers occurred during April when up to 600 birds an hour were recorded passing Drums and November when up to 120 birds per hour were recorded passing Balmedie. Aside from these two peak counts numbers passing all Vantage Point sites were considerably lower and often less than 10 birds per hour at other sites during the same period (Alba Ecology 2008a). During the breeding season the numbers of unidentified Auks was lower than during the post-breeding season.

Bird Detection Radar

A total of 38 Auks were not identified to species level during surveys undertaken at Drums and Easter Hatton during October 2005. During the seventeen days of radar surveys undertaken in April 2007, a total of 7,787 unidentified Auks were recorded with a mean passage rate of 153 birds per hour making this the most frequently recorded 'species' during the April surveys. There was a distinct peak of up to 2,500 birds passing per hour on the evening of 12 April (Simms *et al*. 2007). The majority of sightings were within 1.5 km and 3 km from the coast (Figure 4-117)



(Adapted from Simms *et al*. 2007)

Figure 4-117: Distances from shore for Auks Sp. from Blackdog (April 2007).

4.37.2 Summary of Results

Unidentified Auks were widely recorded across Aberdeen Bay from all surveys. Relatively low numbers were present at the beginning of the year but increased from April onwards. Data from surveys indicate peak numbers in the bay during July with a decrease in numbers from August onwards. Significantly more birds were recorded in the 'control' area than within the proposed development area.

Data from boat-based surveys recorded unidentified Auks widely across the surveyed areas and land-based observations recorded most from between 2.0 km and 4.0 km from the coast.

4.37.3 Initial Assessment of Significance

Guillemot/Razorbill	Overall sensitivity	Magnitude	Significance
Collision	Very High	Negligible	Minor
Barrier	Medium	Medium	Minor
Displacement	High	Low	Minor

4.37.4 Species Sensitivities

Qualifying species

There are four SPAs in the region for which both guillemots and razorbills are a qualifying species: Buchan Ness to Collieston Coast, Fowlsheugh, Troup, Pennan and Lion's Head and Forth Islands SPA.

Flight height

Flight heights for both guillemots and razorbill are discussed previously and both species show that between 96% and 100% of flights are below turbine height.

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that both guillemots and razorbill are widespread and frequent within Aberdeen Bay and occur throughout the area.

Collision Risk Modelling undertaken for guillemot has indicated a very low risk of collision and it is likely that the majority of unidentified guillemot/razorbills will be of this species. The number of birds recorded in flight was very similar to guillemot and it is therefore predicted that the total number of birds at risk of collision is very low and that there will not be a significant impact on the guillemot/razorbill due to collisions.

Barrier effect

The potential barrier effect for guillemot/razorbill has been addressed previously under the respective species sections.

Displacement

To determine the potential impacts on guillemots/razorbill from displacement it is assumed that there will be total displacement within the proposed development area and out to a distance of 1 km and then a further 50% decrease in abundance out to 2 km from the proposed development area.

Based on the peak density obtained from boat-based surveys of 79.8 birds/km^2 in the 'control' area during July, should there be a total displacement of guillemot/razorbills from within the proposed development area it is predicted that up to 2,133 birds may be displaced out to 2 km during periods of peak density. Based on peak densities recorded within the proposed development area, which were lower, 850 guillemots/razorbill may be displaced.

Based on the regional population 101,000 guillemot and razorbills obtained from the regional SPA counts then between 1% and 2% of the regional population may be displaced. However, as previously discussed, total avoidance is not considered likely and any displaced birds will be able to find other alternative foraging areas based on the broad distribution of guillemots in the area and their wide foraging areas. Consequently it is not thought any significant impact or adverse effect will occur.

Calculations used for displacement	'control'	EOWDC
Area	*Peak density of guillemot/razorbill – 79.8 birds/km^2*	*Peak density of guillemot/razorbill –31.8 birds/km^2*
Area of EOWDC – 4.3 km^2	4.3 * 79.8 = 343	4.3 * 31.8 = 137
Area of 1 km buffer – 12.3 km^2	12.3 * 79.8 = 981	12.3 * 31.8= 391
Area of 2 km buffer – 20.3 km^2 (50% displacement)	(20.3 * 79.8)/2 = 809	(20.3 * 31.8)/2 = 322
Total potential displacement	343 + 981 + 809 = 2,133	137 + 391 + 322 = 850

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on either guillemots or razorbills. Information required to inform potential cumulative impacts from possible future offshore wind farm projects outwith Aberdeen Bay is currently unavailable. However, the relative distance the proposed development is from the other planned offshore wind farms and its relatively small scale reduces the risk of a potentially significant cumulative or in-combination effect.

4.37.5 Conclusions

Habitats Appraisal

Based on site specific data and broad distribution of both guillemots and razorbills in Aberdeen Bay plus evidence from existing offshore wind farms indicating a very low collision risk and recognising that there is potential for some but not total avoidance and, potentially, some displacement it is predicted that there will not be any adverse effects on the SPAs for which either guillemot or razorbill are qualifying species.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on guillemots or razorbills.

4.38 Atlantic Puffin (*Fratecula arctica*)

4.38.1 Protection & Conservation Status

The (Atlantic) puffin is listed in Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.38.2 Background

Puffin		
GB Population	Breeding: 579,000 prs	BTO 2011
Scottish population	Breeding: 493,000 prs Winter: est. 20,000 ind	Forrester *et al.* 2007
International threshold	Unknown	-
GB threshold	10,400 ind.	1% of GB Pop[n]
Designated east coast sites where species is a noted feature	Firth of Forth (58,867 AoN)	SNH 2011 JNCC 2011a
European population estimate	Breeding 5,700,000 – 7,300,000 pairs Wintering – unknown	Birdlife 2004
European population trend	Status 'depleted' Trend 'unknown'	Birdlife 2004
World population	5,500,000 – 6,600,000 pairs	Mitchell *et al* 2004

Puffins are restricted to the North Atlantic and adjacent waters of the Arctic, with the species main stronghold in Iceland and north Norway. Puffins remain offshore until the breeding season when they move inshore and start attending colonies during early spring. The species is highly colonial, with pairs typically nesting in underground burrows dug in the soil of offshore islands. Following breeding, puffins leave the colonies and disperse widely to offshore waters. Puffins mainly feed on fish with sandeels a favoured prey item that they catch by underwater pursuit after diving from the surface.

The UK breeding population is estimated to be approximately 600,000 pairs of which 493,000 are in Scotland and 2,500 nest in North-east Scotland.

In North-east Scotland puffins are rarely recorded outwith the breeding season with peak counts past Peterhead of up to 15 birds per hour in June and July.

Boat-based survey

Unlike guillemots and razorbills, puffins were recorded predominantly in water depths of 30 m or more, with relatively few birds in near-shore waters. There were very few records of puffin between November and February with numbers increasing from March onwards. However, numbers in Aberdeen Bay were still relatively low with peak concentrations during the breeding season near Collieston where small numbers breed. Peak numbers occurred in the post-breeding season between August and October with the majority of birds to the north and very few records within the footprint of the proposed development area (Figure 4-118, Figure 4-119, Figure 4-120).

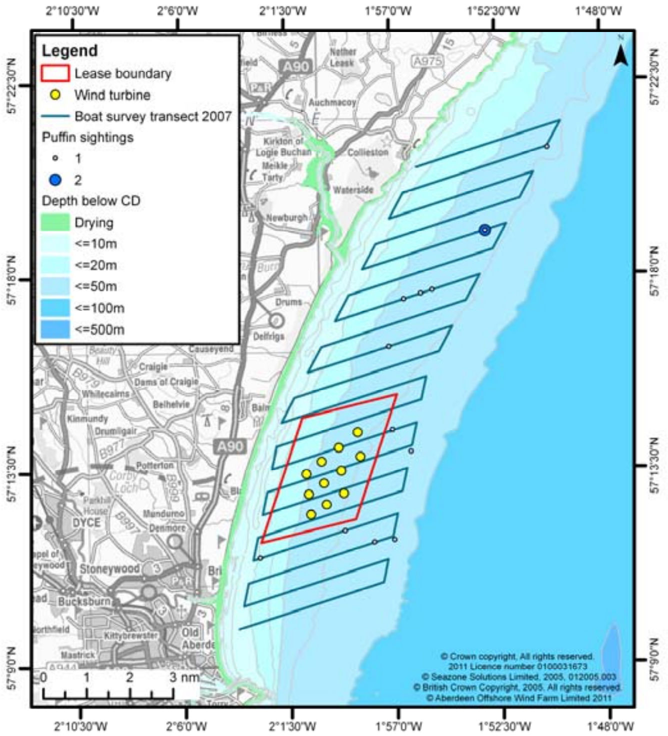


Figure 4-118: Puffin distribution in Aberdeen Bay during winter period: October to February (all sightings).

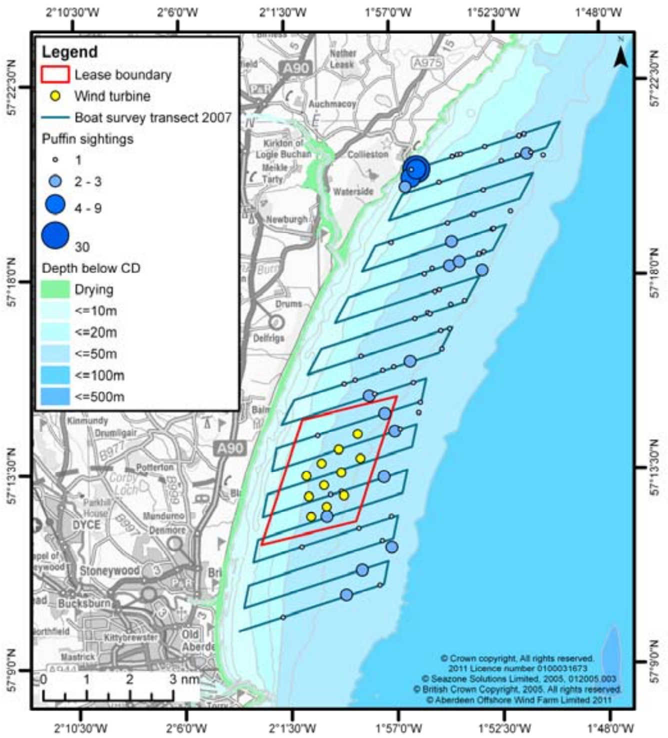

Figure 4-119: Puffin distribution in Aberdeen Bay during breeding season: March to July (all sightings).

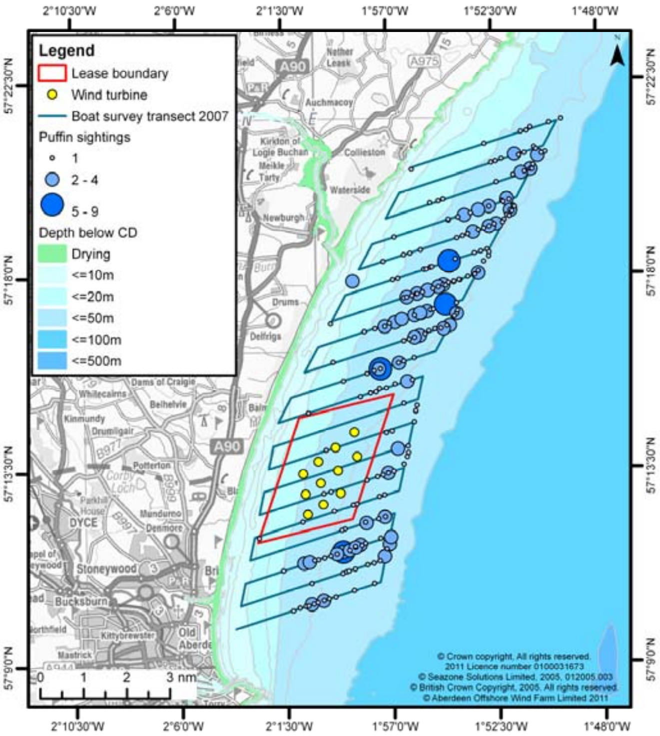

Figure 4-120: Puffin distribution in Aberdeen Bay during post-breeding: August to September (all sightings).

Puffins were only recorded between May and November with peak counts in the post-breeding season with an estimated population of 700 and 800 birds in the northern survey area during August and September 2010 and 1,347 individuals in offshore waters during August. Within the 'control' area peak abundance was during September when 357 individuals were estimated within the 'control' area and 48 were present in the proposed EOWDC development area. Within the proposed EOWDC development area peak numbers of puffin occurred during August and October when peak counts of 175 and 163 respectively were recorded (Figure 4-123, Figure 4-121).

Peak densities also occurred between August to October when 12.8 birds/km^2 were recorded in offshore areas during August and 7 birds/km^2 during October in the 'control' area. Within the proposed development area a peak density of 3.4 birds/km^2 was recorded in August.

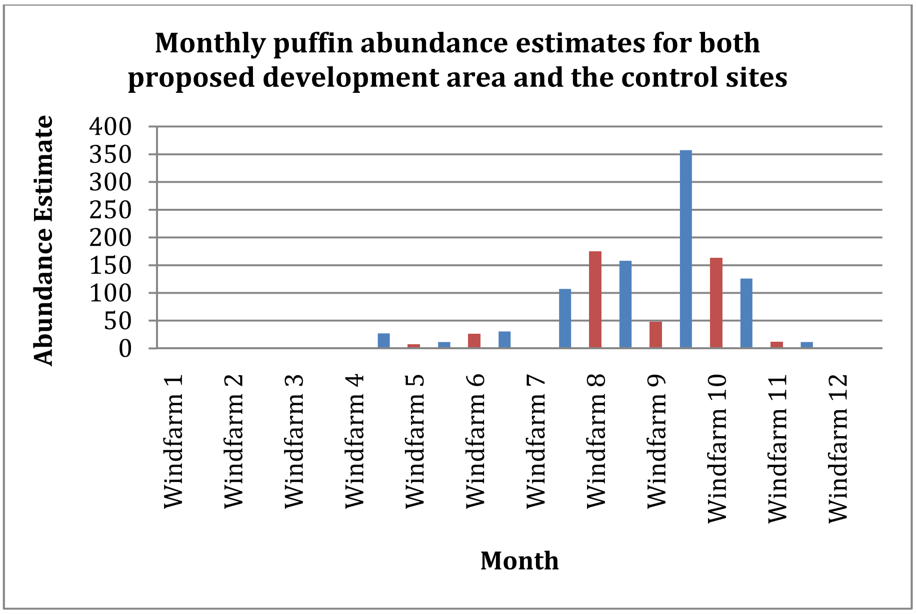

Figure 4-121: Monthly estimates (+/- SE) of abundance of puffins in the proposed EOWDC and 'Control' areas; February 2007 to January 2008 ('Windfarm' 1-12 and 'Control' 1-12 refers to months).

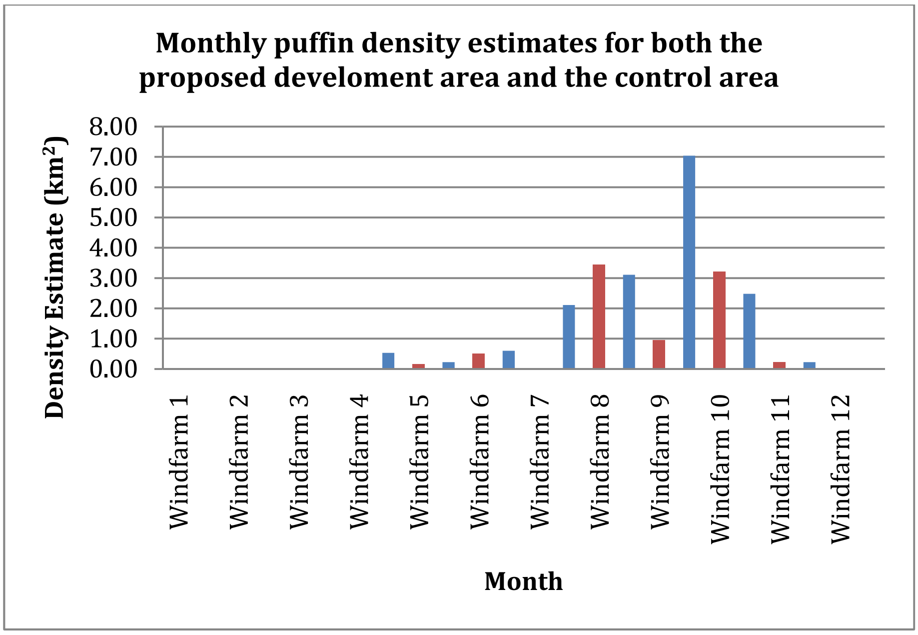

Figure 4-123: Monthly estimates (+/- SE) of density of puffins in the proposed EOWDC and 'control' areas February 2007 to January 2008 ('Windfarm' 1-12 and 'Control' 1-12 refers to months).

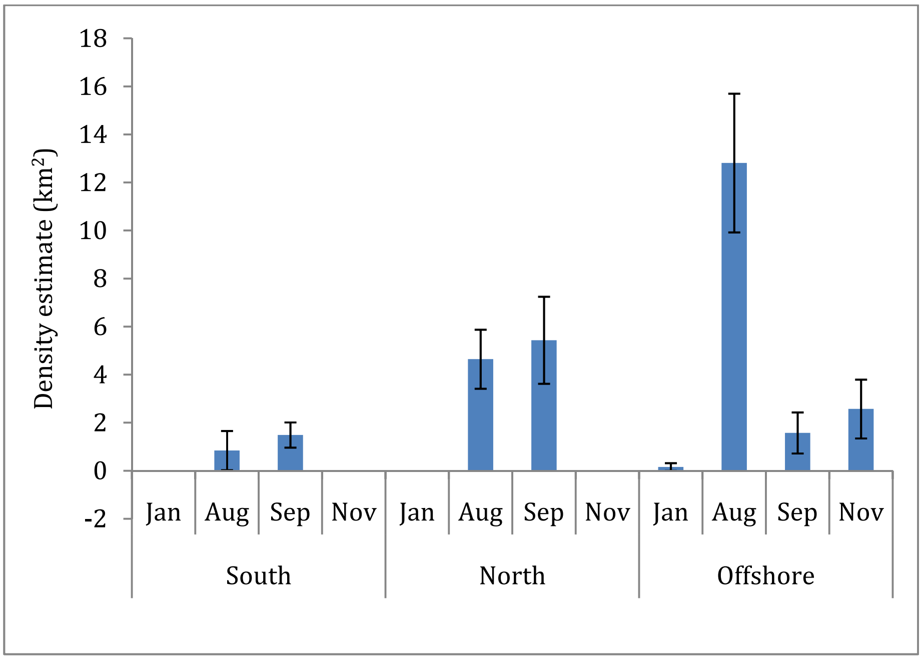

Figure 4-124: Monthly estimates (+/- SE) of density of Atlantic Puffin in the South, North and Offshore Strata; August 2010 to January 2011.

Vantage Point surveys

In Aberdeen Bay puffins were scarce during the winter period with only one sighting between October 2006 and March 2007. Between April and September low numbers of puffin were recorded with a passage of two birds per hour and a peak of three birds per hour in April. All sightings were of birds flying below 30 m and between 1 km and 3 km from shore.

Bird Detection Radar

One puffin was recorded during radar studies in October 2005 (Walls *et al* 2005).

4.38.3 Summary of Results

Puffins were widely recorded across Aberdeen Bay from all surveys. No puffins were recorded between December and March and relatively low numbers were recorded until July when the number of puffins recorded increased with a peak during the post-breeding period. Peak numbers of puffins during July and September were recorded within the 'control' area whereas in August and October peak numbers were within the proposed development area.

Of those recorded in flight, all puffins recorded during boat-based and land-based surveys were recorded as flying below 30 m.

No counts of puffin from any of the surveys undertaken within Aberdeen Bay were of national importance.

4.38.4 Initial Assessment of Significance

Guillemot	Overall sensitivity	Magnitude	Significance
Collision	Very High	Negligible	Minor
Barrier	Medium	Medium	Minor
Displacement	Medium	Low	Minor

4.38.5 Species Sensitivities

Qualifying species

The only SPA in the region for which puffin is a qualifying species is the Forth Islands SPA where 58,867 pairs of puffins nest on the Isle of May.

Flight height

Flight heights obtained from boat-based surveys undertaken in Aberdeen Bay recorded 32 puffins in flight none of which were recorded as flying above 25 m and therefore at risk of collision.

Elsewhere in the UK very few puffins have been recorded in flight and all have been below turbine height (n=35).

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that puffins are widespread and frequent within Aberdeen Bay and occur in relatively low densities throughout the area.

No puffins were recorded as flying at rotor height within Aberdeen Bay or from other wind farms and no reports of collisions of puffins have been found. Consequently, it is concluded that the risk of a collision with a turbine is very small and that any collision mortality, should it occur, will not cause an adverse effect or significant impact to puffins

Barrier effect

There is no data available to determine whether puffins may be impacted by a barrier effect as very few puffins have been reported near to constructed offshore wind farms.

During the breeding season it is predicted that there may be regular flights to and from colonies some of which will intersect the proposed development area. The distance puffins' forage varies depending upon the availability of suitable prey and at what stage during the breeding season they are. Maximum foraging ranges are up to 137 km away from the colony although most foraging ranges will be considerably closer than this (Roos 2010; Thaxter *et al*. 2010). Should a barrier effect occur with birds from Fowlsheugh or to the north of Collieston making daily movements from one location to another around the proposed development area then they may incur an additional flight distance of up 3.2 km each way, or a total of 6.4 km. This may increase the daily energy expenditure to between 2.0% and 2.5% (Speakman, Gray & Furness 2009).

The location and size of the proposed development is such that it will only occupy a relatively small zone through which birds may avoid flying. No significant concentrations of puffins were recorded but they did tend to occur further offshore than either guillemot or razorbill and therefore have a higher potential to interact with the proposed development. However, puffins had a wide distribution offshore and regular daily movements by individual birds that could cause an incremental increase in the length of foraging flights on a daily basis is not predicted to occur, i.e. birds from colonies will forage over a wider area and will not need to detour around the proposed development on a regular daily basis.

Based on the above it is concluded that the potential incremental increases in foraging distances are unlikely to cause an adverse effect or significant impact on puffins.

Displacement

The worst-case scenario is that should 100% displacement occur, no puffin will be within the proposed development area out to a distance of 1 km and then a further 50% decrease in abundance occurs out to 2 km from the proposed development area.

Based on the peak density obtained from boat-based surveys of 12.8 birds/km^2 in the offshore area during August, should there be a total displacement of puffins from within the proposed development area it is predicted that up to 55 puffins may be displaced during periods of peak density. Based on a 100% displacement out to 1 km from the proposed development area then it is predicted that up to 157 puffins may be displaced and a further 130 out to 2 km should there be 50% displacement from between 1 km and 2 km. Therefore, the maximum number of puffin potentially displaced is up to 342 birds based on the highest densities recorded from any survey within Aberdeen Bay and displacement out to 2 km.

Based on the estimated total of 342 puffins potentially displaced out of a peak reported count of 1,347 (Figure 4-121), it is predicted that up to 25% of the puffins within Aberdeen Bay may be displaced. However, this is based on a peak density obtained from surveys further offshore from the development and densities within the proposed development area were significantly lower at between 3 and 5 birds per/km^2.

Based on the regional SPA population 117,734 puffins and the highest densities recorded from site specific surveys approximately 0.3% of the regional population may be displaced.

Site specific surveys recorded puffins throughout the survey area and no specific concentrations were detected; although densities tended to be higher further offshore compared to those recorded from the proposed development area. Should there be a displacement effect there is no evidence to suggest that the loss of the area of the proposed development will be significant and that individuals displaced will not be able to find suitable foraging areas elsewhere. Therefore, there is no evidence to suggest that any displacement will have a negative impact on puffins.

Densities of puffins within the proposed development area were not higher than elsewhere and consequently it is not thought that the proposed location is of particular importance for puffin, particularly as densities tended to be higher further offshore and in the 'control' area. Consequently, should displacement occur there are other areas where puffins could relocate and it is predicted that any potential impact caused by displacement will be minor.

Calculations used for displacement	
Area	*Peak density of puffin – 12.8 birds/km^2*
Area of EOWDC – 4.3 km^2	4.3 * 12.8 = 55
Area of 1 km buffer – 12.3 km^2	12.3 * 12.8 = 157
Area of 2 km buffer = 20.3 km^2. Area of 50% displacement	(20.3 * 12.8)/2 = 130
Total potential displacement	55 + 157 + 130 = 342

Cumulative and in-combination

There are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts on puffins.

Outwith Aberdeen Bay there are a number of planned offshore wind farms in the Firth of Forth and the Moray Firth. The only data available is that from the Beatrice Demonstrator Project which recorded 16 puffins over a period of 12 months pre-construction surveys (Talisman 2005). The size, scale and exact locations of the Round 3 and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of puffins that may be present in the planned development areas. Consequently, it is not possible to determine whether there will be a cumulative or in-combination impact arising from the proposed plans. However, although the developments within the Firth of Forth area are within foraging ranges of puffins from the Isle of May the relatively large distance the proposed development is from the other planned offshore wind farms and its relatively small scale reduces the risk of a potentially significant cumulative or in-combination effect.

4.38.6 Conclusions

Habitats Appraisal

Based on the distance the relevant SPA is from the proposed development site and the broad distribution of puffins in Aberdeen it is predicted that there will not be an adverse effect on the SPA for which puffin is a qualifying species.

Environmental Impact Assessment

Based on the numbers and distribution of puffins in Aberdeen Bay and their predicted behaviour towards wind farms it is concluded that there will not be a significant environmental impact arising from the proposed development on puffins.

5 OTHER SPECIES

The following bird species were recorded during the surveys undertaken within Aberdeen Bay, including radar studies and Vantage Point Counts. The numbers recorded for the following species were either low or they are not qualifying species for any SPAs likely to be affected by the proposed development.

Further detailed assessment for these species has not been undertaken as either the numbers recorded were very low or, as was the case for most waders, the majority of records were of birds within very close proximity to shore or even, on occasions, overland. Consequently, the risk of an interaction with the proposed development is negligible.

5.1 Mute swan

Four mute swans were recorded during the Vantage Point surveys with three in April 2007 and one in December 2006 (AlbaEcology 2008a, EnviroCenter 2007b).

5.2 Brent goose

Twenty Brent geese were recorded of Murcar in September 2005 and a further 19 from visual observations undertaken at the same time as the Bird Detection Radar studies in October 2005. A further skein of five birds was recorded in during further radar studies in April 2007 (Walls *et al.* 2006, Simms *et al.* 2007).

5.3 Tufted duck

A pair of tufted duck were recorded flying north in April 2007 from boat-based surveys and 11 were recorded at Blackdog during the radar surveys undertaken in April 2007 (Simms *et al.* 2007).

5.4 Black-throated diver

A single black-throated diver was recorded heading south past Blackdog in September 2006 it was recorded flying between, 0-30 m above sea level and between 1-2 km offshore (EnviroCentre 2007a). A further black-throated diver was seen flying past Blackdog in January 2007 and two past Don Mouth in February 2007 (EnviroCentre 2007b). One black-throated diver was recorded at Blackdog during the April 2007 radar surveys (Simms *et al.* 2007).

5.5 Great northern Diver

One great northern diver was recorded from boat-based surveys in January 2011.

Seven great northern divers were recorded from Vantage Point surveys undertaken between March 2005 and March 2008. Singles were recorded in June, July, August, and December and three in September. All were recorded flying below 30 m (Alba Ecology 2008a, EnviroCenter 2007b).

5.6 Sooty shearwater

A single sighting in November 2010 was the only record from boat-based surveys (SMRU 2011b). During Vantage Point surveys undertaken between April and October 2006 a total of 12 sooty shearwaters were recorded and a further 15 between April 2007 and November 2007 (EnviroCentre 2007a, Alba Ecology 2008a,b). All sightings were of birds flying below 30 metres and predominantly more than 2 km from shore. One sooty shearwater was recorded flying north in October and one was recorded at Drums, during the radar studies in October 2005. (IECS 2008; Walls *et al*. 2005).

5.7 European Storm petrel

One record from Vantage Point surveys was of a single bird in October 2007.

5.8 Grey Heron

Singles at Murcar in August 2005, Drums in October 2005, Donmouth in June 2006 and Balmedie in August 2006 were the only records. One was seen from boat-based surveys undertaken in August 2010.

5.9 Sparrowhawk

One was recorded during radar surveys in April 2007.

5.10 Kestrel

One kestrel was recorded at the Donmouth in March 2007.

5.11 Buzzard

One was recorded during radar surveys undertaken in April 2007.

5.12 Osprey

A single osprey was seen at the Donmouth in July 2007.

5.13 Oystercatcher

Small numbers recorded from land based observations with maximum counts of 10 in August 2006 and 11 in April 2006 at Drums and 43 at Blackdog in April 2007.

5.14 Ringed plover

Fifteen ringed plover were recorded at Drums in October 2005.

5.15 Northern Lapwing

A total of 930 lapwing were recorded at Drums in October 2005.

5.16 Knot

15 at Balmedie in August 2005 and Four in January at the Donmouth were the only records.

5.17 Sanderling

Small numbers of sanderling were regularly recorded along the beach of Aberdeen Bay. Peak totals were of 110 at Blackdog in April 2007, 49 at Easter Hatton in October 2005 and 12 at Blackdog during September 2006.

5.18 Dunlin

Small numbers of dunlin were recorded during land-based counts with four at Drums and 11 at Blackdog in June 2006. Two dunlin were recorded from boat-based surveys both flying below 30 m.

5.19 Black-tailed godwit

Eighteen black-tailed godwits in April at Blackdog in 2007 was the only record.

5.20 Bar-tailed godwit

Six at Balmedie in April 2005, one at Drums in October 2005, one in September 2006 and two in April 2006 both at Blackdog were the only sightings.

5.21 Whimbrel

Singles at Drums in April 2005 June 2006 at Blackdog and Drums in April 2006 were the only records.

5.22 Curlew

Curlew were generally regularly recorded in small numbers of less than 40 birds throughout the year from land-based observations. One exception was of counts undertaken in October 2005 when 941 were recorded at Drums and 235 at Easter Hatton.

5.23 Redshank

Three sightings of redshank were all from Blackdog where there were 25 in April 2006, seven in June 2006 and 27 in April 2007. There were no other sightings of redshank from other land-based or boat-based surveys.

5.24 Turnstone

Three turnstone were recorded from land-based counts in October 2005.

5.25 Long-tailed skua

There was one record, in May, of an adult long-tailed skua flying north from boat-based surveys.

5.26 Pomarine skua

In Aberdeen Bay, Pomarine skuas were recorded in very small numbers between June and September with 2 in June and one in August. All records were of birds flying below 30 m. A further 12 Pomarine skuas were recorded during radar studies undertaken in October 2005. Six were at Drums and six at Easter Hatton (Walls *et al* 2005).

5.27 Glaucous gull

A total of seven glaucous gulls were recorded from the surveys. All were made during Vantage Point counts with a total of six records at Blackdog between November 2007 and March 2008 and one at the Donmouth in February 2008.

5.28 Little gull

In Aberdeen Bay little gulls are scarce with four at drums in May 2005 and a total of twenty recorded between April and July 2006 with a peak count in May 2006 of up to 2 birds per hour (EnviroCentre 2007a). There were no records of little gulls during 2007 surveys and only one record in March 2008.

There was one further record in August 2010 (SMRU 2011b).

Little gulls were recorded out to 3 km from shore and half of all sightings were of birds flying between 30-150 m.

One little gull was recorded at Easter Hatton during the radar studies in October 2005. (Walls *et al* 2005).

5.29 Sabine's gull

One was seen from Easter Hatton during radar studies in October 2005 (Walls *et al*. 2006).

5.30 Black guillemot

There were two records of black guillemot from Vantage Point surveys: four birds of Drums in November 2007 and one there in March 2008.

5.31 Little auk

The majority of records of little auk were from surveys undertaken in November 2007 when up to 194 little auks were recorded from land-based observations. Boat-based records were during October and November with a total of 12 birds seen. A further five were recorded in April 2007. All sightings were of birds in flight, flying below 15 m.

5.32 Woodpigeon

A single woodpigeon was seen in April 2007.

5.33 Swift

Two in June 2007 at the Donmouth.

5.34 Skylark

Two skylark were seen in April 2007.

5.35 Swallow

There were only a few sightings of swallows reported from land-based observations with a maximum 8 at Blackdog in April 2007 and ones or twos from other observation points during the summer months.

5.36 Sand martin

A single sand martin was recorded during April 2007 at Blackdog.

5.37 Meadow pipit

A single meadow pipit was recorded in March 2007 at the Donmouth.

5.38 Redstart

Two redstarts were recorded at Easter Hatton during October 2005.

5.39 Blackbird

A flock of 25 blackbirds were recorded from land-based observations undertaken at Drums during November 2007.

5.40 Redwing

A single redwing was recorded in October 2005.

5.41 Carrion Crow

Four carrion crows were recorded from land-based observations in April 2007. One at the Donmouth, two at Blackdog and one at Balmedie.

5.42 Linnet

Four linnets were recorded from land-based counts in April 2007.

5.43 Snow bunting

A flock of thirteen were recorded at Blackdog during November 2007.

6 SUMMARY

For the main species recorded from surveys undertaken within the proposed development area the results from the Impact Assessment presented in Section 4, are summarised in Table 6-1. The results presented do not take into account any specific mitigation measures that may be developed in the future that would further reduce the risks and remove or remedy any significant or adverse impacts that may arise (see Section 7).

The results of the assessment identified 36 species of bird that due to either their conservation status, i.e. are a qualifying species for an SPA or due to the numbers recorded within the proposed development area could be impacted by the proposed development.

Three potential impacts were identified: Collision, Displacement and Barrier effects. The potential for both direct and indirect disturbance has also been considered as part of the displacement assessment.

Following the use of a series of matrices to indicate the significance of a potential impact arising from the construction, operation and decommissioning of the proposed development an evidence based assessment has been undertaken to determine the overall significance of the potential impacts.

The results indicate that for most species the proposed development is only likely to have a negligible or at worse a minor effect on the species present.

The impact assessment has identified the potential for impacts of moderate significance on four species of bird: red-throated diver, little tern, Sandwich tern and common tern.

Red-throated diver may be displaced from the area of the proposed development during construction, operation and decommissioning phases. Site specific data indicate that although the higher numbers of red-throated diver occur to the north of the proposed development area a proportion of the local regional population may be displaced. The effects of the possible displacement on red-throated divers are unknown but could be significant were all those displaced not to survive. However, this scenario is considered improbable as the proposed development is in an area not favoured by red-throated diver and any Divers that may be displaced will be able to move to other suitable foraging areas. Therefore, although the impact may be moderate in terms of displacement the actual impact on the Diver population within Aberdeen Bay will be negligible or minor.

Three species of Tern were identified as being at potential risk of a moderately significant impact due to possible indirect impact on their prey should pile driving occur during the construction period. However, it is also considered that any displacement of prey would be temporary as fish would return to the area following cessation of piling. Consequently, the possible impacts were considered to be of a temporary nature and would not have a long-term effect.

Table 6-1: Summary of Species Impact Assessment.

Species	Collision Risk	Barrier	Displacement	Overall Assessment
Whooper swan	Negligible	Negligible	Negligible	**Negligible**
Pink-footed goose	Negligible	Negligible	Negligible	**Negligible**

Atlantic puffin	Negligible	Negligible	Minor	**Minor**

7 MITIGATION & MONITORING

Detailed mitigation and monitoring measures aimed to avoid, remove or reduce any potentially significant impacts will be developed more fully during consultation with the Regulator and their statutory advisors and other stakeholders.

The main potential impacts arising from the proposed development relate primarily to direct or indirect displacement effects on Divers and Terns. Mitigation measures that may be considered as measures to help avoid, remove or reduce them include:

Minimising the proposed development area: By reducing as far as practicable the overall area of the proposed development, the total area and consequently the total number of red-throated divers that may be displaced will be minimised. A number of factors need to be taken into consideration when identifying the location of turbines, including the minimum distance turbines may be able to operate effectively. The current lay out is based on the minimum practical distance possible between turbines, taking into account the physical properties of the likely turbines, features of the seabed, water depth, other sea users as well as comments received during the consultations undertaken during the development of this project. Subject to further consultation, it is currently predicted that there will not be any significant change in the positions of the currently planned wind turbine locations, which covers an area of 4.3 km^2.

Vessel management plans: The potential disturbance of seaduck and Divers and other seabirds from the proposed development area by construction, maintenance or decommissioning vessels may be reduced by minimising the number vessels used during any of phases of the proposed project. Furthermore, ensuring that all vessels use the existing shipping lanes within Aberdeen Bay for as much time as possible will minimise the number of birds potentially displaced.

Foundation types: The use of monopiles as a type of foundation requires the use pile-driving to install them, which may cause an indirect effect on prey species. By selecting alternative foundation types, e.g. gravity based structures or jackets that require smaller piles, there is the potential to reduce the risk of an impact on the prey species and therefore reduce the possibility of a displacement effect being caused by construction activities. Further consideration of the foundation types used by the proposed project will be made during the consenting process. Means to minimise the potential effects of noise generated by pile-driving, should it occur, would be considered in line with the latest relevant guidance and would for example include ‘soft-start’.

Timing and duration of installation: The timing and duration of installation have still to be determined. Site-specific data indicate that there are birds present in Aberdeen Bay throughout the year with peak numbers occurring at different times of year depending on the species. Therefore, it may not be possible to select a period for construction activities to take place at a specific time of year that has relatively lower bird numbers present and therefore less sensitive. It is also recognised that there may be other environmental and project aspects, e.g. fish spawning periods or vessel availability that will need to be considered when identifying potential development construction periods. The timing of possible construction would be further considered during the consenting process when details on the potential project schedule are developed.

Minimising aviation and navigation lighting: Birds can be attracted to bright lights, e.g. lighthouses, particularly during poor weather conditions. In order to reduce the risk of birds being attracted to the proposed development all lighting will be kept as far as practicable to a minimum but still kept within the requirements to ensure safety.

Discussions with the relevant authorities on minimum lighting requirements to ensure safety would be held.

It is essential that any monitoring undertaken is designed to address specific concerns or potential impacts identified during the EIA process. Poorly designed *ad hoc* monitoring is likely to be inefficient and not provide useful or meaningful results. It is therefore important that any monitoring programme is developed in collaboration with the Regulator and statutory advisors and takes note of key stakeholders comments arising from the consultation period.

A detailed monitoring programme aimed at specific issues or concerns would be developed with the Regulator and advisors should consent be granted.

8 APPENDIX A

8.1 Collision risk modelling

The following section describes and defines the key terms used in the collision risk modelling, following the recommendations made in the SNH approach and also to that having been used in previous offshore wind farm assessments.

The *risk area* is the two-dimensional window facing a bird approaching the proposed development from any given direction. It is defined here as the width of the application area multiplied by the height of the proposed turbine rotors.

Birds may face a wider span of turbines if they approach from other directions (east to west) across the proposed development but, the assumption of this particular flight path is precautionary, since this approach direction has the highest *rotor-swept area* to risk-area ratio and so the highest potential collision risk of any approach path.

The number of birds that are expected to pass through the airspace that would actually be swept by the rotors (the "rotor swept area") was calculated using the following equation:

- *total passing through the risk area * ratio of the rotor swept area to the risk area.*

The proposed development design is planned to use a number of yet undeveloped turbine types with the exact detail of these machines not yet known. The maximum turbine that is expected to be deployed could be up to 10MW. In order to make predictions for the worst-case scenario, the turbines were assumed to be 11, 10MW machines, because these machines result in a greater rotor-swept area than the alternative machines.

Any birds that were recorded as flying through the proposed development at Potential Collision Height was considered to be "at risk" of passing through the airspace swept by a turbine rotor (a rotor transit). Potential Collision Height was defined as a height band between 25-150m. Bird flight height information was used to calculate the portion of flying birds expected to be at potential collision height.

The directional modelling process is described below and illustrated using the real data for gannet. The following steps relate to the steps set out in the collision risk calculations for each species, given in the results section.

Step 1:

The peak totals of each key species seen flying at the EOWDC within the 300m transect during the snapshot scans were calculated. In order to build a degree of precaution into the model, the month with the highest peak total of birds detected in flight was used. In order to calculate the % of birds at collision risk height taken as birds flying 25m – 150m, both site specific survey data was used (where available) and generic information on flight height information (Cook, Wright & Burton *in prep*.). The rate at which birds were detected during the surveys was calculated by dividing the species total by the total number of survey minutes.

<u>Example</u>:

- *29 Gannets recorded in flight during the September survey.*
- *Total gannets flying at Potential Collision Height (using 17 site specific collision height value) = 4.93*
- *Total gannets flying at potential collision height (using 14% site specific collision height value) = 4.06*

Step 2:

The rate at which birds were detected during the survey was calculated by dividing the species totals by the total number survey minutes.

Example:

- *Gannets recorded during the IECS survey (361 minutes of survey effort in the EOWDC area) = R = 0.0136 birds per minute, (or 0.011 using 14% generic collision height)*

Step 3:

The bird detection rates collected in survey areas (e.g. 'control' or EOWDC) were scaled down to the size of the proposed development licence area. This was accomplished by multiplying the survey detection rate by the ratio of the transect area to the proposed development area.

Example:

- For gannet R_{SITE} = ratio EOWDC transect to survey area (0.393) x survey detection rate (0.0136) = 5.34×10^{-3}

Step 4

The number of birds flying through the Risk Area during an average year was then extrapolated from the overall detection rate. This was calculated by multiplying the rate per minute (R_{SITE}) by the total number of minutes that the species was considered to be potentially active during the year. In the absence of good information on the potentially active periods of any of the key species, it was assumed, as a precaution, that all could fly at any time of the day. Thus the potentially active period was taken to be 365 days x 24 hours, or 525,600 minutes for all.

Example:

- *The average number of gannets flying through the EOWDC Risk Area was estimated to be 0.0136 x 525,600 = 7,148 birds (or 5,781 birds using 14% of birds at collision height)*.

Step 5

The size of the *risk area*, which is defined as the width of the proposed development area multiplied by the height of the proposed turbine rotors was = 540,000 m^2.

Example:

- *The risk area at EOWDC was calculated by: Width of EOWDC area (2,600 m) * Height of turbines (10MW 150 m)*.

Step 6

The total rotor swept area was calculated using the following equation: total passing through the risk area * ratio of the *rotor swept area* to the *risk area*.

Example: The areas swept by one 10MW turbine rotor of up to 150 m diameter was $\pi \times 75^2$ = 17,671. With their being potentially up to 11 of these turbines at the EOWDC, the total *rotor swept area* was taken to be 11 * 17,671 = 194,161.

Step 7

The ratio of the rotor-swept area to the risk area was calculated by dividing the rotor swept area by the risk area.

Example:

- *rotor swept area (194, 161) / 540,000 = 0.35*

Step 8

The annual number of birds flying through the rotor swept area was calculated from the annual numbers through the risk area by direct proportion.

Example:

*At the EOWDC the rotor swept area formed 0.35 of the risk area, so the estimated number of gannets through the rotor swept area is 7,148 * 0.35 = 2,501 birds (or 2,023 birds using 14% flying at collision height)*.

Step 9

The probability of collision was calculated for each key species, using the spreadsheet supplied by SNH for this purpose. The input parameters relating to the species were sourced from Snow and Perrins (1998) (length and wingspan) and Alerstom *et al*., (2007) (average flight speed). The parameters for the likely turbine specifications for a 10 MW machine were provided by AOWFL and are outlined in the Project Description (Chapter 3).

Example:

- *The probability of collision for the gannet was calculated as 12, or 0.12*

Step 10

The estimated number of turbine collisions each year, assuming no avoiding action and that the turbines were operating 85% of the time to take account of periods when the winds would be inefficient to operate, was calculated as the estimated annual numbers of birds flying through the rotor swept area, multiplied by the probability of collision, multiplied by 0.85.

Example:

- *For the gannet, 2,501 (estimated number of bird collisions per year) *0.12 (probability of collision) * 0.85 (time that turbines were operating) = 255 birds per year (or 206 when applying 14% flying at collision height)*.

These values are both precautionary as it assumes birds are active 24 hours a day and do not avoid the turbines.

Various plausible avoidance rates were then applied to this estimate to give a more realistic range of collisions. The avoidance rates applied were 98% (assumed to be the worst case scenario) 98% and 99%.

98% avoidance 255 (or 206) birds * 0.02 = 5.1 (or 4.1*) gannet collisions annually,

99 % avoidance 255 (or 206) birds * 0.01 = 2.55 (or 2.06*) gannet collisions annually,

99.5% avoidance 255 (or 206) birds * 0.005 = 1.27 (1.03*) gannet collisions annually,

*Uses 14% of birds in flight flying at collision height

Goose collision risk methodology

In the absence of site specific survey data that was suitable to estimate collision risk for the pink-footed goose and barnacle goose a different approach was applied based on the assumption that the whole UK wintering populations of pink-footed goose and Svalbard population of Barnacle goose undertake a twice yearly migration across the proposed development area in a 10 km band.

Pink footed geese:

The proposed development risk area in a north south direction has a length of 3.6 km and it was assumed that 244,800 pink footed geese would migrate through the risk area every year. The number of birds flying across the risk window at potential collision height was calculated as 46% of 244,800 = 112,608 individuals. The rotor swept area is 194,161 m^2 and the proportion of the rotor swept area to the risk window is 0.35. The number of birds calculated to fly across the rotor swept area is 39,412.

Barnacle goose:

The proposed development risk area in a north south direction has a length of 3.6 km and it was assumed that 32,000 barnacle geese would migrate across a 10 km band of the offshore area, twice a year. The number of birds potentially flying through the risk area is 23,040 birds per year. The number of birds flying across the risk area at potential collision height was calculated as 46% of 23,040 = 10,958. The rotor swept area is 194,161 m^2 and the proportion of the rotor swept area to the risk window is 0.35. The number of birds calculated to fly across the rotor swept area is 3,709.

8.2 Summary of the collision risk outputs

Table 8-1: Pink-footed goose Collision Risk Calculations

Step in collision risk Process	Peak numbers of flying birds (applying generic flight height information 46%)
Step 1: Number of birds in transect at Potential Collision Height	Used proportion of UK population of pink footed geese migrating along a 10km band
Step 2: Rate at which birds detected at PCH	Not applicable
Step 3: Rate of bird detections scaled to EOWDC area	Not applicable
Step 4: Estimated annual total of birds through the risk area	112,608.0000
Step 5: Size of the risk area	540,000.0000
Step 6: Total rotor swept area	194,161.0000
Step 7: Ratio of rotor swept area to the risk area	0.3500
Step 8: Annual number of birds flying through the rotor area	39412.8000
Step 9: Probability of collision (Band Model)	8.4%
Step 10: Estimated number of collisions per year assuming no avoidance and 100% operational time	3,310.6752
Assuming an operational time of 85%	2,814.0739
Assuming a 98% avoidance rate	56.2815
Assuming a 99% avoidance rate	28.1407
Assuming a 99.5% avoidance rate	14.0704

Table 8-2: Barnacle goose Collision Risk Calculations

Step in collision risk Process	Peak numbers of flying birds (applying generic flight height information 46%)
Step ,: Number of birds in transect at Potential Collision Height	Used proportion of UK population of barnacle geese migrating along a 10km band
Step 2: Rate at which birds detected at PCH	Not applicable
Step 3: Rate of bird detections scaled to EOWDC area	Not applicable
Step 4: Estimated annual total of birds through the risk area	10,598.00
Step 5: Size of the risk area	540000.00
Step 6: Total rotor swept area	194,161.00
Step 7: Ratio of rotor swept area to the risk area	0.35
Step 8: Annual number of birds flying through the rotor area	3709.30
Step 9: Probability of collision (Band Model)	8.5
Step 10: Estimated number of collisions per year assuming no avoidance and 100% operational time	315.29
Assuming an operational time of 85%	268.00
Assuming a 98% avoidance rate	5.36
Assuming a 99% avoidance rate	2.68
Assuming a 99.5% avoidance rate	1.34

Table 8-3: Common scoter Collision Risk Calculations

Step in collision risk Process	Peak numbers of flying birds (applying generic flight height information 46%)
Step 1: Number of birds in transect at Potential Collision Height	1.04
Step 2: Rate at which birds detected at PCH	0.034
Step 3: Rate of bird detections scaled to EOWDC area	0.0013
Step 4: Estimated annual total of birds through the risk area	699.7499
Step 5: Size of the risk area	540,000.0000
Step 6: Total rotor swept area	194,161.0000
Step 7: Ratio of rotor swept area to the risk area	0.3500
Step 8: Annual number of birds flying through the rotor area	244.9125
Step 9: Probability of collision (Band Model)	0.066
Step 10: Estimated number of collisions per year assuming no avoidance and 100% operational time	16.1642
Assuming an operational time of 85%	13.7396
Assuming a 98% avoidance rate	0.2748
Assuming a 99% avoidance rate	0.1374
Assuming a 99.5% avoidance rate	0.0687

European Offshore Wind Deployment Centre

Environmental Statement

Appendix 11.1: Bats Technical Report

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

1 BATS ENVIRONMENTAL IMPACT ASSESSMENT TECHNICAL REPORT

1.1 Introduction

1 This section will review the information available for bats that are present in the Aberdeen Bay area with the focus being on bats that could be present in the offshore area beyond the high water mark. All bat species found in Scotland are classified as European Protected Species and are fully protected under the Conservation (Natural Habitats) Regulations 1994 as amended. This lists a number of offences in relation to bats and the places which they live.

2 Surveys for any bat roosts and feeding areas will be carried out to inform the onshore environmental impact assessment. These surveys will be conducted using qualified surveyors at the proposed substation and cable landfall and the results will be presented in the onshore Environmental Statement.

3 The impacts considered in this report are all related to the operational phase and are listed as:

- physical impacts from direct collision or flying close proximity to wind turbine blades
- indirect impacts, changing foraging behaviour of bats by attraction to lights and increased risk of physical impacts from collision.

1.1.1 Consultation

4 During meetings with SNH bats occurring in offshore were not raised as being a particular cause for concern.

1.2 Baseline Information

5 Seventeen species of bat are found in the UK, six of which are known to occur in north-east Scotland. Three of these species are considered to occur commonly (common pipistrelle, Soprano pipistrelle and the Brown long-eared bat) one species (Daubenton's bat) fairly common and two are considered uncommon (Natterer's bat and Whiskered bat) (SNH, 2009). A brief description of the six species found in Scotland is given below. A single sighting in the north-east Scotland of the Nathusiu's pipistrelle has also been recorded hence a brief description of this species is also given.

6 **Common pipistrelle (*Pipistrellus pipistrellus*) and Soprano pipistrelle (*Pipistrellus pigmaeus*)** - Due to the similarity of the two species Soprano pipistrelle was not discovered until the 1990s but has since been found to be common and widespread throughout the UK, including north-east Scotland. Both species occur throughout mainland Britain and some inner Hebridean Islands. They occur in most habitats but particularly riparian woodland and parkland. Both species will forage up to 5 km from their roosts and are the most frequently recorded species along the Aberdeenshire coast.

7 **Nathusiu's pipistrelle (*Pipistrellus nathusii*)** - A previous migrant species. It has only been classified as a resident in the UK since 1996. To date only one recorded sighting has been made in the in north-east Scotland. Two

recorded sightings from oil platforms suggest that this species may be a very scarce migrant. The range and status of this species is current unclear.

8 **Brown long-eared bat** (***Plecotus auritus***) - This species is widespread in mainland Britain and also occurs in some inner Hebridean Islands, the species of bat is less common than the pipistrelles particularly along the coast. Brown long-eared bats roost in old houses and forage within 1.5 km from their roosts which are invariably near to thick woodland. Consequently they are scarce along the coast.

9 **Daubenton's bat** (***Myotis daubentonii***) - Occur throughout mainland Britain as far north as Sutherland and possibly on some of the larger Inner Hebridean islands. Although widespread in north-east Scotland, Daubenton's bats are closely associated with fresh water and avoid urban habitats. Roosts are in mature deciduous trees and rarely in houses. In the north-east of Scotland the species occurs along the Ythan as well as Deeside and Donside, however, the species is rare or scarce near the coast.

10 **Natterer's bat** (***Myotis nattereri***) - Natterer's bats are found throughout most of the British Isles. Recent records have extended its range in Scotland north to the Great Glen fault. This is a very rare bat in north-east Scotland with few records reported. It does forage widely and over a wide variety of habitats including grassland, but it prefers semi-open woodland often coniferous.

11 **Whiskered bat** (***Myotis mystacinus***) - Very rare with just one record in north-east Scotland. It is found throughout England and Wales and even in southern Scotland and throughout Ireland.

1.3 Impact Assessment

12 It is recognised that bats may be impacted by wind farms; with evidence from a number of onshore wind farms indicating that bats have a higher mortality rate due to wind farms than birds do. Although direct collisions with the wind turbines do occur, a higher mortality rate arises due to barotraumas caused by sudden changes in air pressure causing lethal lung damage. The impacts considered in this report are all related to the operational phase and are listed as:

- physical impacts from direct collision or flying close proximity to wind turbine blades
- indirect impacts, changing foraging behaviour of bats by attraction to lights and increased risk of physical impacts from collision

13 Bats have been recorded foraging around offshore wind farms. Studies undertaken in Sweden to explore potential impacts on migrating bats discovered that non migratory bats also occurred foraging around the wind turbines as far as 10 km from shore (Ahlén et al., 2007).

14 There is no evidence to suggest the offshore area of Aberdeen Bay is used by bats, the decreasing availability of insect prey with increasing distance from the shore reduces the likelihood of bats foraging beyond the coastal environment.

15 Although there are a number of species that are likely to be found in the terrestrial environments of north-east Scotland, there is no evidence to

suggest that any of these bat species currently utilise the offshore areas for foraging or migration corridors. There are no known flyways across Aberdeen Bay and there is no evidence to suggest migration of Scottish bats to, or from other European countries.

16 Unlike other offshore areas where bats have been found to forage offshore, such as Sweden, Aberdeen Bay does not have any known migration corridors or flyways that are actively used by bats to travel across Aberdeen or to migrate to other parts of Europe, such as Scandinavia.

17 It is only when the EOWDC has been built and is operational that there would be any risk to bats that are flying in, or through, the development area. From a the results of literature review there was a lack of any studies which have identified the presence of bats in Aberdeen Bay beyond the high water mark.

18 The threat to populations of bat species present in the north-east Scotland from collisions is shown in Table 1. Both species of pipistrelle (common and soprano) are ranked as having a medium collision risk, all the other four species were considered to have a low risk of collision. The population threat from collisions to all bat species found in the north-east Scotland is low. Although this threat may be revisited by the UK statutory nature conservation agencies depending upon the scale of future wind farm developments particularly those situated onshore.

Table 1 The risk of collision fatalities affecting bat populations (table adapted from Natural England 2009

Species	Relative Population Size and Status	Risk of Collision	Population Threat
Common pipistrelle	Common	Medium	Low
Soprano pipistrelle	Common	Medium	Low
Brown long-eared bat	Common	Low	Low
Daubenton's bat	Common	Low	Low
Natterer's bat	Fairly common	Low	Low
Whiskered bat	Locally distributed	Low	Low

19 During the operational phase of the proposed EOWDC the addition of aviation and navigational safety aids such as lights could act as attractants to insects which in turn may attract predators such as bats from the mainland, however it is known that bats generally avoid artificial lighting (Boshamer and Bekker 2008). Also Aberdeen Bay is frequently used for mooring vessels used to supply the oil and gas industry. These vessels are lit by powerful lights and easily visible from the shore and there have not been any records of bats foraging around the lights of these boats.

20 The addition of permanent lights offshore may influence the foraging flights of bats, although there is no evidence to suggest that lights that are currently present offshore Aberdeen Bay have attracted bats.

21 There are no foreseeable impacts from the construction phases or decommissioning phases.

22 The risk of collision is considered to be negligible once the EOWDC has been constructed and is operational. Although there have been reports of bats discovered on oil and gas infrastructure offshore, there is no evidence for any significant movement, or permanent distribution, of bats in offshore waters in the Aberdeen Bay area and therefore the impact of the EOWDC on the bats is considered to be negligible.

1.4 Mitigation and Monitoring

23 No additional mitigation for the offshore works is planned for bats.

24 If any environmental risk to bats is identified in any subsequent land-based surveys and following the advice of SNH, post monitoring surveys could monitor the EOWDC area to assess if there are any bats that are foraging or moving through the site.

1.5 Summary

25 Six species of bats are thought to occur in north-east Scotland, although only three of them are common species. The bats are not expected to use the waters of Aberdeen Bay for feeding and there are no known flyways or migration corridors in the area. Once the proposed EOWDC is operational there is the small possibility that the EOWDC could attract insects and bats offshore due to the small lights required for safety reasons on the wind turbines. The evidence suggests a lack of bats in the offshore waters of Aberdeen Bay. Impacts from the construction, operation and subsequent decommissioning of the EOWDC on bat species are considered to be negligible.

26 A thorough survey for bat species and their associated roosts will be undertaken as part of the environmental surveys carried out for the onshore Environmental Impact Assessment to look at the impact of the onshore works.

1. INFORMATION FOR THE NON-TECHNICAL SUMMARY

The marine mammal environmental baseline drew upon existing research surveys conducted on marine mammals in the wider area as well as several years of land based and boat surveys of the wider EOWDC development area. Several marine mammal species have been recorded (sighting and/or stranding) in Aberdeen Bay and the surrounding area; including 12 odontocete species, three mysticete species and three pinniped species. Of these, bottlenose dolphins, harbour porpoises, white-beaked dolphins, minke whales, Risso's dolphins, harbour seals and grey seals occur regularly in the area, with other species only being recorded occasionally or rarely.

Bottlenose dolphins in the Aberdeen area are part of the resident population from the Moray Firth Special Area of Conservation (SAC), which have a range extending from the Moray Firth to the Firth of Forth. There appears to be sub-groups within the population with one group spending most of their time within the inner Moray Firth (SAC) and the other group having a wider range and spending less time in the inner Moray Firth area.

The bottlenose dolphin population of the Moray Firth has recently been expanding its range in a southerly direction, beyond the boundaries of the Moray Firth SAC, with an increase in sightings and identified individuals along the east coast of Scotland as far as St Andrews and the Firth of Forth. Although Aberdeen is recognised as an important area for bottlenose dolphins, further studies are required to more accurately determine the proportion of the population that utilises this area throughout the year.

Bottlenose dolphins are generally found within coastal waters, although have been observed in offshore areas off north-east Scotland. Bottlenose dolphins have been observed off Aberdeen throughout the year, although there appears to be an increase in occurrence between November and May.

Bottlenose dolphin were the second most frequently sighted cetacean species during the surveys carried out as part of the EOWDC, with a total of 200 individuals being detected. The majority of the sightings occurred in the spring and summer months. A higher number of bottlenose dolphins were recorded in the wind farm area in comparison to the control site and in the vicinity of the entrance to Aberdeen harbour, which is a known hotspot for dolphin sightings. Their presence at this site has been linked to salmon migration up the river.

Young bottlenose dolphin calves have been observed in the Aberdeen area during spring and early summer, indicating a possible increased sensitivity to any potential disturbance during this time.

From the available information it is apparent that the Aberdeen area is important for bottlenose dolphins, however it is unclear how reliant they are on the area as they are regularly observed, both feeding and with calves, at various locations along the north-east coast of Scotland.

Harbour porpoises are the most common species of cetacean in the North Sea and have a wide range and distribution in both coastal and offshore areas. Harbour porpoises regularly occur in the Aberdeen area throughout the year, with peak occurrence during August and September.

The diet of harbour porpoises is varied and they have been recorded to take a wide range of prey items. In Scottish waters their diet is primarily whiting, sandeels, haddock/saithe/Pollock and *Trisopterus* spp. It is unclear if porpoises in the Aberdeen area are attracted to a specific prey species.

The calving period for harbour porpoises in Scottish waters is estimated to be between April and June, and calves have been observed off Aberdeenshire between May and September, indicating a possible increased sensitivity to any potential disturbance during this time.

Harbour porpoises were the most recorded cetacean species during the EOWDC boat surveys with over 420 individuals detected. The harbour porpoise was the only species that was detected in sufficient numbers to allow a detection function to be applied that would allow for abundance and density estimates to be generated. The density of harbour porpoises was higher in the control area in all seasons except summer. Lowest densities occurred during May and June. The density estimates produced for harbour porpoise all show considerable error margins which is a reflection of the sampling effort, further surveys would reduce this. In the four surveys carried out during 2010-2011 the northern transect had the highest proportion of harbour porpoises, except in January when highest densities were recorded in the southern transect.

The harbour porpoise, as expected, was the most frequently detected cetacean species during the acoustic surveys. In agreement with the results of the visual surveys the control area recorded more acoustic detections than the wind farm survey area. In the acoustic surveys carried out during 2010-2011 higher numbers of detections were made in the offshore survey area during the August and September surveys, although it is too early to conclude whether this represents a movement of animals further offshore during the summer months.

White-beaked dolphins are present in the central and northern North Sea throughout most of the year. Sightings data suggests their presence in the coastal waters off Aberdeenshire is seasonal, with sightings recorded between June and August; however strandings data indicate they may be present in the area between February and October.

The movement of white-beaked dolphins into coastal waters during summer months is thought to relate to the calving period, with calves being observed off Aberdeenshire in all three months that the species has been observed.

The seasonal movement may also be related to the seasonal abundance or movement of prey species, such as herring or mackerel. It is hoped that the marine ecology and fisheries studies will provide more information on potential prey in the area.

Along the Aberdeenshire coast, white-beaked dolphins appear to have a preference for sections of the coast adjacent to deeper waters, with a higher incidence of sightings between Aberdeen and Stonehaven compared to the area between Aberdeen and Collieston.

White beaked dolphins have been detected during the EOWDC surveys over the course of several years during the month of August, this data supports the occurrence of this dolphin as a seasonal summer visitor that possibly moves to coastal waters following prey such as mackerel and for calving purposes. Although white-beaked dolphins are found throughout the central North Sea and generally in more offshore areas, it is apparent that the coastal waters off Aberdeen could be important during the summer/calving period.

Minke whales occur throughout the central and northern North Sea, particularly during summer months. They are generally observed in offshore deeper waters, but appear to move into coastal waters along the north-east coast of Scotland from July.

Minke whales have been recorded off the Aberdeenshire coast primarily during summer months (July – August); although observations and strandings indicate they may be present in the area throughout the year.

The seasonal movement of minke whales into coastal waters during the summer is thought to be related to prey availability. Minke whales generally feed on a small pelagic fish, such as sandeels, herring and sprat.

Six minke whales have been observed as part of the EOWDC surveys. Minke whales are thought to have a preference for water depths of 38m or deeper, these depths are generally found further offshore and beyond the EOWDC crown estate lease, although one minke whale was detected within the lease area during the boat based surveys.

Although minke whales occur regularly in the area off Aberdeen, especially during summer, it is unclear how important the area is relative to other areas.

In the northern and central North Sea, Risso's dolphins are primarily observed around Shetland and Orkney. However, there has been an increase in reported sightings along the north-east coast in recent years. Risso's dolphins have been recorded off Aberdeenshire since 2005 at various times of the year.

The increase in recent sightings in the Aberdeen Bay area may indicate that Risso's dolphins are using the area more frequently, and although occasionally recorded in the area this may change and should be monitored. Possible reasons for the apparent recent increase in observations in the area are unclear, but could be related to prey availability, Risso's dolphins feed primarily on cephalopods, and/or climate change.

Risso's dolphins were observed during vantage point surveys, but not during any of the EOWDC boat surveys. The increase in sightings of Risso's dolphins may point towards an increase in the use of the Aberdeen area in comparison to historic levels.

Harbour seals are widely distributed along the east coast of Scotland. They are present in the Aberdeen area throughout the year. Their occurrence at the estuaries of the Rivers Dee and Don is seasonal with an increase in numbers during the winter and early spring.

Harbour seals use haul-out sites at the Donmouth, at the mouth of the Ythan River and at Catterline. Harbour seals have been observed feeding on salmonids and flatfish at the estuaries of the Rivers Dee and Don, as well as other marine prey species.

The pupping period for harbour seals occurs from June to July and moulting occurs from June to September, during these times they spend a higher proportion of their time ashore and in coastal waters.

Both species of seal grey and harbour seals are regularly present and frequently sighted in Aberdeen bay, especially at the entrances to the rivers Dee and the Don. Grey seals were the most frequently observed seal species recorded during the boat surveys carried out between 2007-2007. Almost equal proportions of grey and common seals were recorded during boat surveys carried out during 2010-2011.

Designated coastal SACs for harbour seals are present along the east coast of mainland Scotland, these are situated in the Dornoch Firth and Morrich Moore in the Moray Firth and Firth of Tay and Eden estuary.

Grey seals are also found along the east coast of Scotland. They are present in the Aberdeen area throughout the year. Grey seals use haul-out sites at the Donmouth, at the mouth of the Ythan River, outside Peterhead harbour, Cruden Bay, Boddom and at Catterline.

The most well established colony in the area is at Catterline, where up to five pups may be born each year. The pupping period for grey seals occurs from October to November and moulting occurs from February to April, during these times they spend a higher proportion of their time ashore and in coastal waters.

Grey seals have been observed feeding on salmonids and flatfish at the estuaries of the Rivers Dee and Don, as well as other marine prey species.

Designated SAC's for grey seals along the east coast of Scotland include the Isle of May at the entrance of the Firth of Forth, and it can be expected that individual seals from these colonies may be passing through and the EOWDC development area.

For species such as white-sided dolphins, killer whales, common dolphins, striped dolphins, long-finned pilot whales, sperm whales, humpback whales, fin whales, northern bottlenose whales, Sowerby's beaked whales and other pinniped species, although present in the area off north-east Scotland this is only a marginal part of their habitat, and is likely to be inhabited only during a restricted part of the year by relatively few individuals.

2. INTRODUCTION

Genesis Oil and Gas Consultants (GOGC) have been commissioned by AOWFL to undertake a marine mammal impact assessment of the EOWDC. The structure of the assessment can be summarised as follows:

- **Baseline Report** (this document) – this provides a summary of the existing information relating to the distribution and abundance of marine mammals in Scotland with a focus on Aberdeen Bay. This report draws on the findings of a desk based study and marine mammal research studies and also dedicated marine mammal surveys carried out for the purpose of supplementing the baseline for the EOWDC.
- **EIA Technical Report** – an assessment of the impact of the project on marine mammals in the study area.
- **Non-Technical Summary Chapter for the Environmental Statement** – a summary of findings from the Baseline Report and EIA Technical Report.

In order to assess the importance of the proposed EOWDC and surrounding area for marine mammals and the potential impacts associated with the project, it is necessary to understand the occurrence and distribution of marine mammals in the area and understand why they are there.

The main aim of the baseline study is to provide detailed information on marine mammals that may be present in the crown estate licence area and also the surrounding area to inform the EIA technical report. The baseline report provides information on the following:

- Marine mammals present in Aberdeen Bay and Scottish coastal waters
- Abundance and distribution of marine mammals, and seasonal patterns of distribution and migration
- Usage of the Aberdeen Bay by marine mammals (feeding, passage area, calving)
- Identification of any potential seasonal sensitivities (e.g. calving period)
- knowledge/data gaps relating to marine mammals in Aberdeen Bay

3. DATA SOURCES

The following key data sources have been used to inform the baseline assessment:

- Boat based surveys of the EOWDC and wider area carried out by Institute of Estuarine and Coastal Studies (IECS) (2007-2008) and the Sea Mammal Research Unit (SMRU) 2010-2011 (Section 3.1)
- Land based Vantage Point surveys carried out as part of the baseline surveys of EOWDC March 2005-2007 Section 3.2
- Joint Nature Conservation Committee (JNCC) aerial survey data of Aberdeen Bay 2005-2006 (Section 3.3)
- Marine mammals present along the Scottish coastline were assessed as part of Strategic Environmental Assessment (SEA) area 5 as part of the oil and gas licensing programme (Section 3.4)
- Northern North Sea Cetacean Ferry Surveys (NORCET) cetacean survey information (Section 3.5)
- Moray Firth cetacean study 2009-2011 into the effects of proposed oil and gas exploration (Section 3.6)
- Cetacean stranding data (Section 3.7)

A full list of documents referenced in the baseline assessment is provided in the reference section.

3.1 BOAT SURVEYS

The aim of all of the boat based surveys was to collect marine mammal data to generate density and abundance estimates by year, month/season and stratified for the wind farm and control site. The passive acoustic monitoring element allowed for the acoustic analysis of marine mammal data to generate detection rates for harbour porpoise and delphinids.

Marine mammal and seabird surveys were carried out on behalf of AOWL by the Institute of Estuarine and Coastal Studies (IECS), University of Hull from February 2007 – April 2008, inclusive.

SMRU Ltd were contracted to undertake 12 monthly surveys for marine mammals and seabirds. Included in the baseline report are provisional survey data collected from the initial four surveys completed in August, September and November 2010 and January 2011.

For all the marine mammals surveys conducted as part of the EOWDC baseline marine mammal observers followed standard survey transect procedures to collect data on marine mammals, and the surveys occurred in a Beaufort sea state 4, or less.

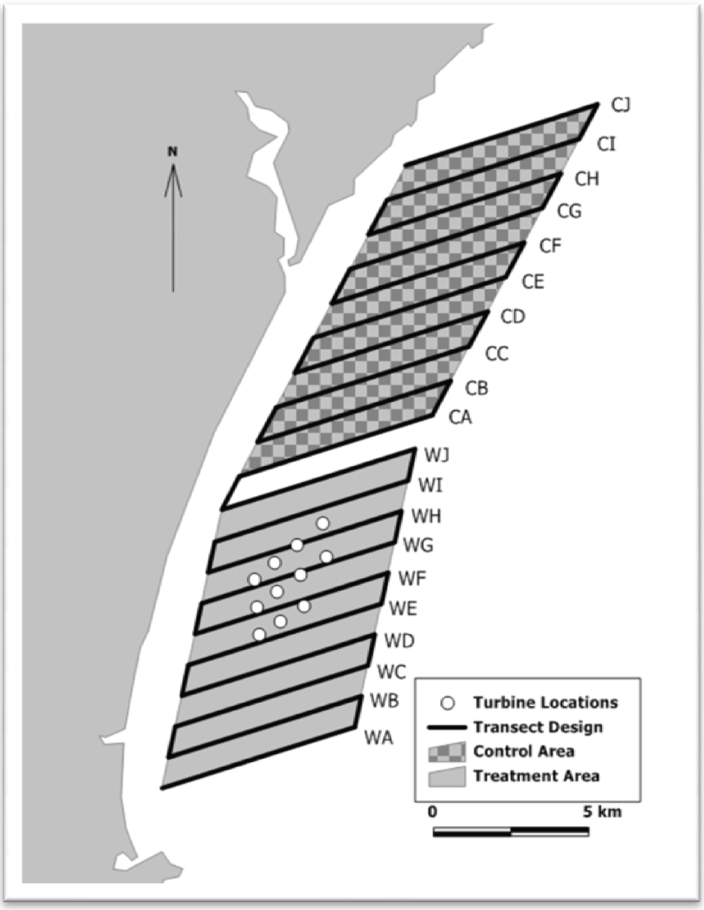
The vessel used for the IECS surveys and the initial 4 SMRU surveys was an ex-Clyde class lifeboat *Gemini Explorer*. It had an observation platform 5.1 m above sea level, cruising speed of 8-9 knots and a clean electronic footprint which was required for the acoustic survey component.

3.1.1 IECS boat based surveys 2007-2008

The survey approach used in the IECS boat based surveys was a Before-After-Control Impact design (BACI) and the scope was for a significantly larger wind farm. The survey approach was developed in consultation with the Joint Nature Conservation Committee (JNCC) and Scottish Natural Heritage (SNH) in 2006. Two survey areas were defined; the ‘wind farm’ area and a ‘control area’, immediately to the north (Figure 1). The terminology control area has been used to define one of the survey areas, however, it is accepted that establishing a true control area with equivalent environmental conditions to the wind farm area is difficult, if not impractical for a coastal environment.

In each area (50.8 km^2), parallel line transect surveys were completed across two survey strata (Wind farm and Control). During each survey month, ten transects of 6.5 km length were surveyed in each of the two areas giving a total survey effort of 130 km per survey month. Surveys were undertaken during a total of 15 months between February 2007 and April 2008 (Table 1), giving 1,950 km of survey effort during this phase of data collection (Travers, *et al*., 2008).

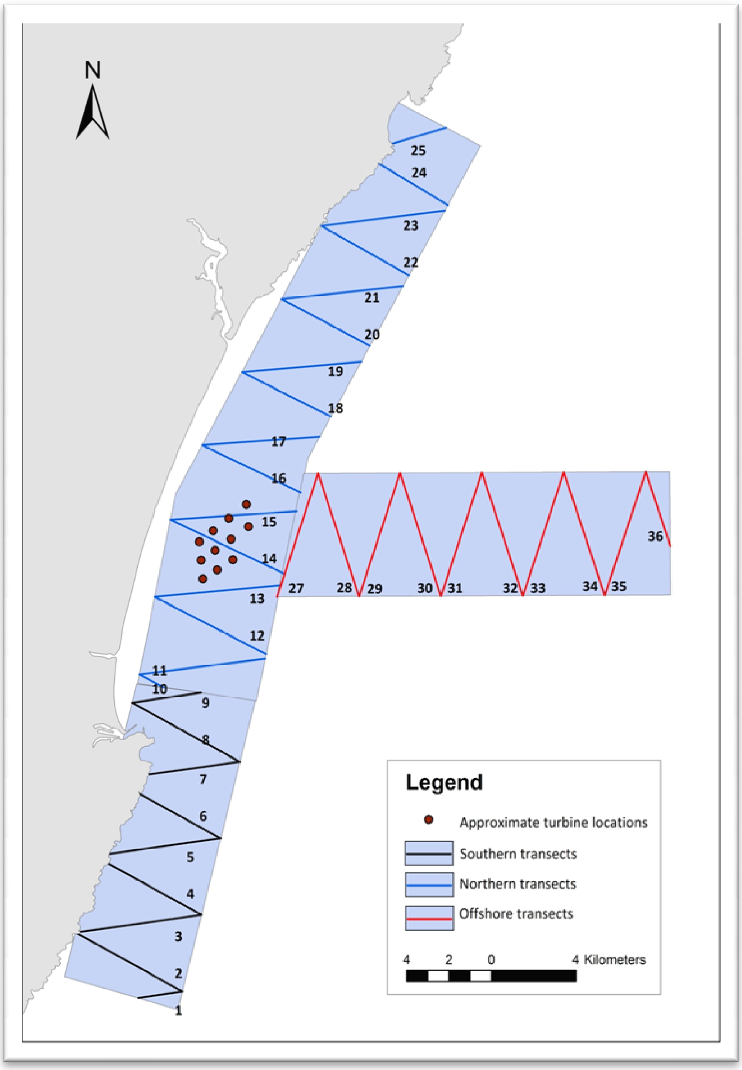
Figure 1 Boat based survey transects 2007-2008 (IECS), the grey area with the turbine locations is the wind farm area and the cross-hatched area is the control area (Travers, *et al*., 2008)



3.1.2 SMRU Ltd boat based surveys 2010-2011

SMRU Ltd were contracted to undertake an additional 12 months of surveys for marine mammals and seabirds. The survey design differed to that used by IECS and is based on zigzag line transects and the survey area is extended into the South, North and Offshore survey areas which were 82.8 km^2, 150.8 km^2 and 105.2 km^2 in area respectively (Figure 2) (SMRU Ltd, 2011a). The North survey area encompassed the Wind farm and 'Control' areas surveyed between February 2007 and April 2008. During each survey , 9, 16 and 10 transects were undertaken in the South, North and Offshore areas respectively, giving a total survey effort of approximately 40 km, 75 km and 60 km per survey block. For each survey a total of 36 transects were therefore surveyed, providing a total of 175 km of survey effort.

Figure 2 The boat based survey areas covered during 2010-2011; the southern area, (survey transects shown in black), the northern area, (survey transects shown in blue), and the offshore area, (survey transects shown in red). The survey transects are also labelled 1-36 (SMRU Ltd, 2011a).



The survey is based on a gradient design and the shortfalls of the 'Before and After Controlled Impact' (BACI) approach used in the first phase of data collection are avoided. The data collected using this gradient approach is compatible, and can be analysed in conjunction with the first phase of boat based surveys. Where sufficient observations of marine mammals have been collected this will allow pooled density estimates and abundances of marine mammals to be generated. The survey results will enable a repeatable baseline to monitor throughout the development of the proposed EOWDC.

All observers operated from the bridge roof (approx 5 m above sea level) and followed standard line transect procedures for marine mammals and modified European Seabird At Sea (ESAS) methods for seabirds. The main change to the ESAS method was the use of a third observer to count flushed birds ahead of the vessel. There were 3 seabird and 4 cetacean observers on each survey. Surveys were carried out in Beaufort sea state 4 or below with good visibility.

Included in this baseline report are the initial results from the data collected from the initial four surveys completed in August, September and November 2010 and January 2011 (SMRU Ltd, 2011a). There have been further surveys carried out in February and March, which have not yet been analysed.

3.1.2.1 Survey Effort during IECS (2007-2008) and SMRU (2010-2011) boat based surveys

The amount of survey effort completed on each transect varied slightly between surveys due to navigational issues (i.e. shipping traffic) or avoidance of heritable fishing grounds. The GPS logger data from each survey were therefore used to provide an accurate measure of survey effort for each transect, and these effort values were used for analysis.

IECS boat based surveys were carried out from February 2007 – April 2008. April was surveyed three times, to concentrate more survey effort during the breeding season, and February was surveyed twice, all other months were only surveyed once. The seasonal survey effort was highest in the winter and spring months with, with 520 km and 650 km, respectively (Table 1).

SMRU surveys were undertaken during August, September and November 2010, and January 2011 a total survey effort of approximately 600 km during this phase of monitoring (Table 2). A survey was not possible during October 2010 due to ongoing seismic surveys and then poor weather. Due to potential access restrictions, that Marine Scotland were made aware of, it was not possible to conduct a December survey.

When the seasonal survey effort collected during the IECS and SMRU surveys are combine there is fairly even coverage during each season, the season with the highest effort is winter (696 km) and the lowest is summer (595 km) (Table 3).

Upon the completion of the final 12 months of survey effort the environmental baseline chapter will be updated and the boat based survey results will be analysed together. Both phases of boat based survey results will be combined and used to develop a spatial model of marine mammal density and abundance throughout the survey area, where sufficient data allows. The results of this further analysis will be considered in any updates necessary to the marine mammal impact assessment and any revisions to the impact assessments will be incorporated.

Table 1 Total number of EOWDC boat based surveys and survey effort between February 2007 and April 2008 (IECS)

Season	Month	Number of surveys	Year	Total Effort (km)	Seasonal effort (km)
Winter	December	1	2007	130	520
	January	1	2008	130	
	February	2	2007, 2008	260	
Spring	March	1	2007	130	650
	April	3	2007, 2008, 2008	390	
	May	1	2007	130	
Summer	June	1	2007	130	390
	July	1	2007	130	
	August	1	2007	130	
Autumn	September	1	2007	130	390
	October	1	2007	130	
	November	1	2007	130	

Table 2 Total number of EOWDC boat based surveys carried out 2010-2011 (SMRU)

Month	Number of surveys	Year	Total Effort (km)
August	1	2010	175
September	1	2010	175
October	0	2010	0

Spring	5	5	0	650	650	0
Summer	3	3	1	565	390	175
Autumn	5	3	2	640	390	250

3.1.2.2 Passive Acoustic Monitoring Methods

Passive Acoustic Monitoring was used during the surveys carried out by IECS in 2007-2008 and the SMRU surveys carried out during 2010-2011; the total number of surveys and associated effort is shown in Table 4 and Table 5.

In the IECS survey a hydrophone array was towed behind the survey vessel during the line transects across both the wind farm and control area. Acoustic effort was calculated by examining the times contained within the acoustic files, and comparing these with the GPS data. If acoustic data was being recorded and the vessel was shown to be on a long transect line, the effort status was classed as being "on effort". If acoustic data was being recorded but the vessel was not sailing a transect line, or was sailing a short transect line, the effort status was classed as "opportunistic".

During the SMRU acoustic survey a hydrophone array was towed behind the survey vessel during all surveys. Acoustic effort was recorded in the field, and is defined as periods when hydrophone and associated recording equipment are operational and the survey vessel is adhering to one of the pre-designed survey transects. If the hydrophone and associated recording equipment are operational but the vessel is not sailing a transect line, the effort status was classed as "opportunistic". During the August survey, poor visibility resulted in the repetition of some of the southern transects for the visual observers and these extra transects have been included in the August acoustic analysis.

Table 4 Total number of IECS surveys with hydrophone deployed and survey effort completed per month between October 2007 and April 2008.

Month	Surveys	Effort (km)
Oct-07	1	111
Nov-07	1	102
Dec-07	1	127
Jan-08	1	88
Feb-08	1	127
March-08	0	0
April-08	2	227

Table 5 Total number of SMRU surveys with hydrophone deployed and survey effort completed per month between August 2010 and January 2011

Month	Surveys	Effort (km)
Aug-10	1	207.5
Sept-10	1	168.6
Nov-10	1	166.7
Jan-11	1	164.2

Hydrophone data were run through a harbour porpoise detection algorithm in real time in the field using the Rainbow Click software (freely available from www.ifaw.org). Rainbow click highlights porpoise-type clicks within the acoustic data, and these detections were validated manually to ascertain the number of harbour porpoise detections. Detection rates are expressed as events per kilometre.

In addition to the Rainbow Click files created during the line transect surveys; recordings were also made at a sample rate of 96 kHz. The combined data set was run through the PAMguard "whistle and moan" detector module (PAMguard software freely available from www.pamguard.org) by SMRU Ltd to identify any dolphin whistles that may have been recorded. Detections were validated manually to ascertain the number of dolphin events. Detection rates are expressed as events per kilometre.

3.1.2.3 Analysis methods for visual marine mammal data

Visual marine mammal data was analysed using conventional and multi-covariate distance sampling using Distance version 6 (Thomas et al. 2010). For the marine mammal species detected, there were only enough sightings of the harbour porpoise to enable detection function to be applied for this species only, for all other species too few observations were recorded. Only on transect effort was used in the analysis (i.e. short transit legs between transects were discarded).

The standard equations for estimating density and abundance are:

$$\hat{D} = \frac{n}{2\mathrm{L.\,esw}}$$

Where *n* is the number of sightings, *s* is the mean group size, *L* is the total length of transect surveyed and *esw* is the effective strip half width. The *esw* is a function (inverse of the detection function *f(y)*) of the perpendicular distances associated with the sighting and is modelled by fitting a key function with series expansion. The best model was primarily judged by the lowest value of the Akaike's Information Criteria (AIC) compared to others. How well the model fitted the data was judged by the Goodness of fit tests and QQ-plots.

Abundance is then simply the density estimate multiplied by the survey area. Variance was estimated empirically using the delta method (Buckland et al. 2001).

Surveys within the same month were combined to generate the density and abundance estimates. The sightings data for harbour porpoises were pooled over the entire 15 month survey period. Data were then stratified at the estimation stage to generate density and abundance estimates by month and season for each of the areas. Months were divided into four seasons: Winter (December, January, and February), Spring (March, April and May), Summer (June, July and August) and Autumn (September, October and November).

3.2 Vantage Point surveys

Shore-based vantage point bird surveys were conducted for two hours weekly at Blackdog and Donmouth and fortnightly at Drums and Balmedie covering a distance of up to 2 km from shore (Figure 10.2). These surveys were designed primarily for bird observations, but collected information on marine mammals observed. Vantage point surveys were conducted from August 2005 until March 2008 (Alba Ecology and Envirocentre 2008).

Bottlenose dolphins have been recorded at all four sites (Donmouth, Blackdog, Balmedie and Drums), with the distance from shore ranging from less than 0.5 km to greater than 3 km and the direction of travel being up and down the coast. Bottlenose dolphins have been observed throughout the year (except in June) and at various times of the day.

Harbour porpoises have been recorded at all four sites (Donmouth, Blackdog, Balmedie and Drums), with the distance from shore ranging from 0.5 km to 2 km and the direction of travel has been both up and down the coast, although the majority appeared to be heading north. Harbour porpoises have been observed in January, February, May, June, July, August, September and December and at various times of the day.

The majority of seal sightings were of individual animals, probably grey seals, although harbour seals were recorded at Blackdog in June 2007 and at the Donmouth in July 2007. Seals have been recorded at all four sites Donmouth, Blackdog, Balmedie and Drums, although there is only one recorded sighting at Drums, with the distance from shore ranging from the surf zone to 1.5 km. Seals have been observed in January, February, March, August and December, at various times of the day.

Other species recorded were Risso's dolphins in April 2006 and April 2007. Single minke whales were recorded at both Donmouth and Blackdog on 13th July 2007, although this may have been the same individual moving along the coast and a large unidentified cetacean more than 5 km from the coast was observed in December 2006.

3.3 JNCC marine mammal observations during winter aerial surveys of Aberdeen Bay

The Joint Nature Conservation Committee (JNCC) conducted aerial surveys of wintering aggregations of seaducks, divers and grebes within Aberdeen Bay in December 2004, February 2005, December 2005, January 2006, May 2006 and April 2007. Surveys were conducted from light aircraft, following a line-transect method (details of the survey methods are provided in Söhle *et al*. (2006) and Wilson *et al*. (2006). During these surveys observations of bottlenose dolphins and harbour porpoises were recorded incidentally (Table 6).

Table 6 Marine mammal observations during JNCC aerial surveys of Aberdeen Bay (2004-2007) (Söhle *et al.*,, 2006; Wilson *et al.*, 2006)

Date	Bottlenose dolphin	Harbour porpoise
11th December 2004	4	0
17th February 2005	1	0
8th December 2005	4	6
24th January 2006	0	5
10th May 2006	0	0
26th April 2007	1	0

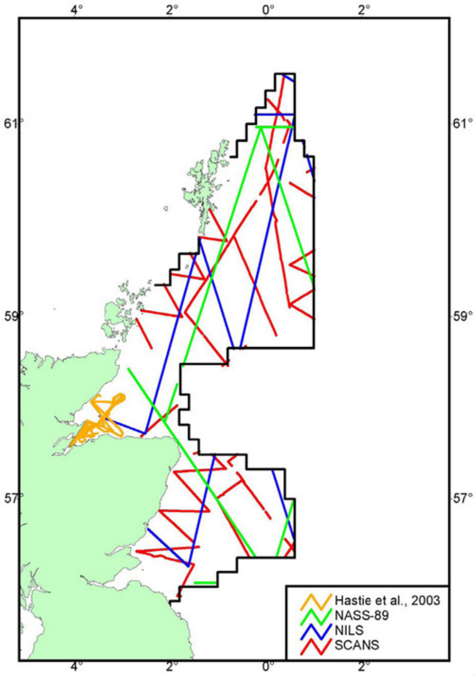
3.4 Distribution and Abundance of Cetaceans to the North and East of Scotland (SEA5)

Hammond *et al*. (2004) examined the distribution and abundance of cetaceans occurring to the north and east of Scotland during the Strategic Environmental Assessment (SEA) 5 (Figure 3). Species that are known to occur regularly in this area are the harbour porpoise, white-beaked dolphin, Atlantic white-sided dolphin, killer whale, bottlenose dolphin and minke whale. In addition there are occasional at-sea records in the area of at least eight further cetacean species: humpback whale, fin whale, sperm whale, northern bottlenose whale, long-finned pilot whale, Risso's dolphin, short-beaked common dolphin and striped dolphin.

Hammond *et al*. (2004) reviewed quantitative information for this area from a variety of sightings surveys including the Small Cetacean Abundance in the North Sea (SCANS) survey in July 1994 (Hammond *et al.* 1995; 2002), the North Atlantic Sightings Surveys (NASS) in July 1989 (Bjørge and Øien, 1995), and the Norwegian Independent Line transect Surveys (NILS) in July 1995 and 1998 (Schweder *et al.,* 1997; Skaug *et al.,* 2003). There are also published cetacean observations made during seismic surveys in 1996 to 1999 (Stone, 1997; 1998; 2000; 2001; 2003a). Acoustic recordings have also been used to determine the general distribution and seasonal patterns of movement of some cetacean species by Cornell University, Aberdeen University and the Joint Nature Conservation Committee using the US Navy's SOSUS hydrophone array and low frequency sonor buoys (Swift *et al.,* 2002).

Information from Hammond *et al*. (2004) has been included in this review, with particular reference to the north-east coast of Scotland.

Figure 3 SEA 5 Area: north and east Scotland, including cruise tracks from various surveys conducted in the SEA5 area and SCANS (Hammond *et al*., 1995; 2002: black line outlines SEA5 area)



3.5 NORTHERN NORTH SEA CETACEAN FERRY SURVEYS (NORCET)

Cetacean surveys have been conducted from the bridge of the *MV Hascosay* ferry between Aberdeen, Orkney and Shetland during daylight hours in summer months (April to September) from 2002 to 2006 (MacLeod *et al*., 2007). Data from these surveys provided important additional information on the occurrence and distribution of cetaceans in areas away from the coast that are not regularly covered by other surveys. Although the surveys have been continuing after 2006, no analysed sightings data was available.

In the first five years, surveys were been conducted on over 100 days and 383 sightings of 1,148 individual cetaceans were recorded. These sightings represent 10 different species. The most commonly sighted species was the harbour porpoise (164 sightings) which were recorded throughout the region. Minke whales were the second most commonly recorded species (55 sightings) and were most commonly sighted in deeper waters of the outer Moray Firth in early summer and in more coastal waters in later summer. The third most commonly seen species was the white-beaked dolphin (53 sightings). Again this species was recorded through out the study area, but was most commonly sighted in July and August in coastal waters. Thirty-nine groups of bottlenose dolphins were sighted, but this species was almost exclusively sighted close to shore as the ferry passed along the coast of mainland Scotland. Only harbour porpoises, minke whales and bottlenose dolphins were recorded in all summer months. The remaining species sighted were the Atlantic white-sided dolphin (10 sightings), the common dolphin (9 sightings), the Risso's dolphin (6 sightings), the killer whale (3 sightings), the fin whale (3 sightings) and the humpback whale (1 sighting).

The data collected from the NORCET ferry surveys 2002-2006 is summarised in Figure 4. The proportion of cetacean species detected during each month and year of survey effort is illustrated in Figure 5 and Figure 6.

Figure 4 Cetacean species detected along the north east coast of Scotland during NORCET Ferry crossings 2002-2006 (MacLeod *et al*., 2007)

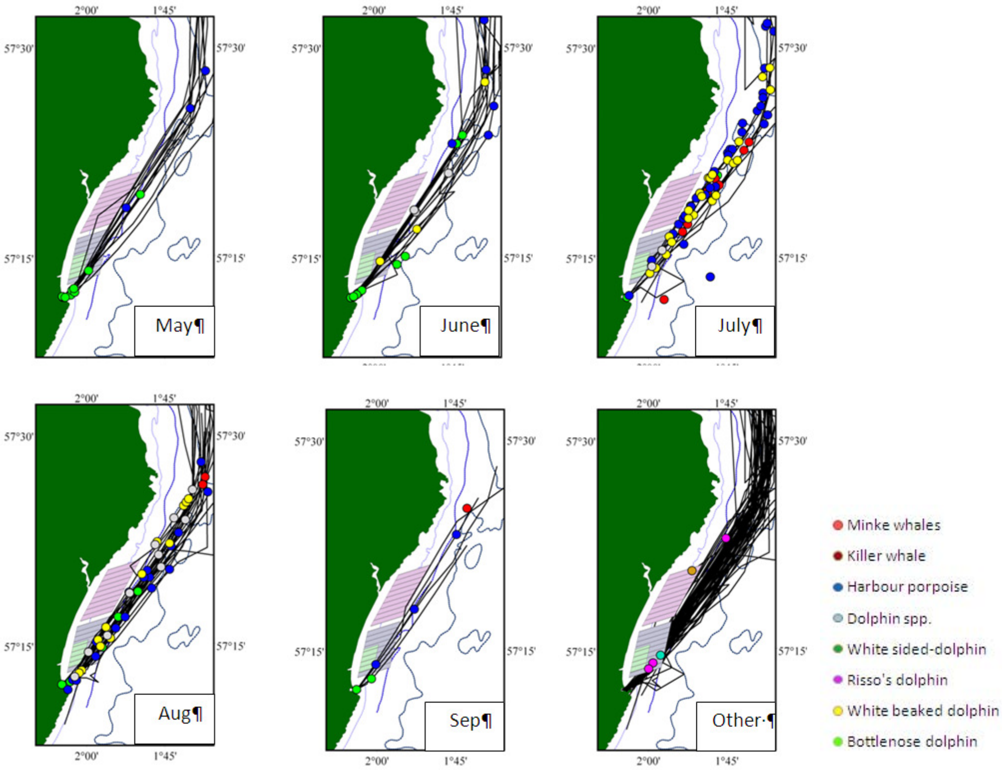


Figure 5 Proportion of cetacean sightings per month during the NORCET surveys 2002-2006(Data used from MacLeod *et al*., 2007)

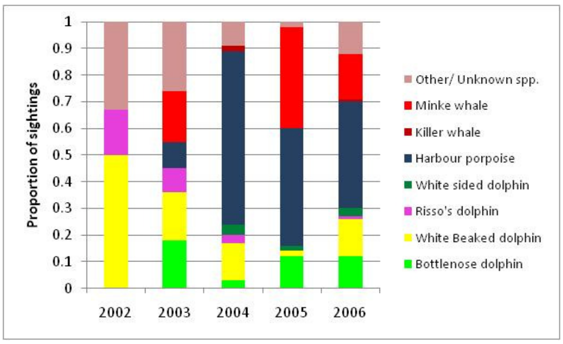

Figure 6 Proportion of cetacean sightings per year during the NORCET surveys 2002-2006(Data used from MacLeod *et al*., 2007)

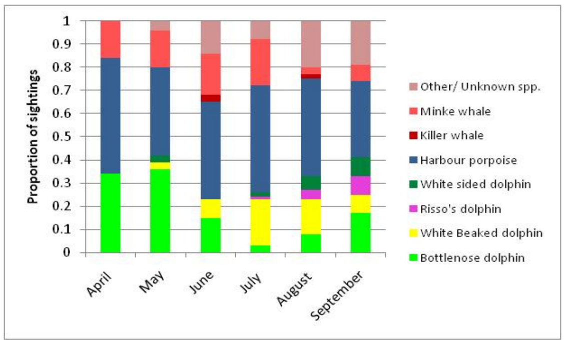


3.6 Moray Firth Study Assessing Impacts of Potential Oil and Gas Seismic Surveys

The Department and Energy and Climate Change (DECC), with co-funding from the Scottish Government COWRIE and Oil and Gas UK funded a three year research programme that will finish in 2012 to assess the potential impacts of proposed oil and gas activities on cetaceans in the Moray Firth. The project involved the collection of boat based survey, aerial survey (2010) and deployment of acoustic hydrophones (C-Pods) to detect the vocalisations of cetaceans. The interim results of the first two years of surveys have been published and results applicable to the two main cetacean species observed in the Moray Firth the harbour porpoise and bottlenose dolphin will be presented (Thompsen, *et al*., 2010; Thompsen *et al*., 2011).

3.7 Cetacean Stranding Data: Fraserburgh to Inverbervie (January 1992 – March 2010)

The Scottish Agricultural College Veterinary Services at Inverness carry out necropsies on stranded and by-caught cetaceans in Scotland for the DEFRA funded Marine Mammal Strandings Program as part of the United Kingdom Government's commitment to a number of international conservation agreements. Post mortem procedures, sampling and data collection by the SAC follow the recommended procedure of the European Cetacean Society (Kuiken and Hartmann, 1991) and the UK Marine Mammal Project (Law, 1994).

Nine cetacean species have been recorded in the strandings database by the Scottish Agriculture College along the northeast coast of Scotland from Fraserburgh to Inverbervie between January 1992 and March 2010 (SAC, 2006; CSIP 2010). Of the 167 cetaceans in the strandings records for the north-east coast the majority (approximately 78%) were harbour porpoises, other species were white-beaked dolphins, sperm whales, minke whales, common dolphins, Risso's dolphins, bottlenose dolphins, long-finned pilot whale and Sowerby's beaked whale (Table 7).

Table 7 Strandings data recorded from Fraserburgh to Inverbervie 1992-2006 (SAC, 2006; CSIP 2010)

Species	Number
Harbour porpoise	130
White-beaked dolphin	14
Sperm whale	9
Minke whale	5
Common dolphin	3
Risso's dolphin	2
Bottlenose dolphin	2
Long-finned pilot whale	1
Sowerby's beaked whale	1

4. MARINE MAMMALS IN ABERDEEN BAY AND SURROUNDING AREA

The northern and central North Sea is in an important area for several marine mammal species. Minke and killer whales, white-beaked and white-sided dolphins and harbour porpoises may occur regularly in the area, of which the harbour porpoises, minke whales and white-beaked dolphins are the most abundant. Bottlenose dolphins are regularly seen in coastal waters in the Moray Firth and along the north east coast of Scotland. Long-finned pilot and sperm whales, common, striped, Risso's and bottlenose dolphins are less frequently sighted in the central and northern North Sea, while other species including northern bottlenose, Sowerby's beaked, fin and humpback whales are encountered infrequently/ rarely (Hammond *et al*., 2001, 2002, 2004; Northridge *et al*., 1995; Reid *et al*., 2003; Stone, 1997, 1998, 2000, 2001, 2003a, b; Weir and Stockin, 2001; Weir *et al*., 2007; Wilson *et al*., 2000).

There abundance of marine mammal species that are known to occur, or have been previously recorded, in Aberdeen Bay area is shown in Table 8.

Table 8 Summary of abundance of marine mammals within Aberdeen Bay

Common name	Latin name	Abundance
Bottlenose dolphins	*Tursiops truncatus*	common/regular
Harbour porpoises	*Phocoena phocoena*	common/regular
White-beaked dolphins	*Lagenorhynchus albirostris*	common/seasonal
Minke whales	*Balaenoptera acutorostrata*	common/seasonal
White-sided dolphins	*Lagenorhynchus acutus*	occasional
Killer whales	*Orcinus orca*	rare
Common dolphins	*Delphinus delphis*	infrequent/rare
Risso's dolphins	*Grampus griseus*	occasional
Striped dolphins	*Stenella coeruleoalba*	rare
Long-finned pilot whales	*Globicephala melas*	infrequent/rare
Sperm whales	*Physeter macrocephalus*	infrequent/rare
Humpback whales	*Megaptera novaeangliae*	rare
Fin whales	Balaenoptera physalus	rare
Sowerby's beaked whales	*Mesoplodon bidens*	rare
Northern bottlenose whales	*Hyperoodon ampullatus*	rare
Harbour seals	*Phoca vitulina*	common/regular
Grey seals	*Halchoerus grypus*	common/regular

Between 1999 and 2001, a total of 9 different cetacean species were reported between Peterhead and Arbroath (Weir and Stockin, 2001). The most frequently sighted cetaceans were the bottlenose dolphin and harbour porpoise. Both species were reported from all along the coastline, although the majority of bottlenose dolphin sightings were in the vicinity of Aberdeen harbour. Other species recorded include the white-beaked dolphin, minke whale, killer whale and long-finned pilot whale (Weir and Stockin, 2001). Since 2001 a further three cetacean species have been recorded for the first time in the area; these were humpback whale, northern bottlenose whale and Risso's dolphins (SGSW unpublished data).

Marine mammal surveys have been conducted along the Aberdeenshire coast from 2001 to 2005 (prior to the EOWDC marine mammal surveys), during these surveys a total of seven different species of cetacean were recorded: bottlenose dolphins, harbour porpoises, white-beaked dolphins, minke whales, long-finned pilot whales, Risso's dolphins and humpback whales (Canning, 2007). Bottlenose dolphins, harbour porpoises, minke whales, white-beaked dolphins, harbour seals and grey seals are known to occur regularly in the Aberdeen Bay area.

For cetacean species such as common dolphins, fin whales, humpback whales, northern bottlenose whales, long-finned pilot whales, sperm whales and striped dolphins the area off north-east Scotland is only a marginal part of their habitat, and is likely to be inhabited only during a restricted part of the year (Hammond *et al*., 2004).

Table 9 Summary of the presence, seasonal occurrence and seasonal sensitivities of marine mammals in the Aberdeen Bay area

Species	Presence	Seasonal Occurrence											
		Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Bottlenose dolphin	regular				*	*	*	*	*	*			
Harbour porpoise	regular				*	*	*	*	*	*			
White-beaked dolphin	regular/seasonal						*	*	*				
Minke whale	regular												
White-sided dolphin	occasional												
Killer whale	rare												
Common dolphin	occasional												
Risso's dolphin	occasional/regular												
Striped dolphin	rare												
Long-finned pilot whale	occasional												
Sperm whale	rare												
Humpback whale	rare												
Fin whale	rare												
Northern bottlenose whale	rare												
Sowerby's beaked whale	rare												
Harbour seal	regular						*	*	*	*			
Grey seal	regular		*	*	*						*	*	
Hooded seal	rare												

Key
- Present in area (sighting and/or stranding)
- Peak abundance
- Potential to be present in area
- * Seasonal sensitivities (e.g. calving period, moulting period)

5. CETACEANS

5.1 BOTTLENOSE DOLPHIN (*TURSIOPS TRUNCATUS*)

5.1.1 Distribution

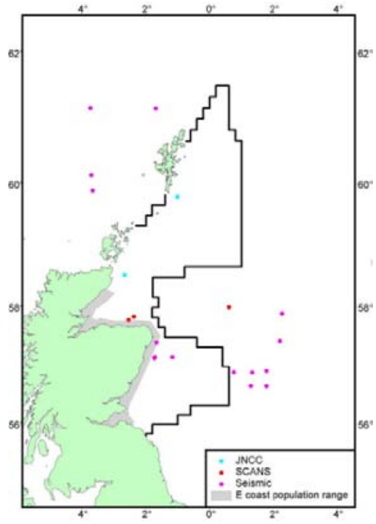
Bottlenose dolphins occur world-wide; they are found in virtually all tropical and temperate seas and occupy most marine habitats from the open ocean to coastal lagoon. Bottlenose dolphins occur in European waters along the Atlantic shores from Portugal to the Faroe Islands. Their distribution appears to be linked to sea temperature; in the north-east Atlantic resident coastal populations extend only as far north as Scotland. However, the species is caught in the Faroes drive fishery, suggesting that it may be more abundant and widespread than is generally thought (Hammond *et al*., 2001). Bottlenose dolphins are not particularly common in the north-eastern area of the North Atlantic but there are a number of well-documented and, in some cases, well-studied coastal populations along the Atlantic margin of Europe (Hammond *et al*., 2004).

There are two main areas of UK territorial waters where there are semi-resident groups of bottlenose dolphins: Cardigan Bay in Wales and the Moray Firth on the north-east coast of Scotland. Both of these areas have been designated Special Areas of Conservation (SAC) for bottlenose dolphins. There are also smaller populations of bottlenose dolphins off south Dorset, around Cornwall and in the Sound of Barra in the Outer Hebrides. Other bottlenose dolphin groups, presumed to be of transients, have been recorded further offshore in deeper water to the west of Scotland.

Figure 9 shows the locations of bottlenose dolphin sightings made during systematic surveys and some platforms of opportunity off north-east Scotland (Hammond *et al*., 2004). The few observations offshore in the North Sea may indicate that animals from the Moray Firth population could be distributed offshore at least for part of the year (Hammond *et al*., 2004).

During the SCANS II surveys in July 2005, bottlenose dolphins were encountered around the coasts of Britain, Ireland, France, Spain and Portugal. They were also sighted in outer shelf waters off Scotland and Ireland and in the Celtic Sea. The total abundance of bottlenose dolphins for the entire SCANS II survey area is estimated to be 12,645 (CV=0.27) (SCANS II, 2008).

Figure 7 Scottish east coast range and sightings of bottlenose dolphins from various sources (Hammond *et al*., 2004)



5.1.2 Occurrence in Aberdeen Bay and surrounding area

Bottlenose dolphins are known to occur regularly in the Aberdeen Bay area. Observations indicate they are present in the area throughout the year, with a peak occurrence during the winter and spring months (November-May), when they can be observed almost daily feeding at Aberdeen Harbour (Canning, 2007; Stockin *et al*., 2006).

The habitation of Aberdeenshire's coastal waters by bottlenose dolphins appears to have increased since the early 1990s and they are now the most frequently reported cetacean species in the area (Stockin *et al*., 2006; Weir and Stockin, 2001). There has been a recent increase in sightings along the east coast of Scotland as far south as St Andrews (Wilson *et al*., 2004).

Analysis of cetacean distribution and habitat use along the Aberdeenshire coast, indicate that the entrance to the River Dee (Aberdeen harbour) is an important feeding area for bottlenose dolphins, especially during the winter and spring when dolphins are most abundant (Canning, 2007). The majority of sightings away from Aberdeen were of groups travelling while those sighted at Aberdeen generally exhibited foraging behaviours (Canning, 2007).

Bottlenose dolphin presence at Aberdeen harbour showed a strong correlation with tidal height and river flow. These factors are also known to influence salmon migration up river, suggesting that salmon presence is the factor attracting these dolphins to this site. The seasonal pattern in the age of salmon that move upstream (with the older, multi-winter fish coming inshore during the winter and spring), matches the seasonal pattern in the bottlenose dolphin sightings suggesting they could be targeting these older fish (Canning, 2007).

The importance of the Aberdeen harbour area during the winter is the opposite of what has been observed within the Moray Firth, where the majority of sightings are during the summer (Wilson *et al.*, 1997a). Bottlenose dolphins are now also regularly recorded off St Andrews (70 miles south of Aberdeen) and again the sightings here are mainly during the summer, with peak sightings occurring between June and August (N. Quick, Pers. Comm.; Hammond *et al*., 2004).

Bottlenose dolphin sightings recorded during targeted project Vantage Point surveys (August 2005 – March 2008) are summarised in Table 10 .

Table 10 Bottlenose dolphin sightings recorded during Vantage Point surveys (August 2005 – March 2008)

VP site	Observations
Donmouth	April 2006, May 2006, March 2007, April 2007, July 2007, August 2007, September 2007 and March 2008
Blackdog	April 2006, May 2006, July 2006, August 2006, January 2007, and July 2007
Balmedie	December 2005, August 2007 and April 2007
Drums	August 2005, November 2005, August 2006, December 2006, February 2007 and July 2007.

During the JNCC aerial survey of Aberdeen Bay, bottlenose dolphins were recorded in December 2004, February 2005, December 2005 and April 2007 (Table 2).

A number of unidentified dolphin species were detected during the four months of SMRU Ltd acoustic surveys carried out for the EOWDC, these results are presented in Appendix 8.2

5.1.2.1 Boat based survey results 2007-2008: Bottlenose dolphins

There were 200 bottlenose dolphins that were recorded during 62 observations both on and off effort during the boat based surveys carried out 2007-2008 (Figure 8). There were 10 observations of 58 bottlenose dolphins collected on effort that would have been available for distance analysis (if statistically feasible). The mean group size of all sightings both on and off effort was 5.2 individuals. The majority of sightings occurred during the spring months with sightings occurring throughout the year. A higher number of individuals were observed in the wind farm survey area in comparison to the control site (Table 11).

Figure 8 Bottlenose dolphins observed on and off effort during the 2007-2008 EOWDC boat surveys

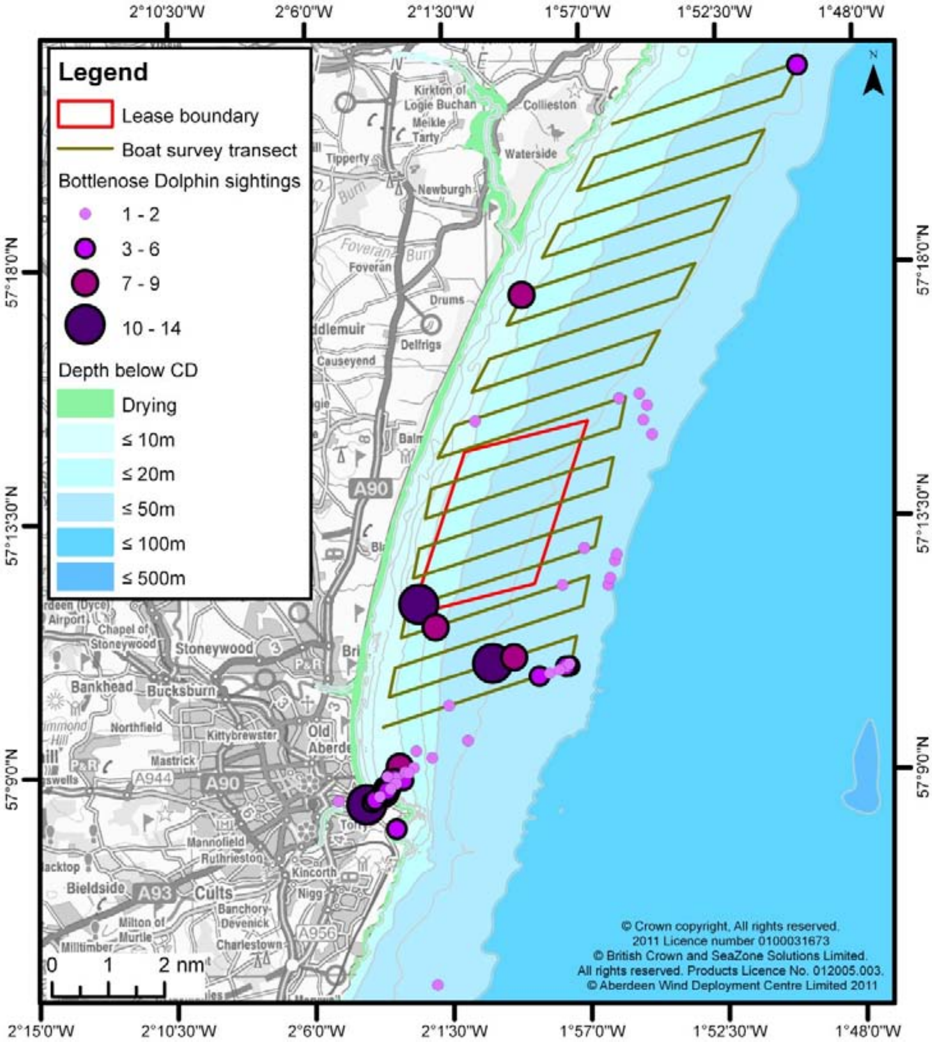


Table 11 Sightings information for bottlenose dolphins recorded during the boat based surveys 2007-2008

Common name	Winter	Spring	Summer	Autumn	Total On effort	Total Off effort	Total On /Off effort	Windfarm	Control
Bottlenose dolphin	0 (9)	20 (76)	34 (45)	3 (13)	58	142	200	46 (69)	13 (71)

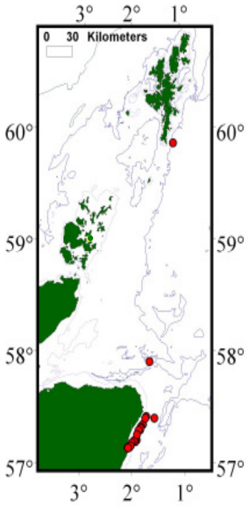
During the boat based surveys in August, September and November 2010 and January 2011 no bottlenose dolphins were recorded, although a total of 13 unidentified dolphins and dolphin vocalisations were detected during these surveys.

5.1.3 Observations from ferry surveys

Cetacean surveys were conducted from the bridge of the *MV Hascosay* ferry between Aberdeen, Orkney and Shetland during summer months (April to September) from 2002 to 2006. During these surveys, bottlenose dolphins were not sighted evenly throughout the study area, and the sightings were concentrated in the region along the coast of mainland Scotland, and particularly in the waters around Aberdeen Harbour (Figure 9). Thirty-nine sightings of bottlenose dolphins were recorded during more than 100 survey days, making it the fourth most commonly sighted species in the region. Bottlenose dolphins were recorded in all months surveyed. The average group size was five individuals, but groups ranged from one to 25 individuals (MacLeod *et al.*, 2007).

Observations during the ferry surveys are consistent with studies conducted in the outer Moray Firth and along the Aberdeenshire coast, which indicate that bottlenose dolphins primarily use coastal waters in this region, and suggest that this population of bottlenose dolphins rarely use the deeper, more open waters of the outer-most Moray Firth and the northern North Sea. In addition, observations during the ferry surveys suggest that bottlenose dolphins rarely, if ever, occur in the coastal waters around Orkney and Shetland (MacLeod *et al.*, 2007).

Figure 9 Distribution of bottlenose dolphin sightings during ferry surveys (April to September, 2002-2006)



5.1.4 Moray Firth population Bottlenose dolphin

5.1.4.1 Distribution and occurrence

In March 2005, an area of the inner Moray Firth (with an outer boundary from Helmsdale on the north coast to Lossiemouth on the south coast) was designated as a marine SAC for the conservation of the bottlenose dolphin population. In the 1980s, the core of this population's range was in the inner Moray Firth. Dolphins are distributed throughout the inner Moray Firth and there are three areas 'hotspots' where sightings are concentrated: the Kessock Channel, Channory narrows, and around the mouth of the Cromarty Firth, all of which are narrow, deep channels associated with strong tidal currents (Wilson *et al.*, 1997a; Hastie *et al.*, 2003b).

Spatial patterns of cetacean distribution within the Moray Firth have been investigated using a combination of visual and passive acoustic boat-based line-transect surveys in the inner and outer Moray Firth during the summers of 2004 and 2005. Bottlenose dolphins had a predominately near-shore distribution with a confirmed preference for hotspots within the inner Moray Firth. However, some regular, but sporadic, dolphin activity was present at the Beatrice wind farm site (offshore) during the late summer/autumn of the sampling period (Lusseau *et al.*, 2005; Talisman, 2005).

Bottlenose dolphins are observed all year round within the Moray Firth SAC, although there is a seasonal pattern to their sightings with peak sightings occurring during the summer months between May and September and lower number in winter and spring (Wilson *et al.,* 1997a).

Systematic boat surveys conducted along the southern outer Moray Firth coastline between the ports of Lossiemouth and Fraserburgh from May to October 2001 to 2005 inclusive by the Cetacean Research and Rescue Unit, found that bottlenose dolphins were only recorded in shallow waters rarely exceeding 25m depth and encounters were highly variable across all months (Robinson *et al*., 2008).

From the analysis of the acoustic data collected as part of the Moray Firth study on the potential impacts oil that and gas exploration has upon cetacean, dolphins tended to be detected most often in the inner Moray Firth and along the southern Moray Firth and less frequently in the central Moray Firth, but with detections increasing again at more offshore locations (Figure 10). Aerial survey data collected during August to November 2010 confirmed that cetacean sightings in the central and offshore waters of the Moray Firth were either the Risso's dolphin, white beaked dolphin or common dolphin and therefore indicated that most if not all of the dolphins detected in the Cpods in more offshore water represent detections of these other species (Figure 10). The 2010 results were compared with acoustic detections in 2009 and the data indicate that the spatial variation in dolphins was consistent between years (Thompsen *et al*., 2011).

Figure 10 Proportion of days that dolphin detections were recorded at the C-pod location sites (reproduced from Thompsen *et al*. 2011)

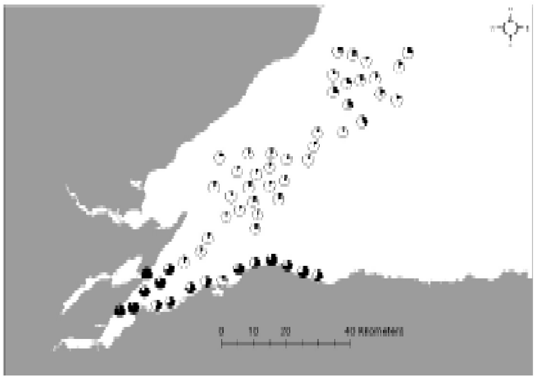


Figure 11 Dolphin observations during the aerial surveys carried out August-November 2010 (reproduced from Thompsen *et al*. 2011)

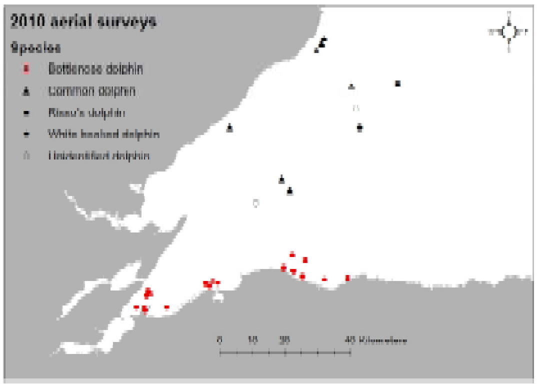


5.1.4.2 Abundance

Data collected during 1990 and 1993 estimated that 129 individuals (95% Confidence Interval (CI): 110-174) used the Moray Firth area at this time (Wilson *et al*., 1999a). Analysis of survey data between 1990 and 2002 indicated considerable variability among years, with estimates ranging between 75-200 (Thompson *et al*., 2004a) and similarly, analysis of data collected in 2001 estimated an average population size of around 85 (95% probability interval = 76-263) (Durban *et al*., 2005), although there is uncertainty about current trends in abundance (Thompson *et al*., 2004a).

Data collected up to 1997 were analysed to estimate rates of survival and reproduction, which were incorporated in a Population Viability Analysis (PVA) to predict likely future population trends (Sanders-Reed *et al*. 1999). These models predicted that, if conditions remained the same, the Scottish east coast population was likely to decline at a rate of around 5% per annum. The results of the modelling study were used to assign the bottlenose dolphin population to 'unfavourable – declining' (according to the framework categories within the Common Standards Monitoring). However, the calculated annual estimates of abundance from 1990 to 2002 showed no clear trend

(Hammond *et al*., 2004). Subsequent results from the monitoring programme that Scottish Natural Heritage established to follow changes in the number of dolphins using the SAC indicated that, whilst the numbers had declined during the 1990's, these appeared to be stabilising by 2004. As a result, the condition was assessed as "unfavourable recovering" in 2005 (Thompsen, *et al*., 2009).

5.1.4.3 Genetic and social structure

The Moray Firth bottlenose dolphin population is thought to be genetically isolated, with studies indicating a low mitochondrial genetic diversity (Parsons *et al*., 2002). From genetic studies it appears that Scottish east coast bottlenose dolphins are more closely related to the Welsh population in Cardigan Bay and to individuals stranded around the southern coast of England than to individuals encountered in the Scottish Western Isles (Parsons *et al*., 2002).

Analysis of the social structure of bottlenose dolphins along the Scottish east coast suggest that the population is composed of two social units with restricted interactions via a few common individuals (Lusseau *et al*., 2005). These two units appear to be related to known differences in the ranging pattern of individuals (Wilson *et al*., 2004). Individuals commonly seen in the inner Moray Firth were not observed in other locations and these individuals tend not to interact with individuals coming into the inner Moray Firth area during summer and mostly remained within their communities. The home ranges of the two social units largely overlap and this may be related to the presence of abundant prey in the area that allows the two communities to co-inhabit in the same area at this time (Lusseau *et al*., 2005).

5.1.4.4 Range expansion

Recent evidence suggests that the Moray Firth bottlenose dolphin population has been extending its range beyond the boundaries of the Moray Firth and associated SAC, with an increase in sightings along the east coast of Scotland as far south as St Andrews and the Firth of Forth (Wilson *et al*., 2004).

Between 1990 and 2000, photo-identification surveys were conducted within the inner Moray Firth, along the coastal waters of the outer Moray Firth and along the coasts south of Fraserburgh (Wilson *et al*., 2004). Examination of the data for 54 distinctly marked individuals (approximately 42% of the estimated population, which were identified in the inner Moray Firth between 1990 and 1992 and were known to have survived through the 1990s), found that the majority (74%) had subsequently been identified in the outer Moray Firth and 61% had been seen along the coasts south of Fraserburgh, confirming that they had come from the 'Moray Firth population' (Wilson *et al*., 2004). The animals seen in other areas continued to be seen within the inner Moray Firth, indicating an expansion, rather than shifting of their range (Wilson *et al*., 2004).

There appears to be a spatio-temporal stratification pattern within the population, with animals using areas outside the inner Moray Firth also spending less time within the inner Moray Firth. Animals that were identified in areas outside the Moray Firth also occupied the areas furthest from the head of the inner Moray Firth when identified within the inner Moray Firth, compared to animals that were predominantly sighted within the inner Moray which tended to be found most often closest to the headwaters (Wilson *et al*., 2004).

In addition, animals that used areas outside the inner Moray Firth appeared to move greater distances between sightings and moved faster during sightings. For example, one individual was identified south of Aberdeen in June 1996 and was re-identified off Burghead 52 hours later, representing a distance of 218 km and a minimum swimming speed of 4.2 km/h (Wilson *et al*., 2004). For consecutive sightings 5 or less days apart, the median rate of travel for dolphins identified primarily within the inner Moray was 0.071 km/h, whereas for dolphins observed using areas outwith the inner Moray Firth it was significantly grater at 0.22 km/h. Similarly, during sightings in the outer Moray Firth and along the coasts south of Fraserburgh the median rate of progress was 7.6 km/h, which was twice as fast as in the inner Moray Firth (3.9 km/h) (Wilson *et al*., 2004).

The reasons for the apparent range expansion appear to be related to changes in prey resources (Wilson *et al*., 2004). For example, the rapid and long-range movements observed outside the inner Moray Firth suggests that prey resources may be more widely dispersed and/or different in these areas. The stratification among individuals may indicate competition for resources (Wilson *et al*., 2004).

5.1.4.5 Diet

Bottlenose dolphins are opportunistic feeders and take a wide variety of fish and invertebrate species. Despite the large amount of information on bottlenose dolphins in the area, relatively little is known about their diet. Stomach content analysis of bottlenose dolphins (n= 10) from Scottish waters indicate that the main prey eaten were cod (*Gadus morhua*), saithe (*Pollachius virens*) and whiting (*Merlangius merlangus*) although several other fish species were also eaten, including salmon (*Salmo salar*) and haddock (*Melanogrammus aeglefinus*) and cephalopods (Santos *et al*., 2001a).

5.1.4.6 Habitat use and foraging

Bottlenose dolphin presence at the mouth of the River Dee (Aberdeen harbour) has been associated with salmon migration, suggesting that salmon presence is a factor in attracting these dolphins to this site (Canning, 2007). Although the River Dee is situated in a large bay, it flows out through a man-made harbour, the entrance to which is narrow and deeper than the surrounding waters, therefore creating a potential "bottleneck" for migrating fish (Canning, 2007).

Within the inner Moray Firth, feeding behaviour by bottlenose dolphins was significantly higher in areas used intensively by dolphins, these discrete areas occur in deep narrow entrances to coastal inlets that have steep seabed gradients and strong tidal currents (Hastie *et al*., 2004; Wilson *et al*., 1997a). Behaviours that were associated with feeding on large prey peaked in deep waters over steep seabed gradients, particularly during June and July (Hastie *et al*., 2004). It has been suggested that these areas create bottlenecks for migratory fish, most likely migrating salmonids (*Salmo salar* and *Salmo trutta*) potentially increasing foraging opportunities (Wilson *et al*., 1997a).

Passive acoustic monitoring within the deep (55m), narrow channel at the entrance to the Cromarty Firth, indicated that bottlenose dolphins used the full water column and consistently dived to depths of around 50 m, close to the seabed. However, the majority of their time appeared to be spent within the surface layers and feeding behaviour occurred primarily at depths between 20 m and 30 m (Hastie *et al*., 2006).

At the Kessock channel within the inner Moray Firth, bottlenose dolphins were most abundant during the flood tide, particularly during the stationary stage of the tidal front. They showed a spatial association with the area near the surface features of the front, which could be related to increasing foraging efficiency resulting from the accumulation of prey in the frontal region (Mendes *et al*., 2002).

During land-based observations at Aberdeen harbour between early May and late July 2002, bottlenose dolphins were found to present during all times of the day and tide, although occurred more frequently around midday and early afternoon, while their abundance was greater around high tide and late afternoon. Foraging was the most commonly observed activity (Sini *et al*., 2005).

5.1.4.7 Life history

Bottlenose dolphins are long-lived animals with life spans of up to 40-50 years. Females are sexually mature at between 5-12 years of age and can produce a calf every 2-3 years, although 3 to 6 year intervals are more common (Connor and Smolker, 1990; Scott *et al*., 1996; Connor *et al*., 2000). Calves stay with their mothers for at least 4 years (Smolker *et al*., 1992). However, studies in the Moray Firth indicate that the association between calves and mothers remains high until the calf is 8 years old (Grellier *et al*., 2003).

Immature bottlenose dolphins (juveniles/calves) have been observed off Aberdeenshire throughout the year, with an increase in the proportion of calves during the spring, between April and June (Canning, 2007; Stockin *et al*., 2006; Weir and Stockin, 2001). Very young calves have been recorded during spring and early summer (Weir and Stockin, 2001).

In surveys along the outer Moray Firth (May to October, 2001-2005), calves were recorded in 84% of all bottlenose dolphin encounters, with newborn animals being observed from July to October inclusive (Robinson *et al*., 2008).

5.1.4.8 Strandings

Two bottlenose dolphins have been recorded stranded by the Scottish Agricultural College along the northeast coast of Scotland from Fraserburgh to Inverbervie between January 1992 and March 2010 (CSIP 2010). One was a male with a body length of 267 cm recovered in December 1999 near Balmedie, the other had a body length of approximately 200 cm, the sex was not determined and it was recovered from Peterhead in December 2005 (SAC, 2006). Although there are only two stranding records of bottlenose dolphins along the north-east coast (1992-2010), this reflects the small population size in the area, rather than their low occurrence in the area.

5.1.4.9 Threats

Post-mortem analyses of stranded animals have identified that some fishery by-catch occurs and that at least some calf mortality results from infanticide (Patterson *et al*., 1998).

Bottlenose dolphins from eastern Scotland have a high prevalence of several different types of skin lesion (Thompson and Hammond, 1992; Wilson *et al*., 1997b). In comparison with similar data from other parts of the world the prevalence and severity of lesions are high but mainly related to exposure to water of low salinity and/or temperature (Wilson *et al*., 1999b). The causal links underlying these patterns remain unknown, but it is possible that they are related to an increase in physiological stress, potentially making the animals more prone to other factors, including anthropogenic agents such as contaminants (McKenzie *et al*., 1997) or infections from viruses, bacteria or fungi. Subsequent studies have shown that severity and prevalence of lesions vary among individuals in the Moray Firth and that variation patterns can be related to the behaviour of infectious diseases (Wilson *et al*., 2000).

5.2 HARBOUR PORPOISE (*PHOCOENA PHOCOENA*)

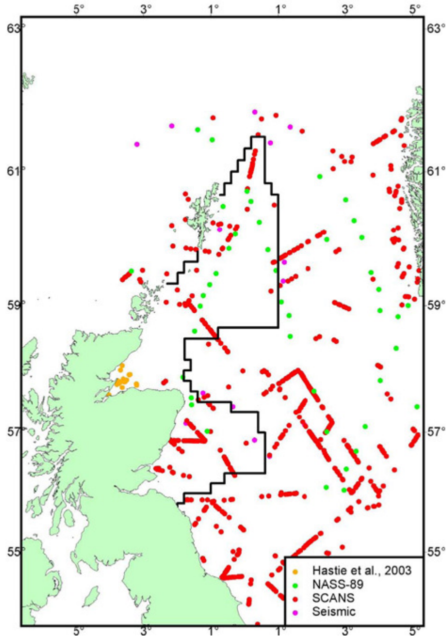
5.2.1 Distribution

Harbour porpoises are found in temperate and sub-arctic waters of the Northern Hemisphere, mainly on the continental shelves. They are distributed around the fringes of the North Atlantic Ocean basin, extending from North Carolina, off the United States, to Greenland and northern Norway and south through European waters as far as North Africa (Hammond *et al*., 2004).

The harbour porpoise is widespread throughout the cold and temperate seas of north-west Europe, including the North Sea, the Skagerrak, Kattegat, Irish Sea, west of Ireland and Scotland, northwards to Orkney and Shetland and off the coast of Norway (Jackson and McLeod, 2002). In the North Sea, sightings from shipboard and aerial surveys indicate that harbour porpoises are widely and almost continuously distributed, with important concentrations in the central North Sea, along the Danish and northern German coasts (Donovan and Bjørge, 1995; Hammond *et al.*, 2002; IWC, 1996). Harbour porpoises are highly mobile and distributed around the UK coast (Reid *et al*., 2003).

Figure 12 (taken from Hammond *et al*., 2004) shows the numerous locations of harbour porpoise sightings made during systematic surveys and some platforms of opportunity in the north and east of Scotland.

Figure 12 Harbour porpoise sightings made during various surveys. Sightings are represented by a coloured circle (Hammond *et al*., 2004).



Harbour porpoises are generally described as a shelf species that frequents relatively shallow bays, estuaries and tidal channels, generally in depths less than 200 m in continental shelf waters (Klinowska, 1991). However, they have been observed in the deep waters of the Norwegian Rinne, in deep water areas between Iceland and the Faroe Islands, and on the Rockall and Faroe Banks (Northridge *et al.*, 1995). Summer surveys in the North Sea and adjacent waters found porpoises in large numbers offshore as well as in coastal waters (Hammond *et al.*, 2002). Porpoises have also been sighted in offshore waters with depths between 953 and 1502 m off north-west Scotland (Atlantic Frontier) (MacLeod *et al.*, 2003). By-catch data from Ireland also suggest that porpoises occur regularly offshore, with records from up to 220 km from land (Rogan and Berrow, 1996). Aggregations of harbour porpoises are often associated at local sites with strong tidal features, such as headlands, and areas with upwellings, tidal races and rips, often close to reefs and small islands, where prey are probably concentrated into patches (Gaskin, 1992; Pierpoint, 2001; Read and Westgate, 1997).

Spatial patterns of cetacean distribution within the Moray Firth were investigated using a combination of visual and passive acoustic boat-based line-transect surveys in the inner and outer Moray Firth during summers 2004 and 2005. These surveys indicate that harbour porpoises tended to have a diffuse and offshore distribution (Hastie *et al.*, 2003a; Lusseau *et al.*, 2005)

During systematic boat surveys conducted along the southern outer Moray Firth coastline between the ports of Lossiemouth and Fraserburgh from May to October 2001 to 2005, harbour porpoises were encountered throughout the study area, although they were usually more abundant in deeper waters, further from shore, with sightings typically occurring along the 20-50 m isobaths. Porpoises were observed throughout the study period, with an increase in encounters from May through to October (Robinson *et al*., 2008).

During the Moray Firth surveys carried out during 2009 and 2010 as part of the research study to investigate potential impacts from oil and gas exploration on cetaceans the harbour porpoise was the most frequently observed cetacean. The results of the acoustic monitoring, using C-pods in 2009 and 2010, found that harbour porpoises were typically detected at each of the monitoring locations on most days, especially at the offshore sites (Figure 13) (Thompsen *et al*., 2011). The spatial occurrences of harbour porpoise during both 2009 and 2010 were consistent. The harbour porpoise was the most frequent cetacean detected during the aerial survey programme, a total of 230 encounters of harbour porpoise were encountered with the mean group size being 1.52 (Figure 14).

Figure 13 Proportion of days that harbour porpoise were detected by C-pods during 2010 (Thompsen *et al*., 2011)

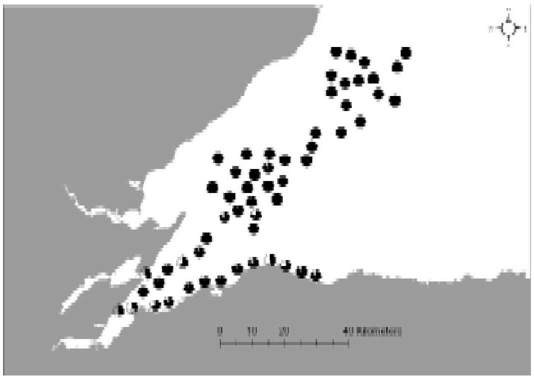


Figure 14 Observations of harbour porpoise during aerial surveys carried out in 2010 (Thompsen *et al*., 2011)

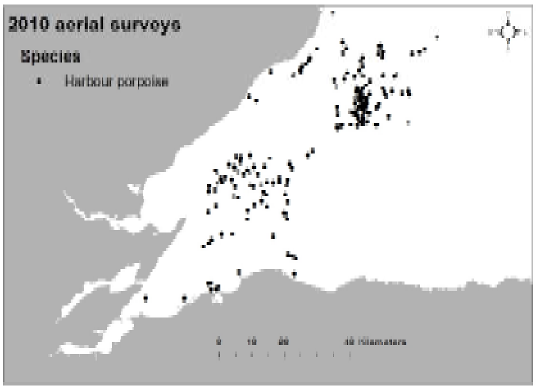


5.2.2 Seasonal movements

The seasonal movements and migratory patterns of harbour porpoises in the North East Atlantic and North Sea are not well understood. Porpoises may reside within an area for an extended period of time, however, onshore/offshore migrations and movements parallel to the shore are also thought to occur (Bjørge and Tolley, 2002). In the North Sea, there may be a general westward movement from the eastern North Sea and possibly from the very northern areas of the North Sea into the western edge of the northern North Sea (along the east coast of Scotland) during April to June and a further influx to the northern North Sea during July to September (Northridge *et al.*, 1995). These seasonal movements are thought to coincide with the calving and mating seasons, respectively.

Animals in the eastern North Atlantic are not known to perform long migrations, but satellite-tagged animals in Canada and Denmark have been shown to move some hundreds of kilometres within a year. Recent satellite-tracking data from Denmark have shown animals moving from northern Denmark to the northern North Sea and Shetland (Hammond *et al*., 2004). Satellite telemetry studies suggest that porpoises are highly mobile and capable of covering large distances in short time periods, with daily distances travelled in the Bay of Fundy varying from 14 to 58 km (Read and Westgate, 1997).

5.2.3 Abundance

The harbour porpoise is the most abundant cetacean recorded in the North Sea (Evans, 1992; Hammond *et al.*, 2002) and was the mostly commonly sighted cetacean during surveys along the southern outer Moray Firth coastline and the second most frequently sighted cetacean along the south Grampian coastline (Weir and Stockin, 2001).

The estimated summer abundance of harbour porpoises in North Sea areas during the first SCANS survey in July 1994 was 268,452 (approximate 95% confidence interval of 210,000 – 340,000). This estimate includes shelf waters to the west of Shetland and Orkney (Hammond *et al.,* 2002). Bjørge and Øien (1995) estimated that there were 82,600 porpoises in the North Sea north of 56^{o}N. This estimate is known to be biased downwards because the probability of detection on the transect line was assumed to be one (certain detection). Seabirds At Sea data from 1979 to 1991 show the highest rate of porpoise sightings in the northern North Sea is in April to June (the calving season), and July to September (Hammond *et al*., 2004).

Initial harbour porpoise abundance estimates in the entire North Sea are 231,000 from the SCANS II surveys conducted July 2005. The total abundance of harbour porpoises for the entire SCANS II survey area is estimated to be 385,616 (CV=0.20) (SCANS II, 2008). During the SCANS II surveys harbour porpoise density was highest in the south central North Sea and coastal waters of northwest Denmark (~0.6 animals/km^2), elsewhere there was relatively little variation in porpoise density (0.3-0.4 animals/km^2) (SCANS II, 2008).

Numbers of porpoises present in UK waters vary seasonally and more animals are likely to pass through UK waters than are present at any one time (Jackson and McLeod, 2002).

5.2.4 Occurrence in Aberdeen Bay and surrounding area

Harbour porpoises are known to occur regular in the Aberdeen Bay area throughout the year. Land- and vessel based sightings between March 1999 and October 2001, along the Aberdeenshire coast (between St Cyrus and Collieston, primarily between Stonehaven and Aberdeen) indicated that harbour porpoises were present throughout the year with peak occurrence during August and September (Weir *et al*., 2007).

Land based surveys carried out by the Seawatch Foundation indicated that porpoises were sighted more frequently between Stonehaven and Aberdeen, than between Aberdeen and Collieston, with the majority of sightings occurring off Cove and Girdleness to the south of Aberdeen (Weir *et al*., 2007). Tidal height and sea depth appears to have a strong influence on where and when porpoises are sighted and it is thought this is a reflection of prey behaviour (Canning, 2007).

Harbour porpoise sightings were frequently recorded during vantage point surveys of the wind farm area between August 2005 – March 2008 and the sightings are summarised in Table 12.

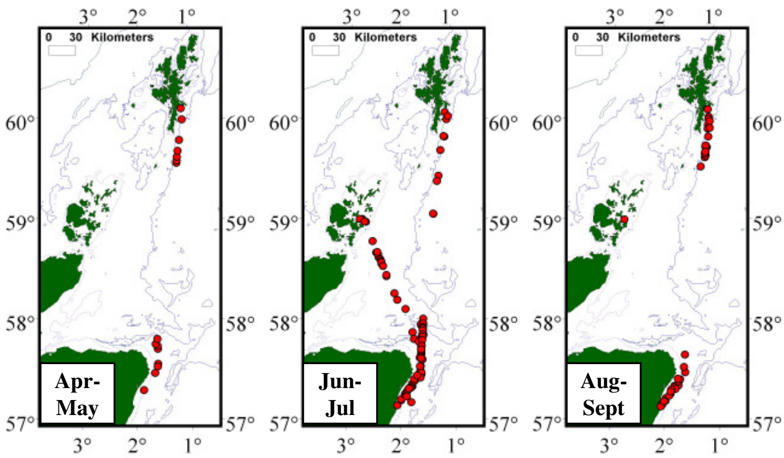
Table 12 Harbour porpoise sightings recorded during Vantage Point surveys (August 2005 – March 2008)

VP site	Observations
Donmouth	August 2006, September 2006, February 2007, September 2007, December 2007 and January 2008
Blackdog	May 2006, August 2006, September 2006, January 2007, February 2007, July 2007, August 2007 and September 2007,
Balmedie	September 2006, December 2006, January 2007, August 2007 and March 2008
Drums	December 2006, January 2007, February 2007, June 2007, August 2007, December 2007 and February 2008

During the JNCC aerial survey of Aberdeen Bay, harbour porpoises were recorded in December 2005 and January 2006 (Söhle *et al*., 2006)

Harbour porpoises were the most recorded cetacean species during over 100 days of surveys conducted from the bridge of the *MV Hascosay* ferry as it travelled between Aberdeen, Orkney and Shetland in summer months between 2002 and 2006 (MacLeod *et al.*, 2007). Porpoises were recorded through out the region and in all months surveyed with no obvious changes in distribution over time (Figure 15). Recorded group sizes ranged from one to six, with an average of two. There was no variation in average group size across the summer months, but the maximum group size peaked in August and was lowest in April and September (MacLeod *et al*., 2007).

Figure 15 Distribution of harbour porpoise sightings during ferry surveys (April-September, 2002-2006)



5.2.4.1 Boat based survey results: Harbour porpoise

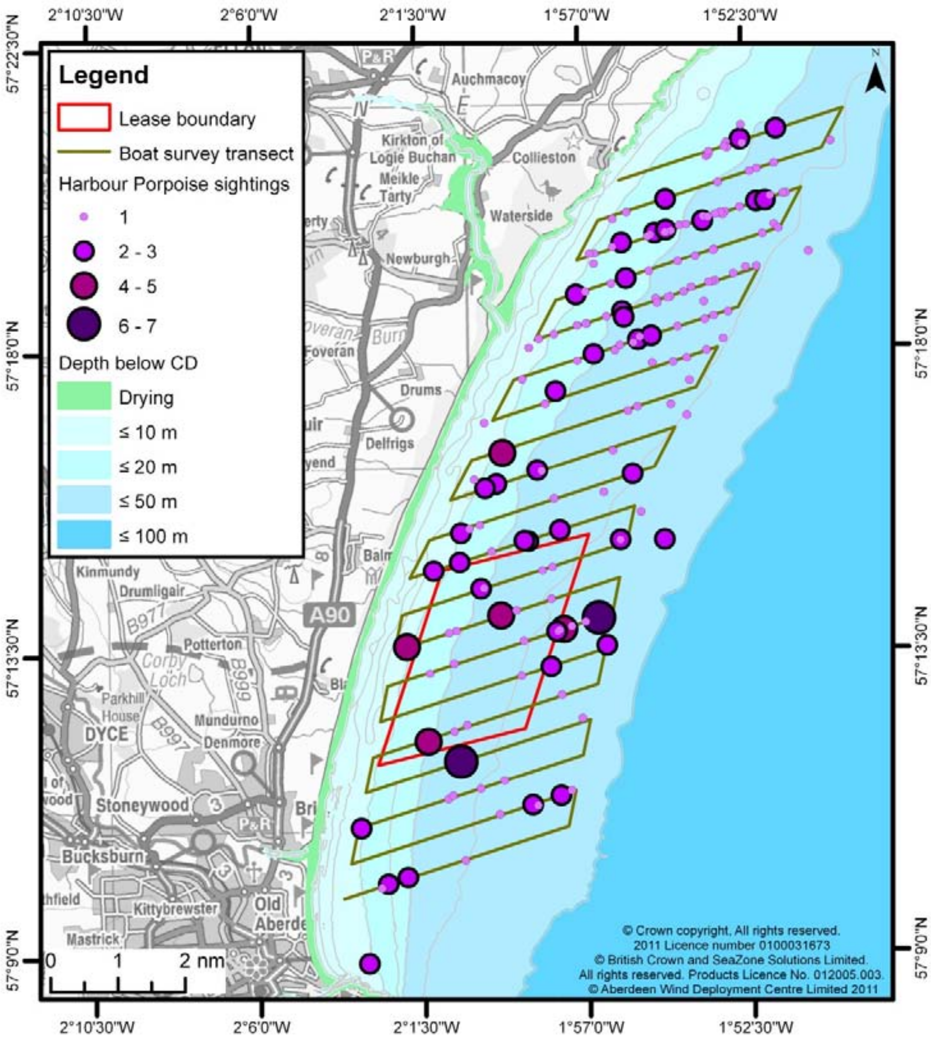
The harbour porpoise was the only species which was detected in sufficient numbers to allow a detection function to be applied. The detection function was applied to both phases of boat based surveying, the initial survey period

2007-2008 and the four months of survey carried out 2010-2011. The results of each phase of boat based surveys are discussed in the following sections.

5.2.4.2 Harbour porpoise survey results 2007-2008

There were 197 observations of 291 individuals observed during the boat based surveys carried out during 2007-2008. The distribution of all observations recorded, including those off effort are displayed in Figure 16.

Figure 16 Observations of harbour porpoise on and off effort during EOWDC boat surveys 2007-2008



5.2.4.2.1 Estimation of density using distance analysis 2007-2008

There were 175 observations of 251 individuals recorded on 1950 km of survey effort. Only on transect effort was used in the analysis (i.e. short transit legs between transects were discarded).

The radial distance and angles recorded to each sighting were converted to perpendicular distances and examined as a histogram (Figure 17). The histogram shows that there a peak in sightings within 100 m of the transect. The data are also spiked at the transect line which means that there are more sightings than would be expected on the transect line. To fit the detection function, the perpendicular distance were grouped with a wide first perpendicular distance bin, extending from the transect line to 200 m. This was done to 'force' Distance to fit a shoulder near the transect line distances rather than the reality, which is a spike. The data were also right truncated at 800 m (*n* = 167).

The best model of the detection function was a simple Hazard-rate without adjustment terms (p = 0.68) (Figure 18). The *esw* was 355m (%CV = 9.7).

Figure 17 Histogram of the perpendicular distances associated with the harbour porpoise sightings 2007-2008 data

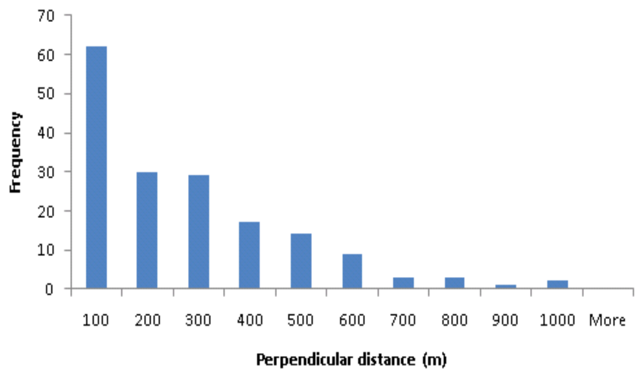


Figure 18 Detection probability fitted to perpendicular distances of harbour porpoise sightings February 2007-April 2008

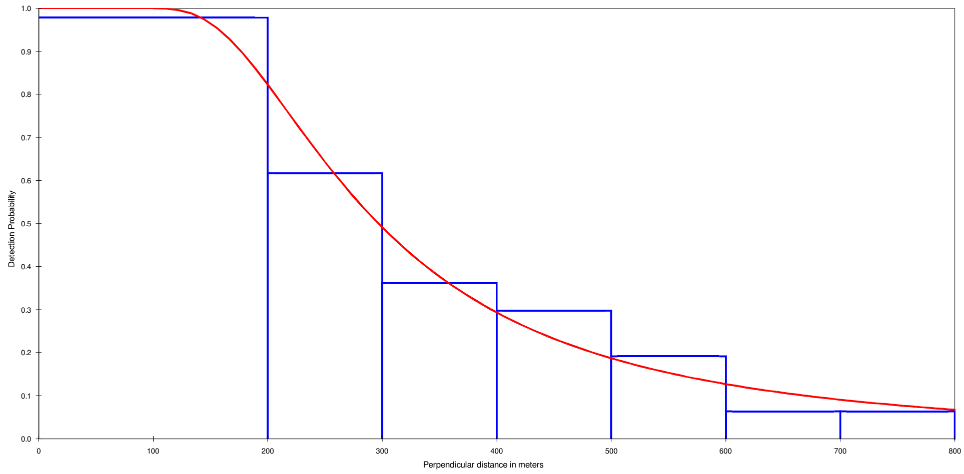

The pooled detection function was then applied to the estimation of density and abundance by month and season. Multiple surveys within the same month were pooled to generate the density and abundance estimates. The mean group size was 1.42 (SE=0.07)). Density and abundance estimates by area/season and area/month are given in Table 13 and Table 14.

Density of harbour porpoise was higher in the control area in all seasons except summer (Table 14). The highest densities at both sites occurred during autumn (September-November). Lowest densities of harbour porpoises occurred during May and June at both the wind farm and control site. Peak densities were recorded during November at the wind farm site but during October and January at the control site (Figure 19).

Table 13 Density and abundance of harbour porpoises by month and area estimated from year 1 survey data (February 2007 – April 2008, where n= number of sightings, DS = density of schools, D = density of animals and N = abundance. CV is the coefficient of variation and CI is the confidence interval

5.2.4.3 Harbour porpoise boat based surveys results 2010-2011

A total of 134 observations of harbour porpoise were recorded, consisting of 296 individuals during the 4 months of SMRU Ltd surveys. The radial distance and angle from the transect line were converted to perpendicular distance within Distance, after truncation of sightings beyond 800 m there were a total of 132 observations of harbour porpoise available for analysis. The model chosen was a half normal key function with second order cosine adjustment terms (Figure 20). Cluster size was regressed against distance from transect and as this regression was non-significant at 0.15, mean cluster size was used throughout. The mean cluster size over all data was 2.13 (SE= 0.15) and the effective strip half width was 241.6 m (%CV=7.3). Density and abundance were estimated by month and assumed certain detection of animals on the transect line (g(0) = 1). The estimates have also been corrected using a g(0)=0.34 (which is the probability of detecting an animal on the transect line) (Hammond et al., 2002). The effects of varying g(0) and the influence that this has on the estimated abundance value is discussed in Appendix 8.1.

Figure 20 Detection probability curve for harbour porpoise observations, based on all data from the four months and three study areas, and using 100m data 'bins'

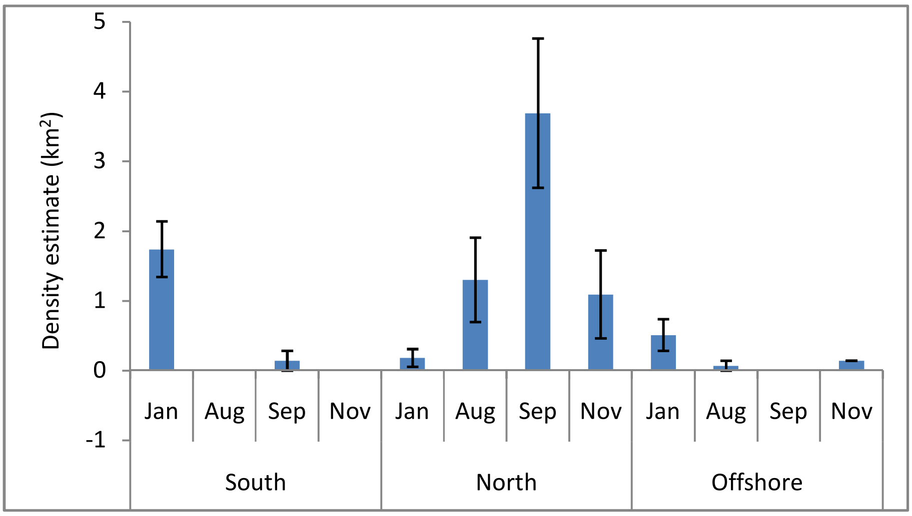
Figure 22 monthly estimates (+/- SE) of density of Harbour porpoise in the South, North and Offshore Strata (Assuming g(0)=1)

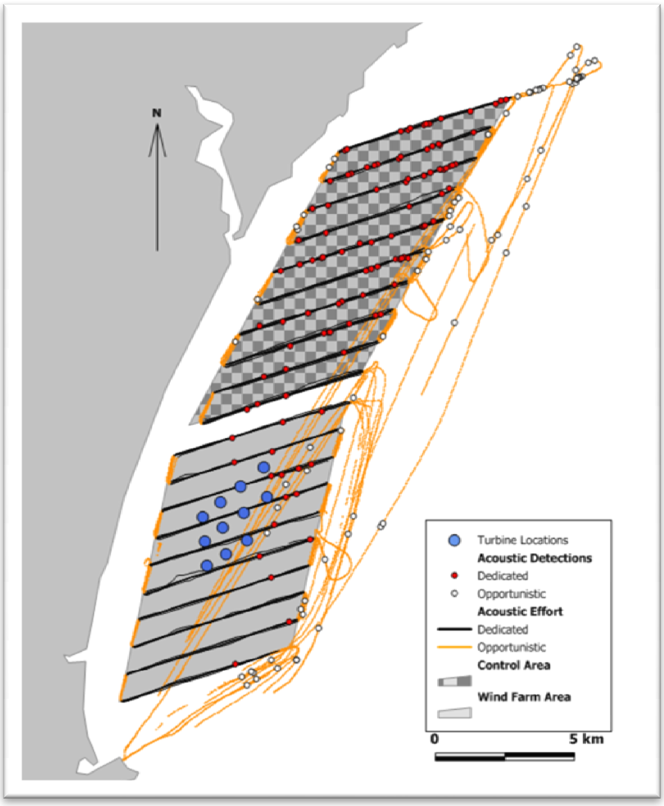


Most of the estimates produced show considerable error margins at present. These errors stem from the small number of surveys currently available for analyses, and are expected to reduce as more surveys are carried out.

5.2.4.4 Towed Passive Acoustic Monitoring (PAM) results for surveys 2007-2008

The harbour porpoise was the most frequently detected marine mammal species during the acoustic surveys. Only the dedicated acoustic effort was used to assess the acoustic detection rates of marine mammals across both the wind farm area and the control area. The harbour porpoise detections 'off effort' that were opportunistic detections are shown in Figure 23.

Figure 23 Combined acoustic effort from Oct-07 to April-08 across both the control and wind farm areas. Yellow lines show the opportunistic acoustic effort. Dedicated acoustic effort is shown by the black lines. Red circles show "on effort" acoustic detections, white circles show "opportunistic" acoustic detections (SMRU Ltd 2011b)



Harbour porpoises were detected on all seven surveys in which the hydrophone was deployed (Table 16). Combined detection rates ranged from 0.03 detections per km of dedicated effort, (early April survey, 2008) to 0.22 detections per km of dedicated effort (November survey, 2007). Detection rates were much lower in both of the April surveys than in any of the preceding five surveys.

Table 16 Number of porpoise detections and detection rate (detection/km) for each of the 7 surveys for which acoustic data were collected

Month of survey	Number of detections	Effort (km)	Detection rate (detections per km)
Oct-07	16	111	0.14
Nov-07	23	102	0.22
Dec-07	23	127	0.18
Jan-08	17	88	0.19
Feb-08	25	127	0.20
Early April-08	3	101	0.03
Late April-08	6	126	0.05

There appears to be marked differences in spatial distribution of porpoises over the areas surveyed, with more detections made in the control area than in the wind farm area. A total of 113 harbour porpoise detections were made overall, of which 96 were made within the control area (0.23) detections per km dedicated acoustic effort), and 17 were made within the wind farm area (0.05 detections per km dedicated acoustic effort) (Figure 23). Figure 24 shows the detection rate per survey in both the control and the wind farm areas. In each monthly survey the detection rate is higher in the control area.

The detection rate per transect is shown in Table 17. All transects recorded acoustic detections with the exception of transect 'WC' located in the wind farm area (Figure 1 provides details of the transect names).

Figure 24 Histogram comparing the detection rate for harbour porpoises in the control area and the wind farm area across all survey months.

5.2.4.5 Towed Passive Acoustic Monitoring (PAM) results for surveys 2010-2011

Harbour porpoises were detected acoustically on all four of the surveys (Table 18). Combined detection rates ranged from 0.08 detections per km of dedicated effort, (January 2011) to 0.15 detections per km of dedicated effort (September 2010).

A total of 85 "on effort" harbour porpoise detections were made across all three strata. Of these, 56.5% were made in the north stratum, 20% in the south stratum and 23.5% in the offshore stratum (Table 18 and Figure 29). The number of detections and detection rate per transect is shown in Table 19. Whilst all strata contained porpoise detections, 10 of the individual transects did not. The locations of harbour porpoise detections in each of the four surveys can be seen in Figure 25-Figure 28 "On effort" sightings are shown by red circles; "off effort" detections by orange circles. In some cases, due to navigational constraints, the actual sailed transects differed slightly from the pre-designed survey tracks. Designed tracks are shown in grey, actual sailed transects are shown in black. Some of the southern transects were sailed twice.

**Locations of transits within the survey design can be seen in Figure 2*

Harbour porpoise acoustic detections appear to follow a similar pattern of distribution to the sightings of animals. The pattern of detections from the November survey most closely resembles the pattern formed from the visual data. Higher numbers of detections were made in the offshore survey area during the August and September 2010 surveys, although it is too early to conclude whether this represents a movement of animals offshore during the summer months. Acoustic detection rates were lowest during the January survey, but again, more data are required to determine if this is part of a trend.

The acoustic dolphin detections (both clicks and whistles) made during the August 2010 survey coincide both temporally and spatially with sightings of white-beaked dolphins made in the offshore strata. Additional detections in the northern stratum which do not coincide with visual observations reinforce the value of carrying out simultaneous passive acoustic data collection alongside the use of visual observers.

5.2.5 Diet

The diet of harbour porpoises in Scottish waters has been determined through stomach content analysis and, although fish from 15 taxa, cephalopods from five taxa and crustaceans from four taxa were recovered from the stomachs of harbour porpoises between 1992 and 2003, the diet is dominated by four main prey categories: (i) whiting; (ii) sandeels (Ammodytidae spp.); (iii) haddock/saithe/pollack and (iv) *Trisopterus* spp. (Norway pout and poor cod) (Santos *et al.*, 2004a). Whiting and sandeels are the most important prey types, in terms of contribution by number and mass, in the diet of harbour porpoises from Scottish waters (Santos *et al.*, 2004a).

The main fish species consumed by porpoises (identified in samples recovered mainly from fishing nets) from the Scottish east coast between 1959 and 1971 were herring, sprats, whiting, sandeels, cod, Norway pout and other gadoids, decapod shrimps were also present (Rae 1965, 1973).

5.2.6 Life history

Harbour porpoises in Scottish waters have a distinct reproductive season. Examination of the reproductive status of stranded harbour porpoises (1992-2005) indicates that conception takes place between April and September, gestation appears to last 10-11 months and the calving period is between April and June. Lactation appears to last 9 to 10 months with weaning taking place in March/April (Learmonth, 2006.).

The period of conception for harbour porpoises in Scottish waters coincides with observations of larger group sizes of porpoises in July and August off the North Sea coast (N. Quick, Pers. Comm.).

In the coastal waters off Aberdeenshire juvenile porpoises and calves have been observed between May and September, with a peak during June (Weir *et al*., 2007). Sightings suggest that calving may take place in June with the observation of very small calves during this time (Weir and Stockin, 2001).

In surveys along the southern coast of the outer Moray Firth (May to October, 2001-2005), neonatal porpoise calves were typically observed between May and July and the progressive increase in harbour porpoise encounters from May through to October was believed to result from the inshore movements of lactating females with their calves, followed thereafter by the males (Robinson *et al*., 2008).

5.2.7 Strandings

One hundred and thirty stranded harbour porpoises have been recorded by the Scottish Agricultural College along the north east coast of Scotland from Fraserburgh to Inverbervie between January 1992 and March 2010(CSIP 2010). Thirty-three were females, 51 were male and the sex was not determined for 48 individuals. Body lengths were between 76 cm and 165 cm. Harbour porpoises were recovered all along the north-east coast of Scotland throughout the year, with the majority recovered in the 1st and 2nd quarters (January-June: approximately 84%), in all years (SAC, 2006; CSIP 2009).

Stranding records indicate that harbour porpoises are regularly present in the area through out the year, with an increase in the number of stranded porpoises between January and June. Similarly, an examination of stranded harbour porpoises around Scotland between 1992 and 2004 found an increase in the number of strandings in March, April and June, with lower numbers in October, November and December, even when porpoises with body lengths less than 110 cm were removed to reduce the bias of the higher number of immature porpoises stranded during the birth and weaning periods (March to June) (Learmonth, 2006).

5.2.8 Harbour porpoises killed by bottlenose dolphins

One hundred and forty-three of the 389 harbour porpoises (37%), for which cause of death was established in Scottish waters between 1992 and 2004, died as a result of attacks by bottlenose dolphins (Learmonth, 2006). All fatal bottlenose dolphin attacks were recorded on the North Sea coast, ranging from Brora in the north to the Firth of Forth in the south, with the majority (66%) in the Moray Firth. The distribution of bottlenose dolphin attacks on harbour porpoises is consistent with an overlap in the distribution of the two species on the Scottish east coast (Wilson *et al*., 2004). The fatal attacks by bottlenose dolphins along the north east coast also indicates that bottlenose dolphins are present in the area throughout the year, despite the low number of strandings recovered.

Fatal bottlenose dolphin attacks on harbour porpoises in Scottish waters were recorded in all months of the year, with higher numbers between April and June (Learmonth, 2006). There was some evidence of a seasonal shift in bottlenose dolphin attacks on porpoises along the east coast, with 75% of bottlenose dolphin attacks within the Moray Firth occurring between April and September and 77% of bottlenose dolphin attacks outside the Moray Firth occurring between January and June (Learmonth, 2006). The increase in bottlenose dolphin attacks outside the Moray Firth between January and June is consistent with an increase in the number of sightings of bottlenose dolphins off Aberdeen between the months of February and May (Weir and Stockin 2001; Canning, 2007).

There were significant annual variations in the number of harbour porpoises that had died from fatal bottlenose dolphin attacks in Scottish waters between 1992 and 2004, although no overall trend increase or decrease in numbers was detected. However, there was evidence of an increase in the number of bottlenose dolphin attacks outside the Moray Firth in recent years. The increase in bottlenose dolphin attacks on harbour porpoises out with the Moray Firth is consistent with a recent range expansion of bottlenose dolphins (Wilson *et al.*, 2004).

Sightings reports suggest fine-scale segregation, both temporal and geographical, in the occurrence of harbour porpoises and bottlenose dolphins (Canning 2007; Thompson *et al.,* 2004b). Segregation within a small area may result from different uses of the area between the two species or could be due to avoidance behaviour by porpoises as a result of the violent attacks by bottlenose dolphins (Thompson *et al.,* 2004b).

5.3 WHITE-BEAKED DOLPHIN (*LAGENORHYNCHUS ALBIROSTRIS*)

5.3.1 Distribution

White-beaked dolphins are most commonly sighted in the central part of the North Sea between 54°N and 59°N (Hammond *et al*., 2001). White-beaked dolphins are restricted to temperate and sub-Arctic waters of the North Atlantic (Reid *et al*., 2003). They are mainly distributed over the continental shelf, usually in waters of 50-100 m depth (Reid *et al*., 2003). In the North Sea they are thought to be more numerous within about 200 nm of the Scottish and north-eastern English coasts (Northridge *et al.,* 1995). White-beaked dolphins are present year round in the North Sea, including waters of Shetland and Orkney (Northridge *et al.* 1997).

The locations of white-beaked dolphin sightings made during systematic surveys and some platforms of opportunity off north-east Scotland are presented in Figure 31 (Hammond *et al,*. 2004). During the SCANS II survey in July 2005, white-beaked dolphins were seen in the northern and central North Sea and west of Britain and Ireland (SCANS II, 2006). Analysis of the UK stranding database suggested that sea temperature influences the distribution of this species around the UK (Canning *et al*., 2008).

There has been a decline in the relative frequencies of strandings and sightings of white-beaked dolphins, a colder-water species and a relative increase in strandings and sightings of common dolphins, a warmer-water species off northwest Scotland. Theses changes in the cetacean community off northwest Scotland have been linked to climate change (MacLeod *et al*., 2005).

Figure 30 Distribution of white-beaked dolphin sightings during ferry surveys (April-September, 2002-2006

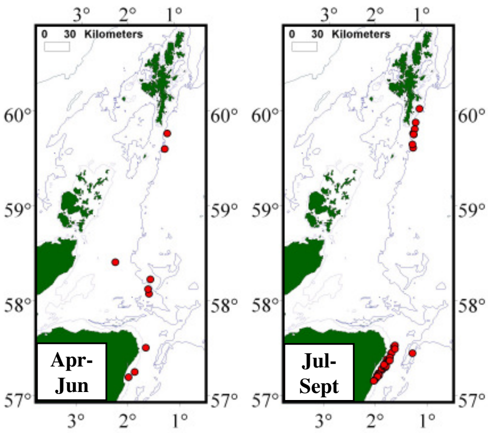

Figure 31 White-beaked dolphin sightings made during various surveys (Hammond *et al*. 2004)

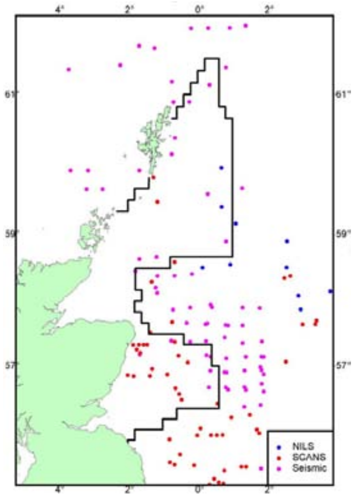


5.3.2 Seasonal Movements

White-beaked dolphins are present year-round in the North Sea, with most sightings recorded between June and October (Evans, 1992; Northridge *et al*., 1995; Reid *et al*., 2003). Seasonal aggregations of white-beaked dolphins have been recorded along the north-east English coast during April and June (Northridge *et al*., 1997).

5.3.3 Abundance

The summer abundance of white-beaked dolphins in the North Sea areas during the first SCANS survey in July 1994 was 7,856 (95% confidence interval 4,000–13,300). This estimate includes shelf waters around Shetland and Orkney in which there were an estimated 1,157 animals (Hammond *et al*., 1995, 2002, 2004).

Current estimated abundance in UK and adjacent waters (shelf only) is 22,400 individuals (SCANS II, 2008). White-beaked dolphins are usually found in schools numbering less than 10 individuals, but schools of up to 50 are not uncommon, and aggregations can comprise 100-500 animals in northern parts of their range and also in the North Sea (Reid, et al. 2003).

5.3.4 Occurrence in Aberdeen Bay and surrounding area

The presence of white-beaked dolphins in the Aberdeen Bay area is seasonal. During land- and vessel based surveys between March 1999 and October 2001, along the Aberdeenshire coast (between St Cyrus and Collieston, primarily between Stonehaven and Aberdeen), white-beaked dolphins were recorded only between June and August, despite good coverage for both land- and vessel-based surveys in most other months. White-beaked dolphin calves were observed in all three months that the species was recorded (Weir *et al*., 2007).

The fine-scale distribution varied within the study area, with an apparent preference for sections of coast adjacent to deeper water. Most white-beaked dolphins were sighted along the Cove to Girdle Ness coast. During the land-based surveys, the incidence of white-beaked dolphins was significantly higher in the area between Aberdeen and Stonehaven than in area between Aberdeen and Collieston (Weir *et al*., 2007).

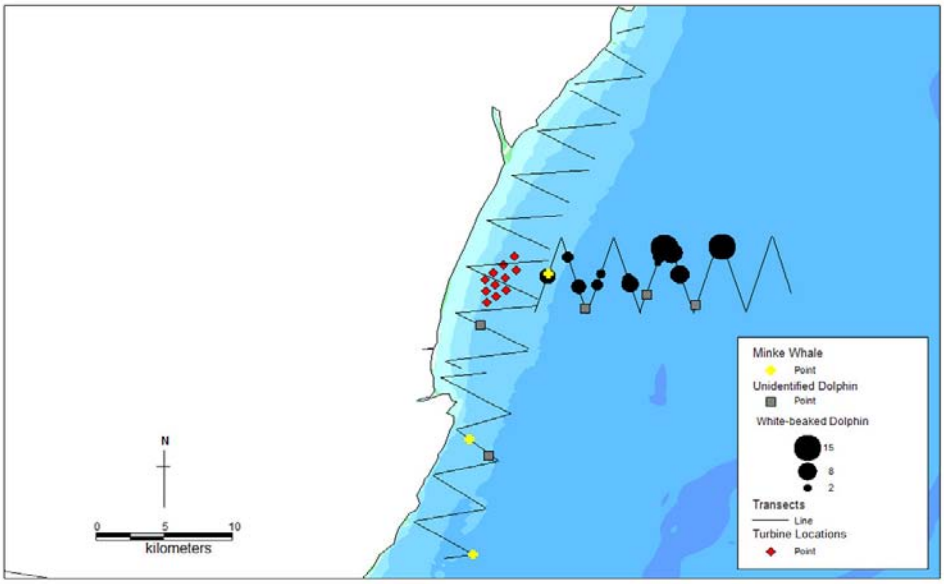
Similarly, white-beaked dolphins were only recorded during summer months during land and boat surveys along the Aberdeenshire coast (Stonehaven to Aberdeen) between 2002 and 2005. During land based surveys at Aberdeen harbour (November 2002 – April 2005), white-beaked dolphins were recorded during the summer of 2004 and during land-based surveys at Stonehaven (March 2003 – March 2005), they were observed between May and August during 2003 and in July during 2004 (Canning, 2007). Analysis of the sightings indicate that seabed depth and slope influence the distribution of white-beaked dolphins in this area and this is thought to be related to prey distribution. Sea temperature was found to influence white-beaked dolphin group size, with smaller groups being recorded at higher temperatures (Canning, 2007).

The high number of calves observed during the boat surveys off Aberdeenshire and in the stranding data during the summer, suggests the inshore movement of this species at this time of year may be related to calving. The stranding data also suggested there may be a difference in when males and females move inshore (Canning, 2007).

White-beaked dolphins were the most commonly-sighted species of dolphin during northern North Sea ferry surveys between Aberdeen, Orkney and Shetland in summer months between 2002 and 2006 (MacLeod *et al.*, 2007). White-beaked dolphins were recorded throughout the study area, but were recorded more frequently in more coastal waters, such as along the coast of mainland Scotland, in the late summer and early autumn. Group sizes ranged from one to 20, with an average of five individuals per group. White-beaked dolphins were the only species of cetacean recorded in all years when surveys were conducted. White-beaked dolphins made up the highest proportion of sightings in July, accounting for almost 20% of all sightings. White-beaked dolphins were not recorded in April (MacLeod *et al*., 2007).

During the boat based survey carried out as part of the wind farm during 2007-2008 one sighting of three individual white beaked dolphins occurred in August 2007, and this was an incidental sighting when the observers were off effort. Again during the August survey there were 14 observations of white beaked dolphins that in the offshore transect comprising a total of 88 individuals (Figure 32). The sightings data collected as part of the EOWDC marine mammal data supports other observational data records which suggests the species is a seasonal summer visitor to the Aberdeenshire coast.

Figure 32 White beaked dolphins, minke whale and unidentified dolphins detected during August, September and November 2010, and January 2011



5.3.5 Diet

White-beaked dolphins take a range of prey, including fish, cephalopods and some crustacean species (Reid *et al*., 2003). Herring and whiting have been recorded as prey items of this species in the North Sea (Fraser, 1974; Harmer, 1927). The diet of those found around Britain includes whiting, hake, herring, cod, mackerel, scad, sandeel, long rough dab, *Trisopterus sp*, and the octopus *Eledone cirrhosa* (Evans, 1992; Santos *et al.,* 1994). Stomach contents analysis of white-beaked dolphin (n=22) stranded around Scotland (1992-2003) identified a wide variety of prey species: haddock and whiting were the predominant fish species and other prey species included cod, herring and mackerel (Canning *et al*., 2008). Elsewhere in the North Atlantic herring and gadoid fishes also appear to be the main diet items (Reeves *et al.*, 1999a).

5.3.6 Life history

Little is known about the reproductive behaviour of this species but mating is thought to occur during the summer with parturition occurring the following summer (Kinze *et al.,* 1997). White-beaked dolphin calves have been observed off Aberdeenshire in all three months (June, July and August) that the species has been observed (Weir *et al*., 2007).

Information on the life history of white-beaked dolphins in Scottish waters is limited. However, the examination of the reproductive status of stranded individuals (1996-2002) suggests that mating occurs between July and August; however the majority of stranded white-beaked dolphins for which age and reproductive data are available, were sexually immature and aged four years and less.

5.3.7 Strandings

The majority of white-beaked dolphins stranded in the UK are found around Scotland and along the east coast of England (Canning *et al*., 2008). Fourteen white-beaked dolphins have been recorded by the Scottish Agricultural College along the northeast coast of Scotland from Fraserburgh to Inverbervie between January 1992 and December 2009. Seven were female and 7 were male, with body length between 119cm and 263cm (Table 21). White-beaked dolphins were recovered along the north-east coast of Scotland between February and October, with the majority in June and July, in 1992-1995 and 2001-2004 (Table 21).

Table 21 White-beaked dolphins stranded along the northeast coast of Scotland January 1992 – August 2009 (CSIP 2010)

Date Found	Location	Sex	Body length
June 1992	Aberdeen	M	132 cm
March 1993	Aberdeen	F	225 cm
September 1994	Aberdeen	M	222 cm
July 1994	Balmedie	M	119 cm
July 1994	Aberdeen	F	134 cm
April 1995	Fraserburgh	F	188 cm
July 1995	Balmedie	F	122 cm
July 2001	Forvie	F	245 cm
June 2002	Forvie	M	263 cm
June 2002	Blackdog	M	155 cm
June 2002	Collieston	F	171 cm
October 2003	Aberdeen	M	158 cm
February 2004	Fraserburgh	M	200 cm
January 2008	Collieston	F	176 cm

Stranding records suggest that white-beaked dolphins may be present in the area throughout the year, with the exception of winter (November-January). The peak occurrence appears to be in summer, especially during the months of June and July.

5.4 Minke whale (*Balaenoptera acutorostrata*)

5.4.1 Distribution

Minke whales are widely distributed in the northern hemisphere, tropical, temperate and polar seas (Reid *et al*., 2003). There are three distinct populations: Southern Hemisphere, Northern Pacific and North Atlantic. In the North Atlantic the International Whaling Commission recognises three stocks for management purposes: NE Atlantic, west Greenland and Canadian east coast. Minke whales off north-east Scotland are part of the NE Atlantic stock (Hammond *et al*., 2004).

Minke whales occur throughout the central and northern North Sea, as illustrated by the distribution of sightings during the SCANS survey and on other surveys on platforms of opportunity Figure 34 (Hammond *et al*., 2001). Minke whales are more frequently sighted inshore during summer months. The locations of minke whale sightings made during systematic surveys and some platforms of opportunity off NE Scotland are shown in Figure 35 (Hammond *et al*., 2004). Minke whales are widely distributed in the area off north-east Scotland, both in offshore and coastal areas. During the SCANS II survey in July 2005, minke whales were found in the northern and central North Sea and west of Britain and Ireland (SCANS II, 2008).

Between May and October from 2001 to 2006 inclusive, systematic boat surveys were conducted along an 83 km length of the southern coastline of the outer Moray Firth between Lossiemouth and Fraserburgh, using four dedicated survey routes positioned parallel to the shore: three outer routes, approximately 1.5 km apart in latitude, and an inner coastal route. Minke whales were encountered throughout the survey area, but were more generally distributed towards the central and eastern area of the study site, with a notable absence to the far west. A larger number of whales were also sighted on the innermost survey route, but once corrections for survey effort had been made, a considerably higher abundance of animals was shown for each of the outer survey routes, typically occurring along the 20-50 m isobaths. Whilst minke whales were recorded during all survey months (May to October inclusive), the animals were typically encountered in this region from mid June onwards, showing a peak in occurrence during July and August. In addition, the temporal distribution of whales suggested an inshore movement of animals across the summer months, with the whales being recorded in deeper, offshore waters in May and June followed by increasing numbers of encounters of animals in more shallow, inshore waters from July onwards (Robinson *et al*., 2007).

5.4.2 Migration

There is no direct evidence that minke whales in the Northern Hemisphere migrate, but in some areas there appear to be shifts in latitudinal abundance with season (Hammond *et al*., 2004). This is true for the North Sea, where minke whales appear to move into the North Sea at the beginning of May and are present throughout the summer until October (Hammond *et al*., 2004; Northridge *et al.*, 1995).

5.4.3 Abundance

A total abundance of 16,400 individuals has been estimated for UK and adjacent waters, and results from the CODA survey in 2007 estimated a total abundance in the survey area to be 6,765 [95% CI=1,239-36,925] (Macleod, *et al*., 2008). Minke whales are usually seen singly or in pairs although, when feeding, they sometimes form larger aggregations that can number 10-15 individuals (Reid, *et al*. 2003).

During the SCANS I survey, the highest densities were recorded in the northwest North Sea, particularly off the mainland coast of Scotland (Hammond *et al*., 2001). Estimates of the number of minke whales in the North Sea, north of 56°N, were 5,430 (SE=1,870) for 1989 and 20,300 (SE=5,240) for 1995. These estimates are approximately 8-18% of the estimated size of the north-east Atlantic stock of 67,000 whales in 1989 and 112,000 whales in 1995 (Hammond *et al*., 2004; Schweder *et al.*, 1997). Abundance estimates for the North Sea from the Norwegian surveys in July 1998 were 11,700 (SE=3,460) (Hammond *et al.*, 2004; Skaug *et al.*, 2003). The SCANS II survey calculated an increased abundance of minke whales for the whole of the North Sea (approximate 95% confidence interval = 10,445-33,171).

5.4.4 Occurrence in Aberdeen Bay and surrounding area

The status of minke whales in the Aberdeen Bay area is unclear. During land- and vessel based surveys along the Aberdeenshire coast (between St Cyrus and Collieston, primarily between Stonehaven and Aberdeen, from March 1999 to October 2001), minke whales were recorded only in the month of August (Weir *et al*., 2007). The five sightings all involved solitary individuals, of which three were adults and two were juveniles, which were observed only in a relatively small spatial region between Aberdeen and Stonehaven (Weir *et al*., 2007). During land-based surveys at Aberdeen harbour (November 2002 – April 2005) and Stonehaven (March 2003 – March 2005), minke whales were recorded during the summer of 2004 and August 2003, respectively (Canning, 2007). However, in recent years minke whales have been observed off the Aberdeenshire coast during most months of the year, with sightings occurring even during the winter months of December and March.

Northern North Sea ferry surveys between Aberdeen, Orkney and Shetland in summer months between 2002 and 2006 recorded minke whales throughout the region, and in all months surveyed (April to September) Figure 35 (MacLeod *et al*., 2007). Most observations of minke whales during the NORCET surveys occurred in more offshore waters in April to June and in more coastal waters in July and September (Figure 5). Minke whales were the second most commonly sighted species during the ferry surveys (MacLeod *et al*., 2007).

During bird vantage point (VP) surveys for the this project, single minke whales were recorded at both Donmouth and Blackdog on 13th July 2007, although this may have been the same individual moving along the coast.

Four minke whales have been recorded during all the boat based wind farm surveys carried out to date. One minke whale was recorded during the surveys carried out in 2007-2008 (Figure 33). Three minke whales were recorded in the four months of boat based surveys carried out during 2010-2011 (Figure 32).

Figure 33 Common dolphin, Minke whale, White beaked dolphin, unidentified dolphin and unidentified cetacean observations during the EOWDC boat based surveys 2007-2008

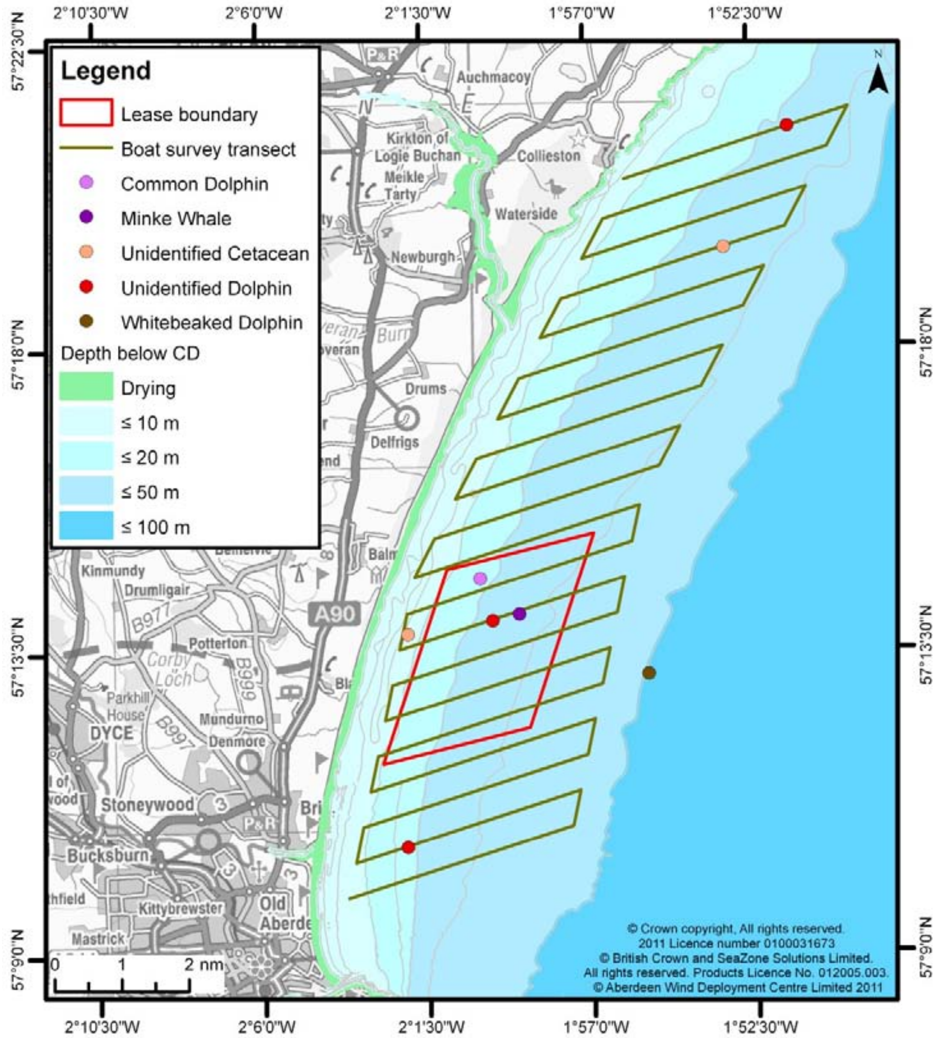


Figure 34 Minke whale sightings made during SCANS, NASS-89, NILS-95, JNCC and seismic surveys (Hammond *et al.*, 2004)

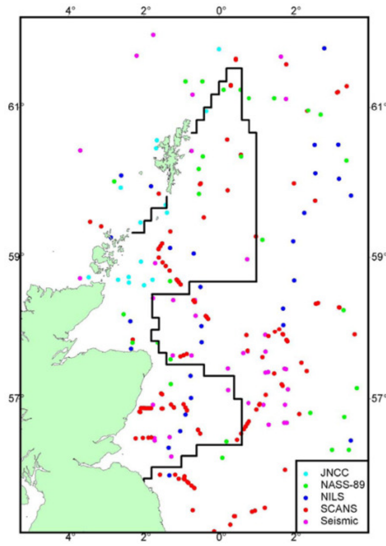

Figure 35 Distribution of minke whales sightings during ferry surveys (April-September, 2002-2006)

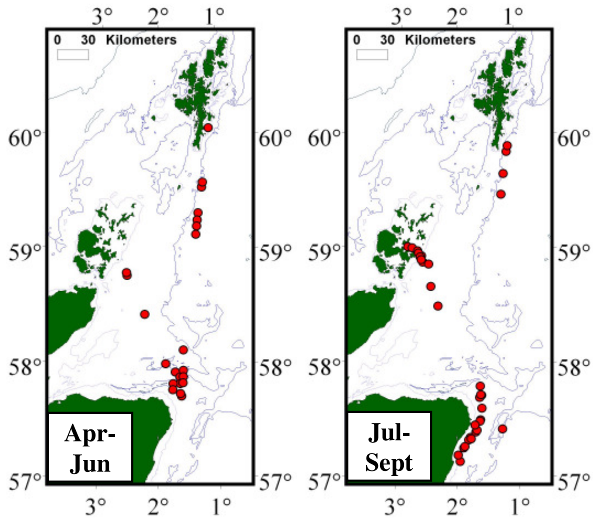

5.4.5 Diet

Minke whales are known to feed on a variety of fish species, including herring, cod, haddock, saithe and sandeel (Reid *et al.*, 2003). In the north-east Atlantic, minke whales feed on small pelagic fish and its distribution has been related to concentrations of sandeels and herring in Scottish waters (Evans, 1980; Macleod *et al*., 2004; Northridge, 1988). Stomach content analysis of minke whales stranded around the Scottish coast between 1992 and 2002 indicates that the diet comprised mainly sandeels, herring and sprat (Pierce *et al*., 2004).

Sightings of minke whales in the outer Moray Firth were found to be significantly higher during warm water plume events than when the colder water Dooley current was prevailing. In addition, GIS plots of the physiography of the coastal study site revealed a strong preference by the species for areas with steep, northerly-facing slopes, mean water depths of 38 m and sandy gravel sediment type. Sandy gravel sediments showed the strongest positive correlation with minke distribution, and this type of substrate is seen to be the optimal habitat utilised by burrowing sandeels (Robinson *et al.*, 2007).

5.4.6 Strandings

During 1992-2002 approximately 110 strandings of minke whales were recorded in Scotland. Most strandings were recorded between April and November, with a peak strandings of males in July and August (Pierce *et al.*, 2004).

Five stranded minke whales have been recorded by the Scottish Agricultural College along the northeast coast of Scotland from Fraserburgh to Inverbervie between January 1992 and March 2010 (SAC, 2006; CSIP 2010). The body lengths of the whales were between 585 cm and 800 cm and three of the five minke whales were identified as male. Minke whales were recovered in the months of July, September, October and November within the years 1993, 1995 and 2000 between Peterhead and Inverbervie (Table 7). Strandings records indicate that minke whales are present along the north east coast of Scotland between July and November.

Table 22 Minke whales stranded along the northeast coast of Scotland (January 1992 – August 2006)

Date Found	Location	Sex	Body length
September 1993	Near Slains Castle	M	760 cm
July 1995	Peterhead	M	585 cm
October 1995	Inverbervie	Unknown	c700 cm
November 1995	Near Catterline	M	700 cm
September 2000	Balmedie	Unknown	800 cm

5.5 ATLANTIC WHITE-SIDED DOLPHIN (*LAGENORHYNCHUS ACUTUS*)

5.5.1 Distribution

Atlantic white-sided dolphins are confined to the North Atlantic (Reeves *et al.*, 1999b). White-sided dolphins live mainly in cool waters (7-12°C), particularly along the edges of continental shelves at depths of 100-500 m, but they can be numerous in deeper waters (Reid *et al.*, 2003). The Atlantic white-sided dolphin is primarily an offshore species, but has been recorded during a number of surveys in the North Sea, especially during summer (Northridge *et al.*, 1997; Reid *et al.*, 2003). They share most of their range with the white-beaked dolphin, but in the eastern North Atlantic they adopt a mainly offshore distribution and are consequently rarer than white-beaked dolphins over shelf waters (Hammond *et al.*, 2001). Around Britain, Atlantic white-sided dolphins have been recorded mainly in the north and appear to be most common in the north-western parts of the North Sea (Hammond *et al.*, 2001, 2004). Compared to white-beaked dolphins, Atlantic white-sided dolphins are generally distributed further northwest in deeper waters. In the North Sea, their presence is seasonal, with the majority of sightings occurring between May and September (Northridge *et al.*, 1997).

5.5.2 Occurrence in Aberdeen Bay and surrounding area

Atlantic white-sided dolphins were recorded on nine occasions in groups of between one and 50 individuals during northern North Sea ferry surveys between Aberdeen, Orkney and Shetland in summer months between

2002 and 2006 (MacLeod *et al*., 2007). The majority of the sightings occurred in the more northern part of the study area around Shetland, with only one recorded sighting near the Scottish mainland coast (Figure 36). The sightings primarily occurred between July and September, with a single sighting being recorded in May. This species appears to be a seasonal but regular member of the cetacean assemblage of the northern North Sea, and primarily occurs in the more northern waters of the area (MacLeod *et al*., 2007). During surveys along the southern outer Moray Firth coast (May to October, 2001-2005), a single sighting of twelve white-sided dolphins was recorded in August 2005 (Robinson *et al*., 2008).

The locations of Atlantic white-sided dolphin sightings made during systematic surveys and some platforms of opportunity off north-east Scotland are illustrated in Figure 37. White-sided dolphins have been observed off the Aberdeen coast at Girdle Ness in June 2002 (Seawatch Foundation, 2011).

No white sided dolphins have been recorded in any of the surveys carried out as part of the EOWDC.

5.5.3 Abundance

There is no reliable total population estimate for this species at present. Abundance estimates have been difficult to obtain due to difficulties in separating white-sided dolphin and white-beaked dolphin identification at long-range (Hammond, *et al*., 2002). The white sided dolphin is known to occasionally be involved in mass stranding events, although none of these have been reported along the east coast of Scotland (Hammond *et al*., 2001).

The SCANS I survey estimated 11,760 *Lagenorhynchus* dolphins (white-beaked plus white-sided) in the North Sea (approx. 95% confidence interval 5,900 - 18,800). This estimate includes shelf waters around Shetland and Orkney (Hammond *et al*., 1995, 2002, 2004). The SCANS II survey estimated a total abundance of 27,227 (CV=0.38) for *Lagenorhynchu*s species in UK and adjacent waters (shelf only) in the summer of 2005 (Scans II, 2006). This species is very gregarious, with observed school sizes frequently numbering in the tens to hundreds, and sometimes up to 1,000, particularly offshore. Within large aggregations, clusters of 2-15 animals can often be distinguished (Reeves, *et al*., 1999a).

5.5.4 Diet

The diet of Atlantic white-sided dolphins consists of a wide variety of fish, particularly gadoids such as blue whiting, whiting, *Trisopterus* spp., cod, clupeids, particularly herring; other species recorded in the diet include hake, mackerel, salmonids and squid (Reid *et al*., 2003). Different prey species may predominate at different times of year, representing seasonal movements of prey, or in different areas, indicating prey and habitat variability in the environment (Cipriano, 2002).

The stomach contents of three white-sided dolphins stranded around Scotland between 1993 and 1995 consisted of Gadidae and cephalopods, predominately the neritic and oceanic squid *Todarodes sagittatus* (Santos *et al*., 1995).

Figure 36 Distribution of Atlantic white-sided dolphin (blue) and common dolphin (red) sightings during ferry surveys (April-September, 2002-2006)

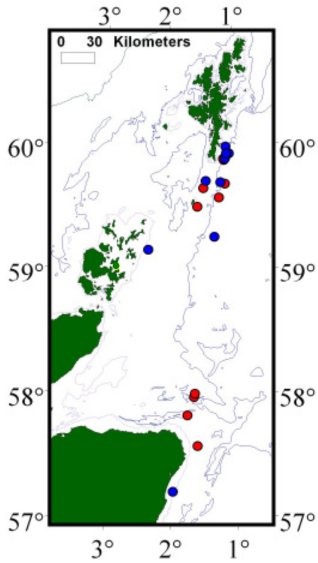

Figure 37 Atlantic white-sided dolphin sightings made during SCANS I survey and seismic surveys (Hammond *et al*., 2004)

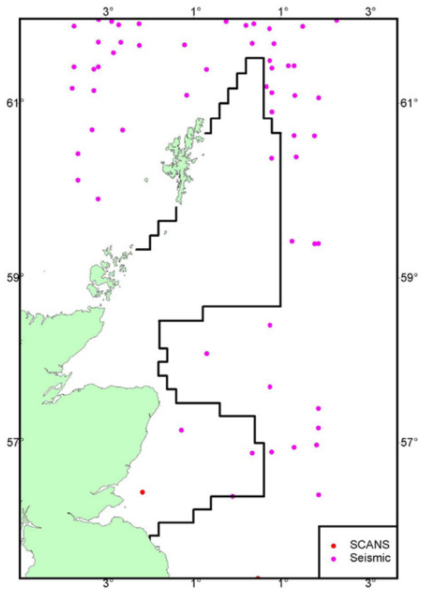

5.6 KILLER WHALE (*ORCINUS ORCA*)

5.6.1 Distribution

Killer whales have a worldwide distribution and are found in tropical, temperate and polar waters in both the northern and southern hemisphere (Reid *et al*., 2003). In the eastern North Atlantic they occur in most areas from coastal fjords to oceanic waters. Any seasonal movements appear to be associated with prey, including seals and herring, and are region-specific (Hammond *et al*., 2001, 2004; Reid *et al.*, 2003).

Killer whales have been observed throughout the north-western North Sea in most months (Hammond *et al*., 2001, 2004; Reid *et al.*, 2003). In UK near-shore waters the species is mainly recorded between April and October (Evans, 1988, 1992; Reid *et al*., 2003). Killer whales are not numerous in the North Sea in general, although they are recorded fairly frequently around Shetland in all months (Hammond *et al*., 2004). The locations of killer whale sightings made during systematic surveys and some platforms of opportunity off north-east Scotland are illustrated in Figure 38.

During opportunistic sightings of killer whales from Scottish pelagic trawlers fishing for mackerel (October to March) and herring (June to September) off north Scotland between 2000 and 2006, encounters with recorded killer whales were recorded between January and February 2006 from pelagic trawlers fishing for mackerel to the north and east of Shetland, no killer whale encounters were recorded from vessels fishing for herring (Luque *et al*., 2006).

Individual killer whales have been documented to move over very large areas, with ranges up to tens of thousands of km^2 for animals from both resident and transient populations (Baird, 2000).

5.6.2 Abundance

The most recent sighting surveys in the eastern North Atlantic (mainly from Iceland to the Faroes) indicate a population of between 3,500 and 1,2500 individuals (Gunnlaugsson and Sigurjonsson, 1990). Most sightings in UK waters are of singles or pods of less than eight individuals (mean = 4.6), although aggregations of up to one hundred have been observed (Macleod, 2004).

5.6.3 Occurrence in Aberdeen Bay and surrounding area

Along the southern outer Moray Firth coast (May to October, 2001-2005), killer whales were only intermittently sighted between the months of June and August (*n* = 6) (Robinson *et al.*, 2008). During ferry surveys between Aberdeen, Orkney and Shetland in summer months between 2002 and 2006, killer whales were encountered on three occasions in groups ranging from one to five individuals (Figure 38). Two of these encounters were in August (2004 and 2006) and one was in June 2006. This suggests that killer whales are rare, but regular members of the cetacean community in the northern North Sea (MacLeod *et al*., 2007).

No killer whales were sighted during any of the EOWDC boat based surveys.

5.6.4 Diet

Killer whales have one of the most varied diets of all cetaceans, ranging from fish and squid to birds, turtles, seals and other cetaceans (Reid *et al*., 2003). Fish species taken in the eastern North Atlantic include herring, mackerel, cod and salmon (Evans, 1980; Reid *et al*., 2003). Little is known about the diet of killer whales in British waters (Hammond *et al*., 2001). Killer whales are thought to prey upon seals around haul outs in Shetland at least, and possibly offshore, as well as at least one porpoise, and have also been reported to feed on mackerel around Shetland (Fisher and Brown, 2001; Hammond *et al*., 2001).

The stomach contents of one killer whale stranded in Scotland between 1993 and 1995 consisted of oceanic cephalopods, including Gonatidae (*Gonatus steenstrupi*) and Histioteuthidae (Santos *et al*., 1995).

Figure 38 Distribution of killer whale (blue), Risso's dolphin (yellow) and fin whale (red) sightings during ferry surveys (April-September, 2002-2006)

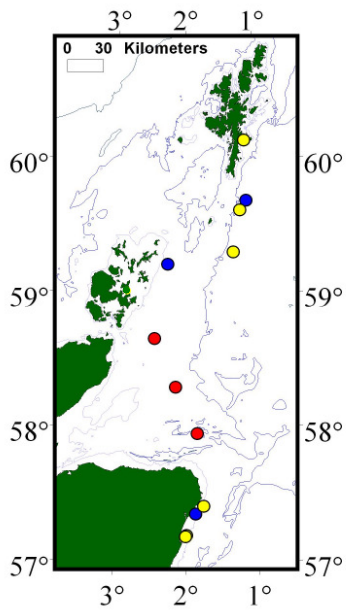

Figure 39 Killer whale sightings made during SCANS I survey, JNCC and seismic surveys and from Evans 1988 (Hammond *et al.*, 2004)

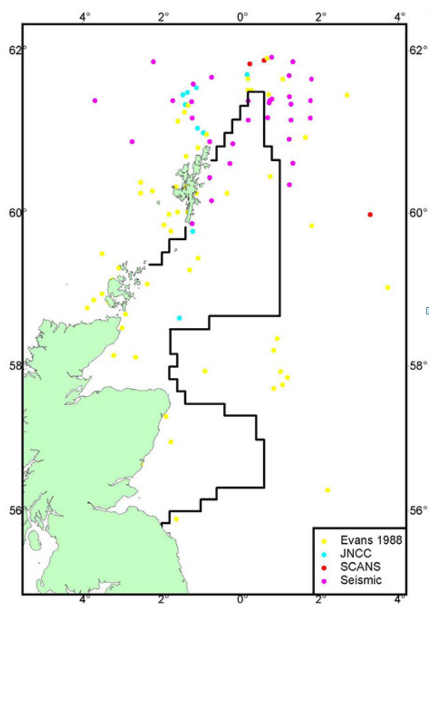


5.7 COMMON DOLPHIN (*DELPHINUS DELPHIS*)

5.7.1 Distribution

Short-beaked common dolphins have a world-wide distribution in tropical and temperate waters (Reid *et al*., 2003). They are generally found in oceanic and shelf-edge waters but do occasionally use coastal areas. Around the British Isles, the species is most often reported from the west coast, especially the Celtic Sea (Hammond *et al*., 2004; Reid *et al*., 2003).

5.7.2 Abundance

There are no known local populations in UK waters, and those animals occurring in UK waters are part of a wider north-east Atlantic population. SCANS II covered all European Atlantic continental shelf waters in June/July 2005 and estimated total abundance in the area as 63,366 (CV=0.46) (SCANS-II 2008).

5.7.3 Occurrence in Aberdeen Bay and surrounding area

There have also been infrequent sightings during surveys in the North Sea, generally during summer months (Hammond *et al*., 2001). The species is also occasionally stranded along the UK North Sea coast (Reid and Patterson, 1998). Figure 40 shows sightings records of common dolphins made during systematic surveys and some platforms of opportunity off north-east Scotland (Hammond *et al*., 2004). During the SCANS II survey in July 2005, common dolphins were sighted in the waters west of Britain and Ireland, in the channel, and in shelf waters off France, Spain and Portugal (SCANS II, 2006).

Nine groups of common dolphins, ranging in size from one to 25 animals, were recorded during NORCET surveys between Aberdeen, Orkney and Shetland in summer months between 2002 and 2006 (MacLeod *et al*., 2007). Sightings occurred from June to August and in every year except 2005. This species primarily occurred in relatively coastal waters near Shetland and north-east Scotland (Figure 40). Therefore, common dolphins appear to be a regular, if rare and seasonal, member of the cetacean assemblage of the northern North Sea (MacLeod *et al*., 2007). In the outer southern Moray Firth, along the Southern Trench, approximately 300+ common dolphins were encountered on 8th July 2007 (Earthwatch, 2011)

One solitary common dolphin was recorded during the project boat based surveys carried out during 2007-2008 (Figure 33).

5.7.4 Seasonal occurrence

Short-beaked common dolphins are occasional summer visitors to the North Sea (Hammond *et al*., 2001; 2004). Most sightings of common dolphins in the North Sea have been recorded between June and September (Reid *et al*., 2003).

5.7.5 Diet

The diet of common dolphins comprises a wide range of small fish and squid (Reid *et al*., 2003). In the North Sea, small pelagic schooling fishes and squids are the likely main food items (Hammond *et al*., 2004). An influx of the squid *Todarodes sagittatus* to the North Sea during 1937 was accompanied by an influx of common dolphins that same year, and it was assumed that the common dolphins were feeding on these squid (Fraser, 1946; Hammond *et al*., 2004).

Two common dolphins stranded in Scotland between 1993 and 1995 had eaten mainly sandeels and Gadidae (such as whiting and haddock/saithe/pollack), but also herring (Clupeidae) (Santos *et al*., 1995). Fourteen fish taxa and two cephalopod taxa were identified from the stomachs of nine common dolphins from Scottish waters between 2000 and 2003. Mackerel, followed by whiting were the main prey, other prey species included herring, sprat, *Argentine* sp., cod, haddock, blue whiting, *Trisopterus* spp., grey gurnard, scad, sandeels and plaice (Santos *et al*., 2004b).

5.7.6 Strandings

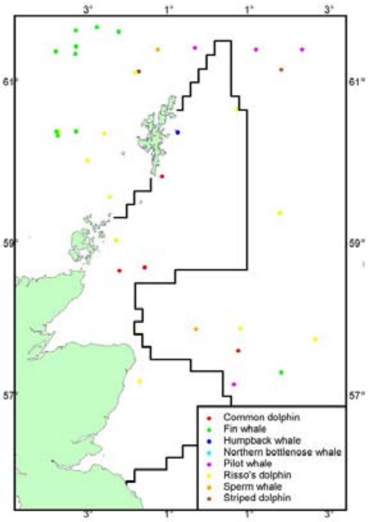
Three stranded common dolphins have been recorded by the Scottish Agricultural College along the northeast coast of Scotland from Fraserburgh to Inverbervie between January 1992 and August 2006 (SAC, 2006). The body lengths of the dolphins were between 150 cm and 220 cm, two were female and one was male. Stranded common dolphins were recorded in March, April and May in 1992 and 2005 between Fraserburgh and Aberdeen (Table 8).

Table 23 Common dolphins stranded along the northeast coast of Scotland (January 1992 – August 2006)

Date Found	Location	Sex	Body length
March 1992	Aberdeen	F	193 cm
April 2005	Aberdeen	F	151 cm
May 2005	Rattray Bay	M	219 cm

Strandings records indicate that common dolphins are present along the northeast coast of Scotland between March and May, although there occurrence in the strandings record is infrequent (SAC, 2006).

Figure 40 Sightings records of common dolphins, fin whales, humpback whales, northern bottlenose whales, pilot whales, Risso's dolphins, sperm whales and striped dolphins made during NASS-87, NILS-95 JNCC seismic and other surveys.



5.8 RISSO'S DOLPHIN (*GRAMPUS GRISEUS*)

5.8.1 Distribution

Risso's dolphins have a wide distribution and are generally found in oceanic waters. Risso's dolphins are primarily a warm water (4.5-28°C) pelagic species that is generally found in continental slope waters (Reid *et* *al*., 2003). In UK continental shelf seas, Risso's dolphins have been recorded mainly over slopes of 50-100 m depth (Reid *et al*., 2003).

Most of the sightings recorded from the northern North Sea are around Shetland, Orkney, Fraserburgh, Aberdeen and Berwick, with only a few sightings in the central North Sea (Reid *et al*., 2003; Hammond *et al*., 2001). The sightings records of Risso's dolphins made during systematic surveys and some platforms of opportunity off north-east Scotland are illustrated in Figure 40.

5.8.2 Abundance

There have been no attempts to estimate the abundance of Risso's dolphins over wide areas of the North Sea, although the animals occurring in UK waters are likely to be part of a population ranging in size from 500 animals to the low 1,000s, similar to population sizes in the north-west Atlantic (JNCC, 2010).

5.8.3 Occurrence in Aberdeen Bay and surrounding area

Sightings of Risso's dolphins in northern North Sea are mainly between July and August, although some animals were present off north-east Scotland and Shetland in winter (Reid *et al*., 2003). Along the southern outer Moray Firth coast (May to October, 2001-2005), Risso's dolphins were exclusively recorded in September and were seen in increasing abundance during the latter years of the study (Robinson *et al*., 2008).

During ferry surveys between Aberdeen, Orkney and Shetland in summer months between 2002 and 2006, Risso's dolphins were sighted on six occasions, with group size ranging from one to four individuals (MacLeod *et al*., 2007). These sightings all occurred in 2006 and were either in relatively coastal waters close to Shetland or north-east Scotland.

Risso's dolphins have been recorded off the Aberdeenshire coast since 2005, with sightings off Girdleness in September 2005 and off Cruden Bay/Bullars of Buchan in October 2005. There were several reported sightings around Aberdeen during July/August 2006 and April 2007 and another from Torry in February 2007, more recently a group of 4 Risso dolphins were observed at Longhaven Cliffs near Aberdeen in 2010 (ACC, 2008; Seawatch Foundation, 2011).

Altghough no Risso's dolphins were observed in any of the EOWDC boat based surveys, during bird vantage point (VP) surveys for this project, 20 Risso's dolphins were recorded at Blackdog on the 28th April 2006 and 10 Risso's dolphins were observed at the Donmouth on the 24th April 2007.

The increase in recent sightings in the Aberdeen Bay area may indicate that Risso's dolphins are using the area more frequently, and although occasional in the area the frequency of the utilisation of Aberdeen Bay area may change and should be monitored.

5.8.4 Diet

Risso's dolphins are capable of deep dives and are thought to specialise in catching squid (Hammond *et al*., 2001). Risso's dolphins have been reported to feed mostly on cephalopods, although small fish are also taken (Reid *et al*., 2003). Analysis of stomach contents from individuals from British waters indicated a diet of mainly octopus *Eledone cirrhosa*, also cuttlefish *Sepia officinalis*, sepioloids and squid such as *Loligo forbesi* and *Todarodes sagittatus* (Reid *et al*., 2003). Three Risso's dolphins stranded in Scotland between 1993 and 1995 had been feeding on cephalopods, primarily the octopus *Eledone cirrhosa* (Santos *et al*., 1995).

5.8.5 Strandings

Two Risso's dolphins have been recorded by the Scottish Agricultural College along the northeast coast of Scotland from Fraserburgh to Inverbervie between January 1992 and August 2006. One was a female with a body length of 325 cm recovered in November 2004 from Blackdog, the other had a body length of approximately 250 cm, the sex was not determined, and it was recovered from Fraserburgh in January 2005 (SAC, 2006; CSIP 2009).

Strandings records suggest that although Risso's dolphins may be present in the area, their occurrence is occasional and the number of animals in the area is likely to be low.

5.9 STRIPED DOLPHIN (*STENELLA COERULEOALBA*)

5.9.1 Distribution

The striped dolphin has a worldwide distribution, occurring in both southern and northern hemispheres mainly in tropical, sub-tropical and warm-temperate oceanic waters. It tends to occur beyond the continental shelf in depths of 1,000 m or deeper, but has been occasional recorded in shelf waters and even in waters of 60 m or less (Forcada *et al*., 1990; Reid *et al*., 2003).

5.9.2 Abundance

The abundance estimate obtained from the CODA surveys is 82,585 (95% CI = 29,548 – 230,819) animals (Macleod, *et al*., 2008).

Striped dolphins were not reported in Scottish waters until 1988 (Reid *et al*., 1993). It has been suggested that *Stenella coeruleoalba*, a warm-water species, could have recently expanded its distribution northwards. Macleod *et al.* (2005) proposed that increased sea temperatures caused by climate change could explain this shift in distribution.

5.9.3 Occurrence in Aberdeen Bay and surrounding area

Striped dolphins are generally rare in UK waters, with its normal distribution reaching its nothern limit at 50^{o}N, although they have been observed in the North Sea (Reid *et al*., 2003; Stone, 2001). Most near-shore records from the UK have been recorded between July and December (Evans, 1992; Reid *et al*., 2003). Sightings records of striped dolphins made during systematic surveys and some platforms of opportunity off north-east Scotland are illustrated in Figure 38.

No stripped dolphin's were recorded in any of the project surveys.

5.9.4 Diet

The striped dolphin diet consists of a variety of mesopelagic and benthic fish, including sprat, blue whiting, *Trisopterus* spp. and whiting, as well as squid and crustaceans (Reid *et al*., 2003).

The stomach contents of four striped dolphins stranded around Scotland (1993-1995) contained mainly Gadidae (whiting and *Trisopterus* spp.), but also cephalopods, including the sepiolid *Sepietta oweniana* and the oceanic squid *Gonatus steenstrupi* (Santos *et al*., 1995). Ten fish taxa and four cephalopod taxa were identified in the stomach contents of seven striped dolphins stranded around Scotland between 2000 and 2003. Crustacean and polychaete remains were found in three and one of the stomachs, respectively. The main prey species were haddock/saithe/pollock (these species are grouped together as their otoliths are very similar and not always possible to distinguish), followed by *Trisopterus* spp. and whiting (Santos *et al*., 2004b).

5.9.5 Life History

Very little is known about the life history of striped dolphins in Scottish waters. The reproductive status was determined for 6 female and 6 male stranded striped dolphins between 2001 and 2003, with the majority being immature but the (small) sample included one pregnant female and one sexually active mature male. The pregnant female was recovered from Skye on the west coast of Scotland in September 2001 and the mature and sexually active male was recovered from the North Sea coast in May (Santos *et al*., 2008).

5.9.6 Strandings

During 1992-2003, 52 striped dolphin strandings were recorded in Scotland. Although strandings were recorded in every month of the year, highest numbers were found in January-March and August. Striped dolphins stranded all around the Scottish coast, but the majority were recovered from the west coast (Santos *et al*., 2008)

5.10 Long-finned Pilot Whale (*Globicephala melas*)

5.10.1 Distribution

Long-finned pilot whales occur in temperate and sub-Arctic regions of the North Atlantic and in the southern oceans (Reid *et al*., 2003). Long-finned pilot whales in UK waters occur mainly off the continental shelf, but their numbers and distribution seems to be highly variable both between seasons and inter-annually. Most records were from waters greater than 200 m, with relatively few occurrences in the shallower waters of the North Sea (Hammond *et al*., 2001). The sightings of pilot whales made during systematic surveys and some platforms of opportunity off north-east Scotland are illustrated in Figure 40.

5.10.2 Abundance

There is no recent population estimate for this species. The NASS-89 survey estimated 778,000 long-finned pilot whales in the eastern North Atlantic (Hammond *et al*., 2001). There has been a sustained catch of pilot whales off the Faroes for many hundreds of years, during which period more than 230,000 whales have been taken. Historically, there were enough whales around Shetland to support a drive fishery. The largest catch on record in this fishery was 1,540 animals caught in 1845 (Nature in Shetland, 2011).

5.10.3 Occurrence in Aberdeen Bay and surrounding area

Incidental sightings of pilot whales in the North Sea appear to be more numerous between November and January (Reid *et al*., 2003). There are a few sightings in the northern North Sea and there are also records from the south-western North Sea during June, July, August, and December (Reid *et al.,* 2003). Pilot whales are seen in Shetland waters in most months of the year.

During land-based surveys at Stonehaven between March 2003 and March 2005, pilot whales were observed in November 2003 (Canning, 2007). Along the southern outer Moray Firth coast (May to October, 2001-2005), pilot whales were intermittently encountered in the study area between the months of July and August (Robinson *et al*., 2008).

No long finned pilot whales were recorded in any of the EOWDC boat surveys.

5.10.4 Diet

Cephalopods generally form the majority of their diet, although they take a range of species. Twelve genera of cephalopods, as well as 15 genera of fish and crustaceans have been recorded in studies near the Faroes, with squid, especially *Todarodes sagittatus* as a key component (Desportes and Mouritsen, 1993; Reid *et al*., 2003).

5.10.5 Strandings

Strandings along the UK North Sea coast have increased since 1947; there were a number of mass strandings involving more than 150 animals in total between November 1982 and January 1985 (Hammond *et al*., 2001; Martin *et al.*, 1987; Sheldrick, 1976). Pilot whales are one of the most commonly mass-stranded whales.

One long-finned pilot whale has been recorded by the Scottish Agricultural College along the north east coast of Scotland from Fraserburgh to Inverbervie between January 1992 and March 2010. The female had a body length of 308 cm and was recovered from Fraserburgh in April 2001 (SAC, 2006; CSIP 2010).

Strandings records suggest that although long-finned pilot whales may be present in the area, their occurrence is occasional/rare and the number of animals in the area is likely to be low.

5.11 Sperm Whale (*Physeter macrocephalus*)

5.11.1 Distribution

Sperm whales have a wide distribution that includes tropical, temperate and sub-polar seas of the both the northern and southern hemispheres (Reid *et al*., 2003). Sperm whales are normally distributed to the west and north of the UK on, and beyond, the continental shelf break. They have also been recorded fairly regularly in Orkney and Shetland waters, with sightings and strandings reported in most months (Hammond *et al*., 2001). A number of sightings and strandings have been recorded from the North Sea in the last decade. Males migrate to high latitudes to feed and, as a result, all sperm whales sighted or stranded in the North Sea to date have been males (Hammond *et al*., 2001) (

Table 24).

The sightings records of sperm whales made during systematic surveys and some platforms of opportunity off north-east Scotland are illustrated in Figure 40. Sightings of sperm whales in British and Irish waters have been mainly recorded between July and December (Reid *et al*., 2003).

5.11.2 Abundance

The world population of sperm whales has been estimated at 2 million individuals, making them the most abundant species of large whale in the world (Hammond *et al*., 2001).

No sperm whales were detected in any of the project surveys.

5.11.3 Diet

Sperm whale diet is varied but primarily consists of medium to large-sized mesopelagic squid and in the North Atlantic most prey comprise mainly of Onychoteuthidae and Ommastrephidae, although other species are also taken (Reid *et al*., 2003).

Stomach contents of sperm whales stranded in Scotland and Denmark during 1990-96 were analysed (Santos *et al*., 1999). All were sub-adult or adult males and stranded between November and March. The diet of these whales was found to consist almost entirely of cephalopods, principally squid of the genus *Gonatus* (probably *G. fabricii*, an oceanic species characteristic of Arctic waters). The other prey species identified were also mostly oceanic cephalopods: the squids *Histioteuthis bonnellii*, *Teuthowenia megalops* and *Todarodes sagjttatus* and the octopus *Hahphron atlanticus*. There was little evidence of predation on fish. Remains of single individuals of the veined squid *Loligo forbesi*, the northern octopus *Eledone cirrhosa* and the saithe *Pouachius virens* provided the only possible evidence of feeding in the North Sea. The study suggested that sperm whales do not enter the North Sea to feed (Santos *et al*., 1999).

5.11.4 Strandings

Nine sperm whales have been recorded by the SAC along the northeast coast of Scotland from Fraserburgh to Inverbervie between January 1992 and December 2009, six of which stranded together in Cruden Bay in January 1996. Nine stranded sperm whales along the north-east coast of Scotland were male during 1996, 2005, 2006 and 2009 and their body lengths ranged between 1,200cm and 1,375 cm (CSIP 2010) (

Table 24).

Table 24 Sperm whales stranded along the northeast coast of Scotland (January 1992 – March 2010)

Date Found	Location	Sex	Body length
January 1996	Cruden Bay	M	1,210 cm
January 1996	Cruden Bay	M	1,260 cm
January 1996	Cruden Bay	M	1,285 cm
January 1996	Cruden Bay	M	1,365 cm
January 1996	Cruden Bay	M	1,365 cm
January 1996	Cruden Bay	M	1,375 cm
May 2005	Cruden Bay	M	c1,350 cm
March 2006	Forvie	M	c1,200 cm
October 2009	Balmedie	M	1,400 cm

Stranding records suggest that although male sperm whales may be present in the area between January and May, their occurrence is occasional and the number of animals in the area is likely to be low (SAC, 2006).

5.12 Humpback whale (*Megaptera novaeangliae*)

5.12.1 Distribution

The humpback whale occurs globally in tropical, temperate and polar seas of the northern and southern hemispheres (Reid *et al*., 2003). It is generally found along and over the edges of continental shelves. In summer they tend to have a more coastal distribution in some areas that is largely depended on local prey availability (Reid *et al*., 2003).

5.12.2 Abundance

In the summer, a very small number of humpbacks are found in British shelf waters, particularly around the Northern Isles and also in western areas from the Hebrides to the English Channel (Evans, 2003).

5.12.3 Occurrence in Aberdeen Bay and surrounding area

Most sightings over the UK continental shelf have been made between May and September (Reid et al., 2003). The sightings records of humpback whales made during systematic surveys and some platforms of opportunity off north-east Scotland are illustrated in Figure 40.

During ferry surveys between Aberdeen, Orkney and Shetland in summer months between 2002 and 2006, one group of humpback whales, consisting of two adults and one juvenile, was seen in July 2005 (MacLeod *et al*., 2007). While this species was once almost completely absent from the North Sea due to the depletion of the North Atlantic humpback whale population by whalers, this species is now becoming regularly recorded in the North Sea in small numbers possibly as a result of a recovery in the North Atlantic population (MacLeod *et al*., 2007). Along the southern outer Moray Firth coast, humpback whales were intermittently encountered in the study area between the months of July and August (Robinson *et al*., 2008).

Humpback whales have been recorded off the Aberdeen coast in the area between Girdleness and Cove, just south of Aberdeen in February 2003 and June 2002 and off Portlethen in 2010 (Seawatch Foundation 2011).

No humpback whales were recorded during the EOWDC surveys.

5.12.4 Diet

The diet of humpback whales in the North Sea area is unknown, but elsewhere they consume planktonic crustaceans and small schooling fish. The fish species most likely to be consumed are those that form dense pelagic schools such as sandeels, herring, sprats and mackerel (Hammond *et al*., 2001, 2004; Reid *et al*., 2003).

5.13 FIN WHALE (*BALAENOPTERA PHYSALUS*)

5.13.1 Distribution

Fin whales occur in the North Atlantic and are mainly found in deep waters (400-2,000 m depth) beyond the edge of the continental shelf, but in some areas they are known to occur in shallower waters less than 200 m deep (Reid *et al*., 2003). In north-west Europe fin whales are mainly distributed along or beyond the 500 m depth contour (Reid *et al*., 2003). The sightings records of fin whales made during systematic surveys and some platforms of opportunity off north-east Scotland are shown in Figure 40.

5.13.2 Abundance

The fin whale is the most abundant large baleen whale species in the North Atlantic. The best available estimates of recent abundance accepted by the IWC Scientific Committee are 25,800 (CV= 0.13) in 2001 for the central North Atlantic (East Greenland-Iceland, Jan Mayen, Faeroes and some waters within the UK 200 nm limit) (IWC, 2007); 4,100 (CV 0.21) in 1996-2001 for the north eastern North Atlantic (North and West Norway); and 17,355 (CV 0.27) in 1989 for the Spain-Portugal-British Isles area (Buckland *et al*., 1992).

5.13.3 Occurrence in Aberdeen Bay and surrounding area

Around the British Isles, fin whales occur mainly between June and December, with most sightings in northern Britain occurring between June and August (Reid *et al*., 2003).

Three groups of fin whales were recorded during NORCET surveys, all in the outer Moray Firth region. However, these were all during a single survey in June 2006 and may represent a small number of stray animals rather than indicating the regular occurrence of this species in the northern North Sea (MacLeod *et al.*, 2007).

No fin whales were recorded during any project surveys.

5.13.4 Diet

Fin whales feed primarily on planktonic crustaceans, mainly euphausiids, but they also take a variety of fish such as herring, sandeel, mackerel and blue whiting as well as cephalopods (Reid *et al.*, 2003).

5.14 Beaked Whales

5.14.1 Distribution

Three species of beaked whale have been sighted in UK waters: northern bottlenose whale (*Hyperoodon ampullatus*), Sowerby's beaked whale (*Mesoplodon bidens*) and Cuvier's beaked whale (*Ziphius cavirostris*). Northern bottlenose whales only occur in temperate, sub-polar and polar seas in the North Atlantic (Reid *et al.*, 2003). Bottlenose whales are mostly recorded in deep water and most sightings have been made north and west of Scotland along the continental shelf edge over the 1,000 m isobath. The species is rarely seen in shelf waters of the North Sea (Reid *et al.*, 2003). Sowerby's beaked whale has the most northerly distribution of all species of *Mesoplodon* in the Atlantic and is the most frequently seen and stranded *Mesoplodon* species in the north Atlantic (Reid *et al.*, 2003). It is generally found in deep water, although has been recorded in the North Sea (Reid *et al.*, 2003). Cuvier's beaked whale, is frequently recorded in the Bay of Biscay and further south, and there have been a few confirmed sightings in UK waters (off west Scotland and in the northern North Sea), all in the summer (Reid *et al.*, 2003).

5.14.2 Abundance

In the western Atlantic several estimates have been made for Mesoplodon spp. Grouped, and Cuvier's beaked whale and these have all been in the low hundreds. However, due to the cryptic nature of these species (deep diving and occurring in small groups) these estimates carry a substantial negative bias

5.14.3 Occurrence in Aberdeen Bay and surrounding area

The sightings records suggest that beaked whales are very rare visitors to the northern and central North Sea. In summer the northern bottlenose dolphin appears to move towards north-west European shelf waters, where most records occur between April and September, peak sightings off northern Scotland have been recorded in August (Evans, 1992; Reid *et al.*, 2003).

A northern bottlenose whale was recently sighted near the entrance to Aberdeen Harbour in 2009 (C. Bloomer Pers comm.)

No beaked whale species were recorded during the project surveys.

5.14.4 Diet

Northern bottlenose whales are predominantly squid feeders. They do not appear to enter the North Sea very frequently and it is likely that when they do, they would be following squid (Hammond *et al.*, 2001). Their diet is dominated by a variety of squid species, particularly *Gonatus fabricii* and species of the genera *Histioteuthis* and *Octopoteuthis*, but also includes some fish species and crustaceans (Reid *et al.*, 2003).

Stomach content analysis of northern bottlenose whales stranded in the North Sea (Netherlands, 1993 and 1956; Denmark, 1997; Dunbar, Scotland, 1885) indicated that the food remains consisted almost entirely of cephalopod beaks, with only a few fish and crustacean remains. The cephalopod prey consisted mainly of oceanic species, in particular *Gonatus fabricii* (Santos *et al*., 2001b).

Sowerby's beaked whale diet is generally dominated by fish and squid. The stomach contents of three animals stranded in Scotland consisted of Merluccidae spp. and Gadidae spp. (MacLeod *et al*., 2003). The stomach contents of one Sowerby's beaked whale stranded in Scotland (1993-1995) had only large Gadidae otoliths (haddock/saithe/pollack) in the stomach (Santos *et al*., 1995).

5.14.5 Strandings

One Sowerby's beaked whale has been recorded by the SAC along the northeast coast of Scotland from Fraserburgh to Inverbervie between January 1992 and March 2010 (CSIP 2010). The male had a body length of 470cm and was recovered from Peterhead in January 2005 (SAC, 2006).

Strandings records suggest that although Sowerby's beaked whales may be present in the area, their occurrence is occasional/rare and the number of animals in the area is likely to be low.

6. SEALS

6.1 Harbour (or common) seal (*Phoca vitulina*)

6.1.1 Distribution

Harbour seals are one of the most widespread pinniped species and have a practically circumpolar distribution in the Northern Hemisphere. Harbour or common seals are found around the coasts of the North Atlantic and North Pacific from the subtropics to the Arctic. There are four sub-species. Only the eastern Atlantic harbour seal, *Phoca vitulina vitulina,* occurs around Britain (Hammond *et al*., 2004; SCOS, 2006).

Britain is home to approximately 40% of the world population of the European sub-species. Harbour seals are widespread around the west coast of Scotland and throughout the Hebrides and Northern Isles. On the east coast, their distribution is more restricted with concentrations in The Wash, Firth of Tay and the Moray Firth (Hammond *et al*., 2004; SCOS, 2006). The Moray Firth supports a population of approximately 1,600 harbour seals, the largest on the east coast of Scotland (Thompson *et al*., 2007).

Figure 41 depicts the distribution of harbour seals in the north-western North Sea as it was believed to be before satellite telemetry studies (after Reijnders *et al*., 1997), at-sea sightings from Pollock *et al*. (2000) are also shown (taken from Hammond *et al*., 2004).

Satellite telemetry of harbour seals found in Orkney and Shetland and seals hauling out in St Andrews Bay and the Moray Firth indicate the true distribution of seals around north-east Scotland as illustrated in Figure 42) (taken from Hammond *et al*., 2004).

Figure 41 Harbour seal distribution in the north-western North Sea after Reijnders *et al*. (1997). Also shown are haul-out sites during the moult (SMRU unpublished data) and at-sea sightings from JNCC surveys

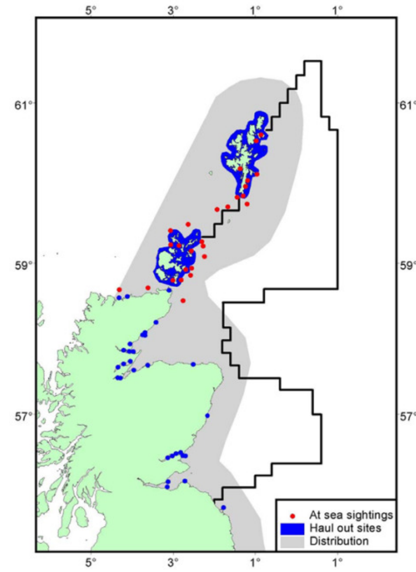


Figure 42 Locations of 55 harbour seals fitted with satellite-relay data loggers covering the period 2002-2004 (SMRU unpublished data) and the area used by VHF-tagged harbour seals in the Moray Firth

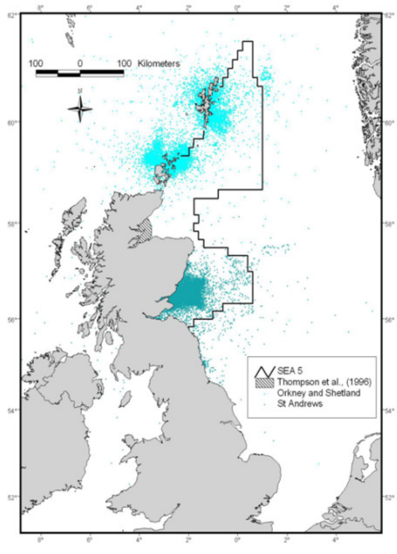

6.1.2 Occurrence in Aberdeen Bay area

Harbour seals are frequently observed in the River Don, and at least nine animals including juveniles and are often seen in the mouth of the Dee or hauled out on sand banks near the Bridge of Don. They are also recorded in Aberdeen Harbour, and may be expected to occur year-round in Aberdeen Bay. During project vantage point surveys, harbour seals were recorded at Blackdog in June 2007, Donmouth in July 2007 and at Blackdog and Donmouth in January 2008.

The SMRU data on haul out locations of harbour seals indicates the nearest harbour seal haul-out site is located 7.9 km from the proposed wind farm site during August 2005 survey (presented in Figure 48 and Figure 49).

Detailed observations of the behaviour of harbour seals at sites within the estuaries of the Rivers Dee and Don, in north-eastern Scotland, were made over two full years between 1993 and 1996 (Carter *et al*., 2001). Small numbers of grey seals were also present. The presence of seals within the estuaries was strongly related to season, with maximum numbers observed in winter and early spring; seals were virtually absent in June and July. The River Don was used largely as a haul-out site, while the River Dee was used predominantly as a foraging site, although it was not possible to determine whether the same seals were using the two estuaries. More seals were hauled-out on the River Don during twilight and dark than in daylight (Carter *et al*., 2001).

Common seals were only detected during the four months of EOWDC boat based survey 2010-2011, the results are discussed further in Section 6.3.

6.1.3 Abundance

The most recent estimate of the number of common seal in Scotland is 19,988, from surveys carried out in 2006-2008 (SCOS 2009). The abundance estimates have a degree of error as only a proportion of the individuals in the population will be hauled out and counted during. The total British population has been estimated at 40,000-46,000, and this takes into account animals missed during the counting (SCOS 2009).

Approximately 20% of the eastern Atlantic harbour seal subspecies breeds in Orkney and Shetland and along the east coast of Scotland (Hammond *et al*., 2004).

Surveys of the east coast populations in 2008 showed continuing declines in the Firth of Tay population and a continued lack of recovery in the Moray Firth; the reasons causing this recent decline are not known at present. The lack of recovery contrasts with the apparent rapid growth in populations in the nearest European populations in the Wadden Sea which increased by 15% between 2007 and 2008 and has grown by approximately 13% per annum since the 2002 PDV epidemic (SCOS 2008).

Due to declines in the numbers of harbour seals counted in Shetland, Orkney, the Moray Firth and the Firth of Tay, the Scottish Executive put in place a Conservation Order protecting harbour seals on the east coast and Northern Isles in March 2007. The Order covers the coast from Garron Point by Stonehaven to Torness Point, south of Dunbar on the south side of the Firth of Forth. Seals in the Moray Firth are already protected by a Conservation of Seals (Scotland) Order 2004.

6.1.4 Haul-out sites and breeding

Harbour seals come ashore in sheltered waters, typically on sandbanks and in estuaries, but also in rocky areas. They tend to be more localised than grey seals, staying in the same general area to breed, feed and rest, and do not form as large breeding colonies. Harbour seals haul out on land regularly in a pattern that is often related to the tidal cycle (SCOS, 2006).

Pupping occurs on land from June to July during which time females and pups spend a high proportion of their time ashore. The moult is centred around August and extends into September. Moulting seals also spend a high proportion of their time ashore, so from June to September harbour seals are ashore more often than at other times of the year (Hammond *et al*., 2004).

6.1.5 Movements and foraging

The radio-tracking of adult female seals in the inner Moray Firth (1988, 1989, 1992) during the breeding season indicated that seals foraged up to 45 km from the haul-out site, but females with pups restricted their range markedly during the early part of the lactation period (Thompson *et al*., 1994).

Generally it has been thought that harbour seals forage relatively close inshore within a range of 60 km from their haul-out sites (Thompson *et al.*, 1996). However, recent information on foraging movements and the distribution at sea of harbour seals has highlighted greater travel distances, ranging from 10 km to 120 km, with a mean of 46 km (Hammond *et al*., 2004).

Data from satellite relay data loggers (SRDLs) have highlighted different foraging behaviour of harbour seals off southeast Scotland and around Orkney and Shetland. Off southeast Scotland, animals were found to be very faithful in their use of haul-out sites on land, and moderately site-faithful in the areas individuals used to forage. Duration of trips ranged from less than one day to 23 days, with a mean of 4.5 days. Foraging in the Moray Firth was mostly closer to the shore. Around Orkney and Shetland there are indications that seals tend to move between haul-outs sites within a 40 km radius of where they were captured with one animal hauling out as far as 200 km from where it was initially tagged. Foraging behaviour is also much more variable both in distance travelled and in the duration of trips. Most foraging trips are within 40 km of haul-outs but there are also longer distance trips to areas more than 200 km from haul-out sites (Hammond *et al*., 2004).

6.1.6 Diet

Harbour seals take a wide variety of prey including sandeels, whitefish, herring and sprat, flatfish, octopus and squid. Diet varies seasonally and from region to region (Hammond *et al*., 2004; SCOS, 2006). In Shetland, Brown and Pierce (1998) found that gadids accounted for an estimated 53.4% of the annual diet by weight, sandeels 28.5% and pelagic fishes 13.8%. The dominant gadid fishes were whiting and saithe. There were strong seasonal patterns in the contribution of sandeels and gadids, with sandeels being important in spring and early summer, and gadids in winter. Pelagic species (mainly herring, garfish and mackerel) were important in late summer and autumn (Hammond *et al*., 2004).

In the Moray Firth, Tollit andThompson (1996) found the key prey during 1989-1992 to be sandeels, lesser octopus, whiting, flounder, and cod. Significant between-year and seasonal fluctuations were evident. In another study in the same area between 1992 and 1994, Tollit *et al*. (1997) found the diet composition was almost totally dominated by either pelagic species or species dwelling on or strongly associated with the seabed, depending upon the relative abundance of pelagic schooling prey (Hammond *et al*., 2004).

In the Firth of Tay, unpublished SMRU data from 1998-2003 show that the diet comprised primarily sandeels, gadids and flatfish. Gadid prey was dominated by whiting, followed by cod and haddock. Plaice was the main flatfish consumed followed by dab, flounder and lemon sole. Strong seasonal patterns in prey consumption were evident (Hammond *et al*., 2004).

During observation at the estuaries of the Rivers Don and Dee, the seals were observed to eat mostly salmonids, *Salmo salar* and *S. trutta*, unidentified roundfish and founder, *Pleuronectes flesus*, there were also observations of seals taking starfish and crabs. Predation on salmonids was observed more frequently on the Dee than the Don, while the reverse was true for predation on flounder. The otoliths identified in scats collected at the mouth of the River Don belonged to marine species, including whiting, sandeels, cod, *Trisopterus* spp., haddock, plaice and lemon sole, as well as three octopus beaks, indicating that the seals were also feeding outside the estuaries (Carter *et al*., 2001).

6.1.7 Special Areas of Conservation

Designated coastal SACs for harbour seals include Yell Sound and Mousa on Shetland, Sanday on Orkney, Wash and North Norfolk coast on the east coast of England, Dornach Firth and Morrich More, in the Moray Firth, and Firth of Tay and Eden Estuary on the Scottish east coast (JNCC, 2011).

6.2 GREY SEAL (*HALICHOERUS GRYPUS*)

6.2.1 Distribution

Grey seals are restricted to the North Atlantic and adjacent seas. There are three recognised populations: the northwest Atlantic (breeding primarily on Sable Island, Canada and in the Gulf of St Lawrence); the Baltic Sea; and the northeast Atlantic (breeding primarily on offshore islands around the British Isles but also in Iceland, the Faroe Islands, France, the Netherlands, central and northern Norway, and around the Kola peninsula in Russia) (Hammond *et al*., 2004). Figure 43 shows the tracks of 108 grey seals recorded over a period of about 10 years and the locations at which it has been determined that the seals were foraging, the specific locations are shown in Figure 44 (McConnell *et al.*, 1999; taken from Hammond *et al*., 2004). More recent analysis of grey seal movements in the Pentland Firth area has been provided by SMRU Ltd, which further illustrates the large scale seasonal movements that occur between seals occurring at spatially separate haul out colonies in the North Sea.

Figure 43 Tracks of 108 grey seals fitted with satellite-relay data loggers over a period of about 10 years (McConnell *et al.,* 1999; SMRU unpublished data)

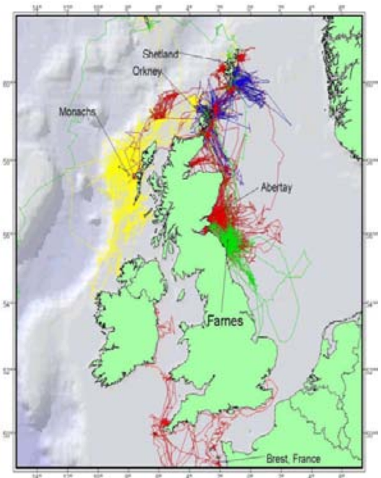

Figure 44 Locations of 108 grey seals fitted with satellite-relay data loggers over a period of about 10 years (McConnell *et al.,* 1999)

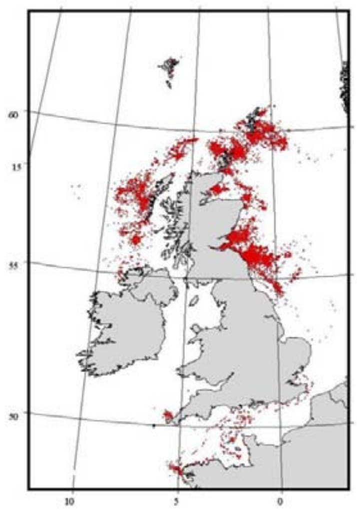

Figure 45 Grey seals tagged with SMRU Argos and SMRU GSM/GPS tags, the tracks are colour coded by capture region (SMRU 2011c)

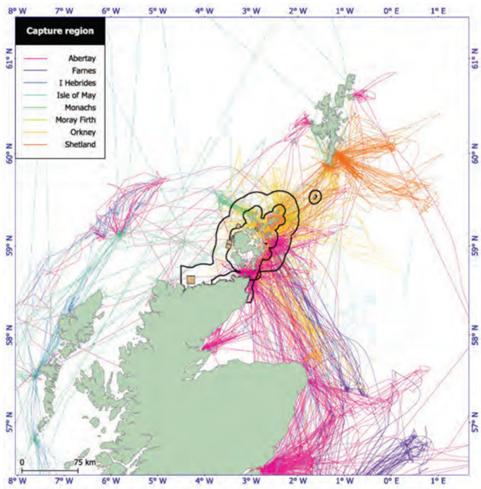


6.2.2 Abundance

The Grey seal population of the UK is significant in a global context as the UK population represents approximately 45% of the world population on the basis of pup production (SCOS 2009). Over 90% of British grey seals breed in Scotland, the majority in the Hebrides and in Orkney (SCOS, 2006).

Combining the abundance estimates for the annually monitored seal colonies with the sites which are monitored less frequently provides an estimated seal population of 205,000, with a large confidence interval of (96,500; 405,000). A large proportion of the populations are associated with the colonies in Orkney, Shetland, and the east coast of Scotland (Hammond *et al*., 2004).

The latest population estimate has suggested an increase of around 2.8% between 2007 and 2008. The British grey seal population has been increasing by around 6% annually since the 1960s.

6.2.3 Occurrence in Aberdeen Bay area

Grey seals are frequently observed at sea during vessel-based cetacean surveys carried out by the Sea Watch Foundation, including large bulls, females and immature animals. Seals use the waters between Stonehaven and Aberdeen as a feeding area, since animals are often observed eating fish at the surface.

Grey seals are frequently observed hauled out on the Skerry just outside Peterhead harbour and may be expected to occur year-round in the area. Grey seals have important haul-out sites at Pennan Head, Rattray Head, Boddam, Catterline and Donmouth.

Grey seal sightings recorded during project VPS surveys (August 2005 – March 2008) are summarised in Table 25.

Table 25 Grey seal sightings recorded during Vantage Point surveys (August 2005 – March 2008)

VP site	Observations
Donmouth	August 2006, December 2006, March 2007, May 2007, August 2007, September 2007
Blackdog	August 2006, December 2006, January 2007, March 2007, May 2007, August 2007, December 2007
Balmedie	December 2006, February 2007, August 2007
Drums	February 2007, August 2007, September 2007

The nearest grey seal haul-out sites identified during the SMRU seal surveys in August 1997 and 2005 were located 7.9 km from the proposed wind farm site (presented in Figure 48 and Figure 49).

Grey seals were present throughout the survey area during all the boat based survey months and the results are presented in Section 6.3.

6.2.4 Haul-out sites and breeding

Grey seals haul out between foraging trips and for pupping and moulting, when they can form large colonies or aggregations (Hammond *et al*., 2004). Grey seals generally form breeding colonies on rocky shores, beaches and in caves, and on small, largely uninhabited, islands (JNCC, 2011). Large rookeries are located in the Inner and Outer Hebrides, Orkney, Isle of May, Farne Islands and Donna Nook (JNCC, 2011).

In Northern Britain, pupping occurs from October to late November and the moulting season is February-April, when they spend more time ashore than at other times of the year (Hammond *et al*., 2001).

Numbered tags attached to the flippers of pups indicate that young seals disperse widely in the first few months of life. Pups marked in the UK have, for example, been recaptured or recovered along the North Sea coasts of Norway, France and The Netherlands, mostly during their first year of life (Hammond *et al*., 2004).

6.2.5 Movements

Adult grey seals routinely move large distances. Grey seal movements have been studied in the North Sea using satellite-linked telemetry. In a study of animals at the Farne Islands and Abertay Sands, McConnell *et al.* (1999) found that movements were on two geographical scales: long and distant travel (up to 2,100 km away) to known haul-out sites; and local, repeated trips from haul-out sites to discrete offshore areas. Long-distance travel included visits to Orkney, Shetland, the Faroes, and far offshore into the Eastern Atlantic and the North Sea (Hammond *et al*., 2004). Recent telemetry studies have found that seals tagged as far south as the Farne Islands, Isle of May and Moray Firth have been found to enter the Pentland firth area (SMRU 2011c).

In 88% of trips to sea, individual seals returned to the same haul-out site from which they departed. The durations of these return trips were short (typically 2-3 days) and their destinations at sea were often localized areas characterized by a seabed of gravel/sand. This is the preferred burrowing habitat of sandeels, an important component of grey seal diet. The limited distance from a haul-out site of return trips (about 40 km) indicates that the seals were foraging within the coastal zone, rather than further offshore (Hammond *et al*., 2004).

The analysis of the seal telemetry data has shown that grey seals tagged in both the Isle of May SAC and Berwickshire and North Northumberland coast SAC appear to routinely travel past Aberdeen through the proposed location on the way to the Pentland Firth.

6.2.6 Diet

Grey seals feed mostly on fish that live on or close to the seabed. The diet is composed primarily of sandeels, whitefish (cod, haddock, whiting, ling), and flatfish (plaice, sole, flounder, dab) but varies seasonally and from region to region (SCOS, 2006).

Studies in 1985 showed that in Orkney sandeels accounted for almost 50% of the diet; the remainder was mostly cod, ling and plaice (Hammond, *et al.*, 1994). In the central North Sea, studies have shown that the diet was dominated by sandeels, cod and whiting (Hammond and Prime, 1990; Hall and Walton, 1999). Overall, grey seal diet comprises primarily sandeels, gadoids and flatfish, in that order of importance (Hammond *et al.*, 2004).

Sandeel, cod, other gadoids and plaice are the most important prey of grey seals in the North Sea (Hammond and Grellier, 2006). There were marked changes in grey seal diet composition between 1985 and 2002. In the east coast region, the percentage of gadoids in the diet was lower and the percentage of sandeels was higher in 2002 compared with 1983-88, and within the gadoids the percentage of cod in the diet overall declined almost 5-fold and the percentage of haddock increased by an order of magnitude (Hammond and Grellier, 2006).

6.2.7 Special Areas of Conservation

Designated coastal SAC sites for grey seals include the Berwickshire and North Northumberland Coast in north-east England, Faray and Holm of Faray on Orkney and the Isle of May at the entrance to the Firth of Forth (JNCC, 2011).

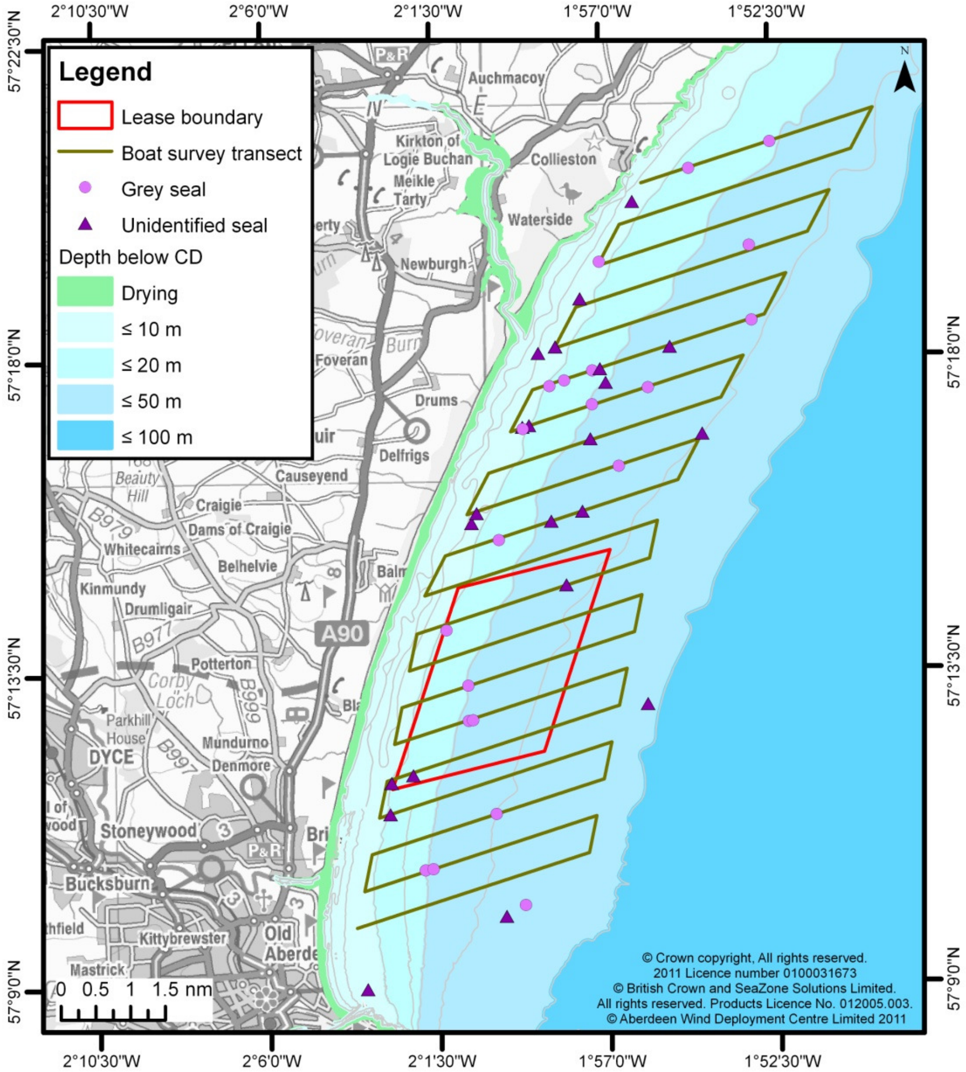
6.3 Boat Based Survey Seal Counts

A summary of the seal species that were recorded during the project boat based surveys are provided in Table 26. A total of 114 individual seals, of which a total of 44 were grey seals, 27 harbour seals and 37 were unidentified seals were observed (Figure 46 and Figure 47).

Table 26 Summary of the seal observations during the IECS (2007-2008) and SMRU Ltd (2010-2011) surveys (collected on and off effort).

Survey	Grey Seal	Harbour Seal	Unidentified
IECS -2007-2008	21	0	25
SMRU Ltd 2010-2011	23	27	18
Totals	44	27	43

Figure 46 Grey and unidentified seals observed during the EOWDC boat based surveys during 2007-2008 (collected on and off-effort)



6.3.1 Grey seals

The grey seal was the most frequently recorded species, with a total of 21 individuals recorded on effort during the boat based surveys 2007-2008 (Figure 46). The grey seal was sighted throughout the survey period with no apparent increase in frequency of sightings with any particular season. There were a higher number of grey seals (n=13) observed in the control area in comparison to the wind farm area (n=8). Despite a lower survey effort there were a higher number (n=24) of grey seals recorded during the 4 months of boat based surveys carried out during 2010-2011 (Figure 47).

6.3.2 Common seals

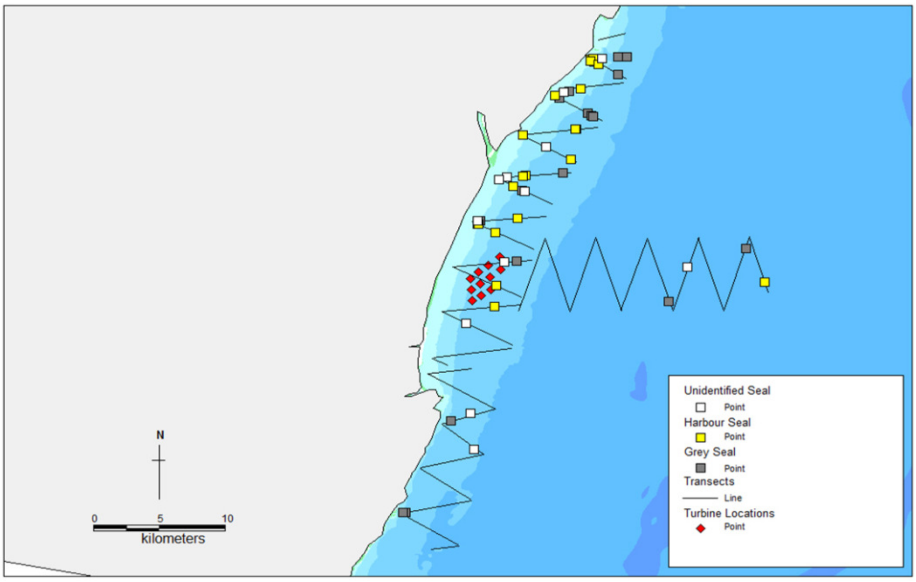
Surprisingly no harbour seals were observed during the boat based surveys carried out during 2007-2008. In the four months of boat based surveys carried out during 2010-2011 there were 27 harbour seals observed;

this suggest that either common seals were present at a lower abundance in Aberdeen Bay during this time, or a proportion of the unidentified seal species that were common seals.

6.3.3 Unidentified seals

During the boat based surveys carried out during 2007-2008 there were 25 seals observed that could not be identified to a species level, three of which were observed off transect (Figure 46). A greater number of sightings of unidentified seals (n=18) were observed in the wind farm area that the control site. There were 15 unidentified seals recorded during the boat based surveys carried out during 2010-2011.

Figure 47 On-effort observations of seals along transects during August, September and November 2010, and January 2011



6.4 Aerial Survey Data Seal Counts

The Sea Mammal Research Unit (SMRU) has surveyed harbour seals along the east coast of Scotland as part of their routine monitoring of seal populations around the UK. Surveys were carried out in 1997 and 2005, 2007 and 2008 (Figure 48 and Figure 49). The surveys were conducted during the harbour seal annual moult, in August, when the most consistent numbers of harbour seals are hauled ashore. The surveys were conducted using a helicopter equipped with a thermal imaging camera which can detect seals hauled ashore up to a 3 km distance. For consistency, surveys are restricted to within two hours either side of afternoon low tides on days with no rain.

Grey seals were also counted during these August surveys. The two species are determined using their thermal profiles and their group structure on shore and species identity is confirmed using a 'real' image from a camcorder and directly using binoculars. However, in some cases this it is not possible and the seals are classified as 'species unknown'. Additional information on grey seals is also obtained during their breeding season, September to November, using fixed wing aerial photography. Repeat surveys are made of the breeding colonies which allow subsequent estimates of pup production to be made on a colony-by-colony basis.

6.4.1 Counts and distribution of seals Fraserburgh to Montrose

The numbers of seals counted during the August thermal imaging surveys between Fraserburgh and Montrose are provided in Table 27. The sections of coast for which numbers of seals are supplied extend from Fraserburgh to Aberdeen and from Aberdeen to the mouth of the River North Esk (SMRU, 2007).

Table 27 Numbers of harbour and grey seals counted between Fraserburgh and Montrose in 1997 and 2005

Date	Region	Harbour Seals	Grey Seals	Species Unknown
Aug-97	Fraserburgh to Aberdeen	0	131	
Aug-97	Aberdeen to North Esk	15	14	
	Total	15	145	
Aug-05	Fraserburgh to Aberdeen	14	400	3
Aug-05	Aberdeen to North Esk	22	11	
Total		36	411	3

In the survey during August 2005 harbour seals were hauled out at the mouth of the River Ythan and at Catterline. Only small numbers of seals were at these haul-out sites at the time of survey. Another group of nine harbour seals were hauled out in the Montrose Basin, just outside the area covered by Table 27 (Figure 49).

Small numbers of grey seals were also hauled out at Catterline and at the mouth of the River Ythan but there were considerably more hauled out between the south end of Cruden Bay and Fraserburgh. The main haul-out sites were: The Scares at the south end of Cruden Bay; around Boddam, south of Peterhead; at the mouth (north side) of Peterhead Bay; Scotstown Head; and at Cairnbulg Point. Another group of grey seals was hauled out just outside this area, at Sandhaven, just to the east of Fraserburgh (Figure 48 and Figure 49).

Variable, but very small, numbers of grey seal pups are born at a number of sites along this section of the east coast of Scotland. The most well established colony is at Catterline, where up to five pups may be born each autumn.

6.4.1.1 Counts and distribution of seals in the wider area Nairn to Kincardine Bridge

Outside the Fraserburgh to Montrose area, but still along the east coast of Mainland Scotland, larger numbers of seals can be found. Information from at-sea tagging studies show the east coast of Scotland is used by individuals of both species which move and forage along this coast. Under the EU's Habitats Directive, the Firth of Tay has been designated a Special Area of Conservation (SAC) for harbour seals and the Isle of May in the Firth of Forth, an SAC for grey seals. Animals from these areas will potentially move along the coast between Fraserburgh and Montrose.

Consequently, survey data from a wider area (Nairn to Kincardine Bridge) is provided in Table 28, to allow the numbers of seals in the area of concern (Fraserburgh to Montrose) to be put into context.

Table 28 Numbers of harbour and grey seals counted between Nairn and the Kincardine Bridge from surveys carried out in the Augusts of 1997 and 2005 (SMRU, 2007)

Date	Region	Harbour Seals	Grey Seals	Species Unknown
Aug-97	Nairn to Fraserburgh	47	65	-
Aug-97	Fraserburgh to Aberdeen	0	131	-
Aug-97	Aberdeen to North Esk	15	14	-
Aug-97	North Esk to Buddon Ness	0	0	-
Aug-97	Buddon Ness to Newburgh	92	61	-
Aug-97	Newburgh to Tayport	56	0	-
Aug-97	Tayport to Fife Ness	485	1,849	-
Aug-97	Fife Ness to Kincardine Bridge	76	176	-
Aug-97	Isle of May	0	46	-
	Total	771	2,342	-
Aug-05	Nairn to Fraserburgh	77	245	-
Aug-05	Fraserburgh to Aberdeen	14	400	3
Aug-05	Aberdeen to North Esk	22	11	-
Aug-05	North Esk to Buddon Ness	9	0	-
Aug-05	Buddon Ness to Newburgh	92	43	-
Aug-05	Newburgh to Tayport	48	0	-
Aug-05	Tayport to Fife Ness	221	530	-
Aug-05	Fife Ness to Kincardine Bridge	176	73	8
Aug-05	Isle of May	0	18	
Total		659	1,320	-

Between Nairn and Kincardine Bridge, the main harbour seal haulout sites are at Findhorn Bay, in the Firth of Tay and the Eden Estuary and between Kirkaldy and Dalgety Bay on the Fife (north) shore of the Firth of Forth.

The main grey seal haulout sites used during August are scattered along the north Grampian coast at Findhorn Bay, Covesea and Halliman Skerries off Lossiemouth, Craigenroan Skerries near Findochty and Strahangles Point near Rosehearty. South of the North Esk, the Firth of Tay and the River Eden are the main grey seal haul out sites, with smaller numbers also using the small islands in the Firth of Forth. The Isle of May, as already mentioned, is a SAC for grey seals, which has supported a total pup production of over 1,800 seals since 1998. It should be noted that the numbers of grey seals counted here during the August surveys are very low.

6.4.1.2 Cautionary note on the counts of seals calculated from aerial surveys

These counts represent the seals that were counted ashore. They do not represent the total size of the local population, since a number of seals would have been at sea at the time of the survey.

Please note that these data refer to the numbers of seals found within these areas in August only; numbers are likely to vary at other times of the year. For instance, small numbers of harbour seals haul out during the winter on the small island at the mouth of the River Don, in Aberdeen. In addition, the numbers of grey seals ashore during the summer can be highly variable from day to day and the numbers presented above should be interpreted with caution.

Figure 48 Haul out locations of harbour and grey seals August 1997

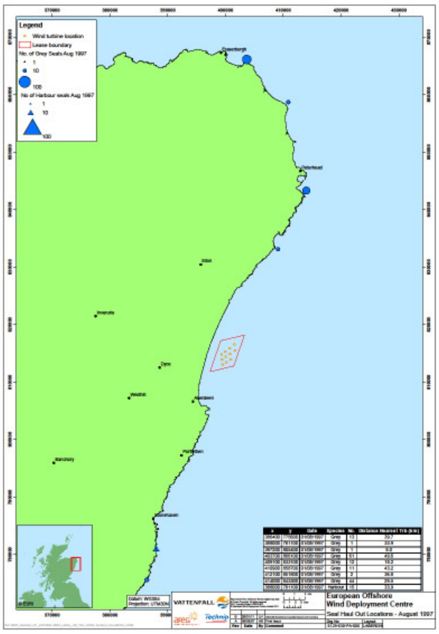


Figure 49 Haul out locations of grey and harbour seals in August 2005

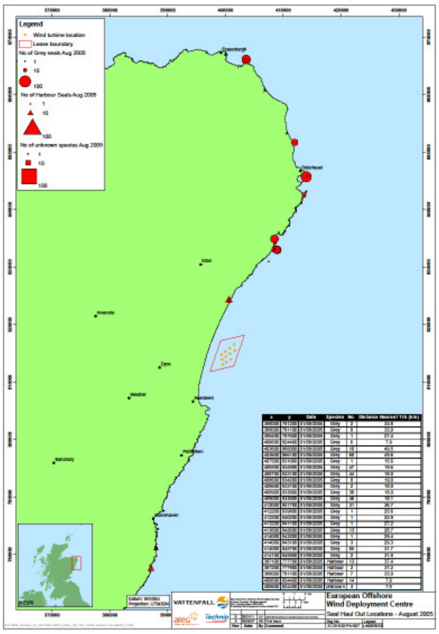

6.4.2 Other seal species

There are occasional records of hooded seal, bearded seal, ringed seal and walrus in the north-east Scotland area (Hammond *et al*., 2004). All these species are considered to be rare visitors to Aberdeen bay area.

7. SUMMARY

The marine mammal environmental baseline is based on available information on marine mammals relevant to the proposed EOWDC and surrounding area, as the project develops and more information becomes available from the additional boat based surveys carried out, the marine mammal environment baseline could be updated.

The review of the distribution of each marine mammal species indicates that although several marine mammals have the potential to be in the area, for the majority of these species the area is only a marginal part of their habitat. Most species, with the exception of bottlenose dolphins, have a wide range and regularly occur throughout the northern and central North Sea, both along the coast and in offshore areas.

Sightings and strandings data provide useful information on the occurrence of marine mammals in the area and indicate that bottlenose dolphins, harbour porpoises, white-beaked dolphins, minke whales, harbour and grey seals have been regularly recorded in the area throughout most the year. Most other marine mammal species have been recorded infrequently and at certain times of the year, suggesting that the area is a small part of their range for a limited time and that relatively low numbers may be present in the area.

In order to understand why marine mammal species may be present in the area it is important to have information on their diet and examine what prey species may be attracting them to the area. The diet of marine mammal species regularly recorded in the area is varied and diverse; however, it is apparent that bottlenose dolphins are feeding on salmon at the mouth of the River Dee, harbour porpoises are probably feeding on whiting and sandeels and the seasonal occurrence of white-beaked dolphins may be linked to seasonal availability or movements of prey, such as mackerel. Harbour and grey seals have been observed feeding on salmonids and flatfish at the estuaries of the Rivers Dee and Don. Although this is a comprehensive baseline assessment, there are some areas for which there is currently limited information, such as what prey several of the marine mammal species that are regularly present in the area are feeding on. Cetacean species are particularly difficult study subjects to collect dietary information on, although strandings data has provided some useful snapshots of prey items consumed prior to beaching events, this data may not always be representative of healthy adults prey choice.

Examination of the life history of marine mammals regularly occurring in the area highlights the seasonal sensitivities, such as calving periods, of these species. Young bottlenose dolphin calves have been observed in the area during spring and early summer. The calving period of harbour porpoises in Scottish waters is estimated to be between April and June, with calves being observed in the area between May and September. White-beaked dolphin calves have been observed in the area between June and August. Seals spend a higher proportion of their time ashore and in coastal waters during the pupping and moulting seasons, for harbour seals pupping occurs from June to July and moulting occurs from June to September and for grey seals pupping occurs from October to November and the moulting season is between February and April.

The main findings from this review indicate that of the marine mammal species recorded in the area, bottlenose dolphins, harbour porpoises, white-beaked dolphins, minke whales, harbour and grey seals are regularly present in the area. Therefore, these species, could be affected by potential impacts associated with the proposed development, such as underwater noise disturbance, changes in prey availability and foraging areas, displacement and barrier effects. These potential impacts and possible mitigation measures will be addressed in the EIA technical report.

Bottlenose dolphin were the second most frequently sighted cetacean species during the surveys carried out as part of the EOWDC, with a total of 200 individuals being detected. The majority of the sightings occurred in the spring and summer months. A higher number of bottlenose dolphins were recorded in the wind farm area in comparison to the control site and in the vicinity of the entrance to Aberdeen harbour, which is a known hotspot for dolphin sightings.

The bottlenose dolphin population of the Moray Firth has recently been expanding its range in a southerly direction, beyond the boundaries of the Moray Firth SAC, with an increasing in sightings and identified individuals along the east coast of Scotland as far as St Andrews and the Firth of Forth. Although Aberdeen is recognised as an important area for bottlenose dolphins, further studies are required to more accurately determine the proportion of the population that utilises this area throughout the year.

Harbour porpoises were the most recorded cetacean species during the EOWDC boat surveys and was the only species that was detected in sufficient numbers to allow a detection function to be applied that would allow for abundance and density estimates to be generated. The density of harbour porpoises was higher in the control area in all seasons except summer. Lowest densities occurred during May and June. The density estimates produced for harbour porpoise all show considerable error margins which is a reflection of the sampling effort, further surveys would reduce this. In the four surveys carried out during 2010-2011 the northern transect had the highest proportion of harbour porpoises, except in January when highest densities were recorded in the southern transect.

The harbour porpoise, as expected, was the most frequently detected cetacean species during the acoustic surveys. In agreement with the results of the visual surveys the control area recorded more acoustic detections than the wind farm survey area. In the acoustic surveys carried out during 2010-2011 higher numbers of detections were made in the offshore survey area during the August and September surveys, although it is too early to conclude whether this represents a movement of animals further offshore during the summer months.

White beaked dolphins have been detected during the EOWDC surveys over the course of several years during the month of August; this data supports the occurrence of this dolphin as a seasonal summer visitor that possibly moves to coastal waters following prey such as mackerel and or for calving purposes.

Six minke whales have been observed as part of the EOWDC surveys. Minke whales are thought to have a preference for water depths of 38 m or deeper, these depths are generally found further offshore and beyond the EOWDC crown estate licence area, although a minke whale was detected within the EOWDC crown estate lease area during the boat based surveys.

Only one solitary short-beaked common dolphin was detected during the boat based surveys. Other cetacean species that were detected were Risso’s dolphins during vantage point surveys, but not during any of the EOWDC boat surveys. The increase in sightings of Risso’s dolphins may point towards an increase in the use of the Aberdeen area in comparison to historic levels.

Both species of seal grey and harbour seals are regularly present and frequently sighted in Aberdeen bay, especially at the entrances to the Rivers Dee and the Don. Grey seals were the most frequently observed seal species recorded during the boat surveys carried out in 2007-2008. Almost equal proportions of grey and common seals were recorded during boat surveys carried out during 2010-2011.

Designated coastal SACs for harbour seals are present along the east coast of mainland Scotland, these are situated in the Dornoch Firth and Morrich Moore in the Moray Firth and Firth of Tay and Eden estuary. Designated SAC's for coastal seals along the east coast of Scotland include the Isle of May at the entrance of the Firth of Forth, and it can be expected that individual seals from these colonies may be passing through the EOWDC development area.

8. APPENDICIES

8.1 THE EFFECTS OF G(0) < 1

This section explains the influence that defining the number of 'missed animals' has on the abundance estimates generated from transect surveys. The probability of detecting an animal on the transect line, g(0), is normally assumed to be 1 which would be for a certain detection, but for marine mammals, which spend a proportion of the time below the surface, this assumption is not generally valid. Double observer methods are needed to accurately calculate the g(0) value specific to each species and survey vessel, and thus for this study, the influence of differing g(0) values on the density and abundance estimates generated are discussed. The study are and month used to illustrate the effects of altering the g(0) <1 value was the survey occurring in the Northern transect, in November 2010).

This area and month had the highest number of observations of harbour porpoises, thus providing the most robust sub-set for demonstration. The detection probability used in they analyses will therefore have a key influence on resulting estimates as is illustrated in Table 29. Detection values that are assigned a certain probability of detection g(0) are associated with the lowest standard error (165) and also the lowest abundance estimates (568).

Table 29 Density and abundance estimates with Standard Errors, generated for the North Strata in November, when assuming a range of g(0) values.

g(0)	Density estimate	SE	Abundance estimate	SE
0.2	18.84	5.45	2841	824
0.34	11.08	3.21	1671	485
0.4	9.42	2.73	1421	412
0.6	6.28	1.82	947	275
0.8	4.71	1.36	710	206
1	3.77	1.09	568	165

8.2 DETECTION RATES OF ODONTOCETE SPECIES DURING ACOUSTIC BOAT SURVEYS

Dolphin detections were recorded on a number of occasions during the EOWDC boat based surveys. It is currently not possible to identify, to a species level, clicks and whistles of the dolphin species that are likely to present in the EOWDC area, although corroboration with observations of cetaceans during visual searches does support species identifications.

Delphinid detections were only made during one of the seven surveys in which the hydrophone array was deployed in the boat based surveys carried out during 2007-2008. This was made during the December 2007 survey on transect CA. The position of the detection is shown on Figure 23. The very low number of detections means that the detection rates for all but one of the surveys are 0. Detection rates (where available) are displayed in Table 30.

Table 30 Whistle detection rates for the survey and transect containing a single whistle detection.

Number of detections	Effort (km)	Detection rate
December survey – all transects combined		
1	127	0.008
December survey – control site transects only		
1	63	0.016
December survey – wind farm transects only		
0	64	0
Detection rates – transect CA (combined all months)		
1	42	0.024

During the four months of boat based surveys deploying a hydrophone array during August, September, November 2010 and January 2011, dolphin detections were made during all 4 surveys; although only during "off effort" sections of the September 2010 and January 2011 surveys. Most of the detections were made during August 2010 survey. Locations of dolphin detections during the August survey are shown in Figure 50 and during all other surveys are shown in Figure 51.

Figure 50 Delphinid click and whistle detections made during the August 2010 survey

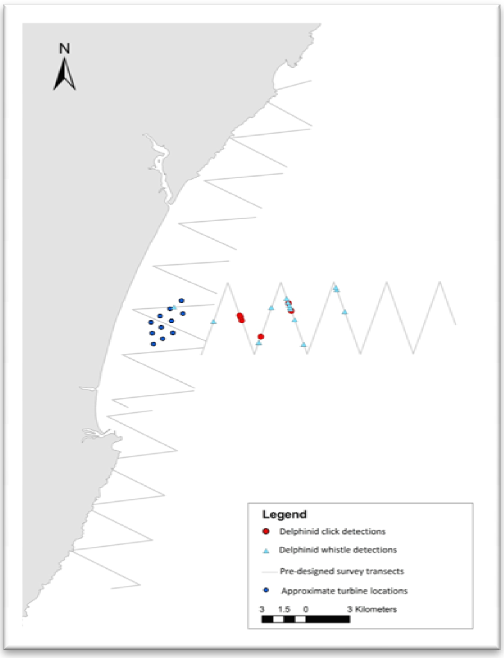

Figure 51 Delphinid click and whistle detections made during the September, November 2010 and January 2011 surveys

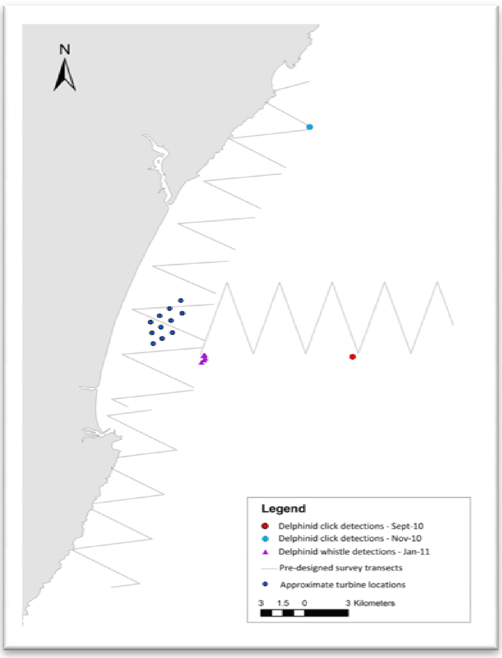

Only the dedicated acoustic effort (Table 6) was used to assess the acoustic detection rates of marine mammals across all three survey strata, for each of the four surveys. The September 2010 detections occurred during periods when the vessel was not sailing a pre-designed survey transect, and these have not therefore been analysed further. Detection rates (detections per km dedicated effort) have been calculated for the remaining click detections that were recorded during August and November 2010 (Table 31).

Whilst whistles were detected on both the August 2010 and January 2011 surveys, all of the January detections occurred during periods when the vessel was not sailing a pre-designed survey transect, and these have not therefore been analysed further. Due to the difficulty in meaningfully defining discrete encounters with dolphin groups when analysing whistles, the ”on effort” whistle data have been expressed as Whistle Positive Minutes”. These are defined as minutes which contain one or more whistle detections. The proportion of whistle positive minutes for each transect is shown in Table 32. It is probable that the click and whistle detections made during the August 2010 survey came from the same group of animals and it is likely that these were white beaked dolphins as they were present in the survey vicinity at the time.

Table 31 Detection rates for dolphin clicks during the August and November surveys- the only surveys on which dolphin clicks were detected during periods of dedicated effort

		August 2010			November 2010		
Strata*	Transect ID	Number of detections	km of survey effort	Detection rate	Number of detections	km of survey effort	Detection rate

1. EUROPEAN OFFSHORE WIND DEPLOYMENT CENTRE: MARINE MAMMAL EIA TECHNICAL REPORT

1.1 INFORMATION FOR NON-TECHNICAL SUMMARY

This report follows the baseline marine mammal assessment report and provides an assessment of the potential impacts of the proposed European Offshore Wind Deployment Centre (EOWDC) upon marine mammals. In order to assess the potential effects of EOWDC relative to the baseline (existing) marine mammal environment a combination of qualitative assessments have been made that incorporate predictive modelling in order to estimate the potential magnitude and significance of any impacts. In the assessment the worst case development scenarios have been applied that are detailed in the Project Description. The impact assessment has considered the risks and impacts to marine mammals from the construction, operation and decommissioning of the EOWDC.

In the assessment of potential impacts a number of impact criteria were used for sound levels likely to cause physiological damage, audiological impact or behavioural disturbance to marine mammals. The use of multiple criteria and presentation of duplicate sets of results, such as potential ranges of impact was considered to be appropriate given the scientific uncertainty of acceptable criteria for impacts of sound upon marine mammals.

The significance of potentially killing a marine mammal during the piling of the EOWDC was assessed as being of major significance, however, with the successful adoption of the mitigation measures for piling, there are not anticipated to be any residual risks given that a marine mammal would have to be present in such close proximity to the pile driver (3 m) to be at risk.

Other forms of physical injury (non-auditory) are estimated to occur out to a greater range (60 m), and the risk of piling causing other forms of physical impacts cannot be ruled out, and has been assessed as being of major significance for all marine mammal species, the natural curiosity of seals may increase the risk of exposing both grey and common seals to sound levels capable of causing adverse physical effects.

The modelling results indicate that unless a cetacean is within the immediate vicinity of piling operations (<1.35 km) or a seal is situated within 3.6 km, the only possibility for an auditory injury to occur is during the initial piling period. It is expected that the perceived loudness of the piling activity will cause the marine mammal to exhibit an aversive behavioural reaction, with the animal moving from the area before the onset of any auditory injury can occur.

There is clearly a risk to individual marine mammals that are exposed to high sound levels in the immediate vicinity of the piling operation, given that marine mammals may be subject to sound levels that are capable of causing physical impacts, including both auditory and non-auditory impacts. Animals would have to be present within the immediate area of the pile driver to be at risk of physical effects and it is considered the risk of marine mammals receiving sound levels capable of causing their death appears to be remote.

The marine mammals which are most likely to be exposed are the more commonly sighted species within Aberdeen Bay, with the harbour porpoise, bottlenose dolphins and grey and common seals being the species most at risk from physical impacts. Given that the relatively small Moray Firth bottlenose dolphin population has been increasing its range expansion in a southerly direction, and that Aberdeen Bay frequently has bottlenose dolphins, especially during the winter and spring months, the potential impact both to the individual and population is considered to be of high magnitude and potentially of major significance. It should be considered the majority of bottlenose dolphins sightings have been observed frequenting the harbour mouth area and that the mitigation measures mentioned below they should be sufficient to ensure that no bottlenose dolphins are situated within 820 m prior to piling activities, if such measures are put in place the anticipated magnitude of the effects is expected to be negligible and thus be of minor significance to the bottlenose dolphin populations.

The range at which potential adverse behavioural responses is considerable being upto 22 km for harbour porpoise and 16 km for common and grey seals. For harbour porpoises the results of post-monitoring studies suggest that after piling stops the animals have been found to return to the area within a few hours. Therefore, behavioural disturbance, which would lead to displacement of marine mammals from the piling activities, is only expected to occur for the duration of piling activities.

The haul out locations of seals could be affected by the piling operations, which could cause the temporarily displacement of seals from such areas, the significance of this is considered to be moderate.

The potential exclusion of bottlenose dolphins through behavioural displacement for the duration of the piling activity and out to an extent of 16 km has been assessed as being of high magnitude, and therefore of potentially of major significance to the bottlenose dolphin. As bottlenose dolphins are present along the east coast of Scotland, it has been predicted that the temporary displacement of animals from the Aberdeen Bay area will be mitigated by animals moving into other areas within their natural range, this is a hypothetical assessment and is based on the available habitat range for bottlenose dolphins being extensive covering the coastal waters along the Scottish east coast.

For the other species of cetacean present in Aberdeen Bay they are not restricted to coastal areas and are present throughout a far wider area. Aberdeen Bay has not been recognised as being of particular importance for breeding or calving purposes for other cetacean species, the possible exception in that shallower coastal water of the east coast of Scotland have been speculated to have a role in breeding or calving for the white beaked dolphin during the summer period.

Any temporary exclusion of the cetacean species from Aberdeen Bay is considered to be of low to negligible magnitude, given that there is likely to be adequate areas for foraging relatively nearby. If piling occurs during summer months (July/August) the significance of this is likely to increase to moderate for the white beaked dolphins, but will still be a minor impact for all other cetacean species.

The vessels used in the construction of Aberdeen Bay may locally increase the ambient sound levels and as such may temporarily contribute to the displacement marine mammal from the vicinity of construction activities, the significance of this local displacement of marine mammals is negligible.

During the pile driving construction activities there is the potential for the sound to mask any seal vocalisations, potentially out to a distance of 80 km. Masking of biologically relevant sounds produced by high frequency cetaceans, such as the harbour porpoise, and possibly mid-frequency cetaceans, such as the bottlenose dolphin, is unlikely as the piling pulses have little high frequency energy. The pile driving pulse are of short duration, and are therefore may be below the time where full detection of signals is possible in cetaceans.

Other forms of construction sounds, such as those associated with vessel activity, are continuous type sounds, as opposed to the short duration impulsive piling sounds, and are therefore likely to be above the timeframe where full detection of the signals is possible by cetaceans, and are therefore likely to be audible. Although the vessel sounds are likely to be audible to marine mammals, they are not considered capable of masking the cetacean species that are most commonly present in Aberdeen Bay.

Marine mammals present in Aberdeen Bay are likely to be tolerant of the range of suspended sediment levels that can be present within background levels, the construction activities are not expected to generate high levels of suspended sediment other than locally elevated areas which will only exist for a short timeframe, such increases are not expected to have any form of impact upon marine mammals.

Marine mammals are highly mobile and are expected to follow their prey should they be displaced from the area during construction activities. Piling will be infrequent and temporary so that any disturbance to prey species will be intermittent and not consecutive so any foraging impacts are unlikely to be of sufficient magnitude or duration to adversely affect any life history traits of marine mammals. The marine mammals present in Aberdeen have been known to feed on varied prey species and should be adaptable should one of the more sensitive species to sound be temporarily displaced from the local area.

Increased shipping levels could be considered to increase the risk of collisions with marine mammals. Construction vessels will be transiting at slow speeds within Aberdeen Bay and are typically slow moving and generate low frequencies. It is considered that any marine mammals will be able to avoid approaching vessels. There have never been any reports of ship strikes from stranding records along the Grampian coast, which suggests the magnitude of the effect to marine mammals is negligible.

The noise from the operational wind farm is not considered to be capable of causing disturbance or displacement to marine mammals. There has been considerable variation in the reported underwater noise measurement from operational wind farms, yet all the sound levels reported thus far are relatively low.

These additional vessel arising from the maintenance of the EOWDC would not represent a significant increase on current vessel activity in this area. Aberdeen Bay is already very busy with a wide range of human activities and the small increase in vessel activity associated with the proposed wind farm is unlikely to cause any notable disturbance to marine mammals.

The worst case scenario in terms of seabed habitat lost would be through the use of gravity based structures for all eleven wind turbines; this would result in the loss of 0.03 km^2 of seabed habitat. The wind turbines are separated by a considerable distance from each other, this separation distance should not restrict the movement of marine mammals through the EOWDC. This loss of seabed habitat, in terms of similar available habitat within Aberdeen Bay is of negligible magnitude, with the significance of the impact being minor.

From the monitoring studies of constructed wind farms there is no evidence of any increases or decreases in marine mammal activity that would suggest attraction or avoidance related to magnetic fields. The information on the potential effects of EMF on marine mammals is largely unknown and further research is required to determine the potential risks this may pose to these species. The ecological significance of EMFs is an area of research which requires further study.

The Marine Mammal Protection Plan (MMPP) will be developed to address and mitigate any of the impacts identified as being of concern to marine mammals. The MMPP will outline the chosen mitigation procedures during any piling operations and construction activities to minimise the risk of impacts to marine mammals, the final MMPP will be developed in consultation with advice from statutory consultees. The programme of boat based and acoustic monitoring using C-Pods (moored hydrophones will continue throughout the development and construction of the EOWDC to enable any potential impacts upon marine mammals to be identified and recorded.

AOWFL will follow any advice provided by Marine Scotland on the European Protected Species licences to apply for, if these are required.

1.2 Introduction

Genesis Oil and Gas Consultants (GOGC) has been commissioned by AOWFL to undertake a marine mammal impact assessment of the EOWDC. The structure of the assessment can be summarised as follows:

- **Baseline Report** – this provides a summary of the existing information relating to the distribution and abundance of marine mammals in Scotland with a focus on Aberdeen Bay. This report draws on the findings of a desk based study and marine mammal research studies and also dedicated marine mammal surveys carried out for the purpose of supplementing the baseline for the EOWDC (GOGC, 2011).

- **EIA Technical Report** (this document) – an assessment of the impact of the project on marine mammals in the study area.

One of the primary issues identified at an early stage of the Impact Assessment was the potential impact of underwater sound from during both the construction, operation and decommissioning of the EOWDC. To aid the assessment Subacoustech Ltd were commissioned to provide underwater noise modelling for the installation of the foundations and determine potential impacts upon the marine mammal and other receptors within the developmental area. The impact assessment summaries the main findings of the Subacoustech report (Appendix 3.1 of the Environmental Statement for Subacoustech Ltd Report).

2. METHODOLOGY

Within the Environmental Impact Assessment Scoping Report (AOWFL, 2010) a number of marine mammal issues were raised and it is important to make due consideration of these in the impact assessment. The principal organisation which raised comments in respect of the marine mammal interests were Scottish Natural Heritage (SNH). The Joint Nature Conservation Committee (JNCC) had previously provided advice on the project, particularly the baseline survey design, as part of the originally proposed Aberdeen Offshore Wind Farm Scoping Report (AMEC, 2005).

- SNH (2004). Marine renewable energy and the natural environment heritage: An overview and policy statement. Policy statement number 04/01
- Subacoustech (2011). Subsea noise modelling in support of the European Offshore Wind Deployment Centre Development
- Reports from previous studies occuring in the EOWDC development area that describe the marine mammal features of the study area have been summarised below:
    - IECS (2008). Boat based survey results for the AOWF 2007-2008
    - SMRU (2011). Boat based survey results for the EOWDC 2010-2011 (4 months of data)

2.2 Temporal Scales

There are four main phases in the development programme of the EOWDC that will be considered, these are:

- baseline (pre-construction)
- construction
- operation; and
- decommissioning

2.2.1 Baseline

The baseline or pre-construction phase considers the marine mammal abundance, distribution and seasonal occurrence within the EOWDC development area prior to any wind farm construction. The pre-construction environmental marine mammal baseline allows for a benchmark to which any changes to marine mammals can be compared. Any changes to marine mammal populations that could occur throughout the lifetime of the project that are the result of potential wide scale environmental changes such as climate change, or changes in prey availability, will also be compared to this phase. The pre-construction marine mammal baseline is discussed within the marine mammal baseline report (GOGC, 2011).

2.2.2 Construction

The construction phase considers the activities that are associated with installing the 11 foundations, wind turbines and subsea cables. A number of different foundation structures are being considered including: gravity based structure; monopiles; steel jackets; tripod on piles; and suction caisson. The final engineering for the subsea cables has yet to be completed but it is currently expected that there will be up to 4 main cables to the EOWDC and inter-array cables between the wind turbines. Potential impacts that have been assessed include:

- physical injury; including auditory and non-auditory injury;
- behavioural disturbance;
- interference with sound produced by marine mammals,
- indirect impacts of increasing suspended sediment levels; and
- displacement of prey species.

2.2.3 Operational

The operational phase will consider the impacts associated with the operational EOWDC. Potential impacts that will be assessed include: the loss of habitat as a result of the placement of the wind turbines, operational sound and Electromagnetic Fields (EMF) generated from the subsea cables.

2.2.4 Decommissioning

The decommissioning plan for the EOWDC has yet to be finalised and as such a detailed impact assessment on this section is not possible, the Description of the Proposed Project (Chapter 3 of the ES) provides an outline of the activities that are expected to be associated with the decommissioning of the EOWDC. The assumption taken in this assessment is that the wind farm and associated infrastructure, with the potential exception of the subsea cables, will be removed from the seabed as per the statutory requirements that will be in force at the time. The impacts upon marine mammals are expected to be similar to the construction activities as comparable vessels will be required. The main difference is that the removal of the foundations will not require pile driving and it is expected that impacts of underwater sound will be lower through the use of cutting techniques. The use of explosives has been ruled out. Certain foundations types will not requiring cutting and could be lifted from the seabed. The main impacts of decommissioning activities are expected to be physical and behavioural responses of marine mammals to the underwater sound levels generated.

2.3 Impact Methodology

Whilst the matrix approach has been applied as a way to categorise and assess the significance of any potential impacts to marine mammals, through discussions with SNH it has been communicated the importance of also applying rigorous professional judgement in determining significance of potential impacts. The assessment, where possible, has assessed potential impacts and the rationale behind arriving at such judgements with as much information on the reasons for arriving at a particular judgement for each of the environmental receptors involved.

For each impact, the assessment aims to describe the magnitude of effect (i.e. the change created by an activity in terms of its spatial extent, duration and scale) and the sensitivity of each receptor, that is, the resources that would be affected (based on the importance of the receptor and its recoverability). The combination of the effect and the sensitivity of the receptor are then used to derive the significance of the impact. The criteria used in the assessment are given below.

The spatial extent of effect:

- a national/international effect
- a regional effect
- a local effect (within 5 km of the site)
- a site-specific effect

The duration of effect:

- a long-term/permanent effect (more than ten years)
- a medium term effect (existing for five to ten years)
- a short-term effect (existing for one to five years)
- a temporary effect (existing for less than one year)

The scale of the effect:

- above accepted standards/guidelines
- within accepted standards/guidelines
- where no standards/guidelines available, impact relative to background conditions

The recoverability of the receptor:

- low or none
- medium
- high

The importance off the receptor (taking into account international, national and regional legislation and function within the ecosystem):

- high
- medium
- low

Impact significance is then given as Major, Moderate, Minor, or Negligible guided by the following matrix.

Table 1 Matrix used to assign level of significance of impact

Magnitude of Effect (spatial extent, duration of effect and scale)	**Sensitivity of Receptor (based on importance and recoverability)**			
	Very High	**High**	**Medium**	**Low**
Very High	Major	Major	Major	Moderate
High	Major	Major	Moderate	Minor
Medium	Major	Moderate	Moderate	Minor
Low	Moderate	Minor	Minor	Negligible
Negligible	Minor	Negligible	Negligible	Negligible

2.3.1 Implications of Significance

Where the significance is classified as moderate to major or major this is considered to be a potentially significant effect. It should be noted that significant effects need not be unacceptable or reversible.

2.3.2 Sensitivity of Marine Mammals and their Protected Status

For the purpose of this assessment, all cetacean species and seals that are likely to be found in Aberdeen Bay are of either national or international importance due to their conservation status. All cetacean species and seals are considered to be receptors of high importance due to the national and international protection measures afforded to them which are discussed in more detail below.

The Habitats Directive is implemented in Scotland through the Conservation (Natural Habitats, &c.) Regulations 1994 (as amended in Scotland) termed the 'Habitat Regulations'. The Habitat Regulations provide the protection afforded to European Protected Species (EPS) animals listed on Annex IV of the Habitats Directive which includes all species of cetacean whose natural range occurs in Great Britain.

The European Protected Species Provisions create a number of offences that relate to causing injury or disturbance to EPS species as defined in regulation 39 of the Conservation (Natural Habitats, &c.) Regulations 1994 (as amended). Before an EPS licence can be issued there are three tests which must be met by the appropriate licensing authority, which in the case of a renewable energy development would be issued by the Scottish Government. The EPS provisions do not apply to any of the seal species.

Test 1 – The licence application must demonstrably relate to one of the purposes specified in Regulation 44(2). In the case of this application any EPS licences would be issued are likely to be granted by Scottish Government on the basis of Regulation 44(2)(e) *for imperative reasons of overriding public interest including* *those of a social or economic nature and beneficial consequences of primary importance for the environment*.

Test 2 – A licence may not be granted unless Scottish Government is satisfied "*that there is no satisfactory alternative*".

Test 3- A licence cannot be issued unless Scottish Government is satisfied that the action proposed "*will not be detrimental to the maintenance of the population of the species concerned at favourable conservation status in the natural range*".

The harbour seal, common seal, the harbour porpoise and bottlenose dolphin are listed on Annex II of the Habitats Directive which require member countries to consider the designation of Special Areas of Conservation (SACs) for these animals. The cetacean species which require the designation of SACs are the bottlenose dolphin and the harbour porpoise (this is assessed separately in Chapter 29 Information to Inform the HRA).

The Marine (Scotland) Act 2010 introduces a number of measures for seal protection to update and replace the earlier Conservation of Seals Act 1970. It is now an offence to kill or take any seal at any time (with exceptions only under specific licence or for animal welfare) and it is also now an offence to harass seals at their haul-out sites.

2.4 ASSESSMENT OF CUMULATIVE IMPACTS

The cumulative assessment will address where predicted impacts of the EOWDC construction and operation could interact with impacts from other industry sectors within the same region and impact sensitive receptors. This may be through direct effects or spatially/temporally separated impacts on the same population of a receptor.

The main industries that will be considered for potential cumulative impacts are the renewable energy industry, aggregate industry, oil and gas and shipping.

A total of nine sites within Scottish Territorial Waters have been awarded for the construction of offshore wind farms. Since the announcement one of the sites, the Forth Array, has been withdrawn. Of the remaining 8 offshore wind farms the nearest three proposed wind farms are the Beatrice wind farm in the Moray Firth; approximately 150 km away and Neart na Gaiothe and Inch Cape are in the Firth of Forth, approximately 120 km to the south.

There are two Round 3 wind farms proposed off the east coast of Scotland outwith Scottish Teritorial Waters. The Moray Firth Offshore Wind Farm (eastern and western development) which is adjacent to the Beatrice offshore wind farm zone beyond the 12 nautical mile boundary, and the Firth of Forth Offshore Wind Farm which lies approximatley 70 km to the south of the proposed EOWDC.

According to the project timescales of the other foreseeable renewable energy projects, the construction of the EOWDC is planned for 2013, this is before any of the proposed renewable energy developments (Table 2). As such the assessment of cumulative impacts from construction will only assess the renewable energy developments that are already constructed, or are forecast to be constructed, within the same timeframe, not those that are planned to be developed in the future. Given the stage of development of the renewable projects yet to be constructed and the uncertainty as to the types of foundations and wind turbines that will be used, there is sparse information available to incorporate into any environmental impact assessment, which limits the effectiveness of cumulative assessments considering conceptual projects yet to be subject to a formal planning application.

This will limit the assessment of cumulative impacts from construction impacts to the Beatrice demonstrator, other operational and decommissioning impacts will make assessment, where possible, of the cumulative impacts from other yet un-consented renewable projects.

Table 2 Renewable Energy Developments that are Proposed within Scottish Territorial Waters and Beyond Territorial Waters

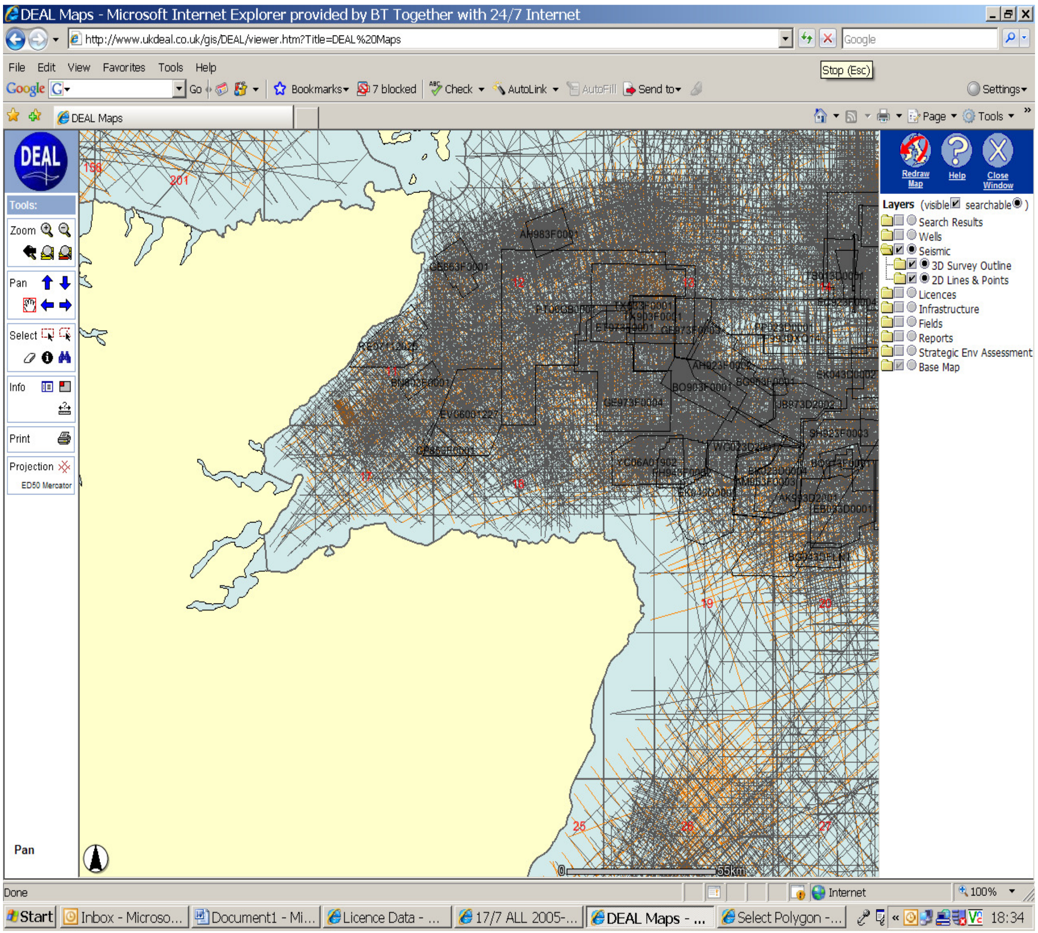
Name of development	Developer	MW	Wind turbines	Project timeframe construction
The Beatrice Demonstrator	Joint Venture Talisman and Scottish and Southern Energy	10	2	Installed operational
The Moray Firth Eastern Development	Moray Offshore Renewables Ltd	1300	67	Construction starts 2015
The Moray Firth Western Development			Not yet known	Unknown >2015 (EIA commences 2013)
Beatrice	Sea Energy Renewables Ltd & Scottish and Southern Energy	920	184	April 2014
Firth of Forth: Phase 1	Scottish and Southern Energy and Fluor	1075	215	2015
Firth of Forth: Phase 2		1435	287	Unknown >2015
Firth of Forth: Phase 3		955	191	Unknown >2015
Neart na Gaoithe	Mainstream Renewable Power	420	130	April 2014

The potential Ocean Laboratory will be considered in the assessment of cumulative impacts, although the design of the structure has yet to be completed it is possible that the foundation could be piled.

There are no known commercial aggregate dredging activities within the wider Aberdeen Bay area. Maintenance dredging does occur in the Aberdeen Harbour, with the next dredging scheduled to occur in 2012, there are no current dredging activities planned to occur during the construction phase.

The oil and gas industry has a considerable presence in the North Sea, the activities that are considered to be of most concern for marine mammals are the exploration activities including the seismic surveys and vessels used to support their activities. Seismic surveys in the North Sea are typically associated with areas of historic oil and gas activity (Figure 1).

Figure 1 Locations of previous seismic surveys in the North East of Scotland (DEAL 2011)



The locations of future seismic surveys are not yet known, as the industry is only required to submit details of the planned surveys a few months in advance of the planned operations. There are a number of seismic surveys that have been planned to in the Moray Firth but have yet to get final regulatory approval. PA Resources have proposed a 2-D seismic survey with a total duration of seven days using a 470 cubic inch array. Caithness Petroleum Ltd has submitted a proposal to undertake four exploration seismic surveys and one site survey, this is expected to last a total of 14 days, both surveys are planned to occur within the timeframe 1st August – 21st October 2011. Subject to these surveys occurring within the proposed timeframe they will both be completed in advance of any construction activities occurring in the EOWDC, as such they will not be considered as part of the in-combination assessment.

Aberdeen Harbour is an important base for the movement of vessels associated with supporting the oil and gas industry, transport of goods to the islands, and also to a lesser extent vessels used in the fishing industry. The disturbance and underwater sound produced by these vessels will be considered in the in-combination assessment.

2.5 Assessment of in-combination impacts

The term 'in-combination' will be used when considering the impacts of the proposals with other plans or projects on European sites. There is a degree of similarity and cross-over between cumulative and in-combination impacts as many of the activities that will be considered in the cumulative assessment are part of UK Government Plans or Project.

3. IMPACT ASSESSMENT

3.1 Construction Phase

3.1.1 Noise Generated during the Construction of the EOWDC May Cause Physiological Damage to Marine Mammals (Non-audiological Injury and Audiological Injury)

Worst Case Scenario: Piling of 8.5 m diameter pile at all eleven locations during one phase of installation (sequentially).

3.1.1.1 Potential Impacts

The construction activities will generate a number of sources of underwater sound, by far the loudest impulsive sound will be generated during the piling of the wind turbines. There have been several studies which have measured the underwater sound levels generated during piling of offshore wind turbines (Bailey, *et al*., 2010; Nedwell, *et al*., 2007). A general observation is that the source levels and underwater sound pressure levels have been found to increase with increasing diameter of the pile being driven, although other factors such as sediment type, energy of the pile driver have an influence on the overall sound levels generated. At the highest level, typically during underwater blast from explosives, sound has the ability to cause injury and, in extreme cases cause the death of exposed animals. Although, to date, there has never been any records of piling having caused any form of physical injury to a marine mammal.

Due to the current lack of information on potential lethal and physical injury effects from impact piling, this study has used the best available data from blast exposures to estimate impact zones. The wave forms from blast waves and piling are rather different; the transient pressure wave from an impact piling operation has roughly equal positive and negative pressure amplitude components and a relatively long duration of up to a few hundred milliseconds. By contrast, blast waves have a very high positive pressure peak followed by considerably lower amplitude, negative wave due to the momentum imparted to the water surrounding the explosive gas bubble. The pressure of a blast wave is normally quantified therefore in terms of the peak level, due to the dominance of the positive peak of the waveform. There is, therefore, a level of uncertainty as to whether a blast wave criterion can be directly applied to a transient waveform arising from an impact piling operation.

Lethal and direct physical injury from an underwater transient pressure wave are related to the peak pressure level, rise time and duration that the peak pressure acts on the body (usually measured by the impulse of the blast wave). The criteria that have been developed for assessing gross injury of this type are based on data from blast injury, at close range, to explosives. Injury has been related both to the incident peak positive pressure of the wave and to the impulse. A number of different techniques for assessing the duration of an impulsive waveform are described by Hamernik and Hsueh (1991) based on the studies by Coles, *et al*., (1968), Pfander, *et al*., (1980) and Smoorenburg (1982). The measure of impulse will, therefore, depend upon which technique is applied.

One of the challenges that AOWFL faced was determining appropriate source levels to model given that the wind turbines installed in Aberdeen Bay could potentially be the largest diameter wind turbines installed to date in offshore waters. In order to generate appropriate source levels to use, Subacoustech Ltd were commissioned to generate predictive underwater noise modelling for the pile to be installed and they used available piling measurements to derive suitable source level to model (Subacoustech, 2011 ref to Appendix 3.1).

The underwater sound modelling applied the Impulse Noise Sound Propagation and Impact Range Estimator (INSPIRE) model that has been specifically designed over five years to predict the likely level of underwater noise from impact piling operations. INSPIRE is a broadband model, that is, it does not calculate levels frequency by frequency, but in terms of the physics of the absorption of a pulse. INSPIRE uses a combination of loss caused by the spreading of the energy of the sound field (geometric loss) and loss caused by energy in the water column being absorbed in the underlying sea bed (absorption losses). This is used to estimate the likely transmission losses as the sound propagates away from the source; in this case impact piling. The model is therefore capable of estimating the effect of rapidly varying water depths that are commonly found in UK coastal waters.

The other main factor that affects the level of underwater noise is the local bathymetry, with sound attenuating at a faster rate over shallow water as opposed to deeper waters. The INSPIRE model uses digital bathymetric data provided by SeaZone Solutions Ltd, to input water depth data into the model.

3.1.1.2 Assessment of Noise Levels Capable of Causing Non-audiological Physical Impacts to Marine Mammals

A number of different impact criteria were used for the sound levels likely to cause physiological damage to marine mammals. Two of these criteria have been proposed by Parvin *et al*., (2007) and were developed to be applicable to all marine species, not just marine mammals. It should be stressed that within the scientific community there is yet no definitive accepted criteria for physical injury to marine mammals. For the assessment of physical injury to marine mammals this assessment applies a number of different impact criteria including those proposed by Parvin *et al*., (2007), and also the audiological impact criteria that have been developed by Southall *et al*., (2007). Although audiological hearing impacts are a form of physical injury they are considered in more detail in Section 3.1.1.3.

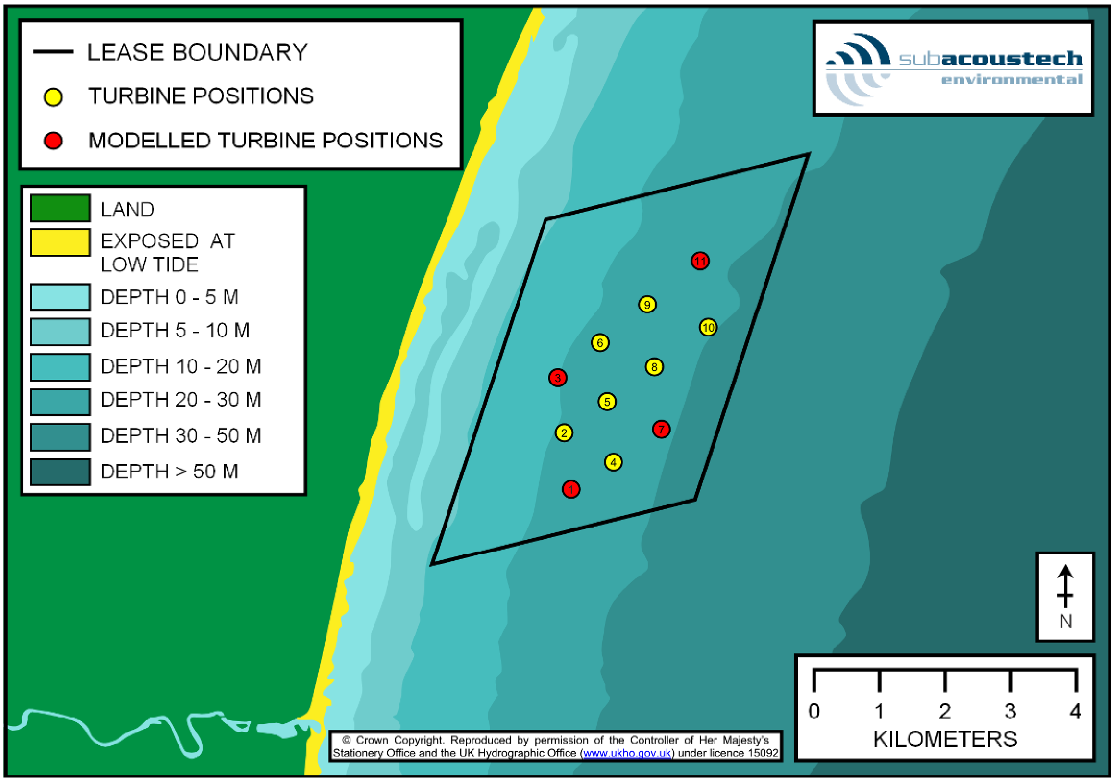
Given that the marine mammal scientific community are still actively debating appropriate impact criteria for marine mammals it was considered best practice to present a number of criteria and choose the most precautionary metric.

The sound levels that will be used in the assessment of physical impacts upon marine mammals are:

- lethal effect may occur in marine species where peak to peak levels exceed 240 dB re.1µPa
- physical injury may occur in marine species where peak to peak levels exceed 220 dB re.1µPa

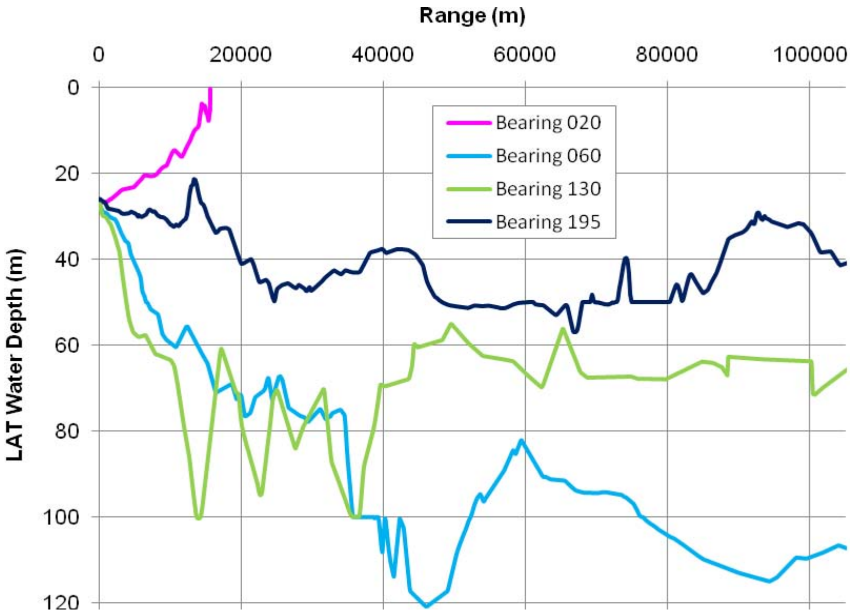
A plan of the proposed EOWDC that illustrates the four wind turbine positions that were used as the basis of the underwater noise modelling is shown in Figure 2. Wind turbine positions 1, 3, 7 and 11 were used and these locations are denoted by red circles. These four positions have been chosen to represent the greatest variation across the site in terms of location and to a lesser extent water depths, ranging from approximately 20 m Lowest Astronomical Tide (LAT) to the west to just under 30 m LAT to the east. The bathymetry is an important factor in underwater sound modelling as it influences the transmission loss that occurs to sound signals with greater losses typically occurring in shallow waters.

Figure 2 The EOWDC lease boundary area and wind turbine positions, wind turbines shown in red were used as representative modelling locations (Subacoustech, 2011)



Aberdeen Bay gradually deepens in easterly direction. In order to illustrate the varying bathymetry in the areas around the proposed EOWDC site, wind turbine number 11 has been used (Figure 3). As expected, the bearing with the shallowest water depth <20 m is bearing 20^0 (orientated towards the shoreline), whereas bearing 60^0 (heading out to the deep waters of the North Sea) encounters water depths in excess of 120 m.

Figure 3 Comparison of four representative depth profiles along transect from wind turbine position 11 indicating the varying bathymetry around the proposed EOWDC site used for the INSPIRE modelling (Subacoustech, 2011)



The underwater noise modelling was carried out at all four wind turbines locations. Shown in Figure 4 is the unweighted (unfiltered) noise generated from the piling of the 8.5 m wind turbine at wind turbine location number 11. The graph indicates that the lethal effect level (240 dB peak-peak) and the physical effect level (220 dB peak-peak) will be exceeded at 3 m and 60 m, respectively. As the environmental conditions are comparable for all the wind turbines; the modelling suggests that for physical impacts the anticipated ranges at which lethal effects and physical effects will be the same for all the wind turbine positions (Table 3).

Figure 4 Graph showing the unweighted peak to peak noise level with range for the four transects extending from wind turbine 11

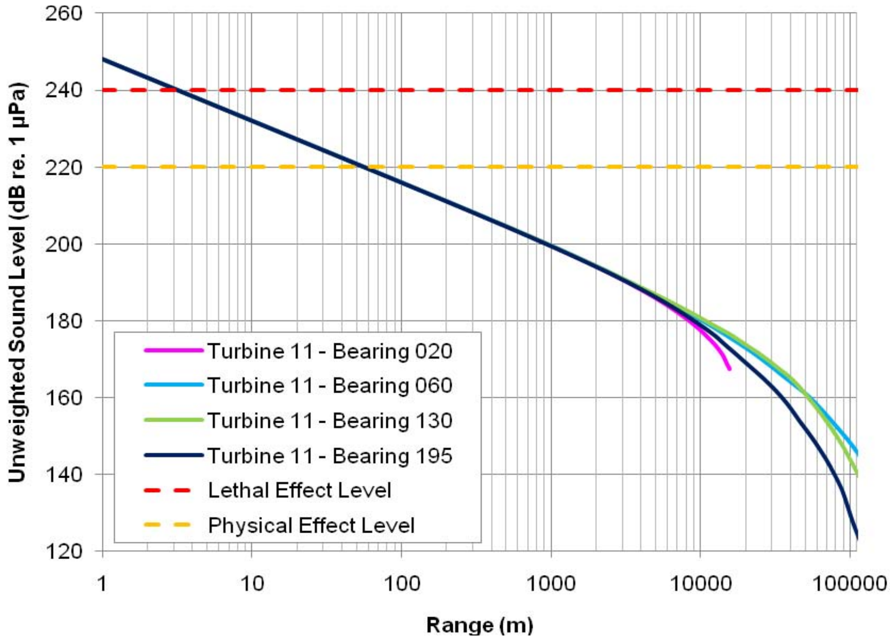


Table 3 Summary of ranges out to which lethal effect and physical injury is expected to occur in marine species using the criteria proposed in Parvin *et al.*, (2007)

Peak to Peak Levels	Wind Turbine 1	Wind Turbine 3	Wind Turbine 7	Wind Turbine 11
Lethal Effect Range to 240 dB re. 1 µPa	3 m	3 m	3 m	3 m
Physical Effect (non-auditory) Range to 220 dB re. 1 µPa	60 m	60 m	60 m	60 m

To date there has been no evidence of wind turbine installations causing any lethal, or physical injury effects upon marine mammals. It should be noted that these impact ranges are based on the extrapolation of data from measurements taken at considerably greater ranges since it is generally not possible to carry out measurements this close to impact piling operations, so the levels of underwater noise maybe lower than those estimated.

Although various species of marine mammals frequently occurring in Aberdeen Bay, some of which occur at high densities, it would still seem unlikely for any species to be present at such close proximity (3 m) to the piling location to suffer outright mortality. It is therefore thought that lethality is therefore unlikely to occur during piling.

In the context of exposure of marine mammal species to underwater sound it is very unlikely that marine mammals would experience injury unless constrained in a very high level continuous sound field for a prolonged period of time (Physical impacts from cumulative exposure are considered in Section 3.1.1.3). Other forms of physical injury (non-auditory) are estimated to occur out to a greater range (60 m), and the risk of piling causing physical impacts cannot be ruled out. However the natural curiosity of seals may increase the risk of exposing both grey and common seals to sound levels capable of causing adverse physical effects.

3.1.1.3 Assessment of Noise Levels Capable of Causing Audiological (Hearing Damage) to Marine Mammals

At a high enough level of sound, traumatic hearing injury may occur even where the time of exposure is short. Injury also occurs at lower levels of noise where the period of exposure is long. In this case, the degree of hearing damage depends on both the level of the noise and the time of exposure to it. To estimate the effect of impact piling taking place over a long period of time this concept of cumulative "Noise Dose" relationship has been used. For complex or time varying signals the degree of hearing damage has been related to the Noise Dose of the noise. The Noise Dose combines the continuous noise level containing the same sound energy as the time varying signal, and the duration of exposure.

This approach appears to translate to the underwater exposure of marine mammals, since for single exposure sounds Ward (1997) developed a level against exposure duration guide indicating that for sounds from 126 to 144 dB above hearing threshold (i.e. dB_{ht}), hearing injury can occur for exposure periods from 60 seconds to 1 second respectively. The data from Schlundt, *et al*., (2000) also indicates that this effect translates to marine mammal exposure to underwater sound. In the study, short duration sound exposures (one second continuous wave) at levels of approximately 130 dB above hearing threshold caused a small Temporary Threshold Shift (TTS) hearing injury in the bottlenose dolphin.

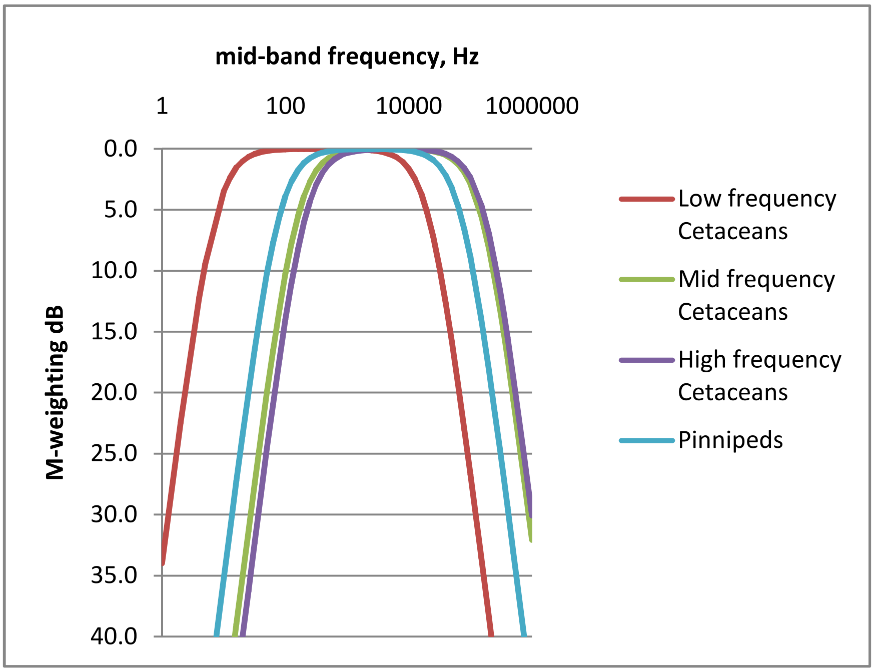
Hearing impairment in the form of a TTS in hearing may occur where an animal is exposed to a these levels, and Permanent Threshold Shift (PTS) will occur with repetitive exposure. The higher the Noise Dose above this limit, the more rapid will be the damage. It is likely that hearing impairment will occur where marine mammals are exposed to continuous or repeated high level underwater sound for relatively long periods of time; for impact piling the noise exposure can build up over many pile strikes. The Noise Dose that the animals will accumulate will depend on the received level of the underwater sound, which varies with range, and hence with the behaviour of the animal, and the time period and repetition rate of the pile strikes.

Nedwell *et al*., (2007) has suggested that the use of a 130 dB_{ht} (Decibels above hearing threshold) level, similar to that used for human exposure in air, provides a suitable criterion for predicting the onset of traumatic hearing damage (that is, where immediate traumatic and irreversible damage occurs), which recognises the varying hearing sensitivity of differing species.

The impact assessment also uses another set of exposure criteria that have been developed based on the evidence of auditory damage from numerous studies, termed the Southall criteria (Southall *et al.,* 2007). The Southall auditory injury criteria are based on both the unweighted peak pressure levels and M-weighted Sound Exposure Levels (dB re. 1 $\mu Pa^2 s$ (M)) for various groups of marine mammals. The use of a dual exposure metric is used, as it has been recognised that it is not only the exposure to peak levels of sound which is important but the total energy throughout the exposure. As a precaution for impact assessments it is recommended to apply the most conservative sound pressure level or sound exposure levels. These sound pressure level and sound exposure level recommended for marine mammals are presented in Table 4.

The sound exposure levels apply M-weighting this is essentially a simple way of applying a frequency dependant weighting to the hearing threshold of an animal, a more complex approach would be the use of the 'dBht'. There are numerous critics of the dBht approach in impact assessment, as it relies on the very few audiogram data that are available for marine mammals being correct and representative of all individuals within the population. Southall, *et al*., (2007) took account of the wide frequency dependence in the auditory response of marine species, and proposed M-Weighting frequency functions for low, mid and high frequency hearing cetaceans and pinnipeds (Figure 5). Otherwise extremely low and high frequency sounds that are detected poorly, if at all, might be subject to unrealistic criteria, for example a reduction of 10 decibels would be applied for a mid-frequency cetacean on exposure to a sound of 100 Hz.

Figure 5 M-Weighting criteria proposed for low, mid and high frequency cetaceans and pinnipeds (adapted from Southall et al., 2007)



The Southall study criteria can be used for both single pulse noise sources and multiple pulse sources (Table 4). The assessment estimated impact ranges for exposure to single pile strikes (Section 3.1.1) and also the cumulative exposure to multiple pulses over a typical installation period using the Sound Exposure Level (SEL) M-weighting metric (Section 3.1.1.3.2); threshold exposure values for single and multiple pulses using the Sound Pressure Level (SPL) and sound exposure levels are shown in Table 4.

Table 4 Proposed auditory exposure criteria for marine mammal frequency specific hearing groups: high, medium and low and seals as defined in Southall *et al.*, (2007)

Marine mammal group	Sound type	
	Single pulses	Multiple Pulses
Low Frequency Cetaceans		
Sound Pressure Level	230 dB re 1 µPa (peak)	230 dB re 1 µPa (peak)
Sound Exposure Level	198 dB re 1 $\mu Pa^2/s$ (M_{lf})	198 dB re 1 $\mu Pa^2/s$ (M_{lf})
Mid Frequency Cetaceans		
Sound Pressure Level	230 dB re 1 µPa (peak)	230 dB re 1 µPa (peak)
Sound Exposure Level	198 dB re 1 $\mu Pa^2/s$ (M_{mf})	198 dB re 1 $\mu Pa^2/s$ (M_{mf})
High Frequency Cetaceans		
Sound Pressure Level	230 dB re 1 µPa (peak)	230 dB re 1 µPa (peak)
Sound Exposure Level	198 dB re 1 $\mu Pa^2/s$ (M_{hf})	198 dB re 1 $\mu Pa^2/s$ (M_{hf})
Seals (in water)		
Sound Pressure Level	218 dB re 1 µPa (peak)	218 dB re 1 µPa (peak)
Sound Exposure Level	186 dB re 1 $\mu Pa^2/s$ (M_{pw})	186 dB re 1 $\mu Pa^2/s$ (M_{pw})

The species upon which the dB_{ht} analysis has been conducted in this study have been based upon regional significance and also crucially upon the availability of good peer-reviewed audiogram data shown in Figure 6.

The species of marine mammal considered in the impact assessment for which suitable audiogram data was available include:

- Bottlenose Dolphin: a marine mammal (toothed whale) with good high frequency hearing sensitivity. It is also used in this assessment as an indicative surrogate audiogram for Risso's Dolphin (Johnson, 1967). Although some audiogram data are available for the Risso's dolphin, it was considered that the quality of the audiogram data is not confirmed. Hence the bottlenose dolphin has been used to provide a conservative over-estimate of potential impacts;
- Harbour Porpoise: a marine mammal (toothed whale) that, based on current peer reviewed audiogram data is the most sensitive marine mammal to high frequency underwater sound (Kastelein *et al*., 2002);
- White-Beaked Dolphin: a marine mammal (toothed whale) with similar high frequency hearing to the bottlenose dolphin, but lower sensitivity to lower frequency noise (using the Striped Dolphin, *Stenella coeruleoalba*, audiogram(Kastelein, *et al*., 2003) as a surrogate as the White-Beaked Dolphin audiogram does not cover the entire audiometric range (Nachtigall, *et al*., 2007);
- Harbour (Common) Seal: a pinniped that based on current peer reviewed audiogram data is the most sensitive seal species to underwater sound (Møhl 1968; Kastak and Schusterman 1998). It is also used as a surrogate audiogram for Grey Seal.

As there is no single published dataset for seal species that covers the full audiometric range, the impact assessment is based on a weighting filter for the harbour seal that is the locus of the minimum threshold (most sensitive) data from several audiogram sources for the harbour seal. The data of Kastak and Schusterman (1998) is used for the frequency range from 100 Hz to 6.4 kHz, and the data from Mohl (1968) over the higher frequency range from 8 to 128 kHz (Figure 6).

It should also be noted that there is an absence of suitable audiogram data to use for baleen whales and there is no appropriate audiogram to use for the minke whale, the baleen whale most commonly sighted within Aberdeen Bay.

Figure 6 Audiograms applied in the marine mammal impact assessment

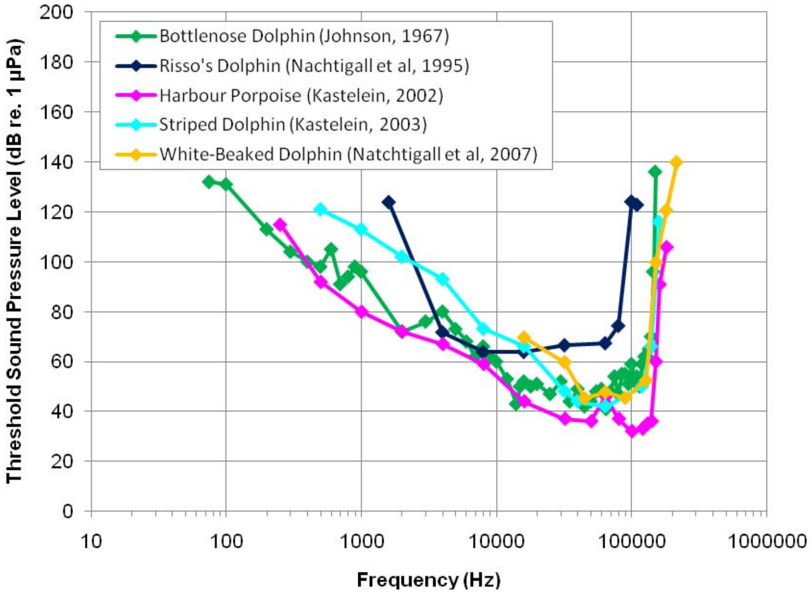


Table 5 shows the estimated impact ranges for traumatic hearing injury, using the dB_{ht} metric, for the marine species of interest, based on the 130 dB_{ht} criterion from Nedwell *et al*., (2007). The results are given for each of the four locations modelled at the proposed EOWDC site. The 130 dB_{ht} perceived level is used to indicate traumatic hearing damage over a very short exposure time of only a few pile strikes at most.

The largest estimated impact ranges out to which hearing damage may occur are for harbour porpoise (570 m; at both wind turbine positions 7 and 11). The modelling indicates that the seal species are likely to suffer these effects out to the smallest ranges (120 m) (Table 5).

Table 5 Summary of ranges out to which hearing injury is predicted to occur in various marine species using the 130 dB_{ht} (Species) criteria while piling a 8.5 m diameter pile (Nedwell *et al., 2007)*

Species	130 dB_{ht} Ranges			
	Wind turbine 1	Wind turbine 3	Wind turbine 7	Wind turbine 11
Bottlenose Dolphin Risso's Dolphin	**290 m**	**290 m**	**290 m**	**290 m**
Harbour Porpoise	560 m	550 m	**570 m**	**570 m**
White-Beaked Dolphin	240 m	240 m	**250 m**	240 m
Harbour Seal /Grey Seal	**120 m**	**120 m**	**120 m**	**120 m**

Figures in bold were the maximum impact ranges for marine mammal species assessed

Table 6 presents the injury impact ranges using the single pulse peak level criteria for species of cetacean and pinniped proposed by Southall *et al*., (2007). The modelling indicates that the range for injury (PTS) to all hearing types of cetaceans when applying the Southall criteria is 5 m at all wind turbine locations modelled. The range for physical auditory injury for seals is a greater distance of 30 m from the wind turbines, as they are considered by Southall *et al*., (2007) to have an increased sensitivity to peak levels of underwater sound in comparison to cetaceans.

Table 6 Summary of the estimated mean ranges to various unweighted peak noise levels during installation of 8.5 m diameter piles, shown are the PTS criteria for all cetaceans and seals (Southall *et al*., 2007)

Peak Levels*	Wind turbine 1	Wind turbine 3	Wind turbine 7	Wind turbine 11
Range to 230 dB re.1µPa (Cetacean Injury criteria, Southall *et al*., 2007)	5 m	5 m	5 m	5 m
Range to 218 dBre.1µPa (Pinniped Injury criteria, Southall *et al.,*2007)	30 m	30 m	30 m	30 m

*Peak levels were calculated by reducing the peak-peak levels by 6 dB.

Table 7 summarises the estimated impact ranges out to which auditory injury may occur, based on the single pulse Sound Exposure Level (SEL) criteria which have taken consideration of the hearing capabilities of marine mammal function hearing groups (Southall *et al*., 2007). The largest estimated ranges are for the seals, the injury range was greater when modelling was carried out for the two deeper water turbines, with a mean range of auditory injury of between 120 and 130 m (130 m taken as the worst case). For the three cetacean groups the largest impact ranges are predicted for the low frequency cetaceans (20 m) followed by the mid frequency cetaceans (10 m) with the smallest ranges predicted for the high frequency cetaceans (7 m). This is due to piling noise containing mainly low frequency components. There was no observable variability between the wind turbine locations using the Southall criteria.

Table 7 Summary of the auditory injury range for marine mammals using the Southall *et al*., 2007 Sound Exposure Level M-weighting criteria for function hearing groups of marine mammals

	Auditory Injury Range* 198 dB re.1 µPa^2/s (M_{lf}/ M_{mf}/ M_{hf}/ M_{pf})
Low Frequency Cetaceans	20 m
Mid Frequency Cetaceans	10 m
High Frequency Cetaceans	7 m
Pinnipeds (in water)	130 m (worst case)

(M_{lf} = M weighted low frequency M_{mf}= M weighted medium frequency / M_{hf}= M weighted high frequency M_{pf})

Southall *et al*., (2007) recommend using the most conservative impact ranges in impact assessments. Therefore the impact ranges for that were based on the M-weighted sound exposure level will be the most precautionary to use for marine mammals for estimating injury from single pulses (Table 7), as opposed to using the peak sound pressure levels (Table 6). The impact ranges for single pulses are not the most appropriate metrics to apply for pile driving applications which consist of multiple pile strikes. For such installations it is important to make assessment of the cumulative nose dosage that could occur over an entire piling sequence, which is discussed further below.

It may be noted that the impact ranges (for single pulses; shown in Table 6 and Table 7) disagree with those predicted using the dB_{ht} model (Table 5). The modelling results indicate substantially lower ranges of effect for the species of cetacean when using the single pulse Southall *et al.,* (2007) criteria. The disparity in values can be attributed to fundamental differences between the sound levels that are considered to be capable of causing physical impact using the dB_{ht} method and Southall *et al*., (2007) approach. It should be noted however that the SEL of a noise source will vary with range in a different way to that which has been assumed for its SPL (as it depends upon the averaging period used to define the pulse); and this may account in part for the differing results, which is to be expected when applying different impact criteria. Irrespective of this, it can be considered that the dB_{ht} approach is more conservative than the Southall *et al*., (2007) exposure criteria in that it produces impact ranges that are far greater than those produced by the Southall criteria. However, it should be pointed out Southall *et al*., (2007), which has been widely supported by the scientific community consider their pressure and exposure values to be precautionary for the assessment of impacts to marine mammals.

3.1.1.3.1 Estimated Ranges at Which Auditory Hearing Damage May Occur for Multiple Pulses

The installation of each pile is anticipated to take a maximum of 24 hours, this value should be considered as the maximum possible duration, and although it is expected piling will be completed within a shorter timeframe (~ 8 hours). The steel pile will be driven into the seabed starting off with a gradual ramping up of power, increasing to a max rate of 32 strikes per minute.

In order to assess the range at which a marine mammal could experience physical injury the model applied different scenarios based on cumulative noise exposure of multiple pile strikes, and the receptor (marine mammal) being either a stationary, or fleeing animal; moving away from the sound source.

3.1.1.3.2 Assessment of Cumulative Exposure Applying the dBht Method

In the assessment of cumulative exposure, a 90 dBht level has been applied as the level at which impacts could occur for an exposure durations of 8 hours. The maximum expected duration of piling has been estimated to be 24 hours, although it is likely to be considerably shorted duration and would be dependent upon the diameter of piles and seabed conditions.

The 90 dBht level was selected on the results of the Masden *et al*., (2006) who demonstrated a near linear relationship between sound exposure level and duration of exposure. A doubling of the noise energy (eg 3 dB increase) results in a halving of the duration of exposure period required. The relationship between sound exposure level and duration of exposure is shown in Table 8.

Table 8 Comparison of noise exposure level and duration of exposure for a sound level of 90 dB_{ht}

Exposure Level dB(A) (dB_{ht})	Exposure Duration
90	8 hours
93	4 hours
99	1 hour
110	Approx. 5 minutes
120	Approx. 30 seconds
130	Approx. 3 seconds

An estimate of the minimum safe standoff distances from the piling operation has been based on the INSPIRE fleeing animal noise dose algorithm. Each standoff range indicates that if a particular species is closer than that range at the onset of piling, then they are unlikely to be able to flee the area before suffering hearing damage. This is based on a conservative swim speed of 1 metre per second (m/s) and takes into account the accumulated noise dose over a typical piling operation.

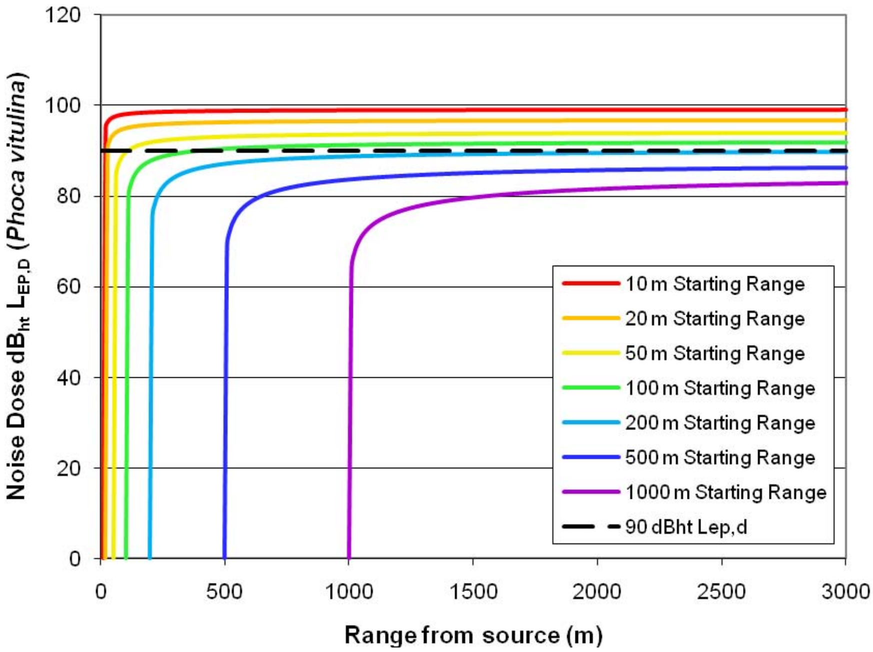
Figure 7 shows a detailed plot of the results of this modelling that has been carried out for each of the key species, in this case the figure is shown for species of seal. It can be seen that the 90 dB_{ht} $L_{EP,\ D}$ (Level of exposure and duration criteria; illustrated by the dashed line) is met between the 100 and 200 m starting range datasets (Table 9). The results of this indicate the ranges at which animals have to be before an injury is to occur, for example if a seal were to be closer to the piling operations than 190 m at the onset of piling it is unlikely to escape the area without receiving a damaging noise dose.

Table 9 presents the results of this modelling for the other species of marine mammal. It can be seen from these data that the harbour porpoise will need to be at the greatest distance (1,350 m) from the piling operation at its onset to avoid suffering hearing damage. If the fleeing animal is beyond the ranges presented in Table 9 they are likely to be able to reach a safe distance before receiving an unacceptable noise dose (when applying the 90 dB_{ht} criteria).

Table 9 Summary of the maximum starting ranges for various marine species using the fleeing animal noise dose model (when applying the 90 dB_{ht} criteria).

Marine Species	Maximum Starting Range for Fleeing Animal
Bottlenose Dolphin / Risso's Dolphin	120 m
Harbour Porpoise	1,350 m
White-Beaked Dolphin	460 m
Harbour Seal / Grey Seal	190 m

Figure 7 Estimated noise dose for a fleeing harbour / grey seal for impact piling of an 8.5 m diameter pile

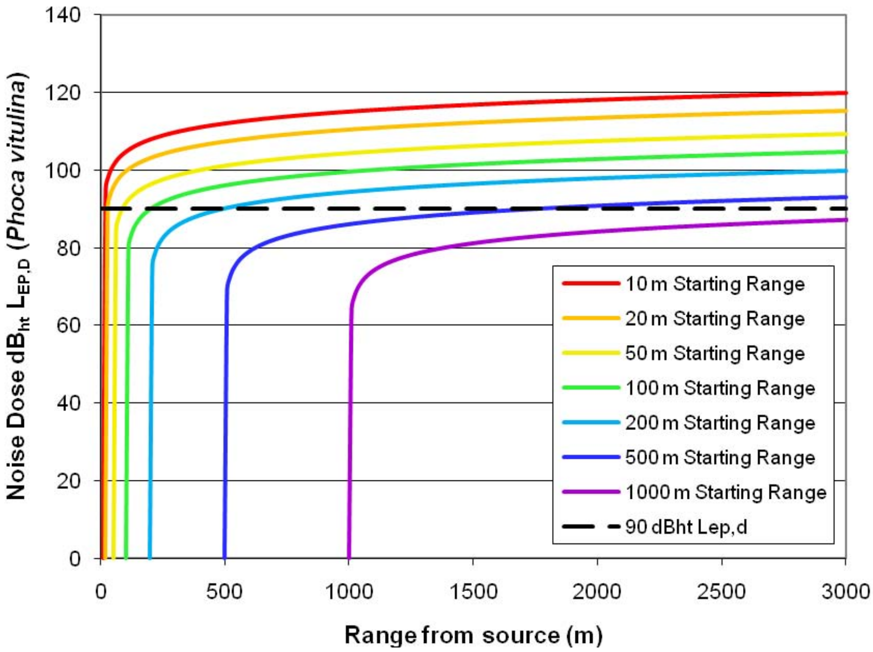


Noise dose modelling has also been carried out for a stationary animal during piling operations. It should be noted that this is considered an unlikely scenario as it implies that the animal makes no attempt to flee the high sound field area. This assessment has only been carried out for the harbour seal / grey seal and the results can be seen in Figure 8.

It can be seen that the results for the stationary animal modelling give much higher starting ranges than for the fleeing animal modelling, with the starting range for the harbour seal rising from 190 m (for a fleeing animal) up to almost 1 km for a stationary animal.

Further modelling to estimate similar impact ranges for other species has not been carried out for the stationary animal scenario as it is not felt to represent a realistic case. The data presented for the seal is provided to indicate the potential differences in the two scenarios.

Figure 8 Estimated noise dose for a stationary harbour / grey seal (used for illustrative purposes)



3.1.1.3.3 Assessment of Cumulative Exposure using Southall *et al*., (2007) Impact Criteria for Multiple Pulses

The accumulated exposure to sound for marine mammals has been assessed using the auditory injury criteria proposed by Southall *et al*., (2007). This has been done by calculating a standoff range for each marine mammal group, whereby it would safely be able to escape the affected area without receiving a damaging exposure to the sound. Table 10 shows a summary of these standoff ranges for fleeing animals, assuming a swim speed of 1 m/s. The largest standoff ranges are calculated for the seals, which, based on the M-weighting criteria are likely to need to be at a range of at least 3.6 km at the onset of piling to avoid a damaging exposure to the sound. Lower standoff ranges are predicted for the three cetacean groups with low frequency cetaceans being the most sensitive to the sound and high frequency cetaceans being the least.

Figure 9 shows the calculated multiple pulse M-weighted sound exposure levels for a fleeing high frequency cetacean at various starting ranges, from this it can be seen that if the animal was situated at a range of less than approximately 500 m from the piling operations at the onset of piling it is unlikely to escape the area without receiving a damaging exposure to noise according to the Southall *et al*., (2007) criteria. Figure 10 shows similar data for the high frequency cetacean group; however, this is for a stationary animal during the piling operations. It can be seen that the animal would have to be between 1 and 1.5 km at the onset of piling to avoid a damaging sound exposure level, assuming that it stayed in the same position throughout the entire piling operation. It should be noted that this scenario is considered highly unlikely as marine species are likely to attempt to escape areas where injury is likely to be caused.

Table 10 Summary of the maximum starting ranges for marine mammal groups before receiving an exposure that could cause auditory injury, using the multiple pulse criteria from Southall *et al*., (2007)

Marine Mammal Group	Maximum Starting Range
Low Frequency Cetaceans	1,350 m
Mid Frequency Cetaceans	820 m
High Frequency Cetaceans	650 m
Seals (in water)	3,600 m

Figure 9 Estimated M-weighting Sound Exposure Levels from various starting ranges for high frequency cetaceans using the multiple pulse criteria from Southall *et al*., (2007) for a fleeing animal

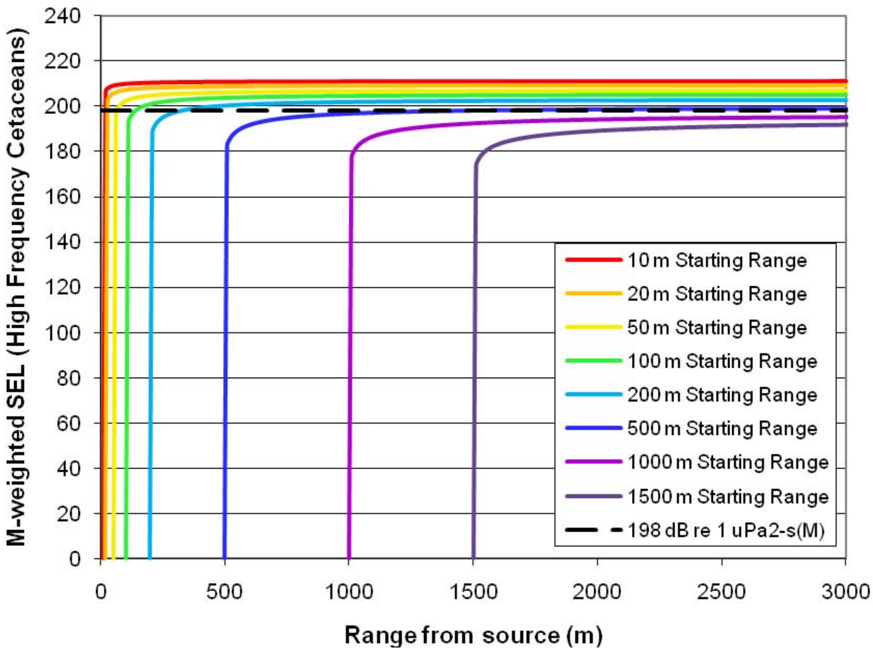


Figure 10 Estimated noise dose for a stationary harbour seal or grey seal for impact piling of an 8.5 m diameter pile

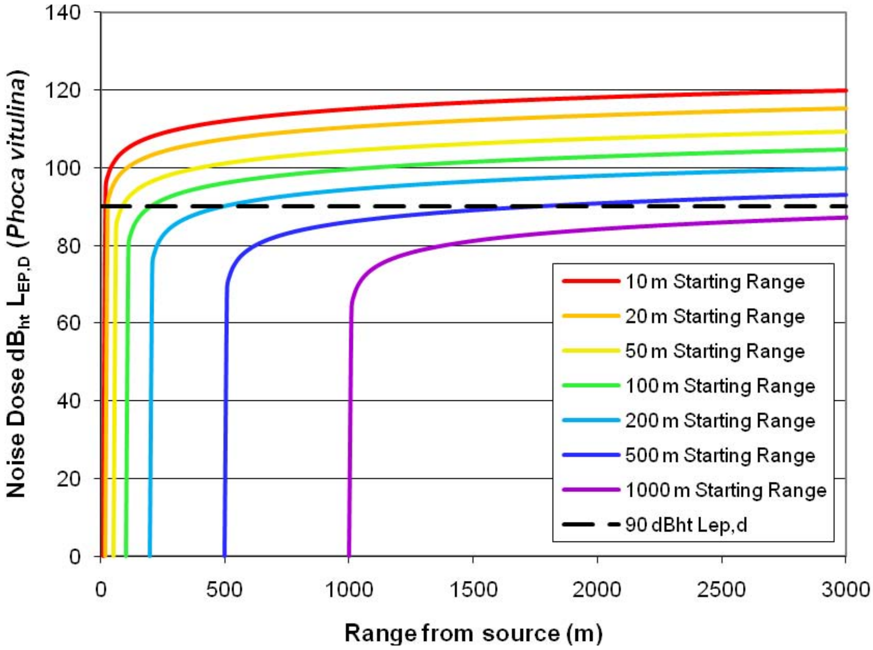

3.1.1.3.4 Summary of Cumulative Exposure Impacts Using the dB_{ht} and Southall *et al.*, 2007 Exposure Criteria

Table 11 shows a comparison between multiple pulse auditory injury impact ranges for three marine mammals species calculated using the dB_{ht} criteria and the three equivalent M-weighted SEL marine mammal groups. The data indicate that, unlike the single pulse exposure modelling, in some cases the dB_{ht} metric provides the largest estimated range of impact and in some cases the M-weighted SEL metric provides the largest impact range. This discrepancy is a result of the different values used in the impact thresholds for the two metrics. Highlighted in bold are the precautionary values which have been chosen to apply in the cumulative impact assessment as the minimum distances that auditory impacts could occur in a fleeing animal scenario.

The ranges at which auditory injury could occur to marine mammals will be factored into the MMPP and the mitigation measures adopted during the construction activities. It should be noted that these results (fleeing animal scenario etc) do not take into account the mitigating effects of a soft start procedure; these results assume a high blow force at the onset of piling. As long as a soft start procedure is used the effect is likely to be considerably reduced.

Table 11 Summary of impact ranges comparing the multiple auditory injury ranges, using the fleeing animal model, predicted using the dBht criteria (Nedwell *et al*., 2007) and the M-weighted SEL (Southall *et al*., 2007) criteria

dB_{ht} (Nedwell *et al*, 2007)		M-weighted SELs (Southall *et al*, 2007)	
Species	**Multiple pulse auditory injury range (fleeing animal)**	**Equivalent M-weighting group**	**Multiple pulse auditory injury range (fleeing animal)**
Bottlenose Dolphin	120 m	Mid Frequency Cetacean	**820 m**
Harbour Porpoise	**1,350 m**	High Frequency Cetacean	650 m
Harbour Seal	190 m	Pinnipeds	**3,600 m**

Figures in bold represent the maximum auditory impact ranges

The modelling results indicate that unless a cetacean is within the immediate vicinity of piling operations (<1.35 km) or a seal is situated (3.6 km) in the local area, the only possibility for an auditory injury to occur is during the initial piling period. It is expected that the perceived loudness of the piling activity will cause the marine mammal to exhibit an aversive behavioural reaction, with the animal moving from the area before the onset of any auditory injury can occur.

There is clearly a risk to individual marine mammals that are exposed to high sound levels in the immediate vicinity of the piling operation, given that marine mammals may be subject to sound levels that are capable of causing physical impacts, including both auditory and non-auditory impacts. Animals would have to be present within the immediate area of the pile driver to be at risk of physical effects and it is considered the risk of marine mammals receiving sound levels capable of causing their death appears to be remote.

The marine mammals which are most likely to be exposed are the more commonly sighted species within Aberdeen Bay, with the harbour porpoise, bottlenose dolphins and grey and common seals being the species most at risk from physical impacts.

To individual marine mammals the potential impact is considered to be of high magnitude and potentially of major significance. In terms of risks to the population most of the marine mammal species; with the exception of the bottlenose dolphin, have wide ranging populations. Subsequently, the risk to the population level is anticipated to be of low magnitude and moderate significance. Given that the relatively small Moray Firth bottlenose dolphin population has been increasing its range expansion in a southerly direction, and that Aberdeen Bay frequently has bottlenose dolphins, especially during the winter and spring months, the potential impact both to the individual and population is considered to be of high magnitude and potentially of major significance. It should be considered the majority of bottlenose dolphins sightings have been observed frequenting the harbour mouth area and that the mitigation measures mentioned below they should be sufficient to ensure that no bottlenose dolphins are situated within 820 m prior to piling activities, if such measures are put in place the anticipated magnitude of the effects is expected to be negligible and thus be of minor significance to the bottlenose dolphin populations.

Other forms of construction associated sounds are expected to be dominated by vessel noise. In terms of direct physical injuries to hearing structures in marine mammals, it appears from the available research that loud and/or sustained exposures are required to cause even temporary changes in marine mammal hearing sensitivity (Southall *et al*., 2007). Consequently, the likelihood that an isolated exposure to vessel noise would be sufficient to permanently damage the hearing of a marine mammal appears to be remote, and the significance of other forms of construction activities causing physical injury to marine mammals is considered to be of minor impact.

3.1.1.4 Mitigation

The mitigation measures that are planned to be used to minimise the risk of causing physical impacts to marine mammals are as follows:

- use of trained and experienced Marine Mammal Observers (having undertaken a JNCC recognised course);
- pre-piling search for marine mammals prior to piling monitoring a suitable sized exclusion zone;
- use of Passive Acoustic Monitoring (PAM) system monitored by experienced PAM operatives; and
- soft-start (gradual ramp up) of pile driver.

The modelling of cumulative exposure to piling noise indicates that in a fleeing animal situation the marine mammal that is most sensitive to pile driving sound are the seals, and that to avoid auditory injury they will have to be 3.6 km away from the piling location. A typical mitigation zone for marine mammal observers to monitor has been recommended as a default 1 km (JNCC, 2010), the results of the modelling indicate that this zone should be increased for seals (but will also be applied to all marine mammal species).

Given that there is a risk to marine mammals in the immediate vicinity of the piling operations, and the risk is apparently greater for seal species, it may be worth considering the use of Acoustic Mitigation Devices (AMD's) which, providing they are used appropriately, could temporarily displace marine mammals from the area prior to piling operations. The use of devices whose purpose is to deter marine mammals could be seen as advantageous given the potential risk to marine mammals from noise impacts from pile driving, by removing animals or certain species from the area of operations this action may minimise the risk of causing injury.

AOWFL recognise that the use of AMD's as part of the mitigation measures for piling is currently an area of active scientific research (Kastelein, *et al*., 2010). From a review of commercially available Acoustic Mitigation Devices there are a number which have been designed as seal deterrents, including the Lofitech, Ace Aquatech (Nedwell, *et al*., 2010), and their use could prove advantageous as part of the overall mitigation strategy during construction. Any use of AMD's will be subject to strict timing constraints so that the underwater noise generated will be minimised. If these are used it is envisaged that they will be subject to timing and deployment constraints, for example being deployed 1 hour prior to the commencement of the soft-start and switched off immediately after the piling has ceased (Kastelein, *et al*., 2010). It is also recognised that the use of any such devices may require European Protected Species licences to deploy as they will constitute deliberate disturbance of marine mammals.

AOWFL are open to incorporating the latest advice on the mitigation procedures used as part of the development of the EOWDC. The final MMPP will be agreed following advice and consultation with SNH and Marine Scotland.

3.1.1.5 Residual Impacts

In order to determine the residual impacts, it has been assumed that the mitigation measures described in Section 3.1.1.4 will be successfully implemented then it is expected that physical impacts to marine mammals are unlikely to occur. Impacts on marine mammals would be of negligible magnitude and, therefore, of minor significance.

3.1.1.6 Cumulative Impacts

There are not anticipated to be any cumulative impacts from other renewable energy projects, as all construction activities of other nearby proposed wind farm developments are expected to commence after the EOWDC has been completed. Should the proposed project timescale for the construction of the EOWDC change and coincide with the commencement of construction activities of other renewable energy projects, then further assessment of cumulative impacts from concurrent piling shall be carried out at a later date.

The development and installation of the proposed Ocean Laboratory could occur within the same construction period as the piling of the foundation structures. The installation of the Ocean Laboratory would be comparable to the installation of another monopole. As a worst case the piling of the Ocean Laboratory will take 24 hours and is unlikely to result in any significant cumulative impacts, providing that the mitigation measures that were used for the wind turbines are applied.

The other industrial activity that could cause physical impacts to marine mammals are seismic surveys. There are currently no planned surveys times to occur during the construction period of the EOWDC. There is unlikely to be any seismic surveys occurring simultaneously with the pile driving, as the sound underwater sound interferes with recording of the sound signals received from the seabed. As such any seismic surveys that are planned to occur in the waters of the North Sea, will be timed to avoid known periods of pile driving activity. The waters immediately offshore the north east of Scotland has a low prospectively for hydrocarbons and as such are of little interest to the oil and gas industry. The closest hydrocarbon field to the EOWDC is the Buzzard field which is situated 100 km away.

3.1.1.7 In-Combination Impacts

No in-combination impacts are anticipated.

3.1.1.7.1 Monitoring

The piling operation will follow the MMPP. The presence of marine mammals will be monitored during the construction period through the continuation of the boat based surveys and through the use of static C-pods deployed throughout Aberdeen Bay. The presence of observers and acoustic recording instrument (C-pods) deployed throughout the development stage will enable an assessment of marine mammals presence during construction. Post construction analysis of the acoustic monitoring data collected by the C-pods with other visual observation effort will allow an assessment and validation of construction impacts.

3.1.2 Noise Generated during the Construction of the EOWDC May Cause Behavioural Disturbance and Displacement to Marine Mammals

Worst Case Scenario: Piling of 8.5 m diameter pile at all eleven locations during one phase of installation (sequentially).

3.1.2.1 Potential Impacts

Behavioural disturbance to marine mammals can be caused by elevated sound levels. Upon receiving a sound level capable of causing disturbance the animal may exhibit a number of behaviours, one of the most apparent would be opting to swim away from the source (considered to be an aversive response to the sound signal). This section will assess the potential for piling sound to displace marine mammals from the area by assessing the potential for sound levels to induce a behavioural response. There are a number of sound sources that will be associated with construction activities, the principal sources being associated with construction vessels including: piling barge, support vessels, and other vessels involved with installing seabed cables and infrastructure.

Underwater sound generated by vessels has been recognised as capable of causing a number of different types of behavioural responses in marine mammals, including changing their distribution and abundances. Also it has been suggested that prolonged exposure to increased ambient noise may lead to physiological and behavioural stress (McDonald, *et al*., 2006; Parks and Clark 2005). Thus chronic exposure to noise can permanently impair important biological functions and may lead to consequences that are as severe as those induced by acute exposure from impulsive type sounds.

The construction vessels will only be present within the Aberdeen Bay for the duration of construction activities, which is a relatively short period of time. Moreover, Aberdeen Bay has a number of well established shipping lanes and the vessel noise associated with construction activities is not expected to cause a significant change to ambient sound levels.

Other types of construction activities that are expected to generate underwater noise other than the foundation installation are the cable trenching activities. Measurements of cable trenching activities at North Hoyle Offshore Wind Farm estimated that the sound levels were dominated by the noise from the vessel, and the predicted source levels (178 dB re.1µPa@1m) were considered to be below the level which would cause any behavioural reaction in marine mammals (npower renewables 2002). The cable laying activities as part of the construction of the EOWDC are likely to utilise a similar type of vessel, therefore the sound levels generated are thought to be comparable and are not of any particular concern for causing behavioural impacts to marine mammals.

In terms of the sound levels generated by construction by far the greatest contributor to underwater sound in terms of its peak sound pressure level will be the piling sound, therefore the assessment of behavioural impacts will focus principally on this noise source. The assessment of behavioural impacts will use and compare the results of two impact approaches, the dB_{ht} criteria; proposed by Nedwell *et al*., (2007) and the behavioural response criteria, Southall *et al*., (2007).

3.1.2.2 Assessment of Behavioural Impacts Using the dB_{ht} mectric

Measurements of underwater noise are frequently presented in terms of the overall linear level of that sound, such as its spectral level or peak pressure. This, however, does not provide an indication of the impact that the sound will have upon a particular fish or marine mammal species. This is of fundamental importance when considering the behavioural response of species to activities generating underwater noise, as avoidance is associated with the perceived level of loudness and vibration of the sound by the species. Therefore, the same underwater noise may have a different impact on different species with different hearing sensitivities.

The dB_{ht}(*Species*) metric (Nedwell *et al*, 2007) has been developed as a means for quantifying the potential for a behavioural impact on a species in the underwater environment. As any given sound will be perceived differently by different species (since they have differing hearing abilities) the species name must be appended when specifying a level. For instance, the same construction event for salmon (*Salmo salar*) might have a level of 70 dB_{ht} (*Salmo salar*) and for bottlenose dolphin a level of 110 dB_{ht}(*Tursiops truncatus*). Table

12 below summarises the assessment criteria for the dB_{ht} metric, the higher dB_{ht} levels are correspond to a greater behavioural effect, or at very high levels hearing damage (Nedwell, *et al*. 2007).

Table 12 Assessment criteria proposed by Nedwell *et al*., (2007) used in the impact assessment for behavioural impacts of underwater noise on marine mammals

Level in dB_{ht}(Species)	Effect
75	Significant avoidance
90 and above	Strong avoidance reaction by virtually all individuals.
Above 110	Tolerance limit of sound; unbearably loud.
Above 130	Possibility of traumatic hearing damage from single event.

In addition, a lower level of 75 dB_{ht} has been used for analysis as a level of "significant avoidance." At this level, about 85% of individuals will react to the noise, although the effect will probably be limited by habituation (Subacoustech 2011).

Figure 11 and Figure 12 shows the results for modelling 8.5 m diameter piles in terms of peak to peak dB_{ht} (*Species*) perceived sound levels for the marine species of interest for a deep water transect and a shallower water transect respectively. The depth profiles for these transects are shown in Figure 3.

Figure 11 Estimated peak to peak dB_{ht} level with range plot of various marine mammals and fish species along a deep water transect (wind wind turbine 11, bearing 60°) during the installation of a 8.5 m pile

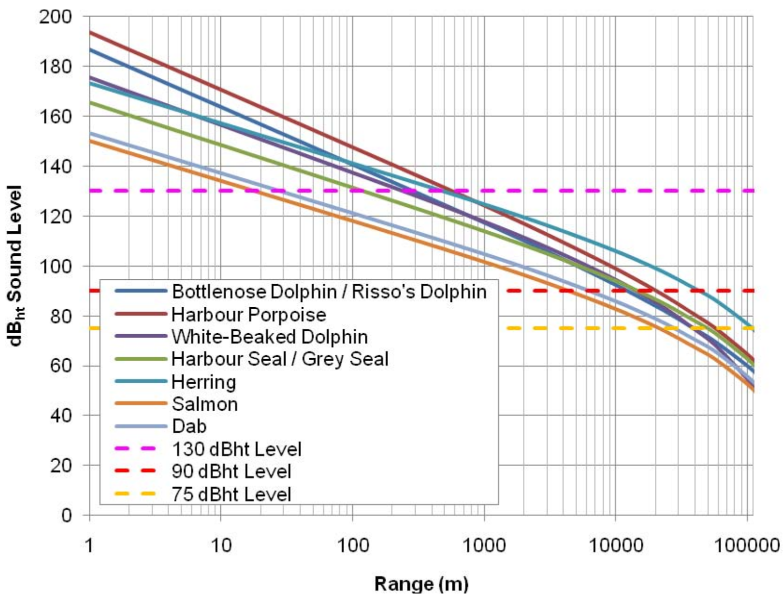

Figure 12 Estimated peak to peak dB_{ht} level with range plot of various marine mammals and fish species along a shallow water transect (wind wind turbine 11, bearing 195^{o}) during the installation of a 8.5 m pile

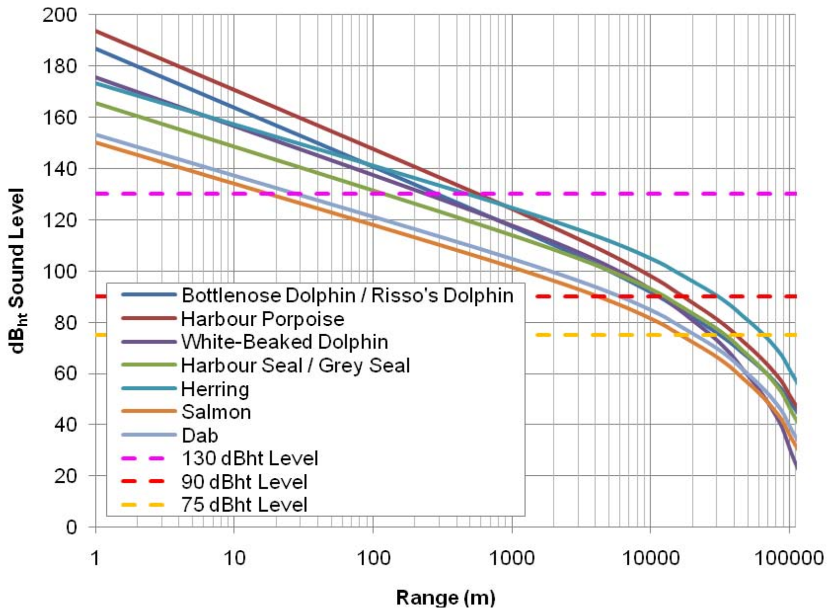

Table 13 - Table 16 present a comparison of estimated 90 dB_{ht} impact ranges for behavioural response for the species of interest. Mean ranges along with the overall range of values are presented for all four wind turbine positions.

The largest range for a behavioural response is predicted for the harbour porpoise, which is likely to receive an underwater noise level of 90 dB_{ht} out to maximum of 22 km from piling operations. The smallest 90 dB_{ht} impact ranges predicted for species of marine mammal is for bottlenose dolphin and Risso's dolphin, with behavioural response ranges of between 12 and 13 km.

The INSPIRE model calculates impact ranges along transect paths from a selected point, in this case the wind turbine positions, along 180 equally spaced transects (one every 2^{o}). The maximum, minimum and mean ranges from all of these transects are collected in the tables below. It should be noted that the minimum ranges are for transects heading into shallow water, and in most cases, are reaching the coastline before the sound has attenuated to below 90 dB_{ht}. Hence why, for example, all the minimum ranges from Wind turbine 1 are calculated to be 3 km, as this is the minimum distance between the wind turbine position and the coastline. All the predicted received noise for all the key species is still above 90 dB_{ht} at this particular piece of coastline.

The mean values quoted in the tables take into account all of the transects, these apparently shorter impact ranges are also used in the averaging.

Table 13 Summary of the estimated behavioural impact ranges for piling an 8.5 m diameter pile at wind turbine position 1 using the dB_{ht} impact criteria

Species	90 dB_{ht} Range	
	Mean	Range of values
Bottlenose Dolphin / Risso's Dolphin	8.5 km	3.0 – 13 km
Harbour Porpoise	12 km	3.0 – 21 km
White-Beaked Dolphin	9.3 km	3.0 – 15 km
Harbour Seal /Grey Seal	9.6 km	3.0 – 16 km

Table 14 Summary of the estimated behavioural impact ranges for piling an 8.5m diameter pile at wind wind turbine position 3 using the dB_{ht} impact criteria

Species	90 dB_{ht} Range	
	Mean	Range of values
Bottlenose Dolphin / Risso's Dolphin	7.9 km	2.3 – 12 km
Harbour Porpoise	11 km	2.3 – 20km
White-Beaked Dolphin	8.4 km	2.3 – 14km
Harbour Seal /Grey Seal	8.7 km	2.3 – 15 km

Table 15 Summary of the estimated behavioural impact ranges for piling an 8.5m diameter pile at wind wind turbine position 7 using the dB_{ht} impact criteria

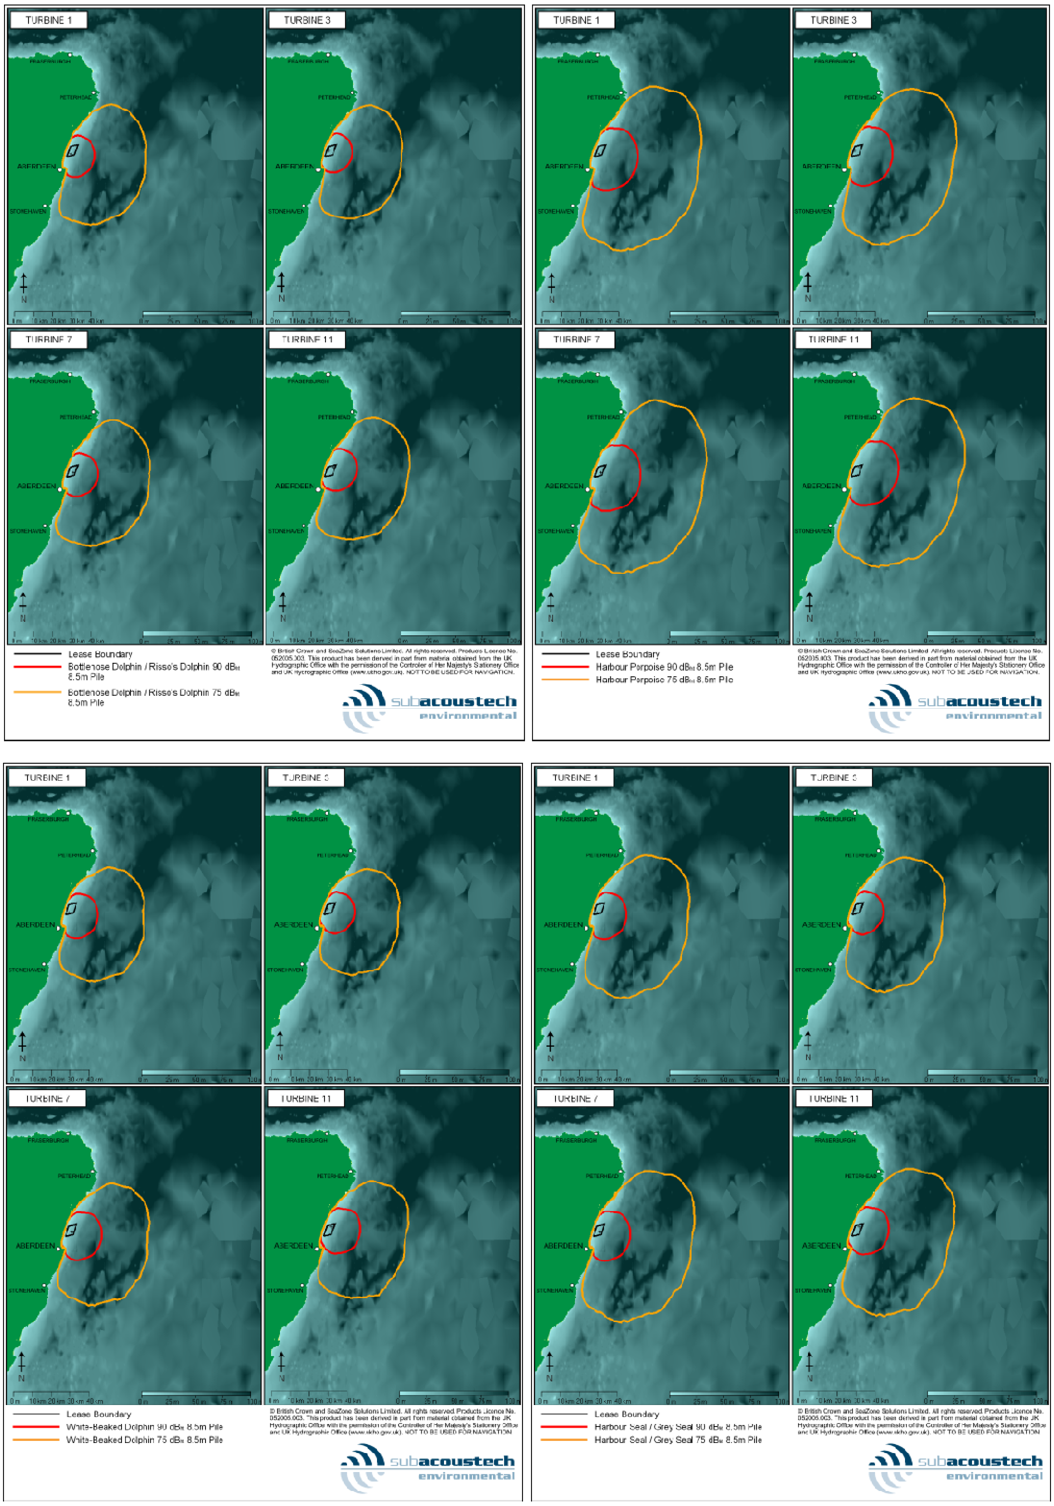
Species	90 dB_{ht} Range	
	Mean	Range of values
Bottlenose Dolphin / Risso's Dolphin	9.5 km	4.1 – 13 km
Harbour Porpoise	13 km	4.1 – 22 km
White-Beaked Dolphin	10 km	4.1 – 16 km
Harbour Seal /Grey Seal	11 km	4.1 – 16 km

Table 16 Summary of the estimated behavioural impact ranges for piling an 8.5m diameter pile at wind wind turbine position 11 using the dB_{ht} impact criteria

Species	90 dB_{ht} Range	
	Mean	Range of values
Bottlenose Dolphin / Risso's Dolphin	9.2 km	3.8 – 13 km
Harbour Porpoise	13 km	3.8 – 21 km
White-Beaked Dolphin	10 km	3.8 – 16 km
Harbour Seal /Grey Seal	10 km	3.8 – 16 km

These results are also presented graphically as contour plots in Figure 13, with each group of images showing the 90 and 75 dB_{ht} impact ranges for each marine species of interest. The 75 dB_{ht} level is a lower behavioural avoidance level, although the effect will probably be limited in duration by habituation. In general, the 90 dB_{ht} criteria level is thought to represent the most useful measure of behavioural disturbance in this case. It can be seen from these figures that the maximum impact ranges stretch out to the east and north east of the proposed EOWDC into the deeper water of the North Sea, where, in some places, water depths are in excess of 100 m LAT. The data indicate that, in nearly all cases, the minimum 90 dB_{ht} contours are the same for each pile; this is due to sound levels being above 90 dB_{ht} for these species at the Scottish coastline. The difference between the impact ranges at the four wind turbine sites is similar. The largest impact ranges are estimated for wind turbines 7 and 11; this is due to being situated on the east boundary of the proposed EOWDC, which is closer to the deep water of the North Sea.

Figure 13 Contour plots showing the estimate 90 and 75 dB_{ht} peak impact ranges for bottlenose / risso's dolphins, harbour porpoise, white beaked dolphin and harbour / grey seals during the installation of an 8.5 m diameter pile (Subacoustech, 2011)



3.1.2.3 Assessment of Behavioural Impacts Using Southall et al., 2007

The assessment of behavioural disturbance also applied the Southall *et al*., (2007) criteria, where the onset of a behavioural response has been proposed as the sound exposure level capable of causing a Temporary Threshold Shift (TTS) in the hearing ability of marine mammals. The criteria associated to be capable of causing a TTS are shown in Table 17 (Southall *et al*., 2007).

Table 17 Proposed behavioural response criteria in terms of single pulses for various marine mammal hearing groups (including low, mid and high frequency cetaceans and seals in water)

Marine mammal group	Sound type
	Single pulses & Multiple pulses
Low Frequency Cetaceans	
Sound Exposure Level	183 dB re 1 µPa^2/s (M_{lf*})
Mid Frequency Cetaceans	
Sound Exposure Level	183 dB re 1 µPa^2/s (M_{mf*})
High Frequency Cetaceans	
Sound Exposure Level	183 dB re 1 µPa^2/s (M_{hf*})
Seals (in water)	
Sound Exposure Level	171 dB re 1 µPa^2/s (M_{pw*})

(M_{lf} = M weighted low frequency M_{mf}= M weighted medium frequency / M_{hf}= M weighted high frequency M_{pf})

The Southall *et al*., (2007) criteria specify that behavioural avoidance is anticipated to occur at a frequency weighted (M- weighted) sound exposure level of 183 dB re.1 µ Pa^2/s (referenced to 1 micro Pascal squared seconds). The sound pressure levels modelled during the piling operation were weighted accordingly and the anticipated maximum impact ranges were determined. Table 18 – Table 21 show summaries of the single pulse behavioural impact ranges predicted. It can be seen that the largest impact ranges are predicted for the seals with behavioural avoidance predicted out to a range of 1.6 km. The three cetacean groups predict lower single pulse behavioural impact ranges, ranging from 280 m, for low frequency cetaceans, to 100 m, for high frequency cetaceans.

Due to these SEL levels predicting relatively low impact ranges, no maximum and minimum ranges have been included as, at these close ranges, changes in bathymetry do not affect the attenuation of sound significantly, resulting in relatively uniform results.

Table 18 Summary of ranges out to which a behavioural avoidance reaction in cetaceans in the low frequency hearing group may occur using the Southall *et al*., (2007) criteria

Low Frequency Cetaceans	Behavioural Avoidance Range 183 dB re. 1 µPa^2/s (M_{lf})
Wind turbine 1	270 m
Wind turbine 3	260 m
Wind turbine 7	280 m
Wind turbine 11	280 m

Table 19 Summary of ranges out to which a behavioural avoidance reaction in cetaceans in the mid frequency hearing group may occur using the Southall *et al.*, (2007) criteria

Mid Frequency Cetaceans	Behavioural Avoidance Range 183 dB re. 1 µPa^2/s (M_{mf})
Wind turbine 1	120 m
Wind turbine 3	110 m
Wind turbine 7	120 m
Wind turbine 11	120 m

Table 20 Summary of ranges out to which a behavioural avoidance reaction in cetaceans in the high frequency hearing group may occur using the Southall *et al.*, (2007) criteria

High Frequency Cetaceans	Behavioural Avoidance Range 183 dB re. 1 µPa^2/s (M_{hf})
Wind turbine 1	100 m
Wind turbine 3	100 m
Wind turbine 7	100 m
Wind turbine 11	100 m

Table 21 Summary of ranges out to which a behavioural avoidance reaction in seals (in water) may occur using the Southall *et al.*, (2007) criteria

Seals in water	Behavioural Avoidance Range 183 dB re. 1 µPa^2/s (M_{pw})
Wind turbine 1	1.6 km
Wind turbine 3	1.5 km
Wind turbine 7	1.6 km
Wind turbine 11	1.6 km

3.1.2.4 Summary of Behavioural Impacts and Comparison between dBht and Southall et al., (2007) approach

Table 22 presents a comparison between the mean predicted dB_{ht} behavioural avoidance impact ranges and the mean M-weighted SEL behavioural avoidance impact ranges for the equivalent marine mammal groups for modelling undertaken for wind turbine position 1.

Again it can be seen that the impact ranges for dB_{ht} differ substantially from those predicted using the M-weighted SEL criteria. The ranges using the M-weighted SEL criteria are thought to be highly optimistic, and are in conflict with the limited amount of published information currently available. For instance, harbour porpoise have been found to avoid an area around similar pile driving operations out to a distance of 15 km (Tougaard, *et al.*, 2006). The most conservative (precautionary) estimates of the extent of potential disturbance have been highlighted in bold (Table 22).

Table 22 Summary of impact ranges comparing the single pulse behavioural avoidance ranges predicted using the dB_{ht} criteria (Nedwell *et al.*, 2007) and the M-weighted SEL approach (Southall *et al.*, 2007) (using wind turbine position 1 for illustration)

dB_{ht} (Nedwell *et al*, 2007)		M-weighted SELs (Southall *et al*, 2007)	
Species	Mean behavioural avoidance range (90 dB_{ht})	Equivalent M-weighting group	Mean behavioural avoidance range
Bottlenose Dolphin	**8.5 km**	Mid Frequency Cetacean	120 m
Harbour Porpoise	**12 km**	High Frequency Cetacean	100 m
Harbour Seal	**9.6 km**	Pinnipeds (in water)	1.6 km

The behavioural effects are only expected to occur during the piling activities and as such as limited to a maximum time period of 24 hours per pile, although it is expected to take considerably less time than this. The piling of jacket structures is expected to require piles with smaller diameters and will take less time to install, although there will be a greater number of piles per platform. Any behavioural effects that occur to the marine mammals are expected to be reversible, in that their behaviour will no longer be changed when the piling activity has ceased.

The range at which potential adverse behavioural responses is considerable being upto 22 km for harbour porpoise and 16 km for common and grey seals. For harbour porpoises the results of post-monitoring studies suggest that after piling stops the animals have been found to return to the area within a few hours. Therefore, behavioural disturbance, which could lead to displacement of marine mammals from the piling activities, is only expected to occur for the duration of piling activities.

The closest seal haul out location identified from SMRU aerial surveys was 7.9 km away (SMRU, 2007), however, harbour seals are also known to occasionally haul out on the sand banks at the Bridge of Don. Both locations are within the radius of potential behavioural displacement. If piling occurs when seals are hauled out no impacts would be expected. Sound impacts would only occur once the animal returns to the water if piling is ongoing. In shallow waters however, the levels of sound an animal receives decreases rapidly due to the greater transmission loss associated with shallower waters. The haul out locations of seals could be affected by the piling operations, which could cause the temporarily displacement of seals from such areas, the significance of this is considered to be moderate.

Aberdeen Bay is recognised as being important for bottlenose dolphins, although there remains some uncertainty as to how the area is used throughout the year by the Moray Firth population of dolphins. The potential exclusion of bottlenose dolphins through behavioural displacement for the duration of the piling activity and out to an extent of 16 km has been assessed as being of high magnitude, and therefore of potentially of major significance to the bottlenose dolphin. As bottlenose dolphins are present along the east coast of Scotland, it has been predicted that the temporary displacement of animals from the Aberdeen Bay area will be mitigated by animals moving into other areas within their natural range, this is a hypothetical assessment and is based on the available habitat range for bottlenose dolphins being extensive covering the coastal waters along the Scottish east coast.

For the other species of cetacean present in Aberdeen Bay they are not restricted to coastal areas and are present throughout a far wider area. Aberdeen Bay has not been recognised as being of particular importance for breeding or calving purposes for other cetacean species, the possible exception in that shallower coastal water of the east coast of Scotland have been speculated to have a role in breeding or calving for the white beaked dolphin during the summer period.

If piling occurs during summer months (July/August) the significance of the behavioural disturbance is likely to be major for the white beaked dolphins, but will still be of moderate impact for all other cetacean species with the exception of the bottlenose dolphin (major). Any temporary exclusion of the cetacean species from Aberdeen Bay is considered to be of minor significance, given that there is likely to be adequate areas for foraging relatively nearby.

The vessels used in the construction of Aberdeen Bay may locally increase the ambient sound levels and as such may temporarily contribute to the displacement marine mammal from the vicinity of construction activities, the significance of this local displacement of marine mammals is negligible.

3.1.2.5 Mitigation

No further mitigation measures above and beyond the MMPP are going to be put in place.

3.1.2.6 Residual Impacts

Upon cessation of piling marine mammals that have been exposed to sound levels capable of inducing behavioural effects (such as swimming away from the area of elevated underwater sound) are expected to return to the abundance and densities levels that are consistent with their redistribution not being significantly changed from levels prior to construction activities. Aberdeen Bay has had a number of notable construction activities in the past including beach protection works and harbour modifications all of which have not appeared to have any lasting impact upon the use of the area by marine mammals. Assuming that marine mammals return to the area after the construction activities have finished there are not anticipated to be any residual impacts.

3.1.2.7 Cumulative Impacts

The cumulative impacts for behavioural disturbance and displacement of marine mammals are not anticipated to be significant during the construction of the EOWDC as this is expected to be the only renewable energy project in Scottish territorial waters where construction is planned to commence during 2013.

3.1.2.8 In-Combination Impacts

There are no other activities that are planned to occur in the wider area that are expected to cause additional behavioural disturbance and displacement of marine mammals.

3.1.2.9 Monitoring

No further monitoring over and above the MMPP is proposed.

3.1.3 Noise Generated during the Construction of the EOWDC May Cause Interference with use of Sound by Marine Mammals

Worst Case Scenario: Piling of 8.5 m diameter pile at all eleven locations during one phase of installation (sequentially).

3.1.3.1 Potential Impacts

Marine mammals use sound for a variety of purposes including in communication, orientation, predator avoidance and foraging. The range of sounds used by marine mammals is broad, and ranges from the low frequency calls of baleen whales to the ultrasonic clicks of 145 kHz in harbour porpoise (Villadsgaard, *et al*., 2007). Harbour seals communicate using low frequency calls and have a well developed under water hearing system (Kastak and Schusterman 1998). Harbour seal males produce underwater vocalisations during the mating season to attract females or to compete with other males and are known to establish territories in the waters offshore of haul-out sites (Hayes, 2004). The results of the acoustic surveys have demonstrate the use of Aberdeen Bay for foraging activities by the harbour porpoise (echolocation clicks) and vocalisations of other dolphin species.

During the pile driving construction activities there is the potential for the sound to mask any seal vocalisations, potentially out to a distance of 80 km (Thomsen, *et al*., 2006). The spatial scale of the potential masking will be dependent upon prevailing ambient sound levels and 80 km is a theoretical maximum. The actual significance of this potential impact is expected to be low given that there are no notable haul out locations in close proximity to Aberdeen Bay and that any potential masking will be temporary.

Masking of biologically relevant sounds produced by high frequency cetaceans, such as the harbour porpoise, and possibly mid-frequency cetaceans, such as the bottlenose dolphin, is unlikely as the piling pulses have little high frequency energy (Thomsen *et al*., 2006). Pile driving pulses are of short duration, and are therefore may be below the time where full detection of signals is possible in cetaceans (Thomsen *et al*., 2006).

Other forms of construction sounds, such as those associated with vessel activity, are continuous type sounds, as opposed to the short duration impulsive piling sounds, and are therefore likely to be above the timeframe where full detection of the signals is possible by cetaceans, and are therefore expected to be audible. Although the vessel sounds are likely to be audible to marine mammals, they are not considered to be capable of masking the cetacean species that are most commonly present in Aberdeen Bay.

3.1.3.2 Mitigation

No mitigation is required.

3.1.3.3 Residual Impacts

The magnitude of the impact on marine mammal vocalisations is considered to be low for seal and negligible for other cetacean species. The overall significance is considered to be moderate for seals and minor for cetaceans. After completion of the construction works there are not anticipated to be any residual impacts.

3.1.3.4 Cumulative Impacts

The Ocean Laboratory will add cumulatively to the construction sound generated, although this is only expected to represent a minor additional cumulative impact that is expected to occur over a short installation timeframe (that would be equivalent of the installation an additional wind turbine), therefore there are no significant impacts expected upon the use of sound by marine mammals.

3.1.3.5 In-Combination Impacts

Cumulatively, vessel noises are a concern for increasing the ambient underwater sound levels, and have been found to influence the vocalisation behaviours of the cetaceans that generate low frequency calls, such as certain species of baleen whales. The development will increase shipping levels and as such will cumulatively contribute to increased underwater sound levels for the duration of the construction activities. Considering Aberdeen Bay is within a relatively busy shipping area, and as large baleen whales are relatively rare in this area of the North Sea, the local elevation of underwater sound is considered to be of minor to negligible significance.

3.1.3.6 Monitoring

No specific monitoring is required.

3.1.4 Installation of Wind Turbines and Cable will Cause Elevated Suspended Sediment Levels within Aberdeen Bay, Which May Impact upon Marine Mammals

Worst Case Scenario: Piling of 8.5 m diameter pile at all eleven locations during one phase of installation (sequentially) and installation the cable within the proposed corridor.

3.1.4.1 Potential Impacts

The impacts of the construction activities of the EOWDC and cable corridor have been considered within the assessment of coastal processes (see the Coastal Process Assessment, Chapter 8 of the ES). This assessment considered the suspended sediment concentrations that would result from the installation of 11 monopiles and the trenching of the cable within the predicted corridor.

The installation of the monopole wind turbines has been shown to result in the release of silts and fine sands which become suspended following mobilisation by the construction works (ABPmer, 2011). The displaced sediment will not act in the same manner of the surficial sediments which are not as easily suspended. The sediment plume has a wider concentration of 8 mg/l, with maximum concentrations reaching 100 mg/l in local areas. The main area of SSC changes lies between the area of Aberdeen Harbour, and 5 km south of the Ythan estuary.

The modelling indicates that the installation of the cable will result in the release of silts and fine sands which become suspended, this material does undergo deposition on the bed when the tidal flow is insufficient to maintain suspension, it does not remain on the seabed long-term such that it becomes resuspended. The cable lay activities are expected to as a worst case generated locally elevated concentrations of 90 mg/l occurring.

Naturally high suspended sediment concentrations are can be found in Aberdeen Bay (43 mg/l), although the installation of the wind turbines is expected to produce levels in excess of these levels, the source of suspended sediment is temporal and will cease once the construction activities are completed. Also it is highly unlikely that all the foundations will be gravity bases, therefore the magnitude of impacts from suspended sediments is expected to be considerably reduced.

Cetaceans generally have poor vision, the exception being the dolphin species which have well developed eyes for seeing above and below the water. In foraging pinnipeds vision has been suggested to be the predominant source of sensory information (Levenson and Schusterman 1999), but the presence of blind but well nourished seals in the wild have challenged this view, although more recently water turbidity has been proposed to be an important factor in the sensory ecology of pinnipeds ((Newby, *et al*., 1970; Weiffen, *et al*., 1996).

Marine mammals present in Aberdeen Bay are likely to be tolerant of the range of suspended sediment levels that can be present within background levels and would be also expected to be resilient to temporary elevation of suspended sediments that would occur during storms and when the Rivers Dee and Don are in flood. The construction activities will not generate excessively high levels of suspended sediment, and any locally high levels will only be present for a temporary duration, the direct impact on marine mammals is anticipated to be negligible.

3.1.4.2 Mitigation

No mitigation is proposed.

3.1.4.3 Residual Impacts

This impact has been assessed as being of negligible significance and no residual impacts are anticipated.

3.1.4.4 Cumulative Impacts

None anticipated.

3.1.4.5 In-Combination Impacts

None anticipated.

3.1.4.6 Monitoring

No specific monitoring is required

3.1.5 Construction of the EOWDC May Cause Displacement of Prey Species of Marine Mammals

Worst Case Scenario: Piling of 8.5 m diameter pile at all eleven locations during one phase of installation (sequentially).

3.1.5.1 Potential Impacts

Changes to prey species as a result of construction activities could potentially have an indirect impact upon marine mammals present in Aberdeen Bay. The impact assessments of the Marine Ecology (Chapter 8 of the ES), Commercial Fisheries (Chapter 21 of the ES) and Salmon and Sea Trout (Chapter 22 of the ES) have been used to assess potential indirect impacts to marine mammals from changes to prey species.

The principal impact identified was from construction associated noise during the installation of the monopiles, this has been assessed as capable of causing displacement of fish species. The magnitude of the displacement is dependent upon the hearing sensitivity of the fish species, with the most sensitive fish species, such as the herring, potentially being displaced as far as 47 km from the piling location

(Subacoustech, 2011). The range of noise induced behavioural displacement for other species of fish which have reduced hearing sensitivity is considerably reduced.

Marine mammals are highly mobile and are expected to follow their prey should they be displaced from the area during construction activities. Piling will be infrequent and temporary so that any disturbance to prey species will be intermittent and not consecutive so any foraging impacts are unlikely to be of sufficient magnitude or duration to adversely affect any life history traits of marine mammals. The marine mammals present in Aberdeen have been known to feed on varied prey species and should be adaptable should one of the more sensitive species to sound be temporarily displaced from the local area.

3.1.5.2 Mitigation

Although the mitigation measures were principally designed for marine mammals, measures such as the soft-start may minimise the risk of causing any physical injury to prey species, as they may move away from the area before any physical impacts are caused.

3.1.5.3 Residual Impacts

This magnitude of the impact upon marine mammals is considered to be negligible, the significance of the impact is considered to be minor.

3.1.5.4 Cumulative Impacts

The construction of the Ocean Laboratory is another aspect that could cumulatively add to the disturbance of marine life and prey species of marine mammals. The associated disturbances that would result from the installation of one additional structure are not considered to result in any significant adverse impacts upon marine mammals.

3.1.5.5 In-Combination Impacts

None anticipated.

3.1.5.6 Monitoring

No specific monitoring is required

3.1.6 Increased Vessel Activity at the Proposed EOWDC May Disturb Marine Mammals

Worst Case Scenario: Installation of 10 MW wind turbines with gravity based foundations.

3.1.6.1 Potential Impacts

The exact vessels requirements have yet to be finalised for each of the development scenarios. It is expected that the required vessels for the wind turbines are a jack-up installation vessel and a feeder barge to transport the wind turbine components to the jack-up vessel. The gravity based structure is considered the worst case foundation structure, as this may require a marginally greater number of vessels (tugs) to float the structure to the location and 2-4 transfer vessels to be used daily in the construction period. Other vessels that will be used in the construction period will include a cable lay vessel and potentially a dive support vessel for rock placement.

During the construction period it is expected that some construction vessels will be undergoing daily movements to and from Aberdeen Harbour, however, at this stage in the project the locations where construction materials will be stored has not yet been finalised as such it is not possible to specify precise details regarding movements of all construction vessels.

Seals have inquisitive behaviour which makes them susceptible to approaching vessels, especially those that are associated with a potential food such as fishing vessels. Certain cetaceans, such as bottlenose dolphins, can be temporarily attracted to moving vessels and bow-ride, whereas other species such as the harbour porpoise appear to exhibit avoidance behaviour and swim away from vessels.

Bottlenose dolphins are often sighted in the middle of the harbour mouth, in the centre of the shipping channel leaving Aberdeen harbour. This species appears to tolerate high levels of daily shipping activity including the movement of large shipping vessels to and from the harbour.

Increased shipping levels could be considered to increase the risk of collisions with marine mammals. Construction vessels will be transiting at slow speeds within Aberdeen Bay and are typically slow moving and generate low frequencies. It is considered that any marine mammals will be able to avoid approaching vessels. There have never been any reports of ship strikes from stranding records along the Grampian coast, which suggests the magnitude of the effect to marine mammals is negligible.

3.1.6.2 Mitigation

All vessels that access the EOWDC site will be instructed to keep within the existing shipping lanes as far as is reasonably practicable and within the zone designated as the wider working area.

3.1.6.3 Residual Impacts

The magnitude of the impact on marine mammals is assessed as being negligible, the significance of this impact is assessed as being minor.

3.1.6.4 Cumulative Impacts

The are not anticipated be any novel types of vessels required to install the Ocean Laboratory that are not already considered to be required as part of the installation of the foundations and turbines (eg heavy lift vessels, barges etc). It is only the duration that vessels are present within Aberdeen Bay that will change during the construction period. The expected installation duration of the Ocean Laboratory has not been finalised, although foundations could be installed in 24 hours, with any topsides potentially taking a similar timeframe. As the Ocean Laboratory will only result in a minor increase in vessel activity, over a short time frame, there are not anticipated to be any adverse cumulative impacts that could disturb marine mammals.

The increase in shipping as part of the construction activities will temporarily, albeit to a small degree, increase the shipping traffic and number of vessels within Aberdeen Bay. The principal effect will be the increase in sound levels and vessel associated disturbance to marine mammals, the overall significance of this is expected to be minor given the volume of shipping traffic that frequents Aberdeen harbour, or transits through the Bay.

3.1.6.5 In-Combination Impacts

None anticipated.

3.1.6.6 Monitoring

No specific monitoring is necessary.

3.2 Operational Phase

3.2.1 The Underwater Sound Generated from the Operational Noise at the EOWDC May Disturb Marine Mammals

Worst Case Scenario: Installation of 10 MW wind turbines with monopile foundations.

3.2.1.1 Potential Impacts

Measurements from operational offshore wind farms suggest that noise generated is generally at low levels and dominated by low frequencies (Nedwell, *et al*., 2007). There have been no measurements from operational wind farms to suggest that source levels ever exceed 145 dB (root mean squared) re.1µPa@1m and such levels are the absolute highest back-calculated source levels recorded (Wahlberg and Westerberg 2005). All measurements of operational wind farm noise have suggested that the received levels (what the animal receives) drop to <120 dB (rms) re.1µPa@1m at 100 m, and that levels propagating in the water column beyond this distance will be low.

Comparing the audiogram data of the harbour porpoise and the bottlenose dolphin with the frequency level of the sound produced from the operational wind farm it becomes highly unlikely that this sound will be audible beyond a distance of 100 m (Madsen, *et al*., 2006). For the low frequency hearing specialists that could be present in Aberdeen such as the harbour seals and baleen whale species, such as the minke whale, Masden *et al*., (2006) estimates that the zone of audibility has a theoretical maximum of >10 km, but the ambient sound levels and propagation losses will reduce this zone considerably. Post monitoring studies at the Barrow Offshore Wind Farm found that the operational noise within the wind farm was detectable out to a distance of 600 m at which it became indistinguishable from ambient noise (BOwind 2008). The known sound levels produced by operating wind farms are low by comparison to modern cargo ships, which have source levels around 175 dB (rms) re.1µPa@1m (NRC 2005).

Marine mammals have been recorded in close proximity to other fixed and noisy features such as drilling rigs and oil production platforms, often using such features for foraging. Therefore, it is not expected that these species will suffer adverse effects from the limited noise and vibration produced by wind turbines. There has been considerable variation in the reported values from operational wind farms, yet all the sound levels reported thus far are relatively low. It is appreciated that no studies have yet attempted to measure marine mammal reactions to operational wind farms and this is a potential area of future research.

Maintenance vessels are only expected to consist of one or two smaller transfer vessels working on at most a daily basis and occasionally larger vessels used for any major repairs. These additional vessel movements would not represent a significant increase on current vessel activity in this area. Aberdeen Bay is already very busy with a wide range of human activities and the small increase in vessel activity associated with the proposed wind farm is unlikely to cause any notable disturbance to marine mammals.

3.2.1.2 Mitigation

No specific mitigation is required.

3.2.1.3 Residual Impacts

The current information suggests that the magnitude of effects upon marine mammals are likely to be negligible, and therefore of minor significance. No residual impacts are expected.

3.2.1.4 Cumulative Impacts

Marine mammals do not appear to be affected by turbine noise generated by wind farms. Therefore the cumulative effects of the EOWDC with the Beatrice demonstrator project is expected to be negligible. Given the potential scale of proposed offshore wind farm developments in Scottish waters with large areas that could be exposed to low levels of operational generated sound the potential for significant cumulative impacts upon marine mammal populations cannot be ruled out, with the significance of such impacts being unknown.

At a local level within Aberdeen Bay the operation of the wind turbines will contribute to increasing the ambient sound levels, the degree of influence will be dependent upon the operational state of the wind turbines (eg wind speed), local weather conditions (eg sea state) and other sources of underwater sound. The operational sound levels are only likely to be detectable from other sound sources within close proximity to the wind turbines and as such are not considered likely to result in any significant in-combination impacts.

3.2.1.5 In-Combination Impacts

None anticipated.

3.2.1.6 Monitoring

No specific monitoring is planned for operational noise.

3.2.2 Loss of Habitat for Marine Mammals within Aberdeen Bay

Worst Case Scenario: Installation of 10 MW wind turbines with gravity based foundations, resulting in a net habitat loss of 0.03 km^2

3.2.2.1 Potential Impacts

Once operational the presence of the wind turbines in the water column removes previously available habitat to marine and could create a barrier to the passage of marine mammals through Aberdeen Bay. The worst case scenario in terms of seabed habitat lost would be through the use of gravity based structures for all eleven wind turbines, this would result in the loss of 0.03 km^2 of seabed habitat (the loss of habitat is a worst case as it takes into potential impacts of scouring). The wind turbines are separated by a considerable distance from each other, this separation distance should not restrict the movement of marine mammals through the EOWDC.

Once operational the wind turbines could act as attractants to colonising benthic fauna, which in turn could attract fish and marine mammal predators. Studies have identified the presence of previously unrecorded species of fish and invertebrates after the development of a wind farm, and it is possible that these in turn could be prey items of marine mammals. The benefit of wind farms to marine mammals is currently uncertain, any positive effects such as providing a limited increase in prey are likely to be only restricted to the immediate vicinity of the EOWDC are as such are expected to have a negligible overall benefit. Further research is needed to justify any claims of positive benefit of renewable energy developments upon marine mammals.

This loss of seabed habitat, in terms of similar available habitat within Aberdeen Bay is of negligible magnitude, with the significance of the impact being minor.

3.2.2.2 Mitigation

No specific mitigation is required.

3.2.2.3 Residual Impacts

The current information suggests that any effects upon marine mammals are likely to be minor, there may be some beneficial effects upon certain marine mammals species, although the overall benefit of this is likely to be negligible.

3.2.2.4 Cumulative Impacts

The Ocean Laboratory will result in the incremental loss of habitat in Aberdeen Bay, the exact dimensions of the structure have yet to be determined so quantification of the loss is not possible, although it is expected to be comparable as a 'worst case' to an offshore oil and gas platform.

The only other offshore wind farm that will have been constructed at the proposed development time for the EOWDC will have been the Beatrice demonstrator, which consisted of two steel jackets in the Moray Firth, the cumulative impacts of the loss of habitat associated with the EOWDC, Beatrice demonstrator and Ocean Laboratory are negligible.

The cumulative impacts associated with the loss of habitat from proposed offshore wind farm developments (including territorial waters and Round 3) is not yet known, although it could result in significant impacts to certain populations of marine mammals, the significance of the impact will depend upon the types of foundations used and the overall footprint of the renewable energy developments in relation to available habitat.

The oil and gas industry has historically been the main offshore industry in the North Sea which places infrastructure, in the forms of platforms, wells and pipeline on the seabed thus removing available habitat for marine mammals. Other industries that contribute to the modification of seabed habitat by laying subsea cables are the telecommunications. The density of oil and gas structures and other subsea cables in relation to total seabed is minimal and therefore no in-combination impacts are expected when the cumulative loss and modification of seabed habitat are considered together.

3.2.2.5 In-Combination Impacts

None anticipated.

3.2.2.6 Monitoring

No specific monitoring is planned for the loss of seabed habitat.

3.2.3 The Cables will Generate Electromagnetic Fields (EMF) Which may Disturb Marine Mammals

Worst Case Scenario: 4 shore cables (total distance 26 km) and inter-array cables (total distance 13 km)

3.2.3.1 Potential Impacts

Electromagnetic fields (EMF) are associated with the operational phase once the cables are conducting electricity. Potential impacts to animals include attraction or repulsion from the fields, behavioural interference (navigation) and physiological effects (Chapter 13 Electromagnetic Fields).

Animals that are attracted to EMFs as a result of confusion with the signal with those of prey species may waste energy, whilst repulsion of animals will result in the reduction of available habitat or disrupt the movement or migration of animals throughout Aberdeen Bay. Disruption to the navigation or orientation may arise for those species using the Earth's geomagnetic field to orientate or time behavioural movements in response to daily events such as tidal cycles. Depending on the magnitude and persistence of the magnetic field, the impact could be a relatively minor temporary change in swimming direction or a more serious impact on migration. The potential physiological effects on marine organisms may include impacts on cell development. There is a lack of targeted research into the potential effects of EMFs generated from offshore wind farms so impacts remain hypothetical.

The current design is planned to use a maximum of 4 shore cables (26 km) and inter-array cables (13 km) that will use an Alternating Current (AC). At this stage in the design process it is not yet known what the power requirements of the cables will be.

There are three components associated with power cables that are elements of EMF. Firstly, there is an electric field, secondly there is a magnetic field outside of the cable and thirdly there is an induced electric field (iE-field). The electric field is of little relevance as the design of the AC cables is shielded by a metallic screen within an industry standard cable this ensures the electric field does is not present beyond the cable.

Magnetic fields from AC power cables rapidly decrease with increasing distance from the cable and within a few metres they are largely undetectable. The magnetic field is proportional to the current, meaning that an increase of the current by five times would lead to an increase of the magnetic field strength by the same.

Cartilaginous fish, which include the elasmobranchs, are the major group of organisms that are known to be electroreceptive. There are no cetacean species which are known to be electroreceptive. Only one semi-aquatic Monotreme (egg laying mammal that is only found in Australia and New Guinea) has been found to use electroreception, which it uses to localise benthic invertebrates (Bullock 1999).

Cetaceans are believed to use weak anomalies in the geomagnetic field as cues for orientation and navigation, this hypothesis was tested by analysing the magnetic fields data of the United States Continental Shelf with cetacean stranding data. The results demonstrate a relationship between cetaceans stranding positions and the geomagnetic field along the U.S Atlantic continental margin (Kirschvink *et al*., 1986).

Marine mammals in Aberdeen Bay in the vicinity of the proposed EOWDC are thought to be able to detect magnetic fields and are also likely to use the Earth's magnetic field for the purposes of orientation and navigation. The magnetic field produced by the EOWDC could possibly result in the disruption of orientation and navigational behaviours. It is not known if the EMF would result in attraction or navigation to marine mammals, or cause other forms of behavioural responses.

The available information on potential impacts from submarine AC cables on magnetoreceptive or electroreceptive species is relatively sparse, with the focus of the studies having been conducted on effects of EMF on migrating eels and elasmobranchs which exhibited behavioural responses to the stimuli. From the monitoring studies of constructed wind farms there is no evidence of any increases or decreases in marine mammal activity that would suggest attraction or avoidance related to magnetic fields. The information on the potential effects of EMF on marine mammals is largely unknown and further research is required to determine the potential risks this may pose to these species. The ecological significance of EMFs is an area of research which requires further study.

3.2.3.2 Mitigation

The electric field will be shielded by an industry standard cable which will stop any electric field being generated beyond the cable. Cable burial increases the distance between any receivers of EMF and the source, but burying the cable only has a minor impact upon the magnetic field as burial of cables to a depth of 5m has essentially the same effect as a cable buried to 1 m.

3.2.3.3 Residual Impacts

Even assuming that marine mammals exhibit some small scale effects, the small areas affected together with the lack of evidence for any significant effects on marine mammals implies that this potential effect is considered to be of minor significance for marine mammals. Further research is needed to fully understand how EMFs are interpreted and used by marine mammals in order to more accurately determine impacts.

3.2.3.4 Cumulative Impacts

The Ocean Laboratory will need to be powered although the electricity generation system has not been selected yet as it will depend upon the requirements of the Ocean Laboratory. A power cable running from the shoreline may be used, and it is initial thought that this will be an AC 11 kV single power line. The magnitude of the EMF effects are likely to be lower than the wind turbine cables, as the strength of EMF fields decreases in lower powered cables, there are not anticipated to be any significant EMF impacts as the result of EMF fields from a power cable to the Ocean Laboratory.

Given the current knowledge of the effects of EMF upon marine mammals it is not expected that there will be any significant cumulative impacts from other constructed renewable energy developments, although it is accepted that further research is required.

The issue of cumulative impacts from power cables may become more of a concern, and the impact of greater significance, with the construction of the proposed wind farms and other forms of renewable energy in UK waters.

There are no known active subsea cables within the Aberdeen Bay area, therefore no cumulative EMF impacts are expected.

3.2.3.5 In-Combination Impacts

None anticipated.

3.2.3.6 Monitoring

No specific monitoring is planned for EMF.

3.3 Decommissioning Phase

3.3.1 Noise Associated with the Decommissioning of the EOWDC May Cause Disturbance to Marine Mammals

Worst Case Scenario: Removal of eleven 10 MW wind turbines, foundations and associated cables and inter-array cables

3.3.1.1 Potential Impacts

The decommissioning plan for the EOWDC has yet to be finalised and as such a detailed impact assessment on this section is not possible, the Description of the Proposed Project provides an outline of the activities that are expected to be associated with the removal of the EOWDC.

The main potential impact to marine mammals is expected to be from the underwater sound and associated disturbance that could arise from decommissioning activities. The activities associated with decommissioning are expected to require similar types of vessel to construction activities including a heavy lift and support vessels. The decommissioning vessels will produce relatively low levels of predominantly low frequency sound throughout during active periods. The impacts from vessels is expected to be temporary and of minor significance.

At the end of the design life the wind turbine foundations will have to be removed from the seabed and if monopiles or steel jackets have been used they will have to be cut. Current non-explosive pile cutting techniques include mechanical and abrasive cutting. Mechanical cutters use either, hydraulically actuated carbide tipped tungsten blades or diamond wire to mill through the inside of piles. Abrasive cutters have mechanisms to direct a water jet containing cutting materials to abrasively wear away steel. In both these techniques sound will be generated by the action of the cutter on the pile and by the machinery which drives the cutter. This sound may radiate into the water directly through the pile via a waterborne path or via the substrate by a ground borne path.

It would be highly unlikely that explosives will be considered for use on the basis of a risk of their perceived environmental impact, with mechanical cutting being the preferred choice to cut structures below the seabed.

AOWFL are not aware of any measurements of the underwater sound levels produced mechanical or abrasive cutters. The lack of published results makes it difficult to assess the environmental impact of cutting steel foundation structures, it is expected that the peak sound levels will be considerably below those generated from impact pile driving. The duration of cutting steel structures will be over a period of hours, per structure, so any impacts will be temporary.

The magnitude of any impacts upon marine mammals will be dependent upon the type of activities that are planned as part of the decommissioning programme; the selection of the removal technique for the foundation is likely to generate the highest sound levels from all decommissioning activities.

Given the current uncertainties in the type of activities that the decommissioning programme will entail, and the lack of any published studies on measurements of cutting of steel structures the magnitude of effect has been assessed as low/medium, with the overall significance being a moderate to major impact on marine mammals. The final decommissioning plan once submitted will allow for a revaluation of the potential impacts upon marine mammals.

3.3.1.2 Mitigation

The Impact Assessment associated with the decommissioning plan will identify any potential impacts and mitigation according to potential environmental risks. It is expected that any risks to marine mammals from decommissioning activities will be mitigated through the use of appropriate measures, such as the use of marine mammal observers and mitigation zones.

3.3.1.3 Residual Impacts

Providing that the mitigation measures are implemented successfully no residual impacts are envisaged from decommissioning activities.

3.3.1.4 Cumulative Impacts

The sound levels generated by decommissioning activities involving mechanical cutting are unlikely to radiate to other areas proposed for renewable energy development. Cumulative decommissioning impacts are only expected to occur if other renewable projects are decommissioning simultaneously to the EOWDC. Consideration will be given to any other renewable energy developments which may be embarking on decommissioning activities within a similar timeframe to the EOWDC, although at this stage there are no significant cumulative decommissioning impacts envisaged.

3.3.1.5 In-Combination Impacts

No in-combination impacts are anticipated from decommissioning activities.

3.3.1.6 Monitoring

Mitigation measures are planned to help ensure that the decommissioning programme will not have a significant impact on the environment. The exact detail of the mitigation and monitoring will be decided during the impact assessment associated with the formulation of the decommissioning plan. During the decommissioning works monitoring of activities will be in place to minimise any impacts that have been identified.

3.4 Summary of Mitigation and Monitoring

The MMPP will specify the procedures to be put in place to minimise the risk of causing adverse impacts to marine mammals. One of the key aspects of the MMPP will be outlining the mitigation measures that are planned to be used in the event of piling, these are:

- Use of trained and experienced Marine Mammal Observers (having undertaken a JNCC recognised course);
- Pre-piling search for marine mammals prior to piling monitoring a suitable sized exclusion zone;
- Use of Passive Acoustic Monitoring (PAM) system monitored by experienced PAM operatives; and
- Soft-start (gradual ramp up) of pile driver.
- Consideration of the use of Acoustic Mitigation Devices; if used they will be subject to stringent operating procedures.
- AOWFL are open to incorporating the latest advice on the mitigation procedures used as part of the development of the EOWDC. The final Marine Mammal Protection Plan (MMPP) will be agreed following advice and consultation with SNH and Marine Scotland.

The disturbance of marine mammals by construction vessels will be controlled and monitored by stipulating working areas.

Throughout the construction of the EOWDC there will be a programme of boat surveys that will be simultaneously collecting data on the distribution and abundance of marine mammals using a combination of visual and towed acoustic techniques. In addition, there will be a series of eleven C-Pods (acoustic hydrophones) that will be permanently moored within Aberdeen Bay. The analysis of these data sources will enable an assessment of the actual impacts of construction activities in relation to the project impacts identified during the impact assessment.

During the decommissioning works monitoring of activities will be in place to minimise any impacts that have been identified, with the exact detail of monitoring programmes having yet to be determined.

Table 23 Summary of Impact Assessment

Impact	Environ-mental effect	Probability of effect occurring	Magnitude	Duration	Spatial extent	Significance level*	Mitigation	Residual impacts	Monitoring
Construction									
Sound	Physiological damage (death) marine mammals	Negligible	High	Temporary	Site specific 3 m from piling	Major	Marine Mammal Protection Plan (MMPP) Including piling mitigation measures; soft –start Marine Mammal Observers, Passive Acoustic Monitoring (PAM).	None	MMPP
	Physiological damage (non-auditory) injury	Very Low			Local (injury possible to 60 m and cumulative dosage impacts upto 3.6 km)				
	Physiological damage (auditory damage) to marine mammals	Very Low	High	Temporary	Local (species specific ranges)	Major	MMPP	None	MMPP
	Behavioural disturbance and displacement	High*(seasonally variable for white beaked dolphins)	High (bottlenose dolphins, White beaked dolphins	Temporary	Regional	Major (piling sound)	MMPP	None	MMPP

			Low (other species marine mammals)			Minor (piling and construction sound)			
Sound (piling)	Interference of sound produced by seals	Low	Low / Negligible	Temporary	Local	Moderate / Minor	MMPP	None	None
	Interference of sound produced by cetaceans	Very low	Negligible	Temporary	Local	Minor	MMPP	None	None
Sound (all other construction sounds)	Interference sound marine produced by mammals	Very low	Negligible	Temporary	Local	Minor	MMPP	None	None
Suspended sediment levels	Impact to marine mammals (foraging etc)	Negligible	Negligible	Temporary	Local	Minor	None	None	None
Disturbance to prey species	In-direct impact upon marine mammals	Low	Low	Temporary	Regional	Moderate	None	None	None
Construction vessels and infrastructure	Disturbance to marine mammals	Negligible	Negligible	Temporary	Local	Minor	MMPP	None	MMPP

Operation									
Operational noise wind turbines	Disturbance to cetaceans	Low	Negligible	Long term	Site specific	Minor	None	None	None
	Disturbance to seals and baleen whales	Medium	Low	Long term	Local	Moderate	None	None	None
Maintenance vessels	Disturbance marine mammals	Negligible	Negligible	Long term	Local	Minor	None	None	None
Wind turbine foundations	Habitat loss	High	Low	Long term	Local	Moderate	None	None	None
Electromagnetic Fields	Disturbance to marine mammals	Negligible	Negligible	Long term	Local	Minor	None	None	None
Decommissioning									
Cutting of foundations	Disturbance to marine mammals	Low / Medium	Moderate	Temporary	Local	Moderate / Major	Decommissioning Plan recommended mitigation	None	None

*All marine mammal species are protected species as such their sensitivity within the impact assessment, is considered to be 'Very high', therefore even when the magnitude of effect has been assessed as being of negligible significance this still results in a 'minor' significant impact.

3.5 SUMMARY

The impact assessment has considered the risks and impacts to marine mammals from the construction, operation and decommissioning of the EOWDC.

The significance of potentially killing a marine mammal during the piling of the EOWDC was assessed as being of major significance, however, with the successful adoption of the mitigation measures for piling, there are not anticipated to be any residual risks given that a marine mammal would have to be present in such close proximity to the pile driver (3 m) to be at any risk. It is considered the risk of marine mammals receiving sound levels capable of causing their death appears to be remote.

Other forms of physical injury (non-auditory) are estimated to occur out to a greater range (60 m), and the risk of piling causing other forms of physical impacts cannot be ruled out, and has been assessed as being of major significance for all marine mammal species. The natural curiosity of seals may increase the risk of exposing both grey and common seals to sound levels capable of causing adverse physical effects.

The cumulative noise dose modelling indicate that unless a cetacean is within the immediate vicinity of piling operations (<1.35 km) or a seal is situated within 3.6 km, the only possibility for an auditory injury to occur is during the initial piling period. It is expected that the perceived loudness of the piling activity will cause the marine mammal to exhibit an aversive behavioural reaction, with the animal moving from the area before the onset of any auditory injury can occur.

The marine mammals which are most likely to be exposed are the more commonly sighted species within Aberdeen Bay, with the harbour porpoise, bottlenose dolphins and grey and common seals being the species most at risk from physical impacts. Given that the relatively small Moray Firth bottlenose dolphin population has been increasing its range expansion in a southerly direction, and that Aberdeen Bay frequently has bottlenose dolphins, especially during the winter and spring months, the potential impact both to the individual and population is considered to be of high magnitude and potentially of major significance. It should be considered the majority of bottlenose dolphins sightings have been observed frequenting the harbour mouth area and that the mitigation measures mentioned below they should be sufficient to ensure that no bottlenose dolphins are situated within 820 m prior to piling activities, if such measures are put in place the anticipated magnitude of the effects is expected to be negligible and thus be of minor significance to the bottlenose dolphin populations.

The range at which potential adverse behavioural responses is considerable being upto 22 km for harbour porpoise and 16 km for common and grey seals. For harbour porpoises the results of post-monitoring studies suggest that after piling stops the animals have been found to return to the area within a few hours. The haul out locations of seals could be affected by the piling operations, which could cause the temporarily displacement of seals from such areas. Therefore, behavioural disturbance, which would lead to displacement of marine mammals from the piling activities, is only expected to occur for the duration of piling activities.

The potential exclusion of bottlenose dolphins through behavioural displacement for the duration of the piling activity and out to an extent of 16 km has been assessed as being of high magnitude, and therefore of potentially of major significance to the bottlenose dolphin. As bottlenose dolphins are present along the east coast of Scotland, it has been predicted that the temporary displacement of animals from the Aberdeen Bay area will be mitigated by animals moving into other areas within their natural range, this is a hypothetical assessment and is based on the available habitat range for bottlenose dolphins being extensive covering the coastal waters along the Scottish east coast.

For the other species of cetacean present in Aberdeen Bay they are not restricted to coastal areas and are present throughout a far wider area. Aberdeen Bay has not been recognised as being of particular importance for breeding or calving purposes for other cetacean species, the possible exception in that shallower coastal water of the east coast of Scotland have been speculated to have a role in breeding or calving for the white beaked dolphin during the summer period.

If piling occurs during summer months (July/August) the significance of the behavioural disturbance could be major for the white beaked dolphins, but of minor significance impact for all other cetacean species with the exception of the bottlenose dolphin (major). Any temporary exclusion of the cetacean species (except bottlenose from Aberdeen Bay is considered to be of moderate significance, given that there is likely to be adequate areas for foraging relatively nearby.

The vessels used in the construction of Aberdeen Bay may locally increase the ambient sound levels and cause disturbance and may temporarily contribute to the displacement marine mammal from the vicinity of construction activities, the significance of this local displacement of marine mammals is minor.

During the pile driving construction activities there is the potential for the sound to mask any seal vocalisations, potentially out to a distance of 80 km (Thomsen, *et al*., 2006). The spatial scale of the potential masking will be dependent upon prevailing ambient sound levels and 80 km is a theoretical maximum. The actual significance of this potential impact is expected to be low given that there are no notable haul out locations in close proximity to Aberdeen Bay and that any potential masking will be temporary.

Masking of biologically relevant sounds produced by high frequency cetaceans, such as the harbour porpoise, and possibly mid-frequency cetaceans, such as the bottlenose dolphin, is unlikely as the piling pulses have little high frequency energy (Thomsen *et al*., 2006). Pile driving pulses are of short duration, and are therefore may be below the time where full detection of signals is possible in cetaceans (Thomsen *et al*., 2006). The magnitude of the impact on marine mammal vocalisations is considered to be low for seal and negligible for other cetacean species. The overall significance is considered to be moderate for seals and minor for cetaceans. After completion of the construction works there are not anticipated to be any residual impacts.

Vessel sounds are likely to be audible to marine mammals, they are not considered to be capable of permanently masking the sounds produced by cetacean species that are most commonly present in Aberdeen Bay.

No impacts to marine mammals are anticipated from an increase in suspended sediments levels as the increases are still within the ranges they are expected to be tolerant of.

Marine mammals are highly mobile and are expected to follow their prey should they be displaced from the area during construction activities. Piling will be infrequent and temporary so that any disturbance to prey species will be intermittent and not consecutive so any foraging impacts are unlikely to be of sufficient magnitude or duration to adversely affect any life history traits of marine mammals. The marine mammals present in Aberdeen have been known to feed on varied prey species and should be adaptable if one of the more sensitive species to sound is temporarily displaced from the local area.

Increased shipping levels could be considered to increase the risk of collisions with marine mammals. Construction vessels will be transiting at slow speeds within Aberdeen Bay and are typically slow moving and generate low frequencies. It is considered that any marine mammals will be able to avoid approaching vessels. There have never been any reports of ship strikes from stranding records along the Grampian coast, which suggests the magnitude of the effect to marine mammals is negligible.

The noise from the operational wind farm is not considered to be capable of causing disturbance or displacement to marine mammals. There has been considerable variation in the reported underwater noise measurement from operational wind farms, yet all the sound levels reported thus far are relatively low.

Aberdeen Bay is already very busy with a wide range of human activities and the small increase in vessel activity associated with the maintenance of the proposed EOWDC is unlikely to cause any notable increase disturbance to marine mammals.

The worst case scenario in terms of seabed habitat lost would be through the use of gravity based structures for all eleven wind turbines; this would result in the loss of 0.03 km^2 of seabed habitat. The wind turbines are separated by a considerable distance from each other, this separation distance should not restrict the movement of marine mammals through the EOWDC. This loss of seabed habitat, in terms of similar available habitat within Aberdeen Bay is of negligible magnitude, with the significance of the impact being minor.

Given the current uncertainties in the type of activities that the decommissioning programme will entail, and the lack of any published studies on measurements of cutting of steel structures the magnitude of effect has been assessed as low/medium, with the overall significance being a moderate to major impact on marine mammals. The final decommissioning plan once submitted will allow for a revaluation of the potential impacts upon marine mammals.

From the monitoring studies of constructed wind farms there is no evidence of any increases or decreases in marine mammal activity that would suggest attraction or avoidance related to magnetic fields. The information on the potential effects of EMF on marine mammals is largely unknown and further research is required to determine the potential risks this may pose to these species. The ecological significance of EMFs is an area of research which requires further study.

The MMPP will be developed to address and mitigate any of the impacts identified as being of concern to marine mammals. The MMPP will outline the chosen mitigation procedures during any piling operations and construction activities to minimise the risk of impacts to marine mammals, the final MMPP will be developed in consultation with advice from statutory consultees. The programme of boat based and acoustic monitoring using C-Pods will continue throughout the development and construction of the EOWDC to enable any potential impacts upon marine mammals to be identified and recorded.

AOWFL will follow any advice provided by Marine Scotland on the European Protected Species licences to apply for, if these are required.

This study has been carried out by Anatec Ltd on behalf of Aberdeen Offshore Wind Farm Limited. The assessment represents Anatec's best judgment based on the information available at the time of preparation. Any use which a third party makes of this report is the responsibility of such third party. Anatec accepts no responsibility for damages suffered as a result of decisions made or actions taken in reliance on information contained in this report.

TABLE OF CONTENTS

1. INTRODUCTION

1.1 Background

Anatec was commissioned by Aberdeen Offshore Wind Farm Limited (AOWFL) to perform a shipping and navigation assessment of the European Offshore Wind Deployment Centre (EOWDC), situated in Aberdeen Bay.

The report presents information on the proposed development relative to the baseline navigational activity and features for the area. Following this, an assessment of the impact of the proposed development on navigation is presented.

1.2 Scope of the Assessment and Methodology

The assessment methodology principally followed the Department of Energy and Climate Change (DECC) Risk Assessment Methodology (Ref. i) and the Maritime and Coastguard Agency's (MCA) Marine Guidance Notice 371 (MGN 371) (Ref. ii).

An overview of the general methodology applied in the assessment is presented in Figure 1.1. (More information on the regulations and guidance being addressed is presented in Section 2.)

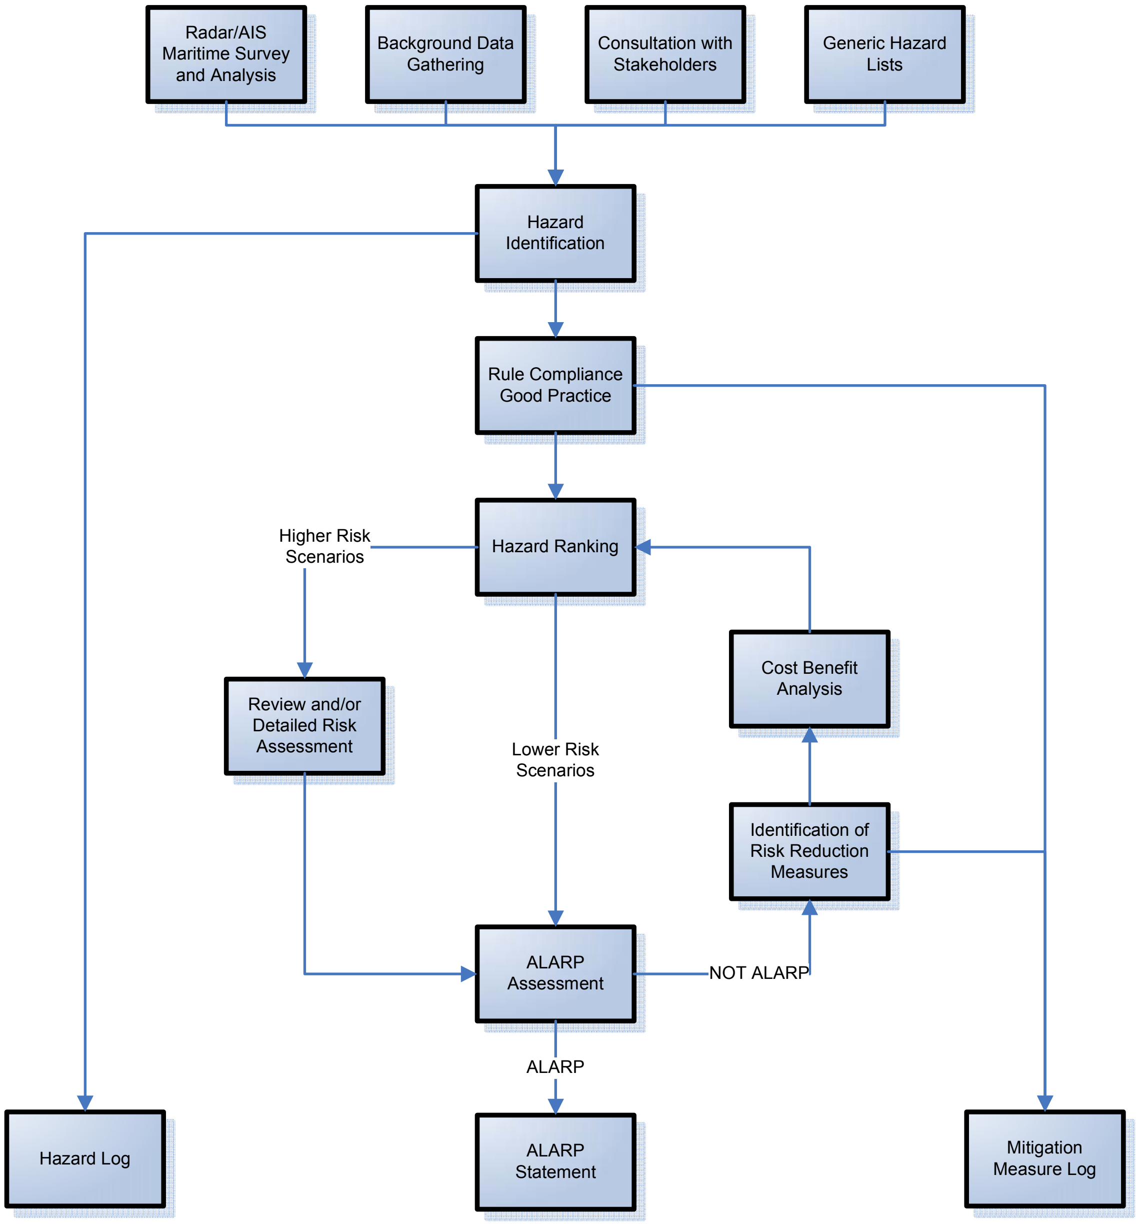

Figure 1.1 Overview of Methodology for Navigation Assessment

The main part of the assessment considers the impact of the surface structures associated with the operational phase of the proposed development on the following maritime activities:

- Commercial Shipping
- Fishing
- Recreational Sailing

In addition to these activities, consideration is given to the following:

- Impacts of Structures on Marine Radar

- Impact of Subsea cables
- Impacts associated with Construction / Decommissioning phases
- Cumulative Impacts with other nearby developments

The assessment is based on the turbine layout 039 which has evolved from various site iterations and extensive consultation. The number of turbines has subsequently been reduced from the initial plans to take on board comments received from navigational stakeholders, in particular Aberdeen Harbour Board and the Marine Safety Forum.

1.3 Abbreviations

The following abbreviations are used in this report:

AHB	-	Aberdeen Harbour Board
AIS	-	Automatic Identification System
ALARP	-	As Low as Reasonably Practicable
ALB	-	All-Weather Lifeboat
AOWFL	-	Aberdeen Offshore Wind Farm Limited
AREG	-	Aberdeen Renewable Energy Group
ARPA	-	Automatic Radar Plotting Aid
ARRC	-	Autonomous Rescue and Recovery Craft
AtoN	-	Aid to Navigation
BATNEC	-	Best Available Technology Not at Excessive Cost
BERR	-	Department for Business Enterprise & Regulatory Reform
BMAPA	-	British Marine Aggregate Producers Association
BWEA	-	British Wind Energy Association
CA	-	Cruising Association
CAA	-	Civil Aviation Authority
CBA	-	Cost Benefit Analysis
COLREGS	-	International Regulations for Preventing Collisions at Sea
CPA	-	Closest Point of Approach
DECC	-	Department of Energy and Climate Change
DEFRA	-	Department for Environment, Food and Rural Affairs
DfT	-	Department for Transport
DSC	-	Digital Selective Calling
DTI	-	Department of Trade and Industry
DW	-	Deep Water
DWT	-	Dead Weight Tonnes
DZ	-	Danger Zone
EIA	-	Environmental Impact Assessment
EOWDC	-	European Offshore Wind Deployment Centre
ERCoP	-	Emergency Response Cooperation Plan
ERRV	-	Emergency Response and Rescue Vessel
ES	-	Environmental Statement
ETV	-	Emergency Towing Vessel
FN	-	Frequency-Number

FSA	-	Formal Safety Assessment
GPS	-	Global Positioning System
GRP	-	Glass Reinforced Plastic
HAT	-	Highest Astronomical Tide
HF	-	High Frequency
HSC	-	High Speed Craft
HSE	-	Health and Safety Executive
HW	-	High Water

RYA	-	Royal Yachting Association

SAR	-	Search and Rescue
SEA	-	Strategic Environmental Assessment
SFF	-	Scottish Fishermen's Federation
SPS	-	Significant Peripheral Structure
SRR	-	Search and Rescue Region
TSS	-	Traffic Separation Scheme
UHF	-	Ultra High Frequency
UKCS	-	United Kingdom Continental Shelf
UKHO	-	United Kingdom Hydrographic Office
VHF	-	Very High Frequency
VMS	-	Vessel Monitoring Service
VTS	-	Vessel Traffic Services

2. REGULATIONS AND GUIDANCE

2.1 Introduction

This section briefly summarises the key regulations and guidance relevant when considering the navigation safety issues associated with offshore wind farm developments in the UK.

2.2 MCA Marine Guidance Notice 371

This guidance notice (Ref. ii) highlights issues that need to be taken into consideration when assessing the impact on navigational safety from offshore renewable energy developments, proposed for United Kingdom internal waters, territorial sea or Renewable Energy Zones.

There are 5 annexes containing recommendations (1-4) and regulatory extracts (5-6) as follows:

- Annex 1: Considerations on site position, structures and safety zones.
- Annex 2: Navigation, collision avoidance and communications.
- Annex 3: MCA shipping template, assessing wind farm boundary distances from shipping routes.
- Annex 4: Safety and mitigation measures recommended for OREI during construction, operation and decommissioning.
- Annex 5: Standards and procedures for generator shutdown and other operational requirements in the event of a search and rescue, counter pollution or salvage incident in or around an OREI.

A checklist referencing the sections in this report which address MCA requirements is presented in Appendix A.

2.3 MCA Wind Farm: "Shipping Route" Template

A trial performed by the Maritime & Coastguard Agency at the North Hoyle Offshore Wind Farm (Ref.iii) indicated that turbines provide erroneous returns to radar transceivers. Multiple side echoes may be generated that have the potential to mask real targets. This has been validated by more recent trials carried out by the industry on the Kentish Flats Offshore Wind Farm in the Thames estuary (Ref. iv). The onset range from the turbines of these returns is about 1.5nm, with a progressive deterioration in the radar picture as the turbines are closed to about 500 m. Adjustment of the radar controls can filter out some of these unwanted radar returns but comes at the cost of potentially losing small radar cross sectional targets such as buoys or small craft.

The MCA's Wind farm Shipping Route Template (Annex 3 of Ref. ii), reproduced in Figure 2.1, indicates that turbines within 0.5nm of a route will be Very High Risk. Close scrutiny and potentially mitigation will be needed between 0.5nm and 5nm to ensure risks are ALARP, particularly between 0.5nm and 2nm which is considered Medium to High Risk. Beyond 2nm is Low Risk although an adjacent wind farm or TSS introduces cumulative effects which have to be scrutinised.

Annex 3 of Ref. ii states that the template is not a prescriptive tool but needs intelligent application to explore where the distance should be measured from, e.g., route centre, 90% traffic level, nearest ship, etc. The potential boundaries are illustrated in Figure 2.2.

Marine traffic survey information collected for the proposed EOWDC site has been analysed in this study to inform such boundaries and investigate influencing factors such as route bias, vessel type, size, cargo, etc.

WIND FARM: "SHIPPING ROUTE" Template

Distance in miles (nm) of Turbine Boundary from Shipping Route	Factors	Risk	Tolerability
< 0.25nm (500m)	500m inter-turbine spacing = small craft only recommended	**VERY HIGH**	**INTOLERABLE**
0.25nm (500m)	X band radar interference	**VERY HIGH**	
0.45nm (800m)	Vessels may generate multiple echoes on shore based radars	**VERY HIGH**	
			TOLERABLE IF ALARP (As Low As Reasonably Practicable)* * Descriptions of ALARP can be found in a) Great Britain Health and Safety Executive (2001) Reducing risks protecting people b) IMO (2002) MSC Circ 1023 dated 5th April 2002 Formal Safety Assessment c) IMO (2007) MSC 83-21-INF2 Consolidated guidelines for Formal Safety Assessment
0.5nm (926m)	Mariners' high traffic density domain	**HIGH**	
0.8nm (1481m)	Mariners' ship domain	**HIGH**	
1 nm (1852m)	Minimum distance to parallel boundary of TSS	**MEDIUM**	
1.5nm (2778m)	S band radar interference ARPA affected	**MEDIUM**	
2 nm (3704m)	Compliance with COLREGS becomes less challenging	**MEDIUM**	
>2nm > (3704m)	But not near TSS	**LOW**	
3.5nm (6482m)	Minimum separation distance between turbines opposite sides of a route	**LOW**	
5nm (9260m)	Adjacent wind farm introduces cumulative effect Distance from TSS entry/exit	**VERY LOW**	**BROADLY ACCEPTABLE**
10nm (18520m)	No other wind farms	**VERY LOW**	

Figure 2.1 Wind Farm "Shipping Route" Template (Ref. ii)

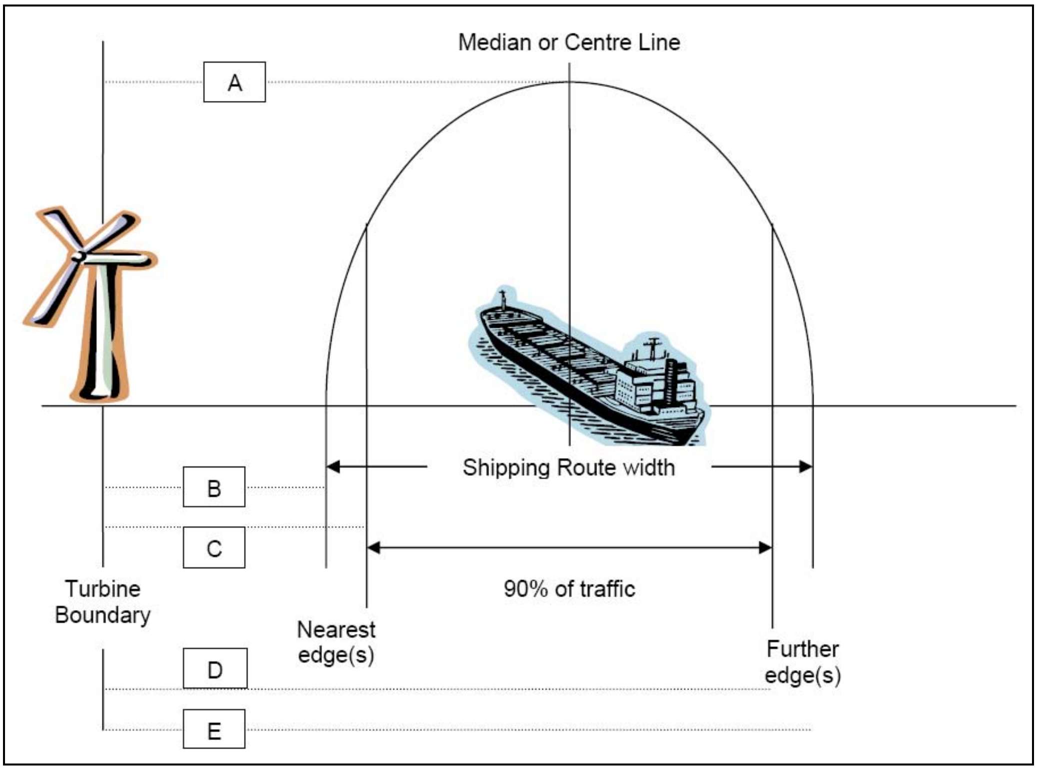

Figure 2.2 Interactive Boundaries (require Interpretative Flexibility), where:

A = Turbine boundary to the shipping route median or centre line
B = Turbine boundary to nearest shipping route edge
C = Turbine boundary to nearest shipping 90% traffic level*
D = Turbine boundary to further shipping 90% traffic level*
E = Turbine boundary to further shipping route edge
(* = or another % to be determined)

2.4 DECC Methodology

DECC (formerly BERR) produced a Methodology for Assessing the Marine Navigational Safety Risks of Offshore Wind Farms in association with the MCA and the DfT (Ref. i).

Its purpose is to be used as a template by Developers in preparing their NRAs, and for Government Departments to help in the assessment of these.

The Methodology is centred around risk controls and the feedback from risk controls into risk assessment. It requires a submission that shows that sufficient risk controls are, or will be, in place for the assessed risk to be judged as broadly acceptable or tolerable with further controls or actions.

The key features of the Marine Safety NRA Methodology are risk assessment (supported by appropriate techniques and tools), creating a hazard log, defining the risk controls (in a Risk Control Log) required to achieve a level of risk that is broadly acceptable (or tolerable with controls or actions), and preparing a submission that includes a claim, based on a reasoned argument, for a positive consent decision.

Table 2.1 Key Features of the DECC Methodology (Ref. i)

1	Define a scope and depth of the submission proportionate to the scale of the development and the magnitude of the risk
2	Estimate the "base case" level of risk
3	Estimate the "future case" level of risk
4	Create a hazard log
5	Define risk control and create a risk control log
6	Predict "base case with wind farm" level of risk
7	Predict "future case with wind farm" level of risk
8	Submission

2.5 Aids to Navigation

The proposed EOWDC would be marked in accordance with the requirements of The Northern Lighthouse Board (NLB) which is the statutory body advising on the marking of Renewable Energy Installations in Scottish waters. The requirements will be agreed for all phases of the development.

3. PROJECT DETAILS

3.1 Introduction

This section presents details on the proposed development in Aberdeen Bay. Improvements have been made to the site layout in order to minimise the risk of the proposed project.

3.2 Lease Boundary

The lease boundary for the proposed EOWDC site is located approximately 1nm east of Black Dog. The total area of the lease boundary is approximately 5.8nm^2 (20 km^2). The corner coordinates of this area are presented in Table 3.1.

Table 3.1 Co-ordinates of EOWDC Lease Boundary (WGS 84)

Corner	Latitude (dd)	Longitude (dd)
c1	57.2060° N	1.9780° W
c2	57.1974° N	2.0454° W
c3	57.2454° N	2.0152° W
c4	57.2540° N	1.9477° W

The proposed turbine layout has a perimeter (area formed by joining outer turbine locations) considerably smaller than the licensed area. The coordinates of the proposed eleven turbine locations are presented in Table 3.2.

Table 3.2 Co-ordinates of Proposed EOWDC Turbines (WGS 84)

Turbine Number	Latitude (dsm)	Longitude (dsm)
1	57° 12' 28.570" N	002° 00' 35.007" W
2	57° 12' 56.899" N	002° 00' 40.259" W
3	57° 13' 25.226" N	002° 00' 45.453" W
4	57° 12' 42.251" N	001° 59' 55.259" W
5	57° 13' 12.197" N	002° 00' 0.801" W
6	57° 13' 42.142" N	002° 00' 6.286" W
7	57° 12' 57.642" N	001° 59' 10.554" W
8	57° 13' 29.399" N	001° 59' 16.385" W
9	57° 14' 01.188" N	001° 59' 22.218" W
10	57° 13' 48.536" N	001° 58' 27.007" W
11	57° 14' 22.331" N	001° 58' 33.185" W

Charts of the lease boundary and proposed turbine locations are presented in Figure 3.1 and Figure 3.2, respectively. Adjacent turbines are located approximately 800-1,110m apart.

Water depths (below chart datum) at the turbine locations range from approximately 20m to 30m.

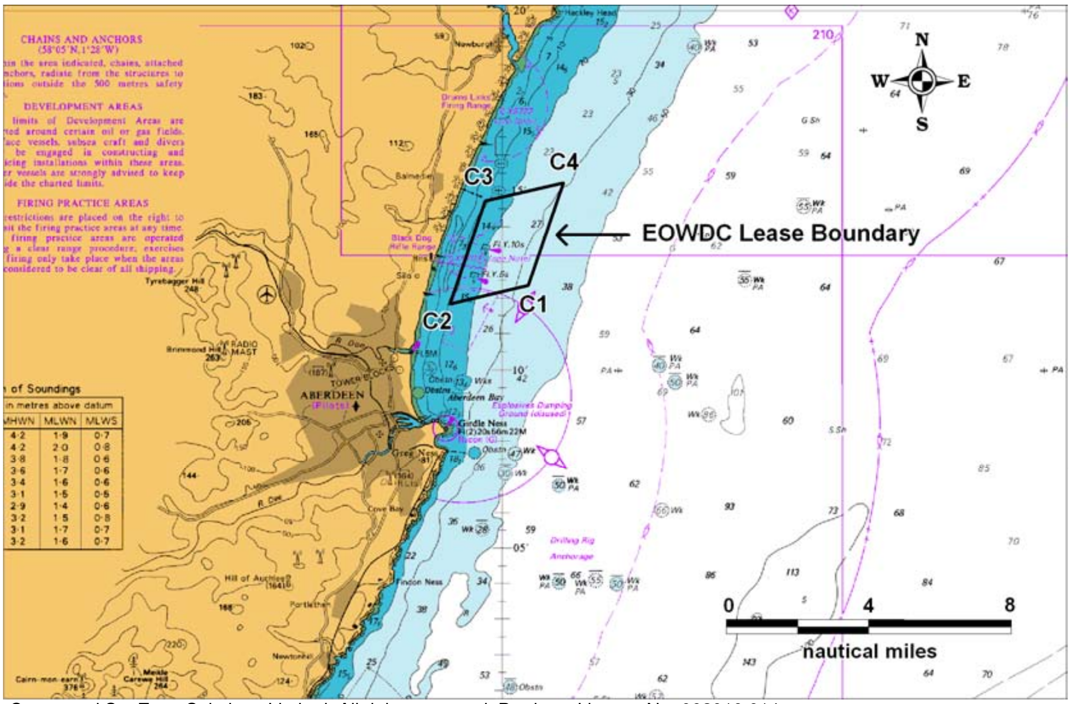

Figure 3.1 Chart Overview of EOWDC Lease Boundary

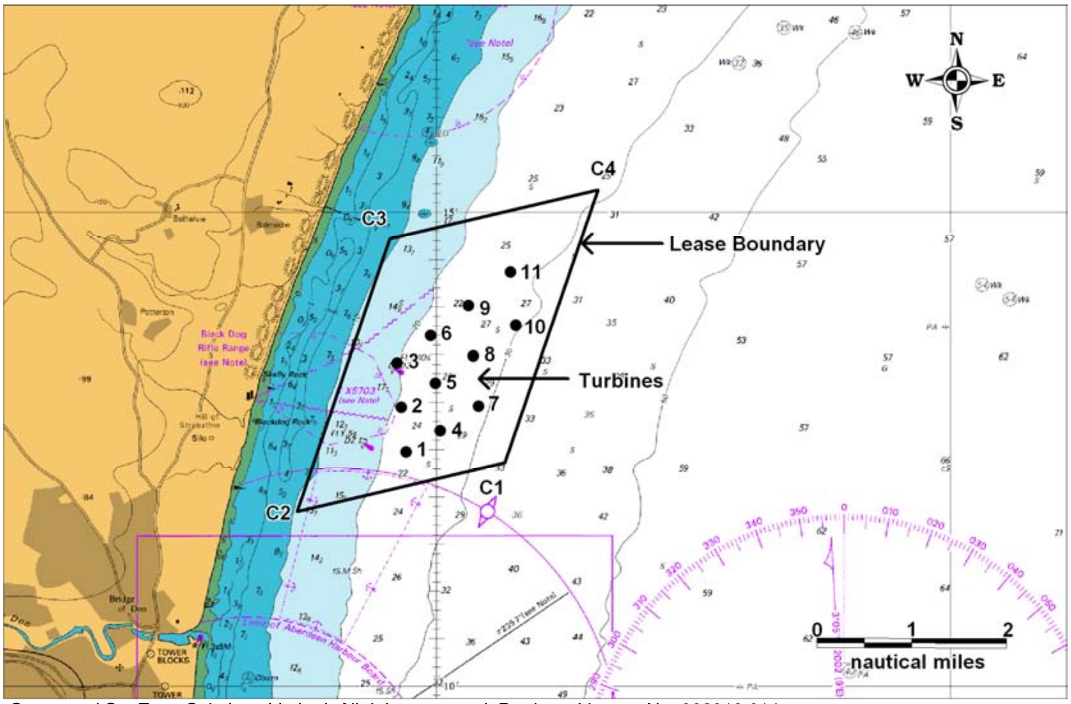

Figure 3.2 Detailed Chart Overview of proposed EOWDC site and Lease boundary

3.3 Site Revision

Figure 3.3 shows the current turbine layout versus a previous layout from 2006. It can be seen that there are now fewer turbines and that the overall 'turbine footprint' area is much smaller. The site has also been moved further north away from Aberdeen port to reduce the impact on ships navigating and anchoring in the vicinity. These changes were agreed with maritime stakeholders, such as the Aberdeen Harbour Board, during consultation on the proposed development.

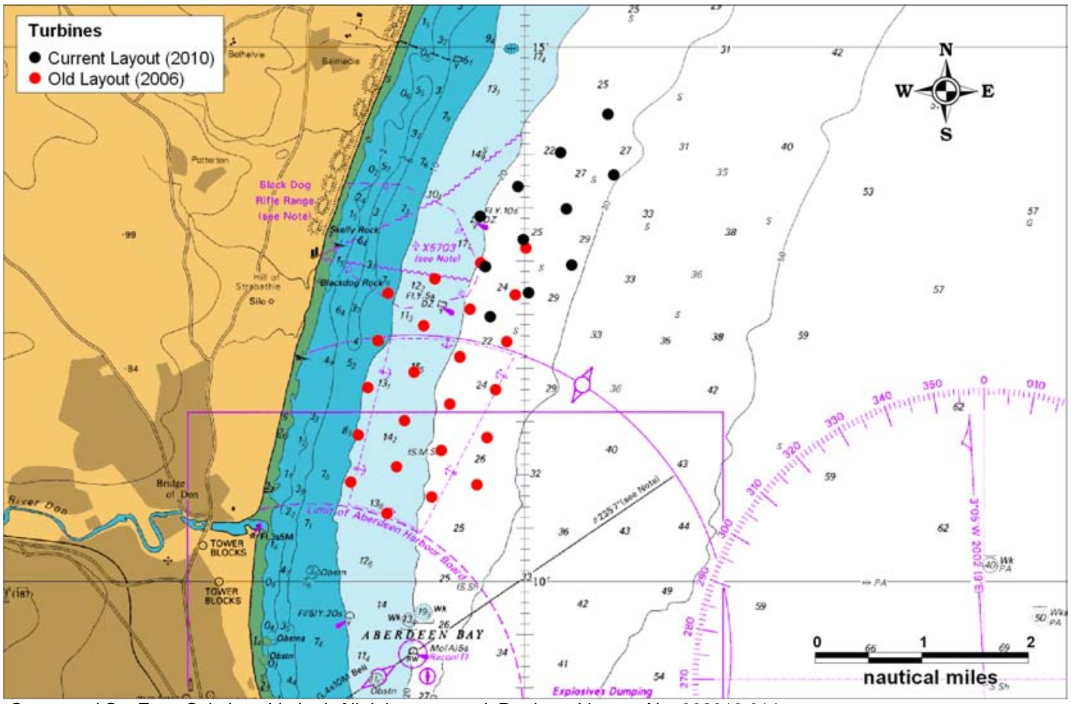

Figure 3.3 Current Layout (2010) versus Old Layout (2006)

3.4 Structure Details

Several layout options have been considered for the proposed EOWDC. The finalised turbine arrangement (layout 39) consists of 11 wind turbines on jacket substructures. It is expected that the turbines installed will vary in size and power. The table below summarises the dimensions of the possible machines ranging from 4 MW to 10 MW.

Table 3.3 Dimensions for Minimum and Maximum Size Machines

Wind Turbine Size	Max Hub Height above LAT (m)	Max Rotor Diameter (m)	Maximum Tip Height above LAT (m)
4MW	100	120	160
10MW	120	150	195

Conservatively, the worst case jacket substructure dimensions of 21m by 21m have been assumed within this collision risk assessment, as a worst case out of all potential foundations being considered for the site as defined by the project.

A typical design of the wind turbine and the jacket sub-structure is represented in Figure 3.4 and Figure 3.5. There will be a minimum 22m rotor blade tip clearance (air draught) over MHWS in accordance with MCA and RYA recommendations.

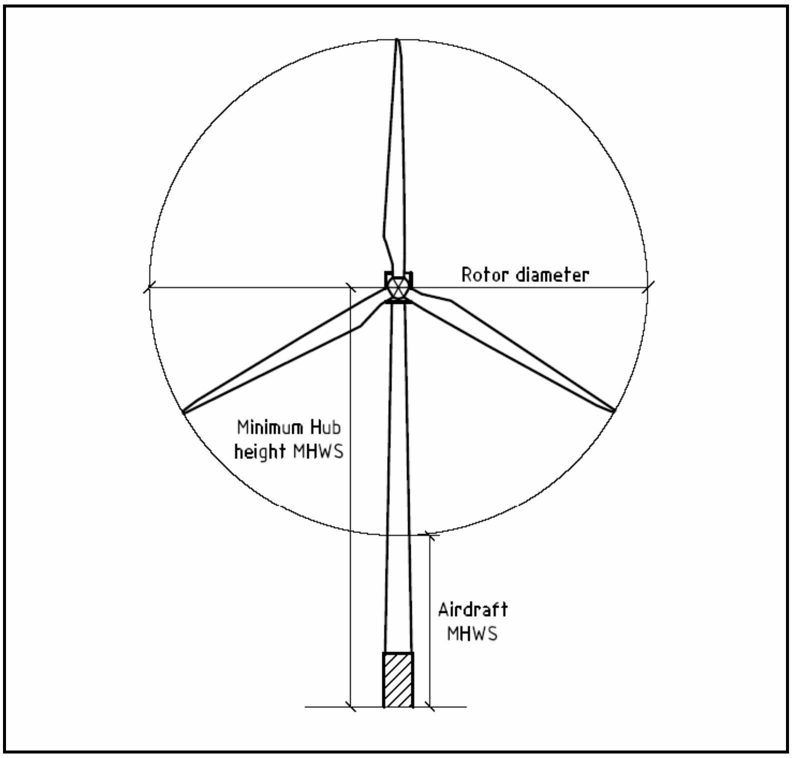

Figure 3.4 Outline of Typical Turbine Structure

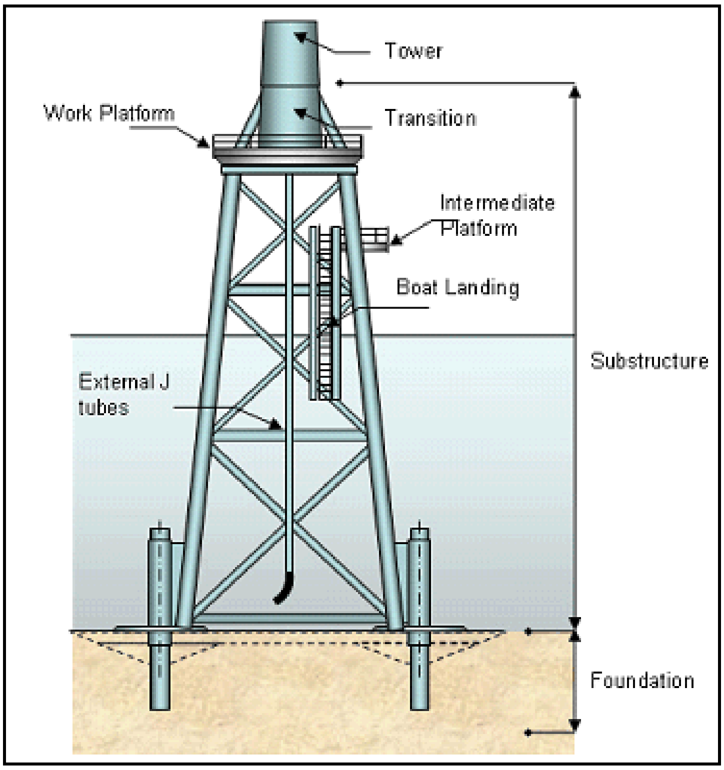

Figure 3.5 Outline of Typical Jacket Substructure

3.5 Offshore Cable Routes

An overview of the cable corridor is presented in the following figure:

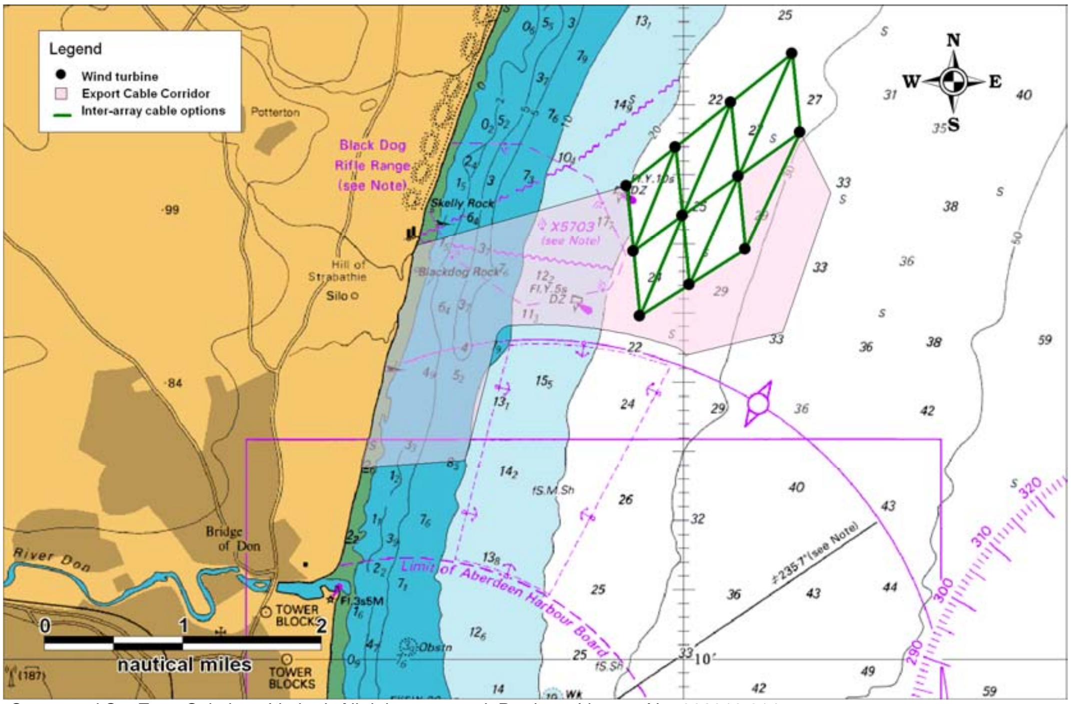

Figure 3.6 Cables associated with Wind Farm

The Rochdale envelope for the project states that the export and inter-array cables will be buried to a minimum depth of 0.6 and to a maximum depth of 3m.

4. MARINE NAVIGATIONAL MARKINGS

4.1 Introduction

Throughout the project marine navigational marking will be provided in accordance with the Northern Lighthouse Board requirements, which will comply with IALA Recommendation 0-139 on the Marking of Offshore Wind Farms and the additional requirements of MCA MGN 371(Ref. ii). It is also noted that there is a requirement to mark selected structures with lights for aviation as per Civil Aviation Authority (CAA) requirements.

NLB have advised that final marking and lighting recommendations will be made in a formal response through the Coast Protection Act 1949: Section 34 consultation process. This will now be implemented through the Marine Licence. All navigational marking and lighting of the site or its associated marine infrastructure will require the Statutory Sanction of the Northern Lighthouse Board prior to deployment.

4.2 Construction/Decommissioning

During the construction / decommissioning of the project, working areas will be established and marked in accordance with the IALA Maritime Buoyage System (MBS). In addition to this, where advised by NLB, additional temporary marking will be applied.

Notices to Mariners, Radio Navigational Warnings-NAVTEX and/or broadcast warnings as well as Notices to Airmen will be promulgated in advance of and during construction / decommissioning of any individual structure/project.

4.3 Marking of Individual Structures

The tower of every wind turbine will be painted yellow all around from the level of Highest Astronomical Tide (HAT) to 12m above HAT or the height of the Aid to Navigation, if fitted, whichever is greater.

As per the MCA requirements, each of the structures will be marked with clearly visible unique identification characteristics at a location that is easily and readily serviceable. The identification characteristics will each be illuminated by a low-intensity light, so that the sign is visible from a vessel thus enabling the structure to be detected at a suitable distance to avoid a collision with it. This will be such that under normal conditions of visibility and all known tidal conditions, they are clearly readable by an observer (with naked eye), stationed 3m above sea level, and at a distance of at least 150 m from the turbine. The light will be either hooded or baffled so as to avoid unnecessary light pollution or confusion with navigation marks.

4.4 Proposed Markings

The markings for the proposed EOWDC will be agreed in consultation with NLB. As per IALA guidelines it is likely that once fully developed:

- All corner towers will be marked as Significant Peripheral Structures (SPSs) and where necessary, depending on spacing, intermediate towers on each of the north, east and south facing boundaries will be marked as Intermediate Peripheral Structures (IPSs).

- In all the layouts, towers designated as SPSs are to exhibit Flashing Yellow 5 second (Fl Y 5s) lights of 5nm nominal range and omnidirectional fog signals with a character of 1 blast of 2 seconds duration every 30 seconds and an IALA usual range of 2nm. Towers designated as IPSs are to exhibit Fl Y 2.5s lights of 2nm nominal range.

- All the lights are to be visible to shipping through 360 degrees and if more than 1 lantern is required on a tower to meet the all round visibility requirement, then all the lanterns on that tower should be synchronised.

- All the lights are to be exhibited at the same height at least 12m above Highest Astronomical Tide (HAT) and below the arc of the lowest turbine blades.

- All the lights are to be exhibited at least at night and when the visibility is reduced to 2nm or less. Fog signals are to be sounded at least when the visibility is 2nm or less.

- All the structures in the boundary of the turbine towers are to be coloured yellow from at least HAT to the height of the lights (the equivalent height on the unlighted structures).

- Any lighting required for aeronautical purposes is to be shielded / arranged such that it is not visible to shipping. If this cannot be achieved, then the requirement will be considered as having been met if the aviation light is reduced to 10% of its peak intensity when the visibility is more than 5km.

Over the period of the site being developed the above may vary but all markings will be agreed with NLB in advance.

4.5 Superintendence and Management

Aberdeen Offshore Wind Farm Limited (AOWFL) will ensure that they have a reliable maintenance and casualty response regime in place such that the required availability targets are met.

5. CONSULTATION

5.1 Introduction

Extensive consultation on navigational issues has been carried out with stakeholders during the evolution of the proposed development. This section briefly summarises the key consultations.

5.2 Aberdeen Harbour

Several meetings have been held with Aberdeen Harbour, including the Harbour Master, over the past five years.

This has led to the changes in the site layout as identified in Section 3.3. Aberdeen Harbour officials also participated in the Hazard Review Workshop discussed below.

5.3 Marine Stakeholders Meetings

A number of consultation meetings have been held with maritime stakeholders during the course of the project, including presentations to the Marine Safety Forum.

More recently, a marine stakeholders meeting was held in Aberdeen on 18th March 2010. The meeting was attended by representatives of various marine stakeholders including Aberdeen Harbour, Craig Group, Gulf Offshore, Trico and Shell Marine.

Within this meeting, the main navigational concerns (associated with the previous layout) were highlighted as loss of anchorage, increased congestion and potential impact on navigational aids.

Further meetings were held on the 26th March and 12th April 2010 involving members of the project team, and aviation and marine stakeholders. From these meetings two optimal layouts were derived (Layouts 038 and 039).

Following this, a consultation document was circulated by the Marine Safety Forum on 10th May with both proposed layouts presented to gather their input (Ref. v). The response to this is quoted below as received on 17th May 2010.

> *"Following feedback we are able to give you our (MSF Steering Group) acceptance of either layout 38 or 39 as the footprint layout for the test facility. Please note we will be attending the risk assessment with a positive attitude to the windfarm on this basis. Should the layout revert to the previous more southerly positions we would then be forced to withdraw our agreement."*

Details on the workshop are provided in Section 12.

NorthLink Ferries operate passenger ferry services between Aberdeen and the Northern Isles (Kirkwall in Orkney and Lerwick in Shetland).

An initial meeting between AREG and NorthLink Ferries was held in Aberdeen on 15 January 2009. The purpose of the meeting was to discuss maritime safety issues associated with the proposed EOWDC.

NorthLink advised that they had two main safety concerns (based on the earlier 23 turbine layout (date)):

- Radar interference
- A navigational hazard, due to the pinching effect of loss of approach width. This would be particularly serious when traveling south with a northerly wind behind.

It was pointed out that radar interference was now a well understood issue which had been dealt with at many sites. On navigation it was agreed that routing issues would be discussed at a follow-up meeting during the risk assessment work.

Two further meetings were held onboard the NorthLink ferries *Hjaltland* and *Hrossey* in Aberdeen on 1 and 2 June 2010 following revision of the turbine layout. The Ferry Masters indicated the new layout was a vast improvement by moving to the north, away from the harbour entrance and anchorage area. The ferries normal passage plan keeps to the east of the current turbine layout, although it can vary in different wind conditions. If necessary the passage plan could be adjusted a few miles to the east without a major problem.

Radar interference was not considered to be a major issue based on past experience at other sites.

5.4 Scottish Fishermen's Federation (SFF)

Meetings have been held in Aberdeen with SFF to discuss the potential impact of the proposed EOWDC site on fishing vessels. No significant navigational issues were identified.

Further consultation on fisheries has been carried out as part of the Commercial Fisheries study (Chapter 7.7).

5.5 Hazard Review Workshop – Aberdeen

A hazard review workshop was held in Aberdeen on the 25 August 2010, hosted by Aberdeen Harbour. The purpose of the workshop was to identify and review the potential navigational hazards associated with the proposed development of the EOWDC.

More details on the workshop are provided in Section 12.

5.6 Other Consultation

Various consultation exercises have been carried out by the project over a number of years including several public events which allowed all stakeholders to contribute opinions on the proposals. This and other feedback was used in developing the current layout.

6. BASELINE ENVIRONMENT

6.1 Introduction

This section presents the following baseline information relating to navigation in the Aberdeen area:

- Ports
- Navigational Aids
- Sailing Directions
- Oil & Gas Infrastructure
- Military Exercise Areas
- Metocean data

6.2 Aberdeen Harbour

Aberdeen Harbour is the principal commercial port serving the northeast of Scotland with approximately 16,000 ship movements in 2009 handling approximately 4.5 million tonnes of imports and exports. The Port is the main marine support centre for the North Sea oil and gas industry. In addition to the oil and gas support services there are regular shipping services to Orkney, Shetland and Scandinavia via Ro-Ro services for passengers and cargo, with 142,468 passengers passing through the port in 2009 (Ref vi).

The Port also has a large modern fish market and although there are no commercial fisheries within the area of jurisdiction of Aberdeen Harbour or proximity, deep-sea fishing vessels and a number of locally registered potters land their catches at the Aberdeen fish market located at Palmerston Quay.

The nearest proposed turbine within the EOWDC site would be located over 2 nautical miles (nm) from the northern limits of Aberdeen Harbour.

A chart of the Aberdeen Harbour limit and main features is presented in Figure 6.1. There is a designated anchorage area just to the north of the Aberdeen Port boundary, which was established in the first half of 2010.

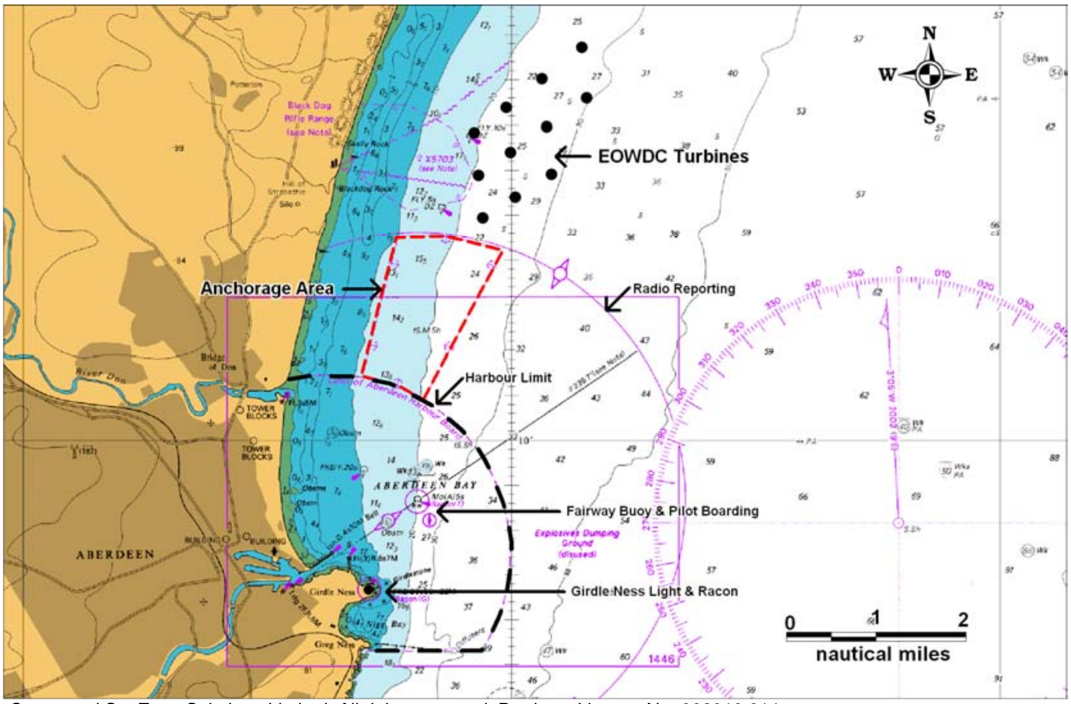

Figure 6.1 Overview of Aberdeen Harbour Limit

6.3 Port Facilities/Services

Aberdeen Harbour is a modern port with a state-of-the-art Marine Operations Centre.

Figure 6.2 Marine Operations Centre at Aberdeen Harbour Entrance

Facilities and services that assist in the safe navigation of shipping within the harbour include:

- Controlling depths & maximum vessel size
- Radar based vessel traffic services
- Pilotage
- Anchorage
- Navigational aids

More details are provided below.

6.3.1 Controlling Depths & Maximum Vessel Size

The maximum dimensions and size for vessels entering Aberdeen are quoted as:

- Length: 165m
- Beam: 26m
- Draught: 8.5m
- Largest Vessel (Tonnage): 18,500 GT

However, it is noted that there are a number of deep-water berths available within the harbour which are restricted by water depth based on mean low water springs (MLWS) and mean high water springs (MHWS) levels. The deep-water berths are given below:

- Atlantic Wharf is 137 m long with depth of 9.3m at MLWS and 13.0m at MHWS.
- Pacific Wharf is 205m long with 9.9m of water at MLWS and 13.6m at MHWS.
- Waterloo Quay West is 172m long with 9.9m of water at MLWS and 13.6m at MHWS.
- Regent Quay East is 255m long with 9.9m of water MLWS and 13.6m at MHWS.
- Telford Dock has 520m of berthing with 9.6m of water at MLWS and 13.3m at MHWS.
- Matthews Quay is 236 m long with 9.6m of water at MLWS and 13.3m at MHWS.

Berthing is also available in six areas within the harbour; the details of each are given in Table 6.1.

Table 6.1 Details of Berthing Locations in Aberdeen Harbour

Location	Area (ha)	Length of Quays (m)	Max depth of berths MLWS / MHWS (m)
Tidal Harbour	14.5	1,574	9.6/13.3
Albert Basin	8.5	1,525	8.4/13.6
River Dee (navigable area)	4.1	928	8.4/10.8

Location	Area (ha)	Length of Quays (m)	Max depth of berths MLWS / MHWS (m)
Dock	1.5	410	9.6/13.3
Upper Dock	2.0	429	6.6/10.3
Victoria Dock	8.5	1,500	9.9/13.6

6.3.2 Vessel Traffic Service (VTS)

All shipping movements in Aberdeen Harbour are controlled and monitored from the state-of-the-art Navigation Control Centre situated at the inner end of the North Pier.

The Centre operates continuously for 24 Hrs and is fitted with radar and VHF Radio (Channels 12 and 16). Masters and boat crews have to obtain permission from the Harbour Master before launching a vessel into the harbour waters, by contacting VTS on VHF Channel 12.

There are reporting procedures as well as reporting points for vessels as listed below:

Vessels Inward Bound:

(1) All vessels (except fishing and recreational craft) should send Aberdeen VTS 24hr prior to arrival (or give as much advance notice as possible) stating:

- Vessels name
- IMO number
- Length overall (LOA)
- Maximum draught
- Last port/location
- ETA
- Pilotage requirements
- Gross tonnage (GT)
- List of defects
- Cargo
- Agent

(2) All vessels (including fishing and recreational craft) must call Aberdeen VTS when 1hr from the Fairway light buoy, and confirm ETA and draught.

(3) All vessels (including fishing and recreational craft) must call Aberdeen VTS when 3nm from the Fairway light buoy to obtain permission to enter the Aberdeen VTS area. Fishing vessels and recreational craft should provide the information listed at (1) if required to do so.

(4) All vessels must maintain a continuous listening watch on VHF channel 12 when navigating within the Aberdeen VTS area.

(5) All vessels must report to Aberdeen VTS when in close vicinity to the Fairway light buoy in order to obtain authorization to enter the navigation channel.

(6) *Vessels within the area:*
(a) All vessels must maintain a continuous listening watch on channel 12.
(b) All vessels must report on anchoring or berthing
(c) All vessels must obtain authorisation from Aberdeen VTS before getting underway from anchor or leaving a berth.
(d) All vessels must report on leaving anchorage or berth

(7) Vessels Outward-Bound and Shifting Berth:
(a) All vessels must send ETD to Aberdeen VTS when known, message should also include:
(i) Draught
(ii) Where bound (next Port/Location/Berth)
(iii) All vessels must obtain authorisation from Aberdeen VTS prior to leaving berth.

All vessels must report to Aberdeen VTS when passing the reporting points I and B. All vessels, when required by VTS to do so, must report when passing Reporting Points A, C and D.

Table 6.2 VTS Reporting Points for Aberdeen Harbour (Note [1])

Reporting Point	Position	Remarks
I	3 nm from Fairway light buoy	Inward and Outward-Bound
B	Close vicinity to Fairway Lt buoy	Inward and Outward-Bound
A	57° 08.52' N, 002° 04.77' W	Entrance to Albert Basin
C	57° 08.63'N, 002° 04.85' W	Entrance to Victoria Dock (the Cut)
D	57° 08.42' N 02° 04.52' W	Entrance to Dee River

Note [1]: Vessels (in particular Offshore Support and Fishing Vessels) may be required to hold at these points.

For entry into the port, there are light signals that have the following meanings:

- A **GREEN** light - No entry into the Navigation Channel for vessels proceeding towards the Harbour.
- A **RED** light - No entry into the Navigation Channel for vessels proceeding to sea.
- A **GREEN** and **RED** light - No entry into the Navigation Channel for any vessel.

The traffic regulations as laid out in Ref. vii state:

The master of a vessel waiting within the limits of the port and harbour to enter the harbour shall so manoeuvre such vessel as to be at all times clear of the ordinary course of ships entering or leaving the harbour.

The master or owner of a vessel which is to enter the harbour shall, on the arrival of such vessel in Aberdeen Bay and before it approaches the harbour entrance, notify the harbour master of the intended entry of the vessel, giving the name of the vessel, the name of the master, the port or place from which the vessel has arrived and the draught of water of the vessel.

The master of a vessel shall not cause or permit such vessel to enter the navigation channel abreast of any other vessel or to overtake any other vessel in said channel, and every master shall keep his vessel at a distance of not less than 70m behind any other vessel proceeding in the same direction ahead of his vessel in the said channel except when towing or being towed.

The master of a vessel shall not cause or permit such vessel to proceed in any part of the harbour at a speed in excess of 5 knots over the ground.

6.3.3 Pilotage & Tugs

All vessel movements within Aberdeen Harbour are well managed by Port Control with set pilotage procedures. Aberdeen has compulsory pilotage for vessels of 60 m and over in length. However, for vessels with an operational bow thruster this limit is increased to 75 m.

The majority of vessels entering Aberdeen Harbour have bow and stern thrusters and are highly manoeuvrable. When pilotage is required the Pilot will normally board vessels in the vicinity of the Fairway Buoy. There are two pilot vessels in operation at Aberdeen, the *Sea Haven* and *Sea Shepherd*, which are show in Figure 6.3 and Figure 6.4.

Figure 6.3 Pilot Vessel *Sea Haven*

Figure 6.4 Pilot Vessel *Sea Shepherd*

It is noted that two tugs are available within Aberdeen Harbour for towing vessels into and out of the port.

6.3.4 Anchorage

Aberdeen Bay is free of danger and has a regular sandy bottom, therefore can be used as a long term temporary anchorage.

A designated anchorage area to the north of Aberdeen Bay was established in 2010.

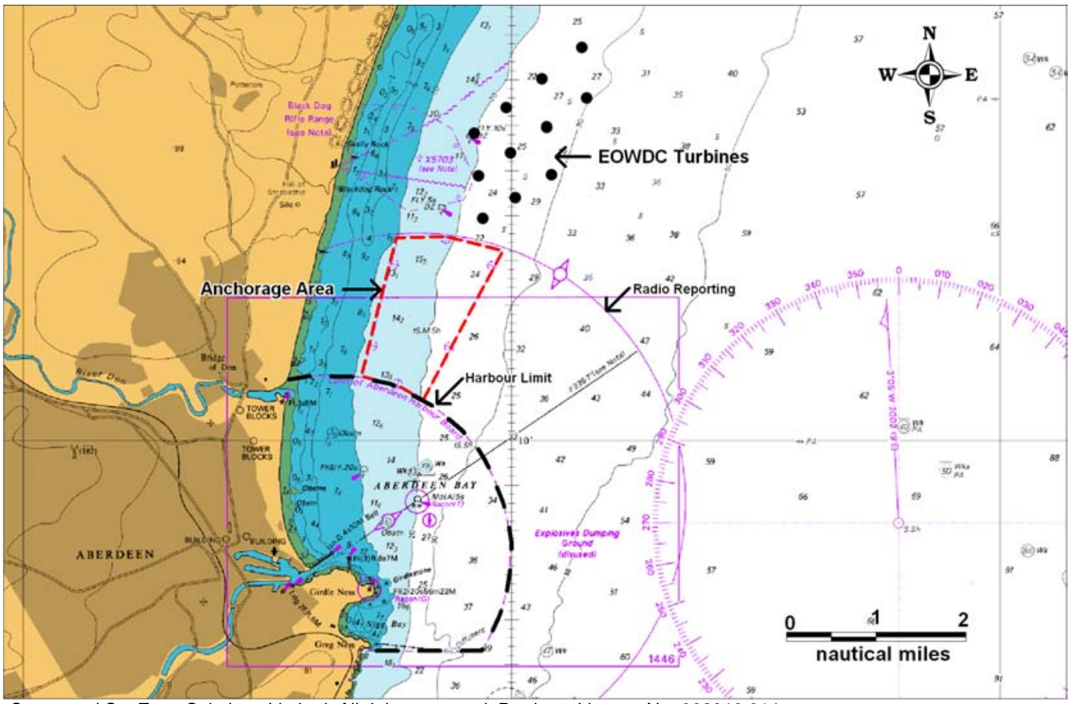

Figure 6.5 Official Anchorage Area to the North of Aberdeen Bay

A detailed analysis of anchoring within Aberdeen Bay is presented in Section 8.6.

6.4 Navigational Aids

A plot of the principal navigational aids within 15nm of Aberdeen Bay is presented in Figure 6.6, with a detailed plot of Aberdeen Bay presented in Figure 6.7.

The principal landmarks are those listed in Admiralty Sailing Directions for the area (Ref. vii). The buoy positions are taken from Admiralty Charts of the area.

The Fairway Buoy (Racon) is the main navigational aid approximately 1 mile from Aberdeen Harbour's South Breakwater.

Other buoys in the vicinity of the Aberdeen Bay are generally located along the coastline. The closest buoys are approximately 4nm and 5nm, respectively, to the north of Aberdeen Bay, marking the limits of a military practice firing range at Blackdog. Other main aids to navigation are located at Stonehaven Harbour approximately 14nm south and at The Skares off Cruden Bay approximately 15nm north.

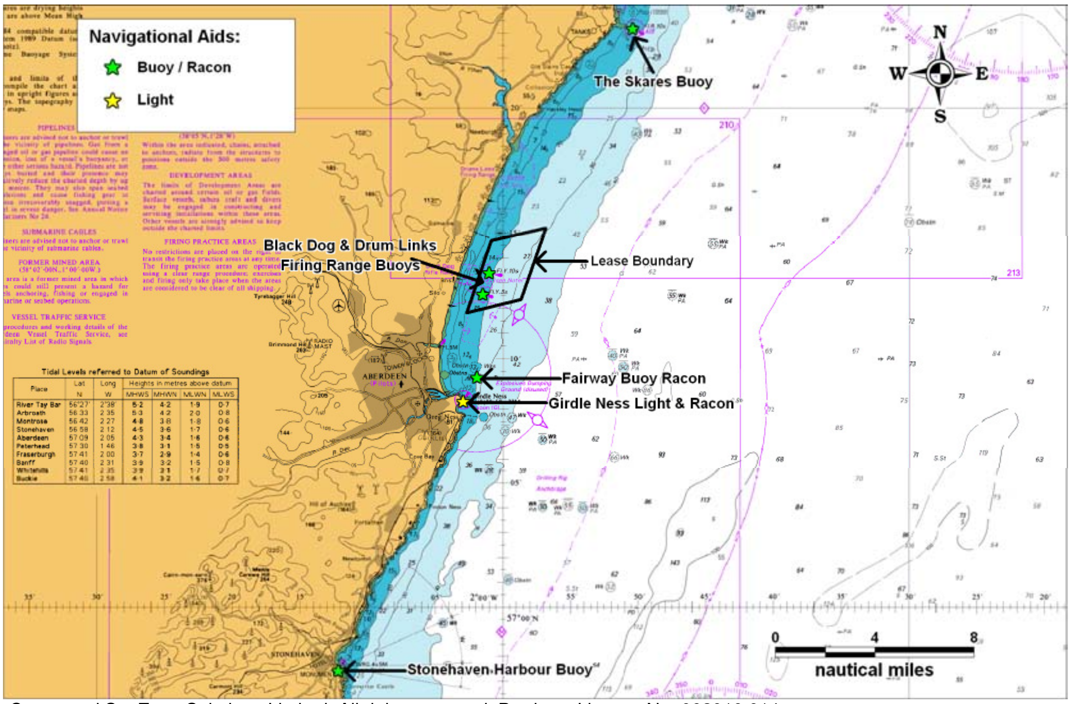

Figure 6.6 Navigational Aids along the North East Coast relative to Aberdeen

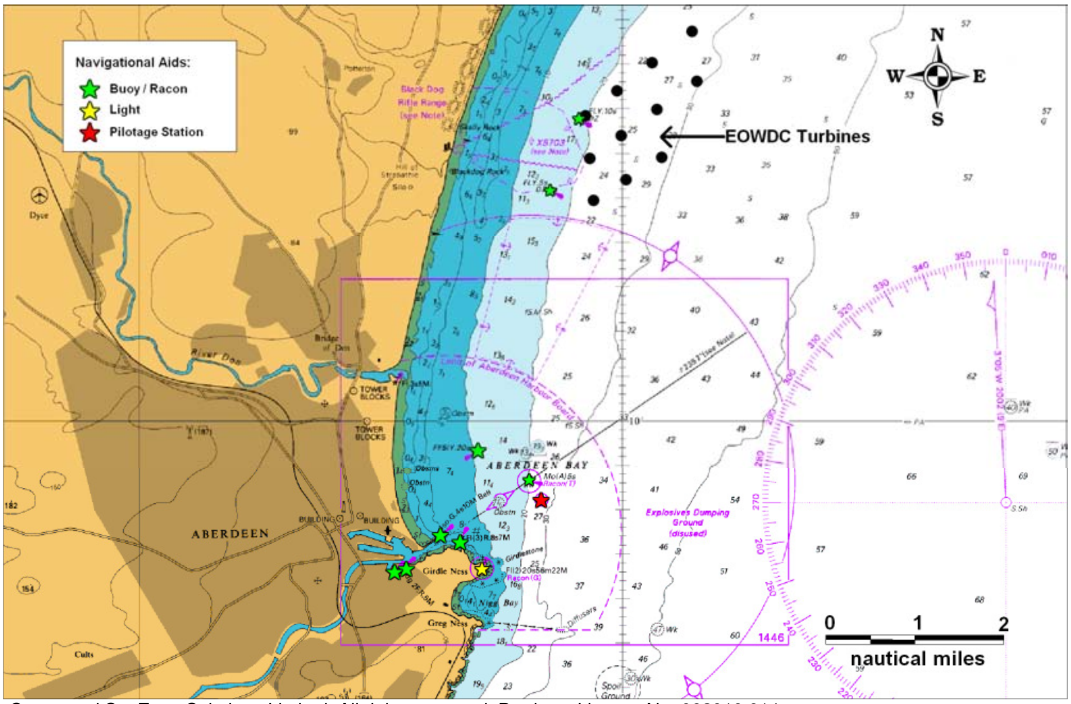

Figure 6.7 Navigational Aids in the vicinity of Aberdeen Bay

6.5 Sailing Directions

Sailing directions for the area are presented in the North Sea (West) Pilot (Ref. vii). A plot of the routes for vessels bound from Rattray Head to Isle of May is presented in Figure 6.8.

The arrows are not accurate if superimposed on a chart but they illustrate the general passages used by ships. A description of the two routes passing the site is given below.

- (3.43) From a position E of Buchan Ness (57° 28' N, 1° 46' W) the route leads SSW for a distance of 22 miles to the Fairway Light-buoy 1 mile NE of the entrance to Aberdeen Harbour.
- (3.86) From a position E of Girdle Ness (57° 08' N, 2° 03' W) the coastal route leads SSW to a position E of Stonehaven.

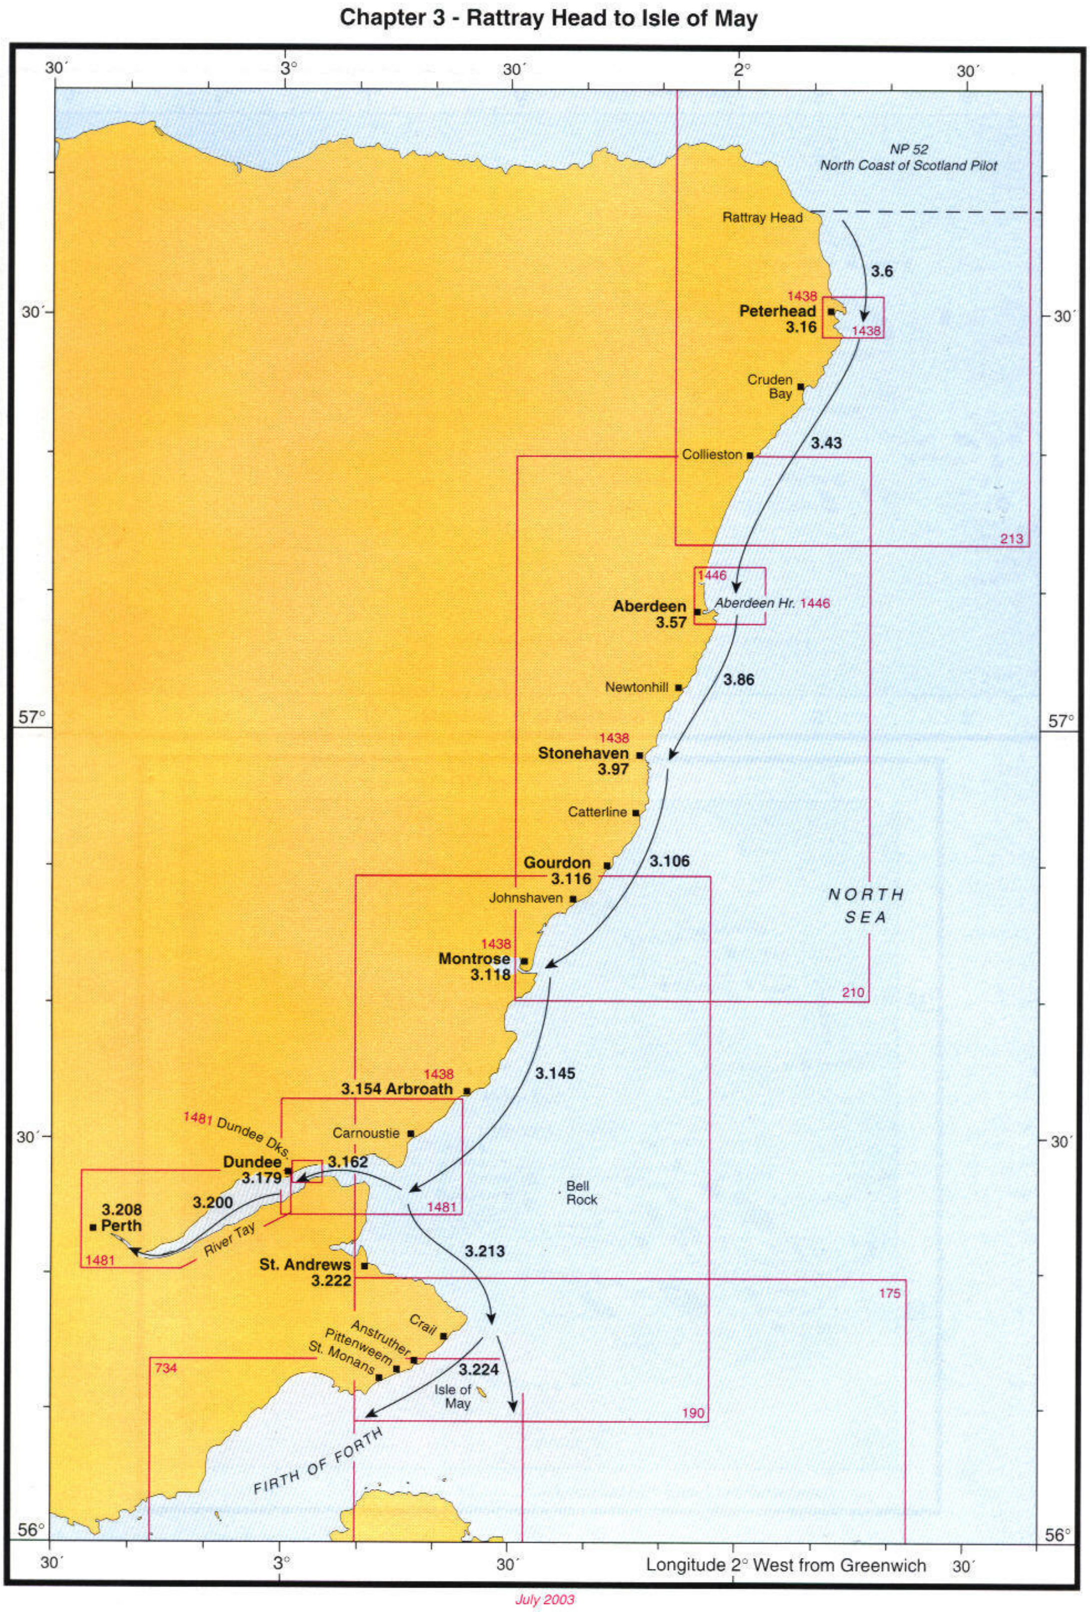

Figure 6.8 Routes from Rattray Head to Isle of May (Ref. vii)

6.6 Wrecks

An assessment of the offshore archaeology has been carried out as part of this ES to identify wrecks and archaeological sites of interest in the area. This identified a single wreck with a height of 0.7m within the area. Further details can be found in the Offshore Assessment Archaeology Section of the ES.

6.7 Oil & Gas Infrastructure

The licence blocks in the area of the proposed EOWDC are presented in Figure 6.9.

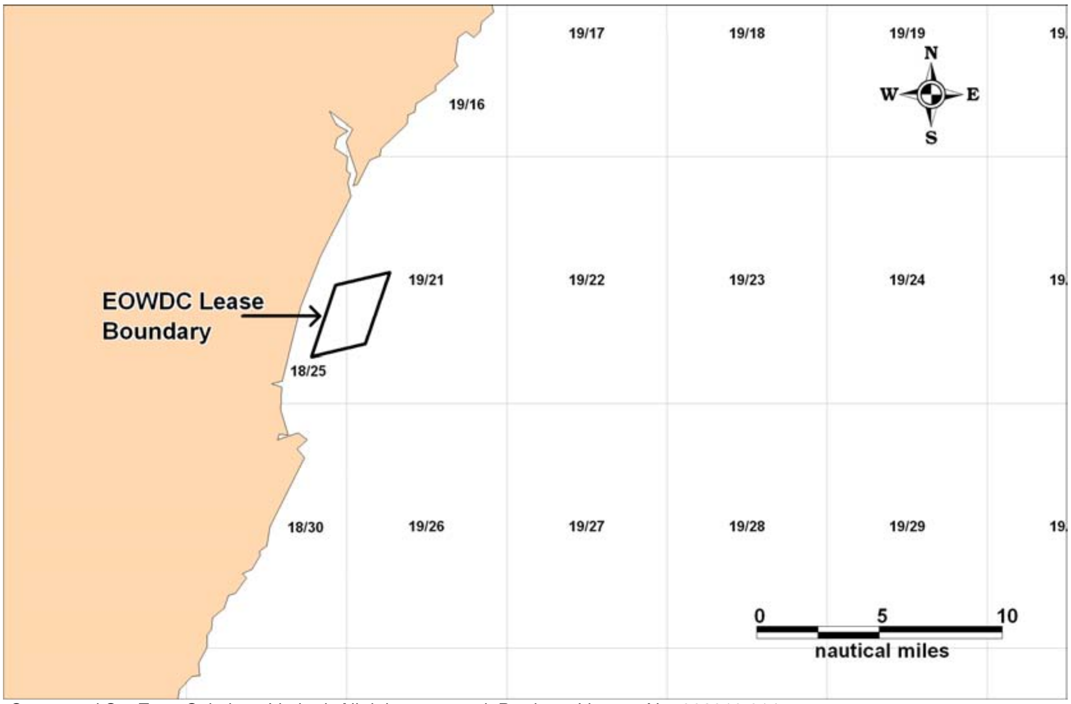

Figure 6.9 Oil & Gas UKCS Blocks, Installations and Licence Areas near Aberdeen

The proposed site is mostly within UKCS Block 19/21 which was on offer as part of the 26th round of UKCS licensing. This block has never previously been licensed and at the moment there is no operator for this block. Block 18/25 which contains part of the EOWDC site was not available due to the MOD military practice area at Blackdog and Drums Links.

The nearest existing offshore surface installation is at the Buzzard Field which is approximately 47nm to the northeast of the site which is remote from the site, beyond the extents of the Figure 6.9.

6.8 Exercise Areas

There is a rifle firing range at Blackdog which borders the western edge of the proposed EOWDC site, and is marked with Danger Zone (DZ) Buoys, as shown in Figure 6.10.

No restrictions are placed on the right to transit the Blackdog firing practice area at any time and they operate a clear range procedure with exercises only taking place when the areas are clear of shipping. Red flags or red lights are displayed to indicate that the area is in use.

The Drums Links military firing range is located approximately 1.7nm to the north of the proposed EOWDC site; this area uses the same procedures as Blackdog, whereby firing will only take place when the area is clear of shipping, as firing takes place seaward. There is also the central Managed Danger Area (MDA), which is a military practice zone for high altitude RAF training exercises and is located approximately 6.7nm to the east of the proposed EOWDC site.

Figure 6.10 Military Practice Areas relative to Site

6.9 Metocean Data

6.9.1 Introduction

This section presents Metocean statistics for the area of the proposed EOWDC site which have been used as input to the risk assessment.

According to the Admiralty Sailing Directions (Ref. vii), the west North Sea region enjoys a generally mild climate.

Rainfall is not considerable, and there is little variation throughout the year. It is frequently cloudy throughout the year; however, the winter months are more susceptible to overcast skies.

Fog (or haar) occasionally affects the east cost of the UK, particularly in the north.

6.9.2 Wind

The wind data presented here has been taken from recordings made at Dyce, Aberdeen (Ref.vii).

The wind direction distribution is presented in Figure 6.11 based on 20 to 30 years observations between 1960 and 2002. It can be seen that the predominant wind direction is from the south.

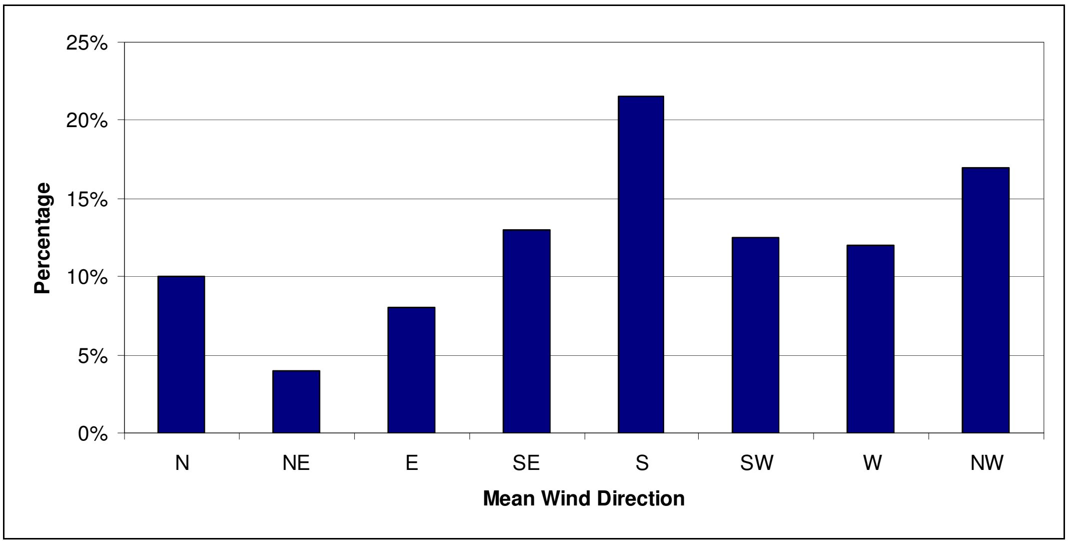

Figure 6.11 Average Annual Wind Direction Distribution

Gales are more common in the winter months, although they still may occur during the summer with the average wind speed recorded over a twenty year period between 10 and 11 knots (height above mean sea level of 65m).

6.9.3 Visibility

Historically, visibility has been shown to have a major influence on the risk of ship collision.

Visibility data was obtained from Dyce, Aberdeen. The number of days with fog per month over 20 years of data is presented in Figure 6.12.

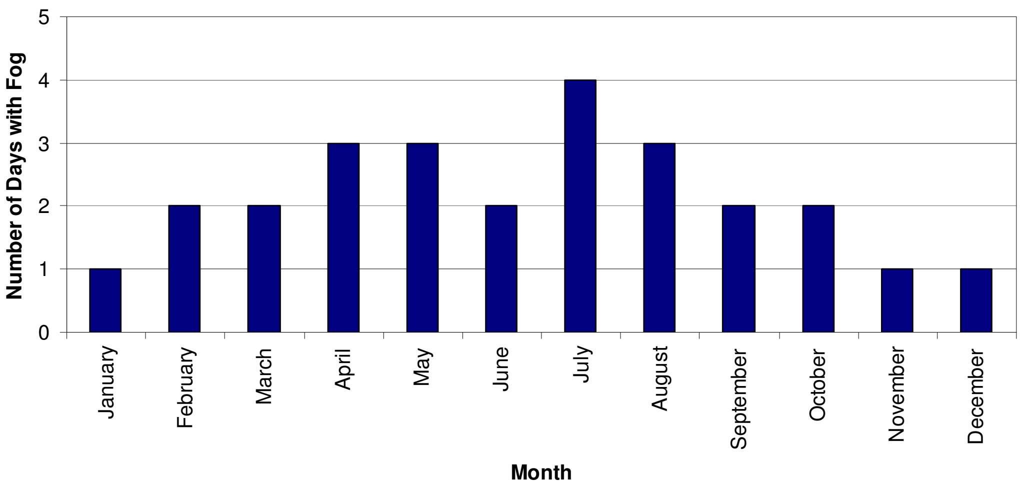

Figure 6.12 Monthly Distribution of Days with Fog (1983-2002)

It can be seen from the above figure that fog is more common between April and August and occurs less frequently from November to January.

6.9.4 Tide

A description of the tidal streams in the general area is provided below (Ref. vii):

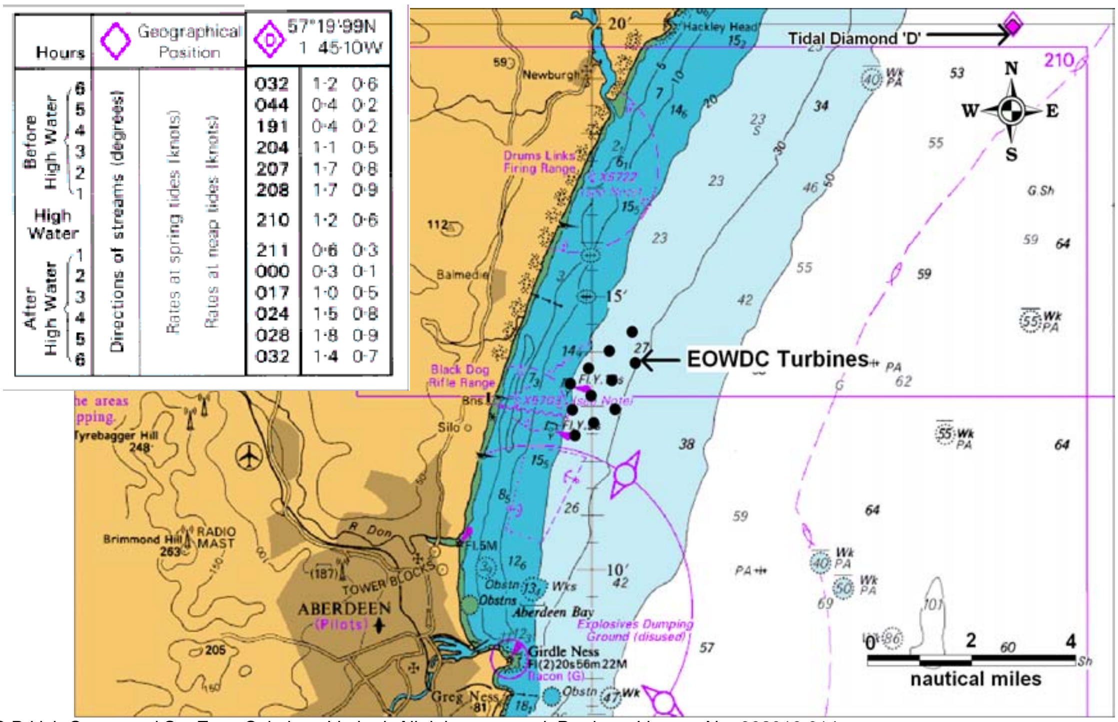
> *The offshore stream runs generally north and south from Rattray Head to Bells Rock and tidal streams in the North Sea generally run N/S parallel to the east coast of the UK.*
>
> *However, as the entrance to Aberdeen is approached the streams heading south become more easterly and the streams running north become more westerly and the tidal stream runs SE/NW across the approach to Aberdeen.*

Tidal levels for Aberdeen above Chart Datum (CD) are presented below.

Table 6.3 Tidal Levels above Chart Datum at Aberdeen

Tidal Level	Height above Chart Datum
Highest Astronomical Tide (HAT)	4.9m
Mean High Water Springs (MHWS)	4.3m
Mean High Water Neaps (MHWN)	3.4m
Mean Sea Level (MSL) (approx.)	2.6m
Mean Low Water Neaps (MLWN)	1.7m
Mean Low Water Springs (MLWS)	0.6m
Lowest Astronomical Tide (LAT)	0.1m

Admiralty Chart 213 (Tidal Diamond "D" approximately 10nm NE of the EOWDC site - Ref. viii) indicates that currents in the area set in a generally SSW direction on the flood and NNE direction on the ebb, with a peak spring tidal rate of 1.8 knots and peak neap rate of 0.9 knots. This has been considered within the drifting scenario modelling for this development (Section 13).



Hours		Directions of streams (degrees)	Rates at spring tides (knots)	Rates at neap tides (knots)
Geographical Position		◇D 57°19'·99N 1 45·10W		
Before High Water	6	032	1·2	0·6
	5	044	0·4	0·2
	4	191	0·4	0·2
	3	204	1·1	0·5
	2	207	1·7	0·8
	1	208	1·7	0·9
High Water		210	1·2	0·6
After High Water	1	211	0·6	0·3
	2	000	0·3	0·1
	3	017	1·0	0·5
	4	024	1·5	0·8
	5	028	1·8	0·9
	6	032	1·4	0·7

Figure 6.13 Tidal Stream Data for Aberdeen Bay (Tide Point "D")

7. MARITIME INCIDENTS

7.1 Introduction

This section reviews maritime incidents that have occurred in the vicinity of the proposed EOWDC site in recent years.

The analysis is intended to provide a general indication as to whether the area of the proposed development is currently low or high risk in terms of maritime incidents. If it was found to be a particularly high risk area for incidents, this may indicate that the development could exacerbate the existing maritime safety risks in the area.

Data from the following sources has been analysed:

- Marine Accident Investigation Branch (MAIB)
- Royal National Lifeboat Institution (RNLI)

(It is noted that the same incident may be recorded by both sources.)

7.2 Marine Accident Investigation Branch (MAIB)

All UK-flagged commercial vessels are required to report accidents to MAIB. Non-UK flagged vessels do not have to report unless they are within a UK port/harbour or within UK 12 nm territorial waters and carrying passengers to or from a UK port (including those in inland waterways). However, the MAIB will record details of significant accidents of which they are notified by bodies such as the Coastguard, or by monitoring news and other information sources for relevant accidents. The MCA, harbour authorities and inland waterway authorities also have a duty to report accidents to MAIB.

The locations[1] of accidents, injuries and hazardous incidents reported to MAIB within 10nm of the proposed EOWDC turbines between January 1994 and March 2010 are presented in Figure 7.1, colour-coded by type. (It is noted that several incidents may have taken place in coastal areas around Aberdeen Bay and therefore a symbol may represent more than one incident.)

[1] MAIB aim for 97% accuracy in reporting the locations of incidents.

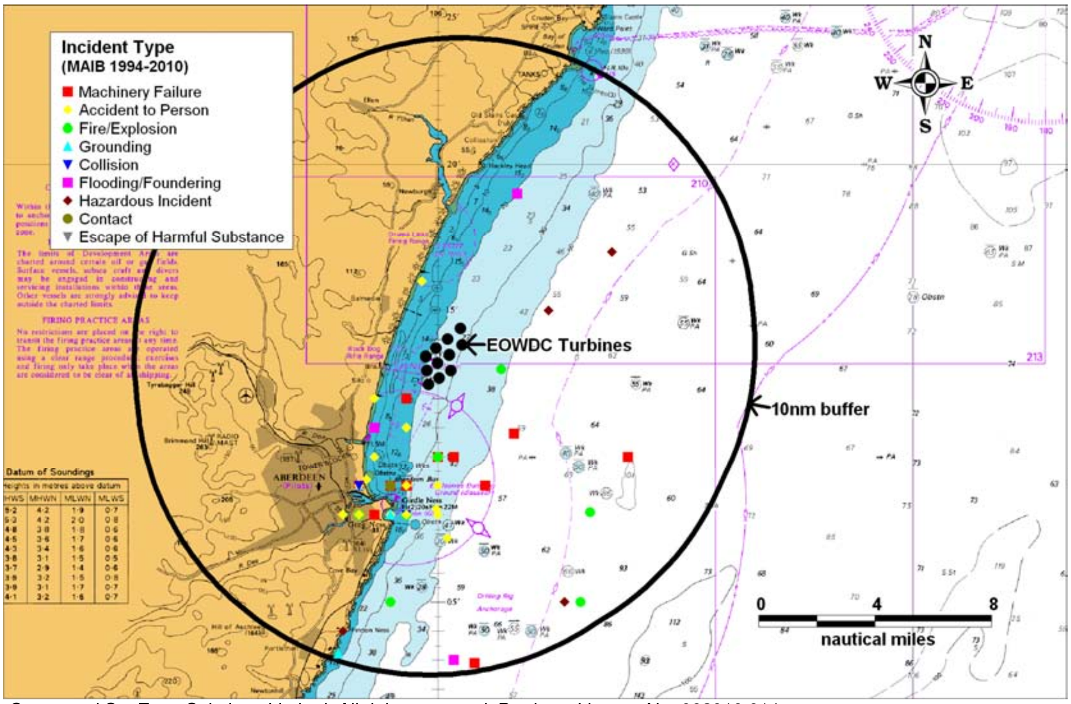


Figure 7.1 MAIB Incident Locations by Type within 10nm of EOWDC Turbines

A total of 162 incidents were reported in the area, corresponding to an average of 9-10 per year. The majority of the incidents occurred in and around Aberdeen Harbour. The distribution by incident type and year is presented in Figure 7.2 and Figure 7.3, respectively.

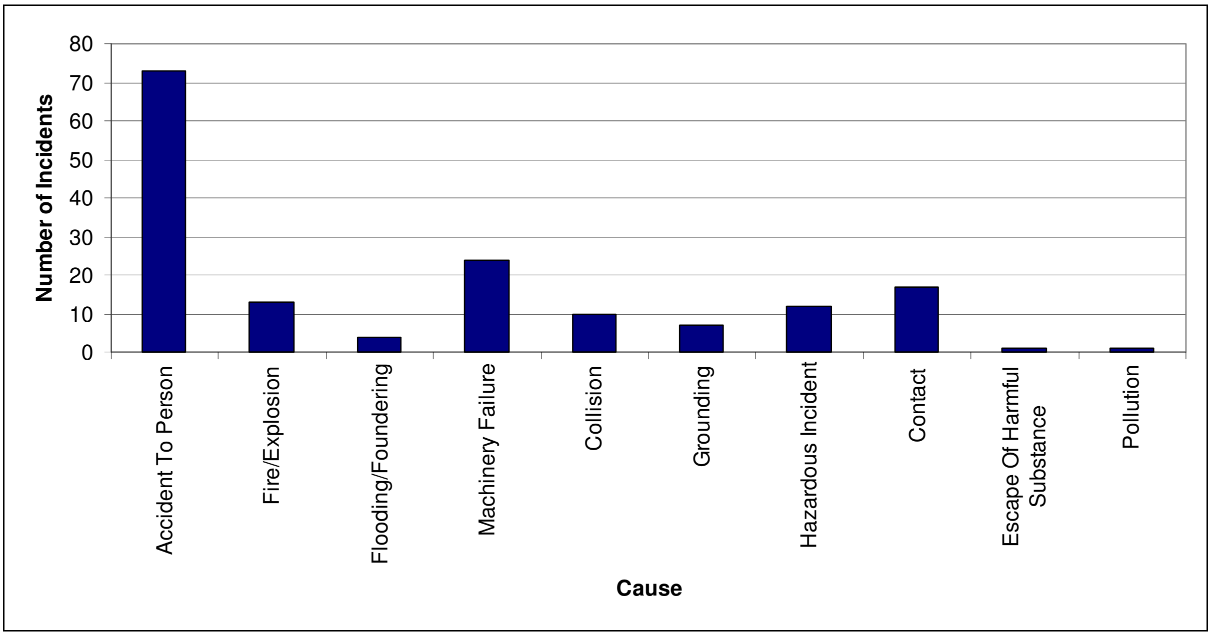

Figure 7.2 MAIB Incidents by Type within 10nm of EOWDC turbines (1994-2010)

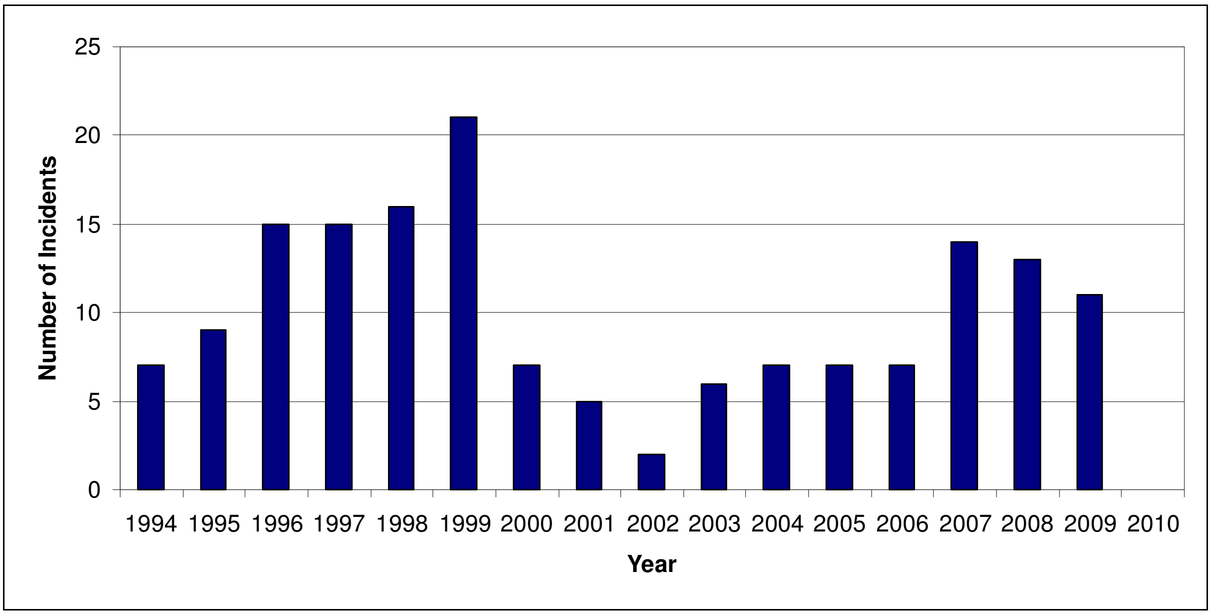

Figure 7.3 MAIB Incidents by Year within 10nm of EOWDC Turbines (1994-March 2010)

The most common incident type recorded within 10nm of the site boundary was accident to person. 1999 was the year with the most recorded incidents with 21 incidents reported during this year. It is noted that 2010 data was obtained up to March and there were no incidents recorded during this period.

There were no incidents reported within the EOWDC turbine locations. The closest incident to the proposed turbines was a machinery failure approximately 0.9nm to the southwest of the most southern turbine on 17 February 2007. The incident involved a non-commercial pleasure craft which broke down and had no working radio. After a considerable search the vessel was located and towed to port with no major damage reported.

Five collisions were recorded within 10 nm of the proposed EOWDC turbines, all within the harbour. Details are as follows:

1. On 31 May 1996 two offshore supply boats collided. Both vessels suffered material damage but no injuries or casualties were reported. One of the vessels was manoeuvring in Aberdeen Harbour and contacted the other vessel which was secured at berth.
2. On 2 November 1998 two anchor handling tug supply boats collided when a manoeuvring vessel collided with a berthed vessel due to a fault in pitch overload. The earth fault was subsequently found and eliminated meaning only material damage was caused to both vessels.
3. On 28 February 1999 an offshore support vessel suffered minor damage after colliding with scaffolding hung off a berthed vessel. This happened while manoeuvring alongside due to a navigational misjudgement.

4. On 30 June 1999 a commercial vessel collided with another berthed vessel after failing to respond to the controls quickly enough when approaching the berth. The system was operating correctly but with a new master and pilot the orders were not given in time. This caused material damage to the colliding vessel.
5. On 10 November 2000 a pilot boat collided with a commercial vessel due to a delay in engine control. The mechanical fault was investigated and rectified and no damage was reported.

None of the reported collisions reported any injuries or fatalities. There were no reported MAIB collision incidents from November 2000 onwards.

7.3 Royal National Lifeboat Institution (RNLI)

Data on RNLI lifeboat responses within 10nm of the EOWDC turbines in the ten-year period between 2000 and 2009 have been analysed. A total of 173 launches were recorded by the RNLI (excluding hoaxes and false alarms).

Figure 7.4 presents the geographical location of incidents colour-coded by casualty type. It can be seen that the vast majority occurred near the coast, with relatively few further out to sea. The area of interest includes various stretches of beach.

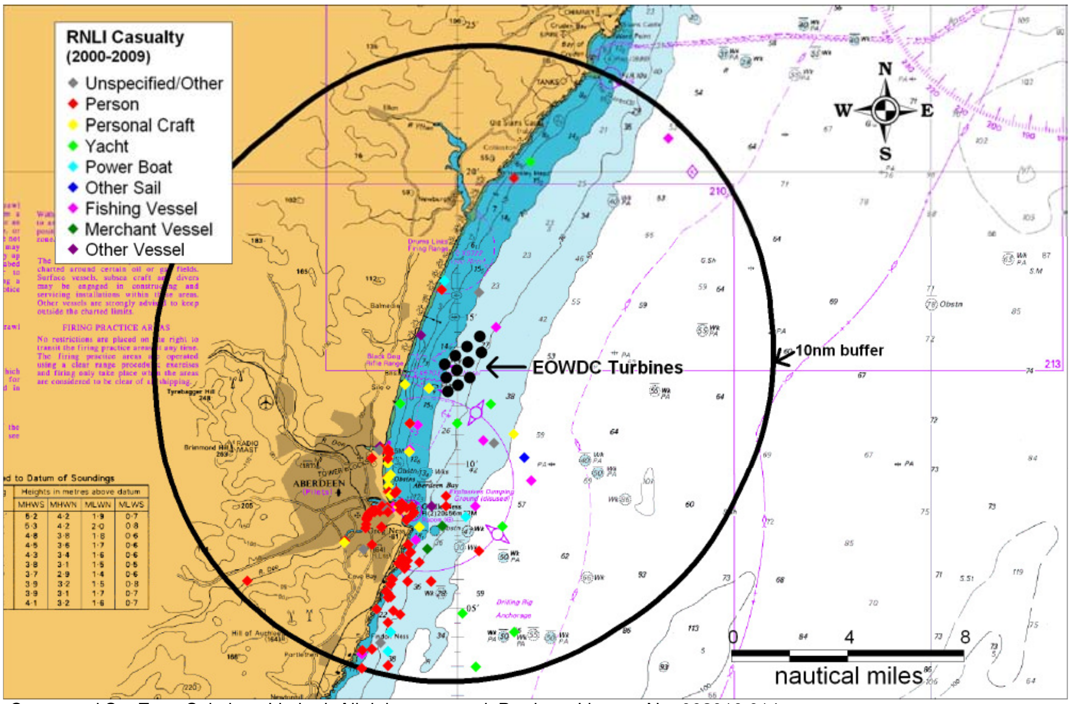

Figure 7.4 RNLI Incidents by Casualty Type within 10nm of EOWDC Turbines

The overall distribution by casualty type is summarised in Figure 7.5. People were the most common casualty type involved, responsible for 60% of RNLI launches.

Personal craft accounted for 12% of all incidents and fishing vessels accounted for 10% with various other vessel types making up the remainder of incidents.

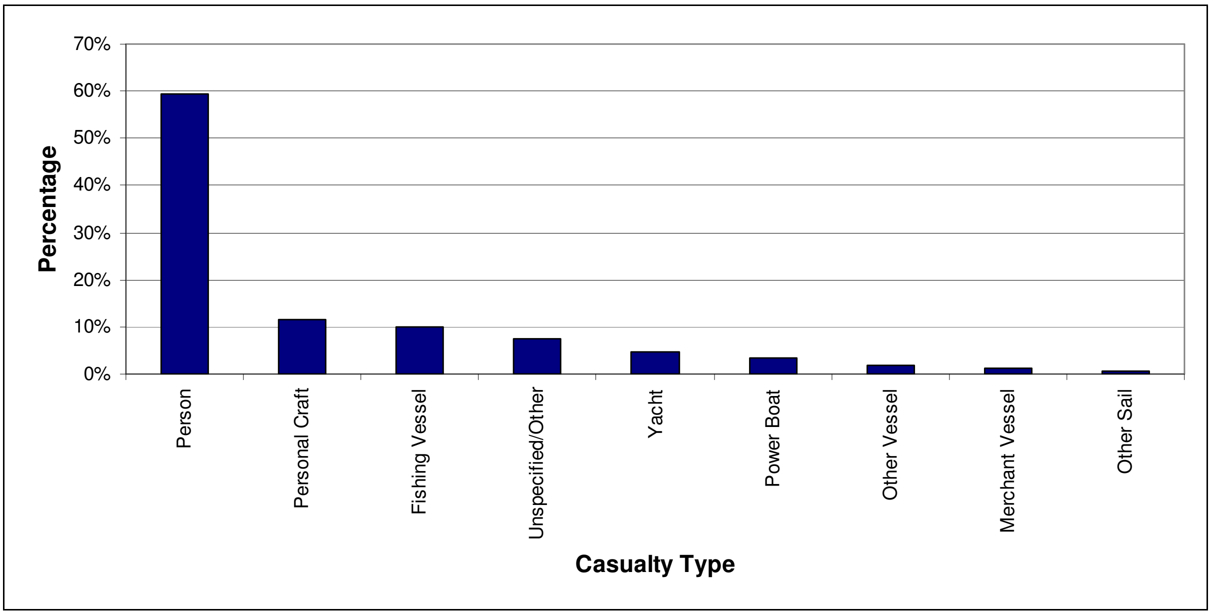

Figure 7.5 RNLI Incidents by Casualty Type within 10nm of EOWDC Turbines (1998-2007)

A chart of the incidents by cause is presented in Figure 7.6.

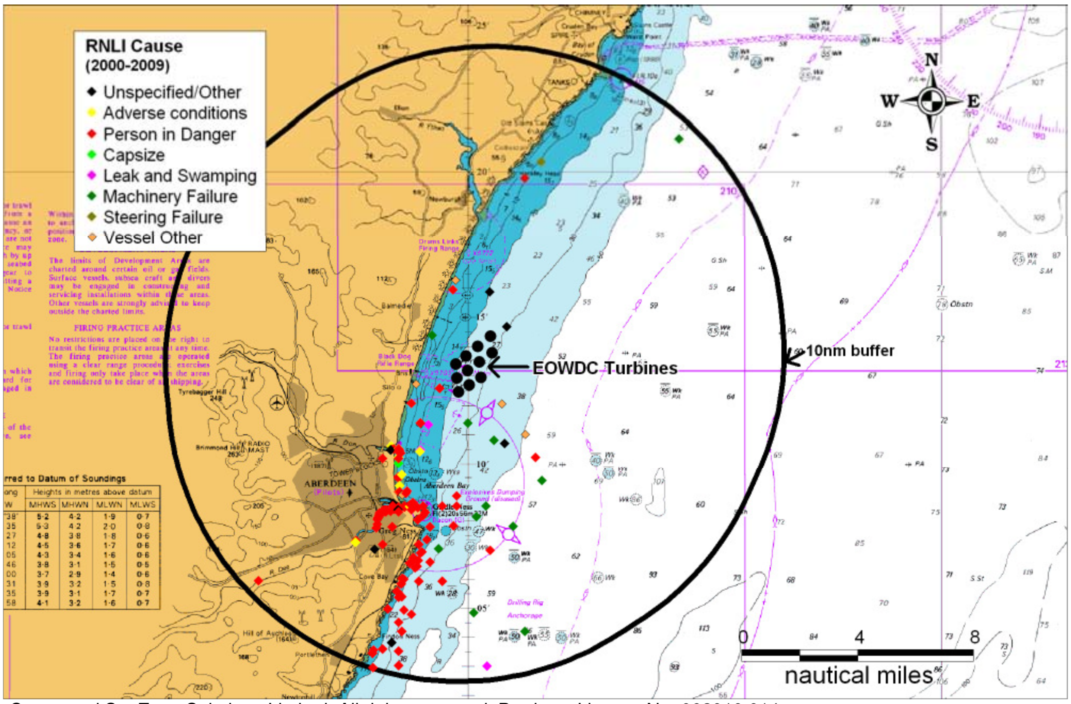

Figure 7.6 RNLI Incidents by Cause within 10nm of EOWDC Turbines

The reported causes are summarised in Figure 7.7. The main cause was "Person in Danger" contributing three-quarters of all incidents.

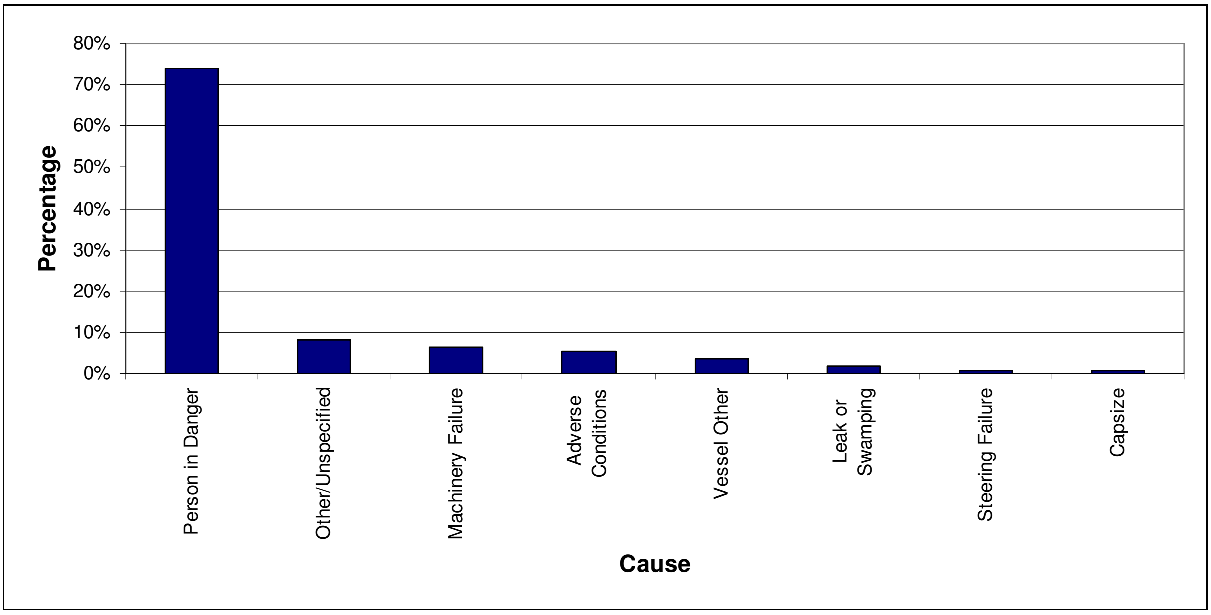

Figure 7.7 RNLI Incidents by Cause within 10nm of EOWDC Turbines (1998-2007)

The annual rate of incidents in the past ten years is summarised in Figure 7.8. The year with the most incidents was 2000.

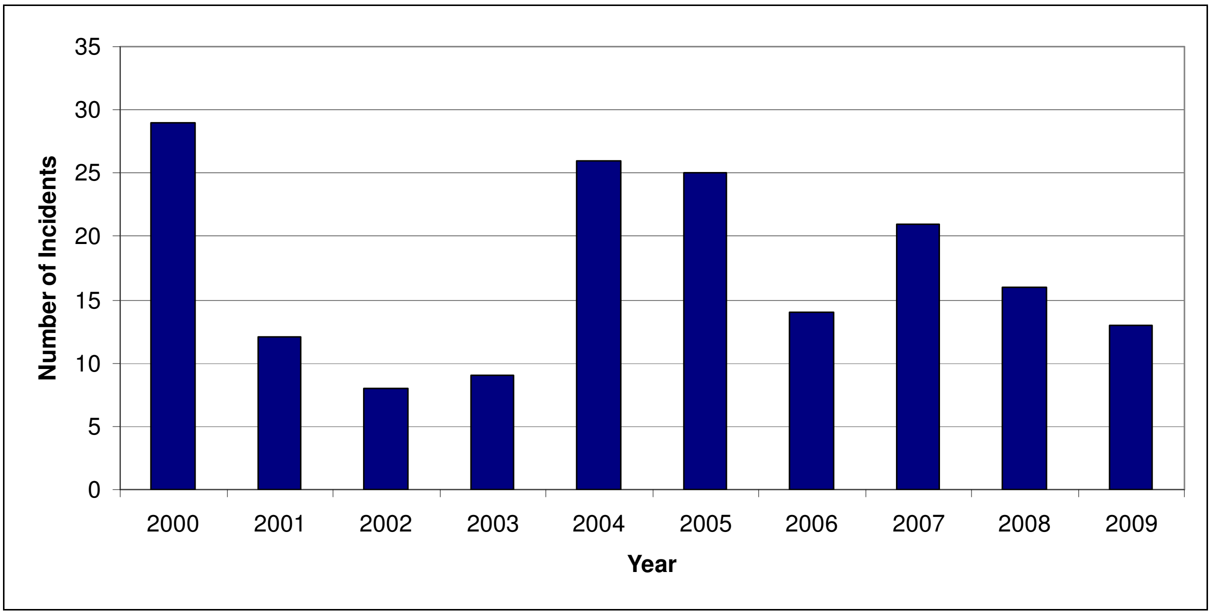

Figure 7.8 RNLI Incidents by Year within 10nm of EOWDC Turbines (1998-2007)

The stations and types of lifeboat responding to incidents (ALB = all-weather lifeboat and ILB = inshore lifeboat) are illustrated in Figure 7.9.

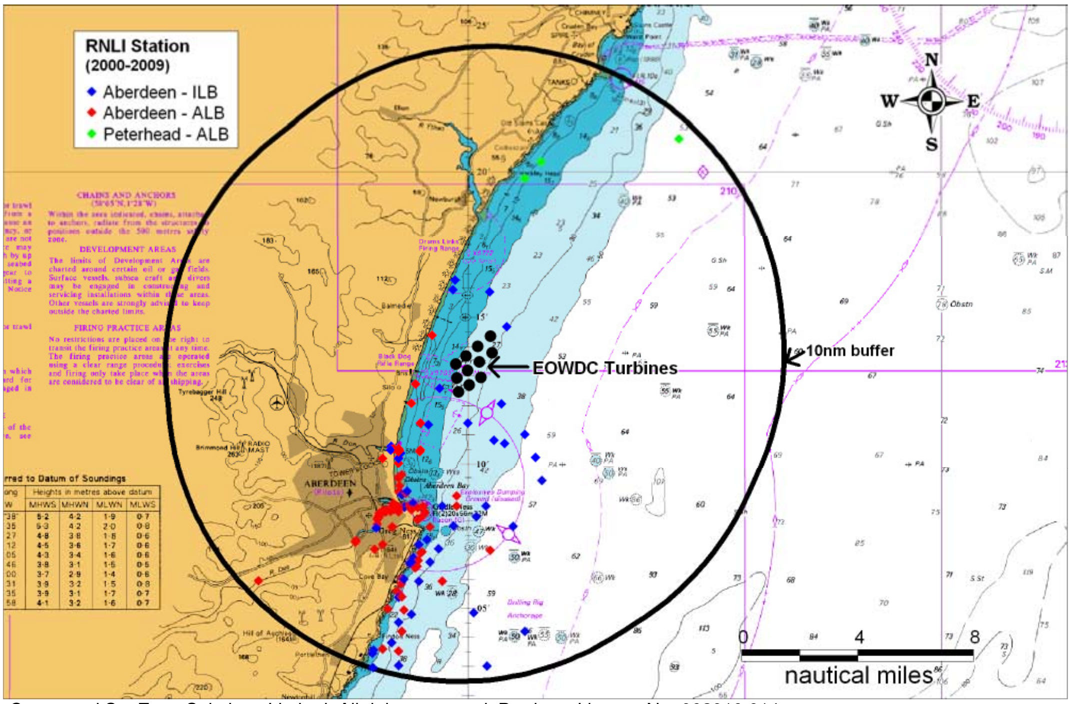

Figure 7.9 RNLI Incidents by Station within 10nm of EOWDC turbines

It can be seen that incidents away from the coast tended to be answered by the all weather lifeboat based in Aberdeen. The inshore lifeboat from Aberdeen tended to respond to calls closer to the coast and the Peterhead all weather lifeboat attended calls further to the north.

There were no incidents responded to by the RNLI within the proposed EOWDC turbine locations between 2000 and 2009.

7.4 Conclusions

Based on the review of incidents, it can be seen that the proposed EOWDC site and its immediate vicinity has experienced a relatively low rate of accidents in recent years. Most incidents in the area have occurred on the coast in and around Aberdeen.

8. MARITIME TRAFFIC SURVEYS

8.1 Introduction

This section summarises the results of the maritime traffic surveys carried out from Girdle Ness Lighthouse in Aberdeen, using a combination of shore-based radar, AIS and visual observations.

Further analysis of survey vessel types according to the DECC Methodology classification (Ref. i) is presented in Appendix B.

8.2 Survey Details

Four 14-day traffic surveys (total of 56 days) were carried out during the following periods:

1. 24 March – 7 April 2009.
2. 21 September – 5 October 2009.
3. 9 April – 23 April 2010.
4. 1 November – 15 November 2010.

(Note: A fifth survey has been carried out between18th February and 4th March 2011 (Ref. ix). Due to it being conducted recently, this has not been fully reported within the NRA but the findings of the survey were well-aligned with the previous four surveys.)

Full details of the survey analyses are presented in separate reports prepared by Anatec (Ref.x, xi, xii, and xiii).

The radar was set up at Girdle Ness Lighthouse (57° 08'.364 N, 2° 02'.916 W) giving good coverage to the north and Aberdeen Bay, including the harbour entrance. The survey location relative to the proposed EOWDC site is shown in Figure 8.1.

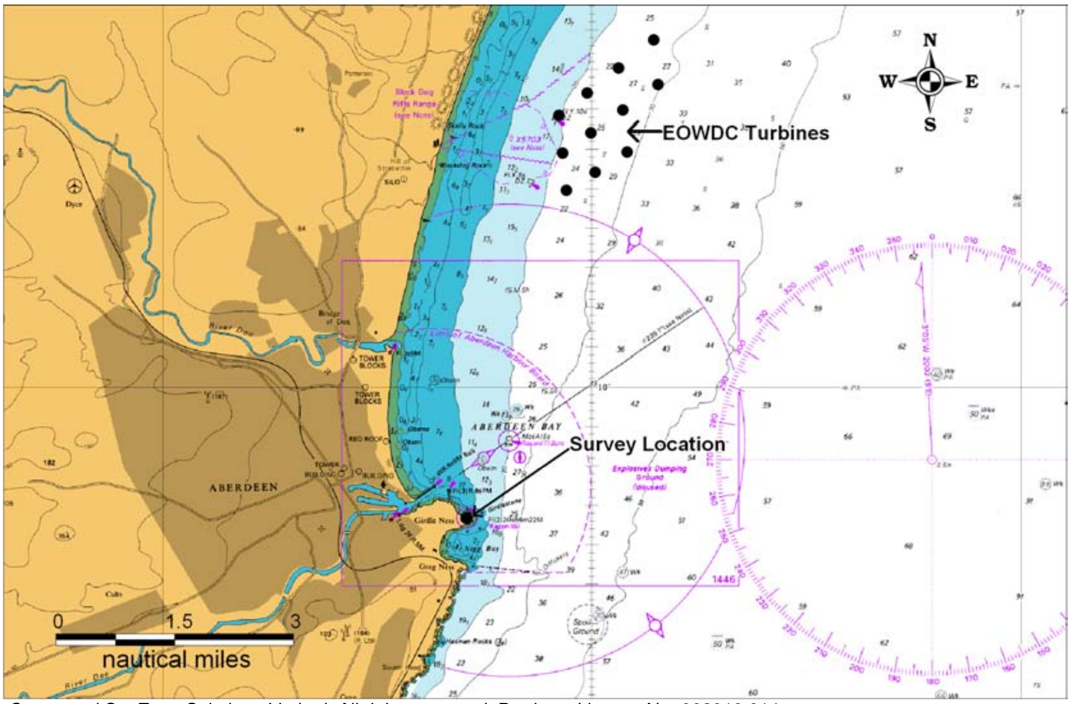

Figure 8.1 Chart Overview of the Survey Location

Figure 8.2 presents the equipment setup at the site.

Figure 8.2 Radar Scanner located next to Girdle Ness Lighthouse

The surveys covered a full range of tidal and weather conditions.

8.3 Survey Analysis

The following filters were applied to the survey data collected in each survey period:

- Removal of tracks more than 20 nm from the survey location.
- Removal of tracks wholly within harbour, i.e., berthed for the entire survey.
- Removal of Aberdeen Harbour pilot vessels.

Plots of the tracks by type recorded on radar and AIS during each fortnight are presented below.

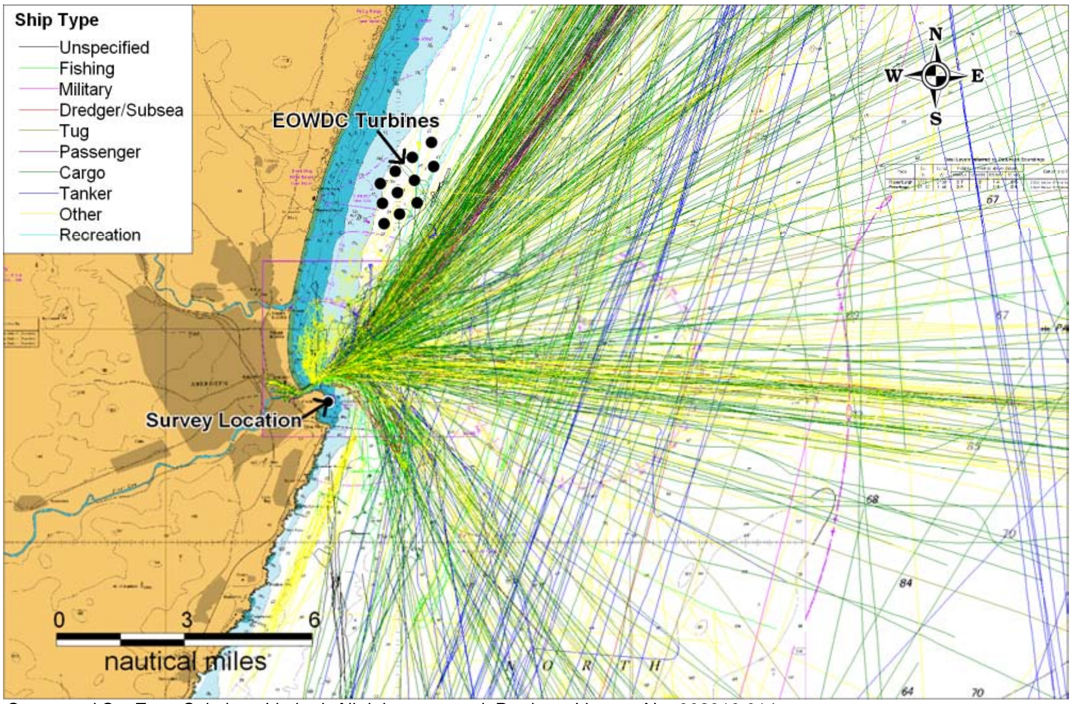

Figure 8.3 Survey 1: 24 March – 7 April 2009 (AIS & Radar tracks)

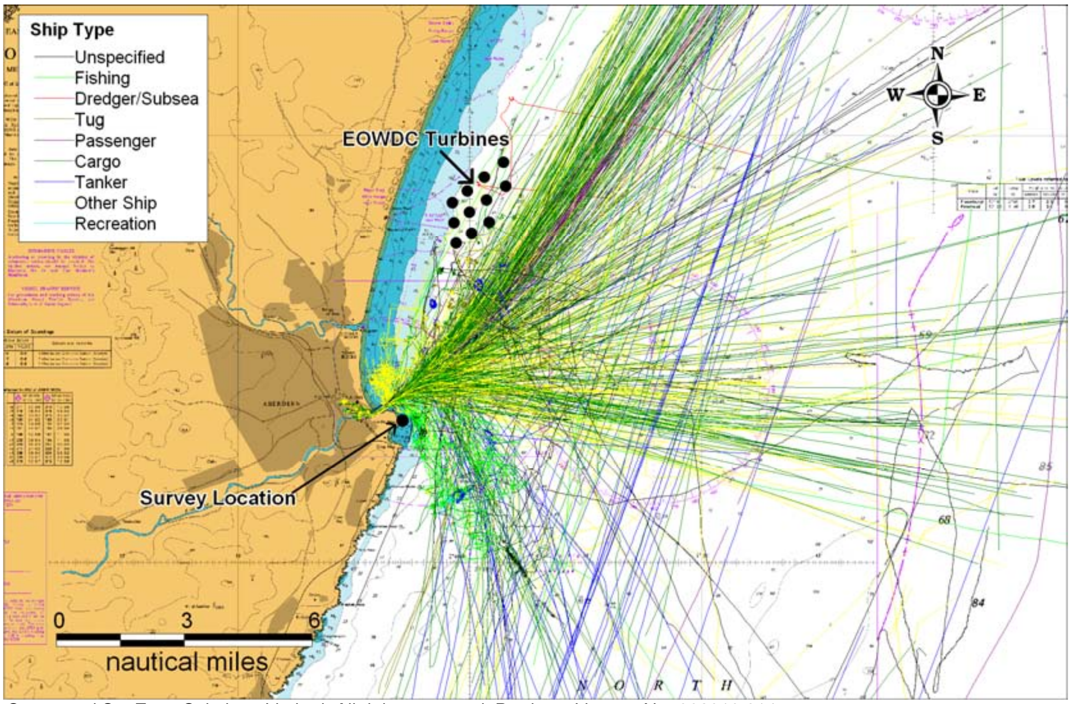

Figure 8.4 Survey 2: 21 September - 5 October 2009 (AIS & Radar tracks)

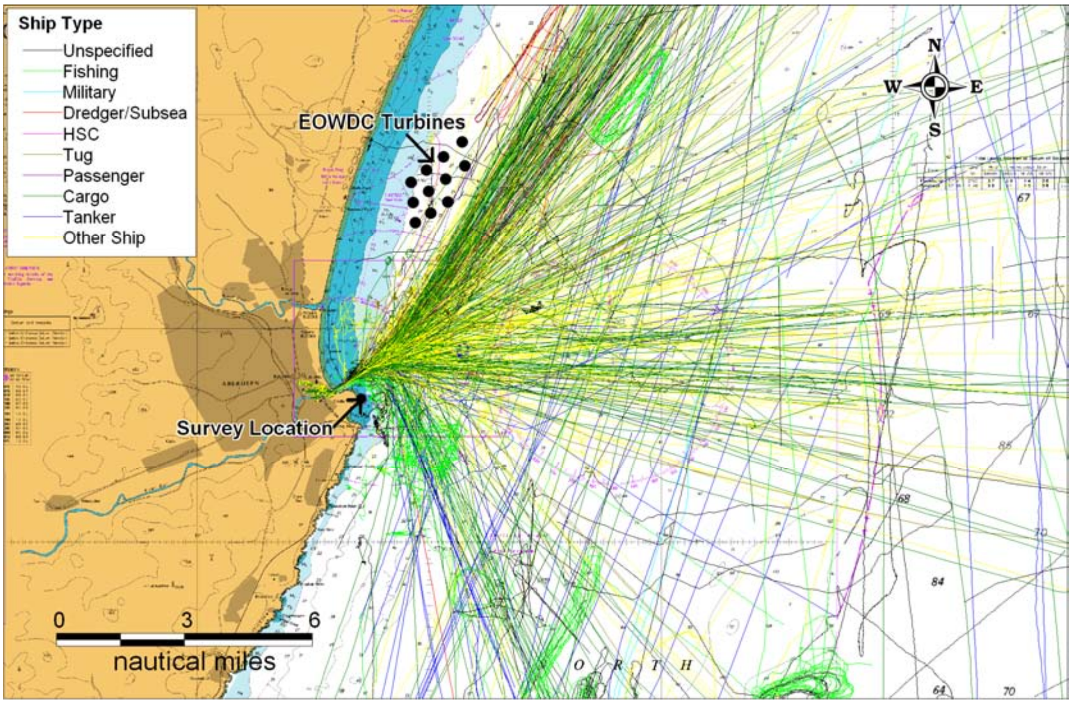

Figure 8.5 Survey 3: 9 April - 23 April 2010 (AIS & Radar tracks)

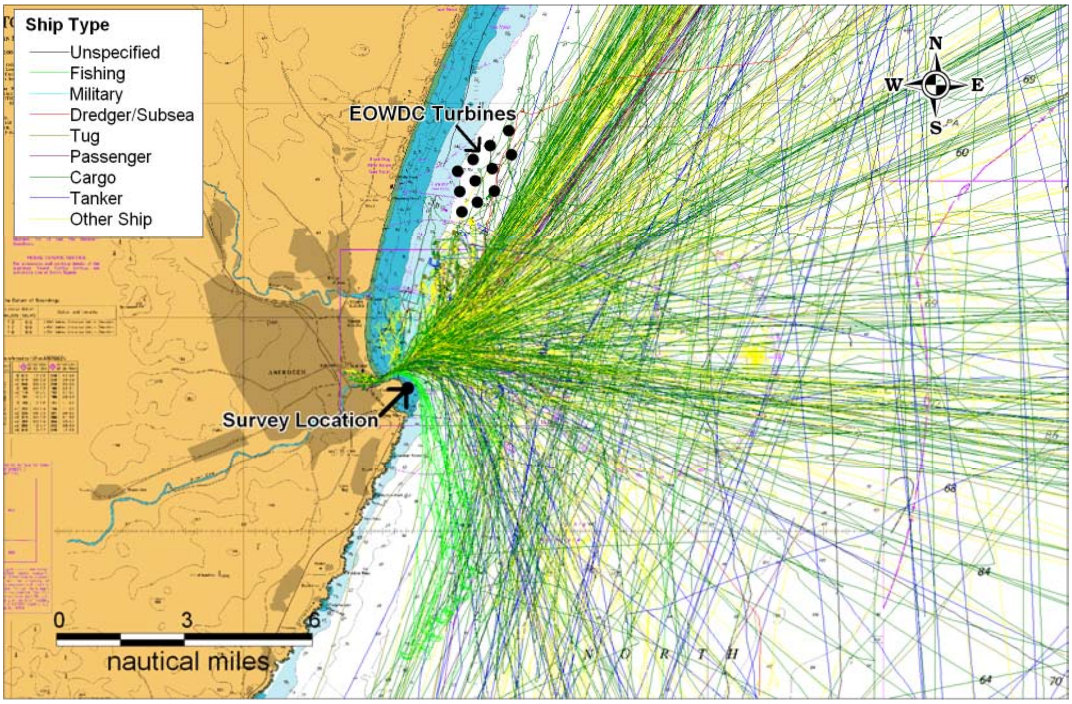

Figure 8.6 Survey 4: 1 November - 15 November 2010 (AIS & Radar tracks)

The number of unique vessels within 20nm of the survey location at Girdle Ness averaged approximately 50-55 vessels per day over the combined 56 days of surveying. The majority of tracks were associated with Aberdeen Harbour with approximately equal numbers inwards and outwards per day.

To put the traffic into a daily context, the tracks recorded on the busiest day during the two most recent surveys are presented below.

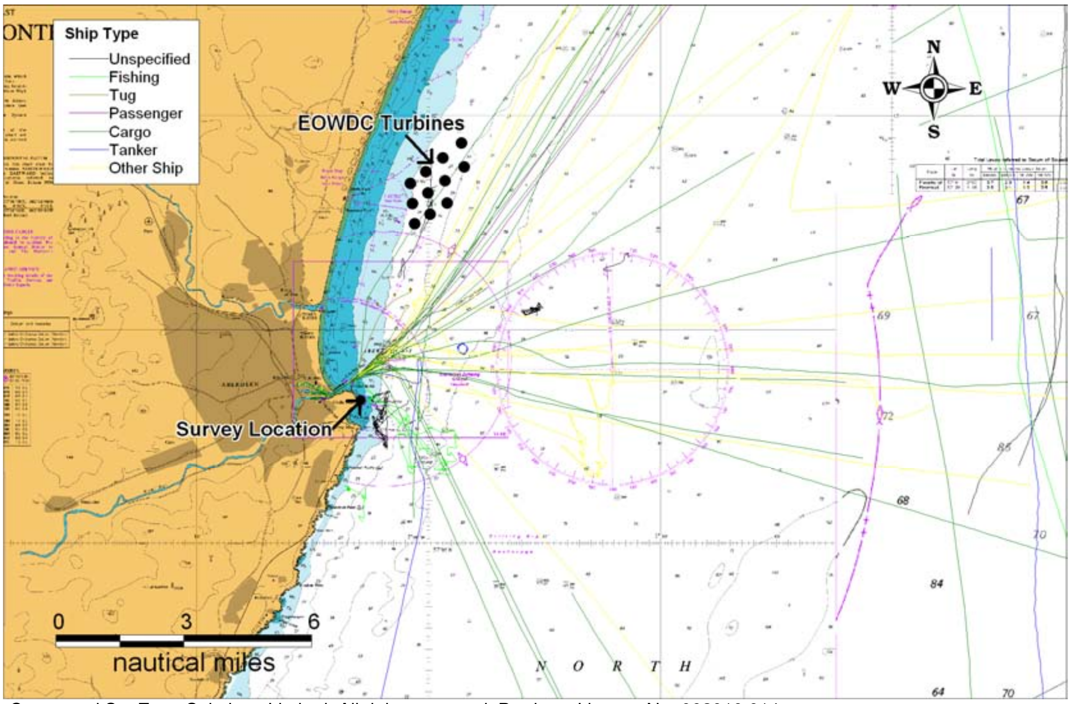

Figure 8.7 Survey 3 Busiest Day – 11 April 2010 (68 Unique Tracks)

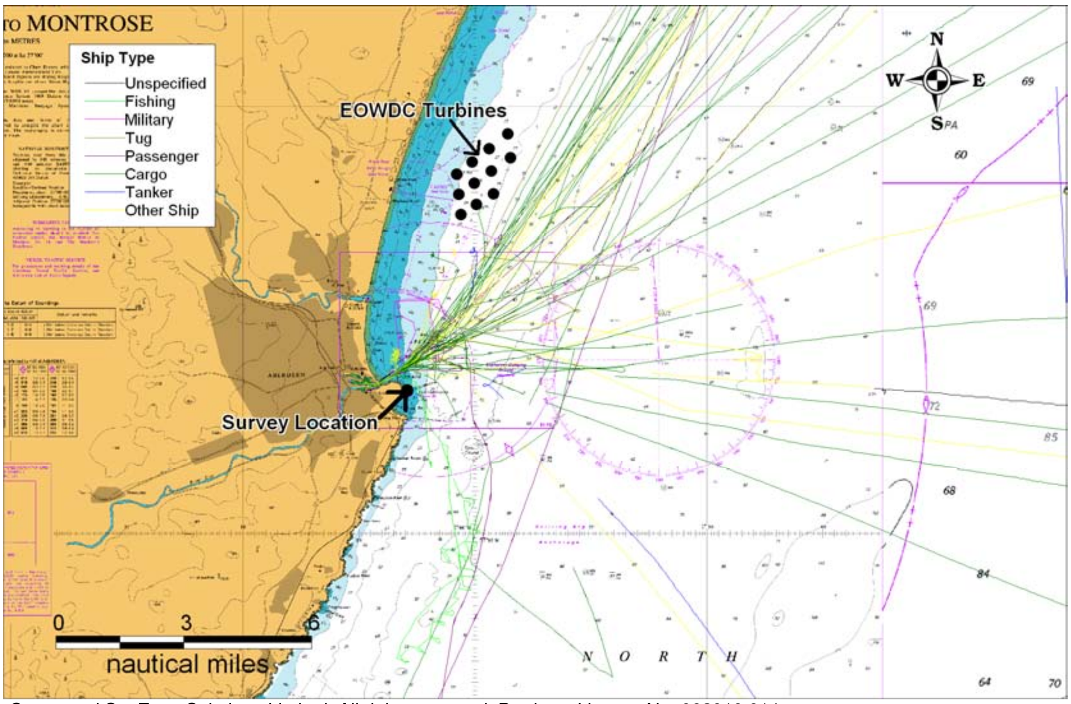

Figure 8.8 Survey 4 Busiest Day –10th November 2010 (74 Unique Tracks)

The breakdown of ships by type for vessels within 20nm of the survey location is presented in Figure 8.9. This considers all vessels recorded during the 56 days of the combined 4 surveys.

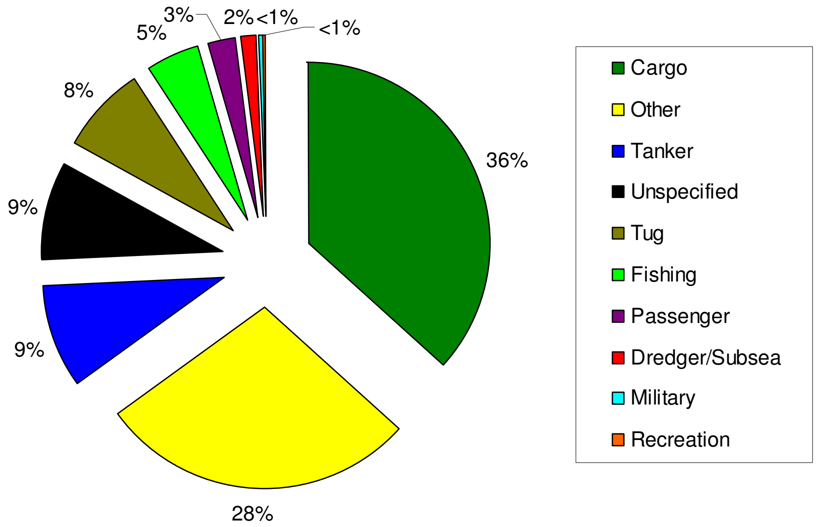

Figure 8.9 Vessel Types identified during the Combined Surveys

The most commonly recorded vessel type during the four surveys was cargo ships (36%) with 'other' vessels the second most commonly tracked (28%). It is noted that a large percentage of both these categories were offshore oil and gas industry related.

The distribution of vessels by draught (excluding unspecified) for the combined 4 surveys is presented in Figure 8.10. It can be seen that the majority of vessels had draughts between 4 and 6 m. Plots of all tracks colour-coded by draught for the two most recent surveys are shown in Figure 8.11 and Figure 8.12.

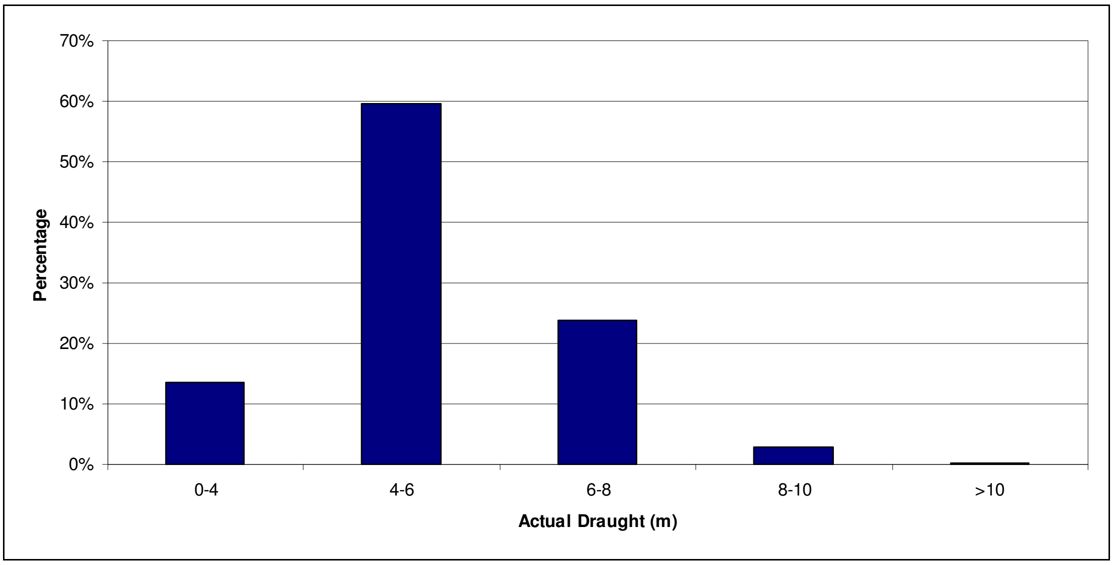

Figure 8.10 Distribution of Vessels by Actual Draught for the Combined 4 Surveys

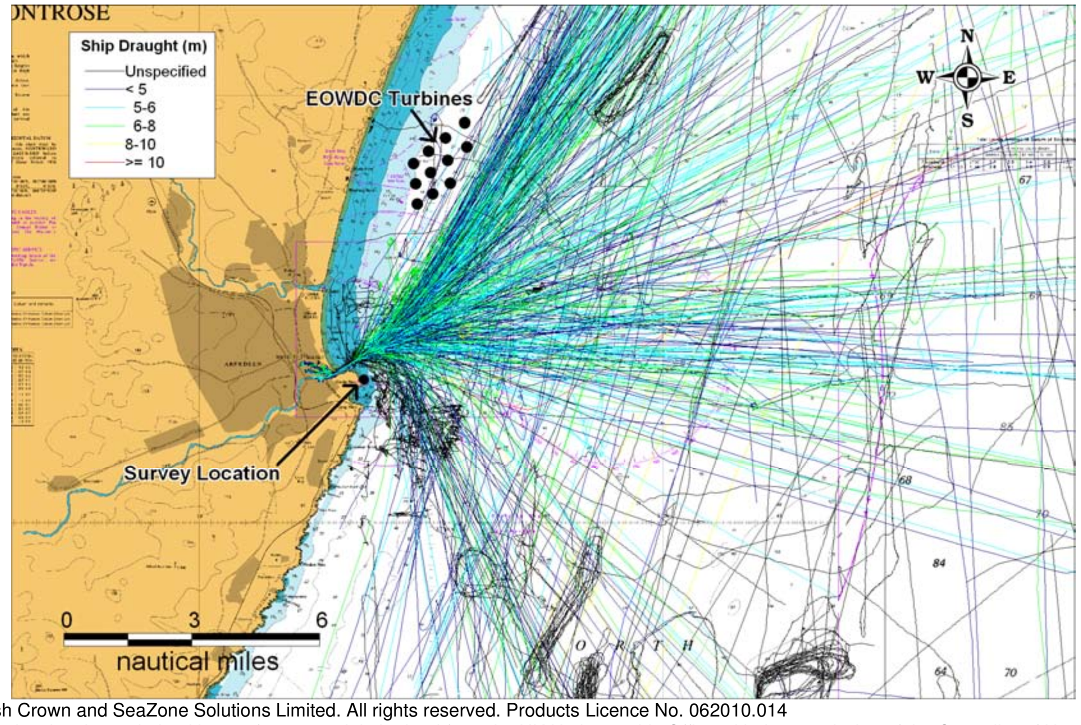

Figure 8.11 Survey 3 Tracks by Ship Draught

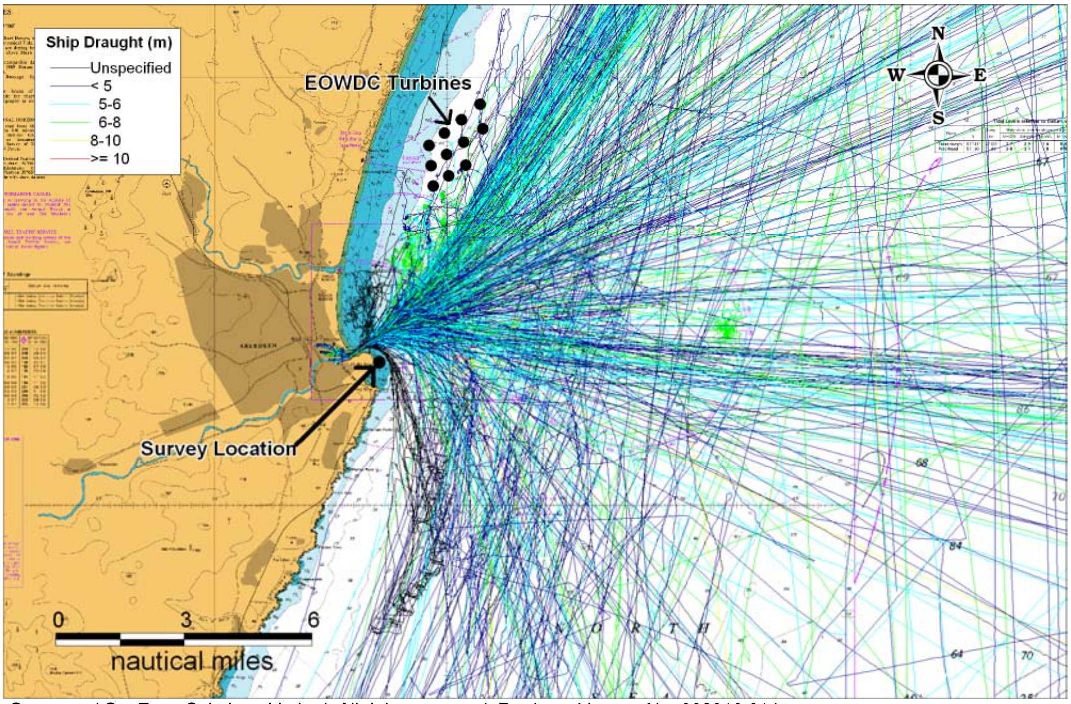

Figure 8.12 Survey 4 Tracks by Ship Draught

The vessel with the deepest draught overall was the shuttle tanker *Navion Fennia* (Figure 8.13) which broadcasted a draught of 11.5m on 10th November 2010 (Survey 4). This vessel approached Aberdeen Bay from the NE, stopping briefly approximately 1.8nm to the east of the survey location before leaving to the SE. It has a deadweight tonnage (DWT) of 95,195 tonnes.

Figure 8.13 Shuttle Tanker *Navion Fennia* (Library Picture)

The distribution of vessels by length (excluding unspecified) for the combined 4 surveys is presented in Figure 8.14. Plots of all tracks colour-coded by length for the two most recent surveys are presented in Figure 8.15 and Figure 8.16. It can be seen that the majority of vessels had lengths between 70 and 90 m.

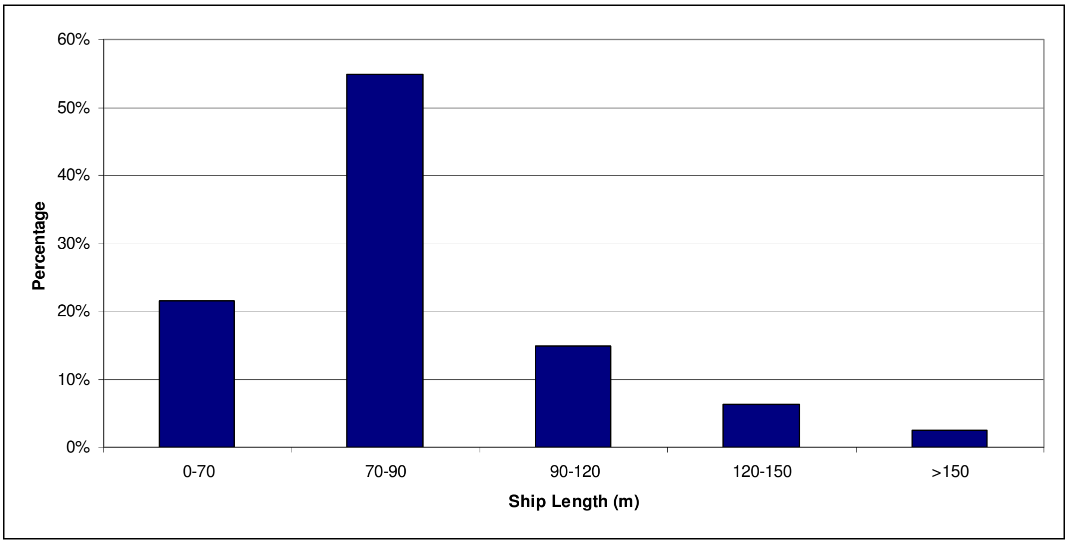

Figure 8.14 Distribution of Vessels by Length for the Combined 4 Surveys

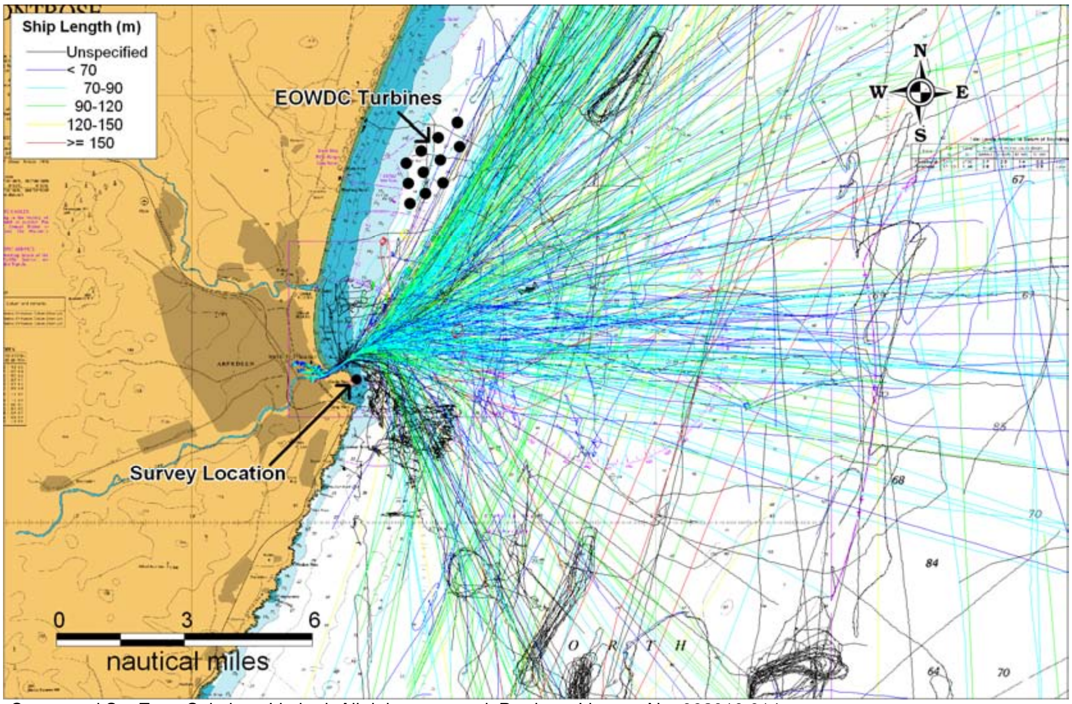

Figure 8.15 Survey 3 Tracks by Ship Length

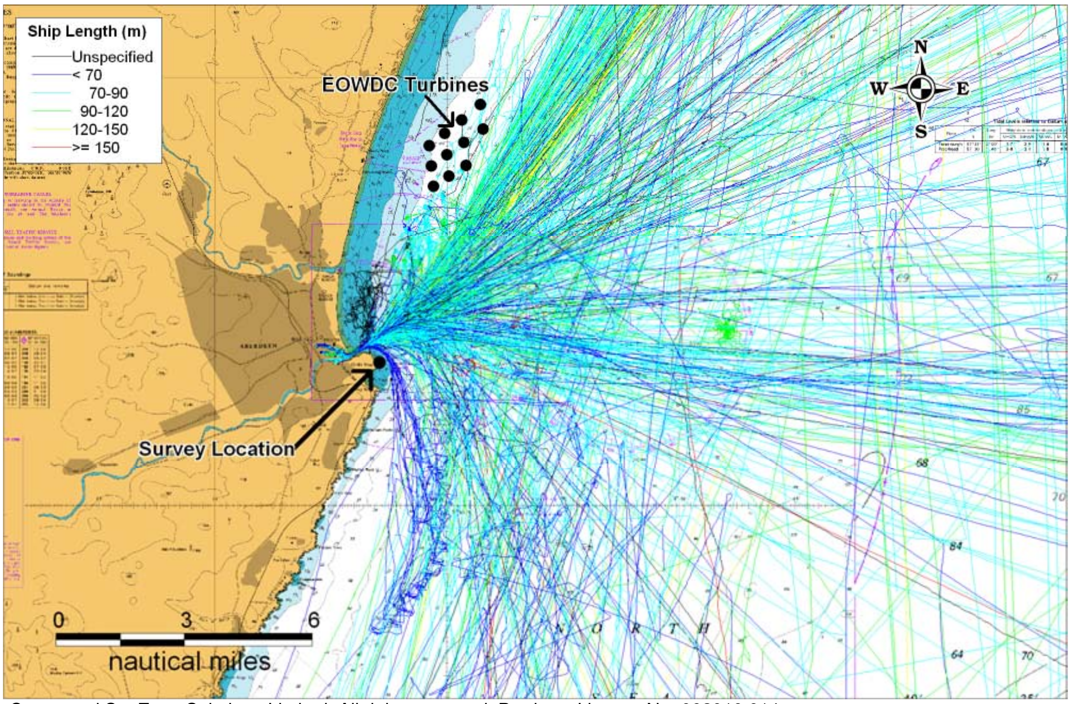

Figure 8.16 Survey 4 Tracks by Ship Length

The longest vessel tracked was the shuttle tanker *Grena* (272m) (Figure 8.17). This vessel anchored for 3 days approximately 1.9nm to the ESE of the survey location before heading to the Captain Oil Field on 23rd September 2009 (Survey 3).

Figure 8.17 Shuttle Tanker *Grena* (Library Picture)

Figure 8.18 presents the distributions of average speed for each of the four surveys.

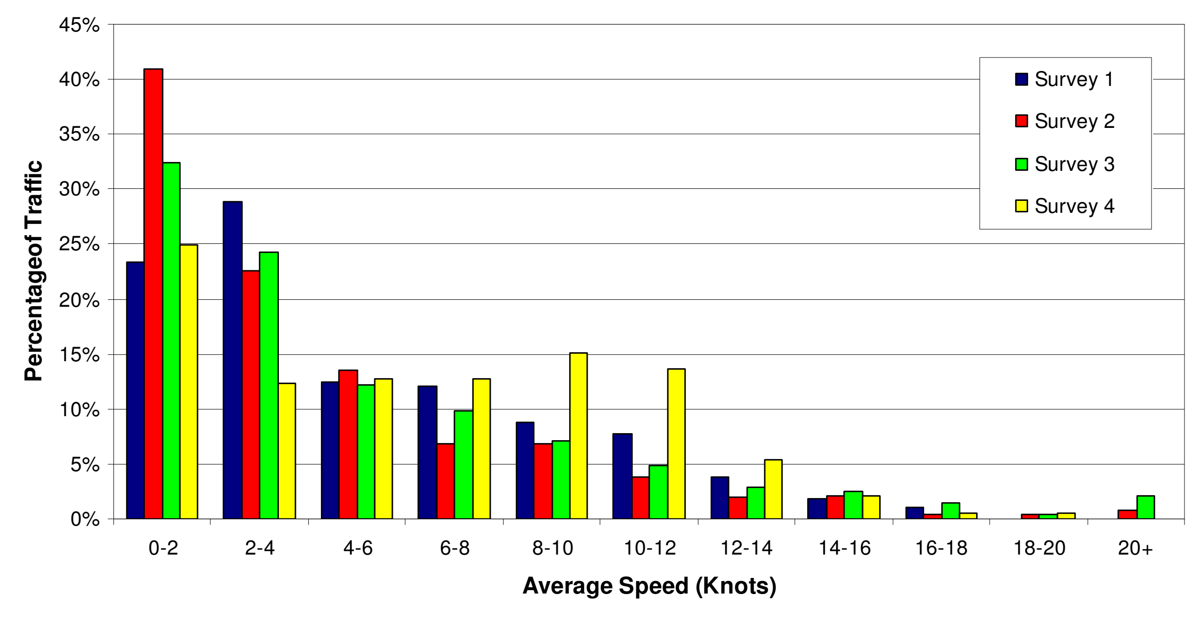

Figure 8.18 Average Speed Distributions for each Survey

The average speeds per survey ranged from 4-6 knots. These relatively low averages can be explained by the large proportion of tracks made by vessels visiting Aberdeen which either were berthed, at anchor or waiting to enter the harbour for part of the tracking period.

Additional analysis indicated the average speed of steaming vessels crossing the Radio Reporting point was 11.7 knots, which reduced to 10 knots crossing the Harbour Limit. At both points the fastest vessels recorded regularly were the NorthLink ferries *Hrossey* and *Hjaltland* travelling at 20-30 knots.

8.4 EOWDC Site-Specific Review

A detailed plot of the 56 days survey tracks passing the proposed EOWDC turbines is presented in Figure 8.19.

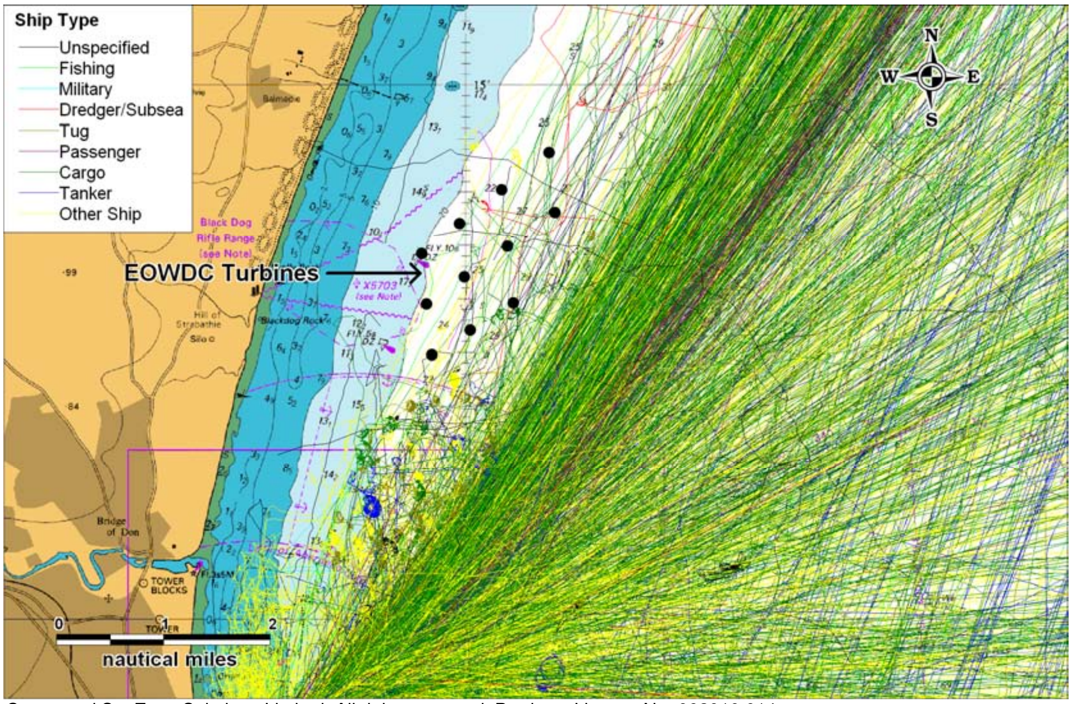

Figure 8.19 Detailed Plot of the Combined 4 Surveys Tracks Passing the Site

In the following figures the plots of vessel tracks passing close to the turbines are broken down into individual types with the following vessel types considered:

- Tankers (Figure 8.20)
- Passenger Ships (Figure 8.21)
- Offshore Oil and Gas Vessels (consisting mainly of cargo and 'other' ships on AIS) (Figure 8.23)

The closest passing tanker to the proposed turbines was the chemical/products tanker *Brovig Bora* recorded approximately 0.2nm from turbine 10 on 2 November 2010 travelling southbound.

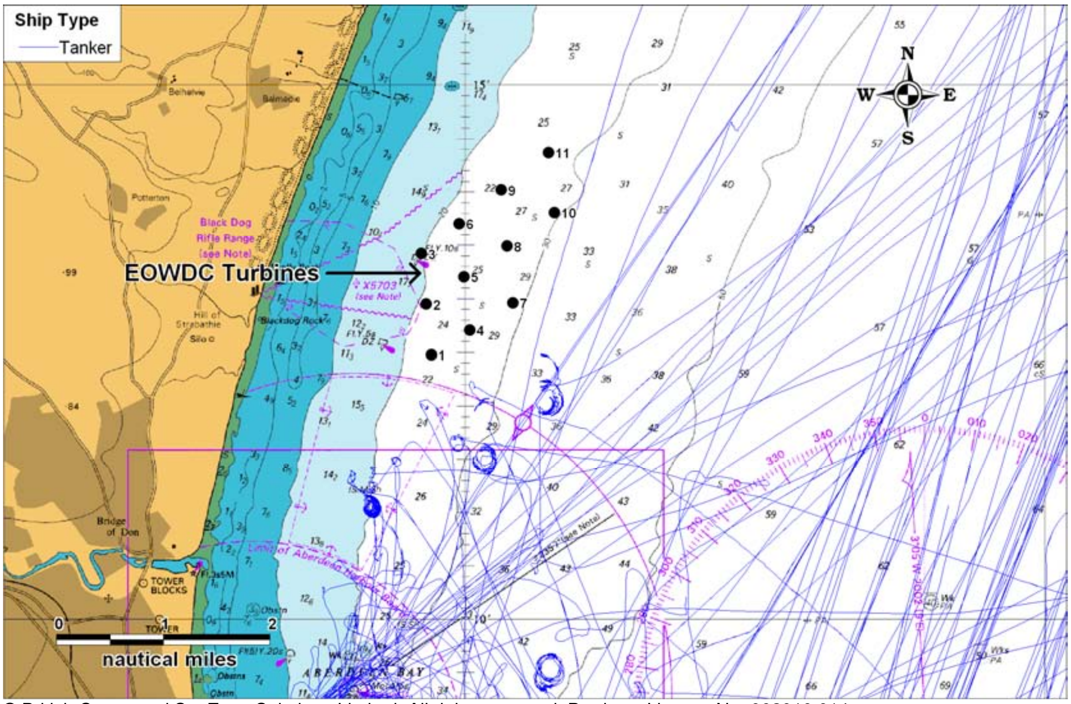

Figure 8.20 Plot of Tanker Tracks Passing Close to the Proposed Turbines

The vast majority of the passenger ships were the NorthLink ferries *Hrossey* and *Hjaltland* between Aberdeen and Orkney/Shetland. A photograph of *Hjaltland* during Survey 4 is presented in Figure 8.22. There was one instance of *Hrossey* passing within 100m of the proposed turbine 7 on 15 April 2010 but generally the vessels pass at least 0.6nm to the east of the proposed turbines with an average Closest Point of Approach (CPA) of 1.3nm.

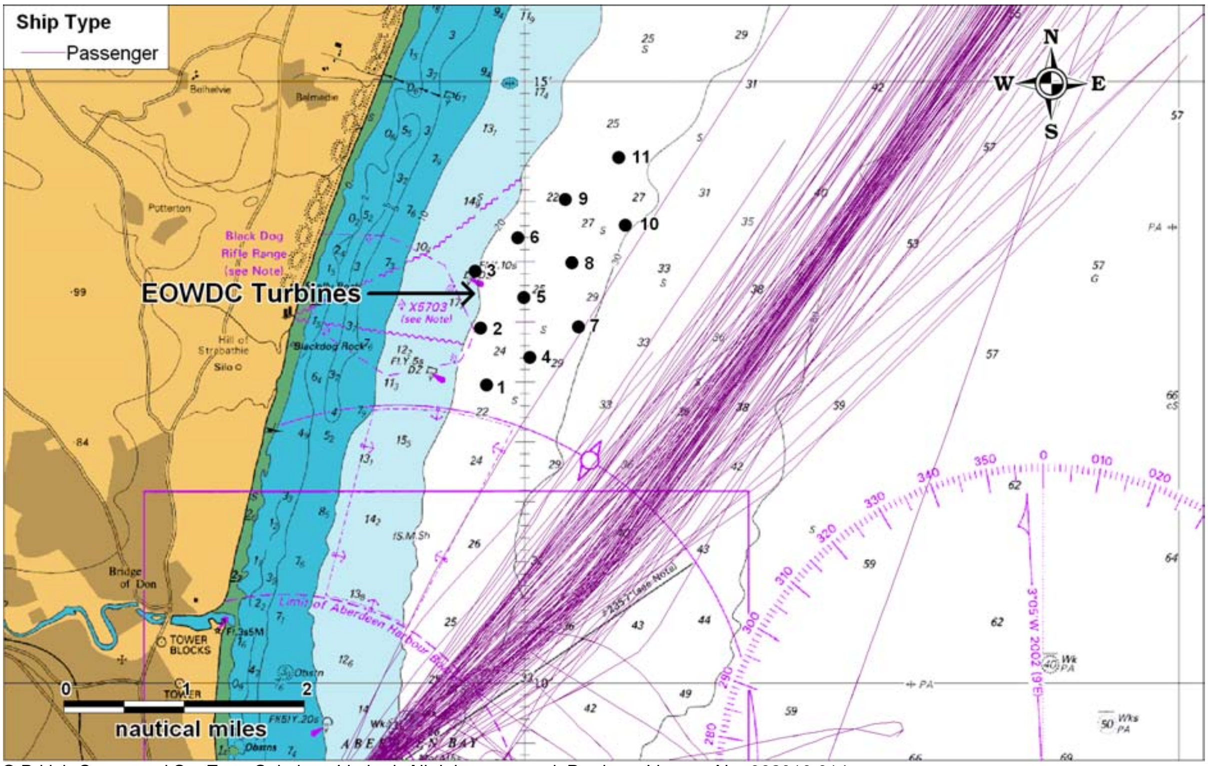

Figure 8.21 Plot of Passenger Ships Passing close to the Proposed Turbines

Figure 8.22 Picture of the passenger ferry *Hjaltland* during Survey 4

A small proportion of offshore oil and gas industry vessels passed through the proposed turbine locations, with the vast majority passing to the east.

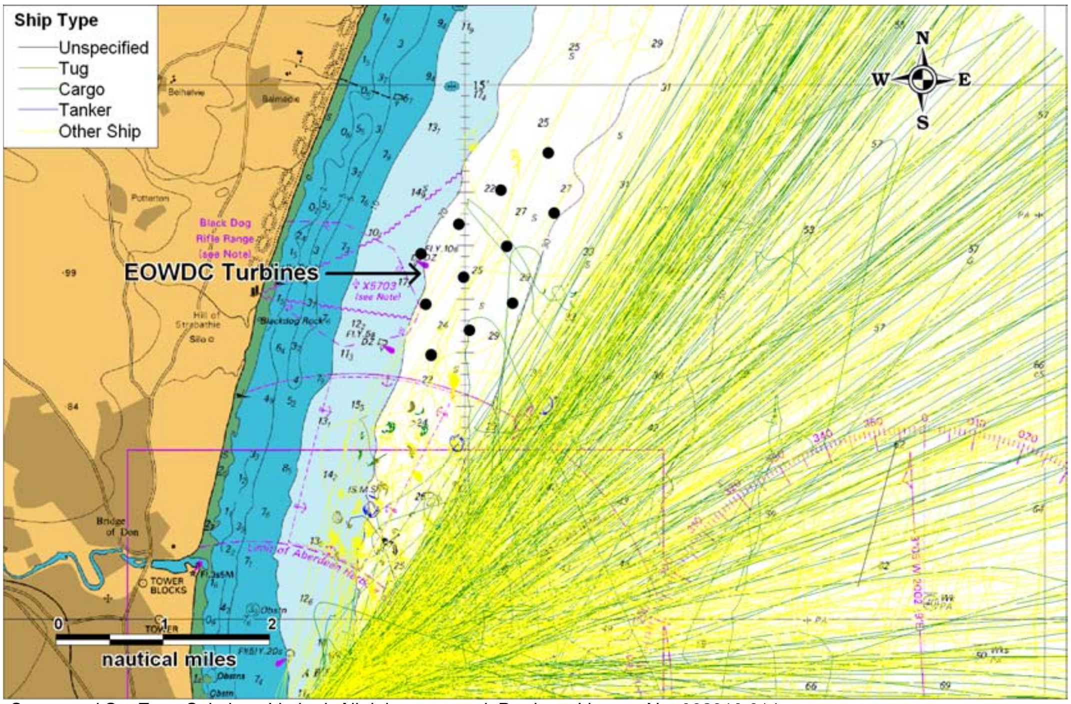

Figure 8.23 Plot of Offshore Industry Vessels passing close to the Proposed Turbines

Figure 8.24 presents the tracks of all vessels which were identified to pass within the proposed turbine locations during the combined 56-day survey period.

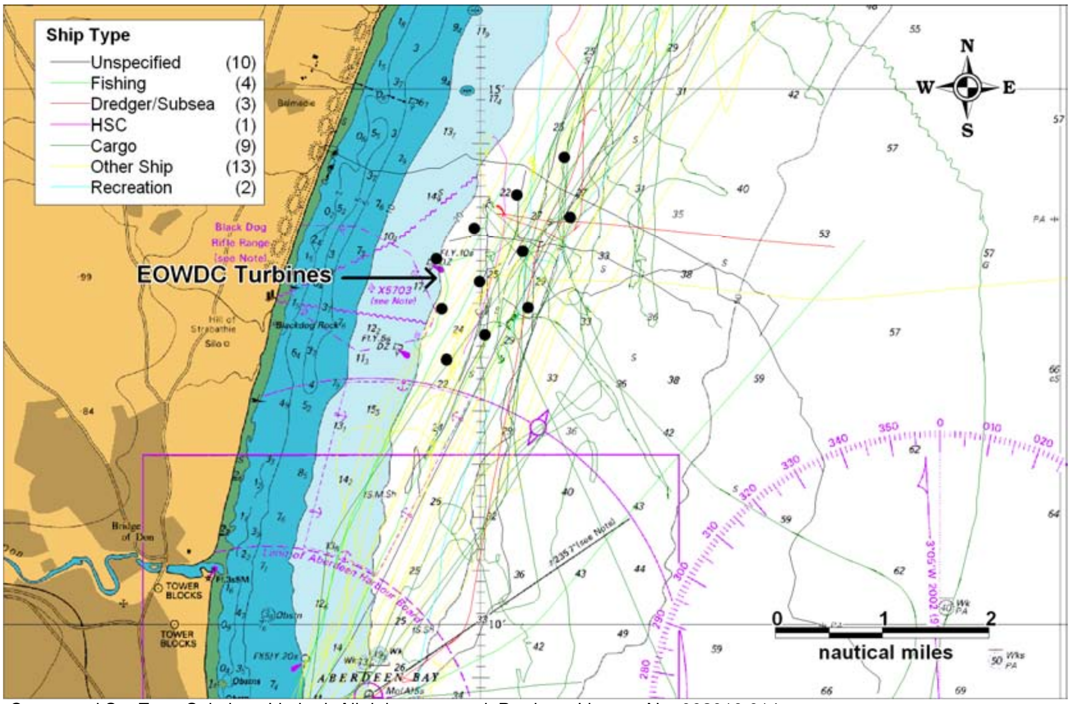

Figure 8.24 Tracks passing within EOWDC Site (All Surveys)

A total of 42 tracks were identified to pass within the proposed turbine locations during the four surveys, corresponding to an average of less than one per day. Excluding unspecified vessels (mainly radar targets which were not identified visually), the most common types of ship passing through the area were 'other' and cargo ships, a large portion of which were offshore industry related.

The traffic on passage through the site was mainly heading in a NNE-SSW direction. Details of the 26 vessels tracked on AIS through the site are given in Table 8.1.

Table 8.1 Details of Merchant Vessels Intersecting EOWDC Site on AIS

Ship Name	Type	Length (m)	Destination	Survey	Tracks
Aberdonian	Other	45	Aberdeen	1	1
Amanda	Cargo	81	Aberdeen	3	1
ARRC03	Other	19	Miller	3	1
Balityskiy-202	Cargo	90	Klaipeda (Lithuania) / Peterhead	3	1
Dea Pilot	Other	11	Aberdeen Bay	1	1
Dea Searcher	Cargo	11	Aberdeen	1	1
Geobay	Dredging	88	Aberdeen	4	1
Grampian Defender	Other	47	J.W. McLean	2	1

Ship Name	Type	Length (m)	Destination	Survey	Tracks
Grampian Frontier	Other	61	Aberdeen	3	1
Havila Fortress	Cargo	83	Aberdeen	4	1
Hellespont Dione	Cargo	73	Aberdeen	4	2
Island Express	Cargo	77	Elgin	1	1
M.V. Skandi Falcon	Other	82	Aberdeen	4	1
North Fortune	Cargo	80	Aberdeen	3	1
Ocean Clever	Other	73	Aberdeen	1 & 3	2
Ocean Seeker	Dredging	Unspecified	Phylis	2	2
Onward BF440	Fishing	25	Unspecified	2 & 4	2
Skagerak	Unspecified	17	Whitehaven	2	1
Toisa Coral	Cargo	73	Aberdeen	4	1
VOS Lismore	Other	54	Buzzard	2	1
VOS Mariner	Other	53	Aberdeen	1 & 3	2

The table above shows that in terms of AIS-equipped ships, no vessels passed through the site on more than two occasions with only 5 vessels passing more than once. The majority of vessels passing through the site were offshore oil and gas industry related vessels travelling to and from Aberdeen. The number of vessels on AIS intersecting the site for each survey was similar with 6 vessels intersecting in Surveys 1 and 2 and 7 vessels intersecting in Surveys 3 and 4.

Sixteen tracks were recorded on radar passing within EOWDC turbine locations during the 4 surveys. Details of these are provided, where available, in the fishing and recreation sections.

8.5 Detailed Analysis of Main Shipping Lane

The main shipping lane in closest proximity to the proposed EOWDC site is the NE-SW lane to/from Aberdeen Harbour. The AIS tracks using this lane during the surveys have been isolated for analysis.

Figure 8.25 presents the aforementioned shipping lane tracks colour-coded by ship type and Figure 8.26 shows the percentage distribution of these tracks.

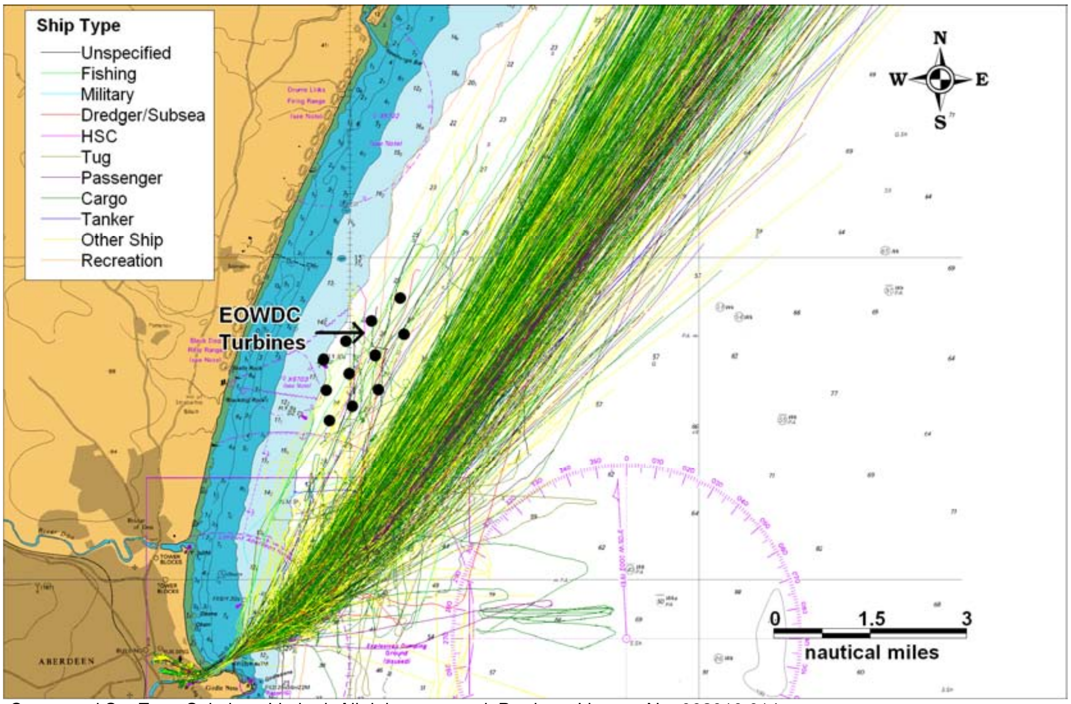

Figure 8.25 Tracks by Type on NE-SW Shipping Lane

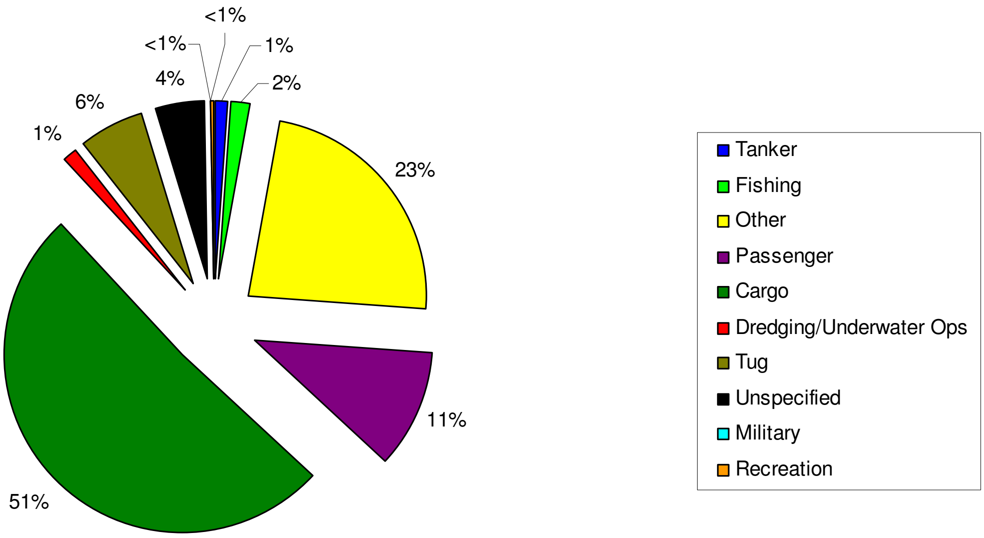

Figure 8.26 Distribution of Vessel Types Recorded on the NE-SW Shipping Lane

During the surveys there was an average of 12 to 13 ships per day using the lane, with offshore industry vessels (cargo and other) the most frequent users.

The tracks are analysed in more detail in Figure 8.27 to Figure 8.29.

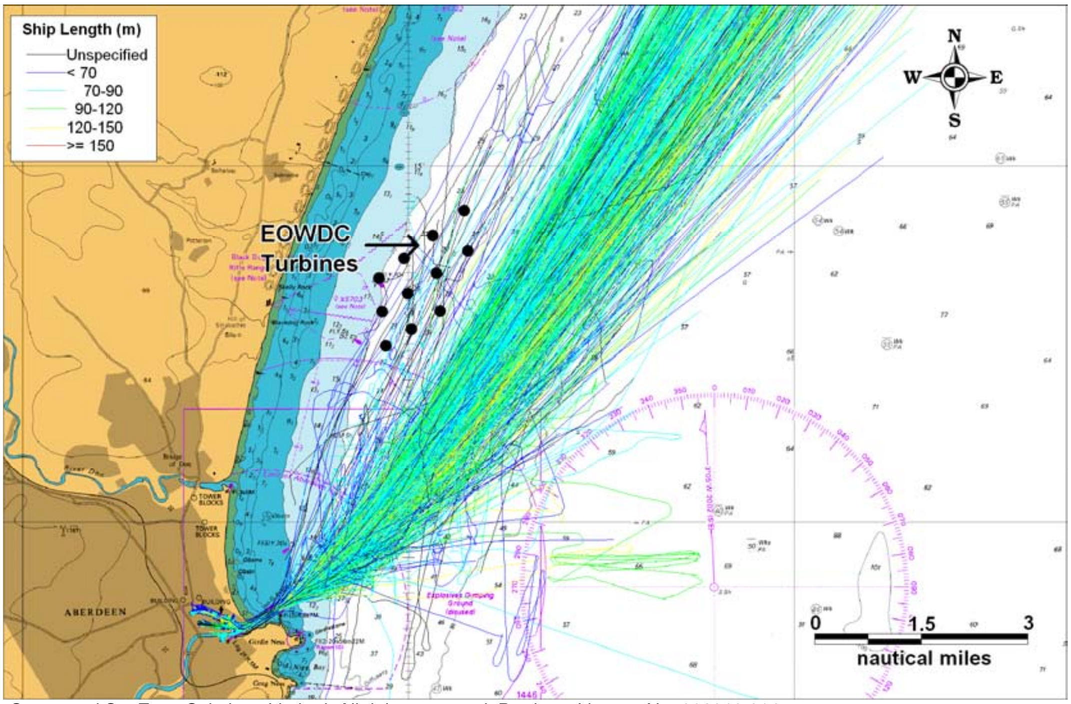

Figure 8.27 Tracks by Ship Length on NE-SW Route

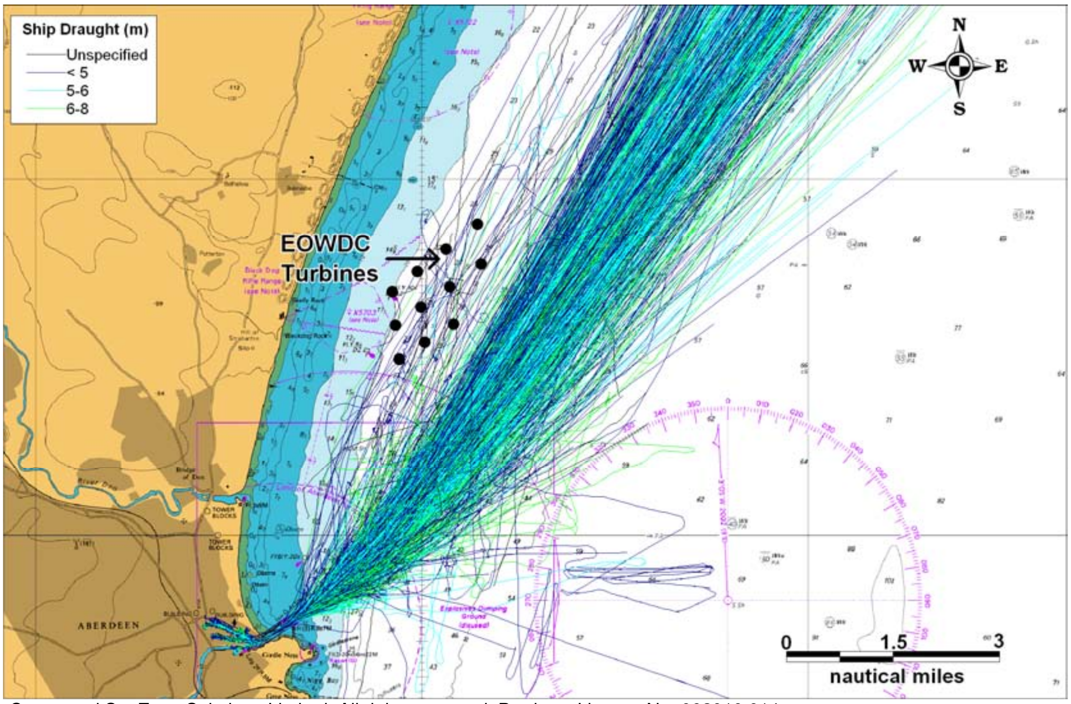

Figure 8.28 Tracks by Ship Draught on NE-SW Route

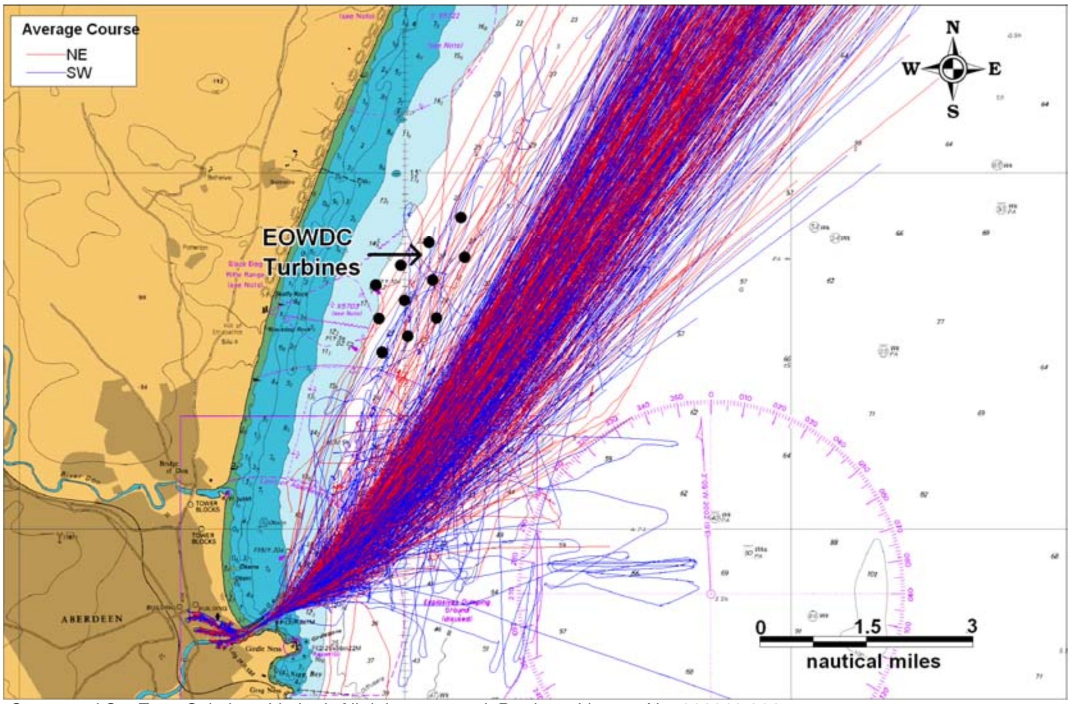

Figure 8.29 Tracks by Average Course on NE-SW Route

Approximately 52% of vessels on the NE-SW shipping lane were travelling NE, while 48% of vessels were heading SW.

8.6 Anchored Vessels

The positions of vessels at anchor recorded during the four surveys are presented in Figure 8.30 to Figure 8.33.

Between Survey 3 and Survey 4, a charted anchorage area was designated off Aberdeen.

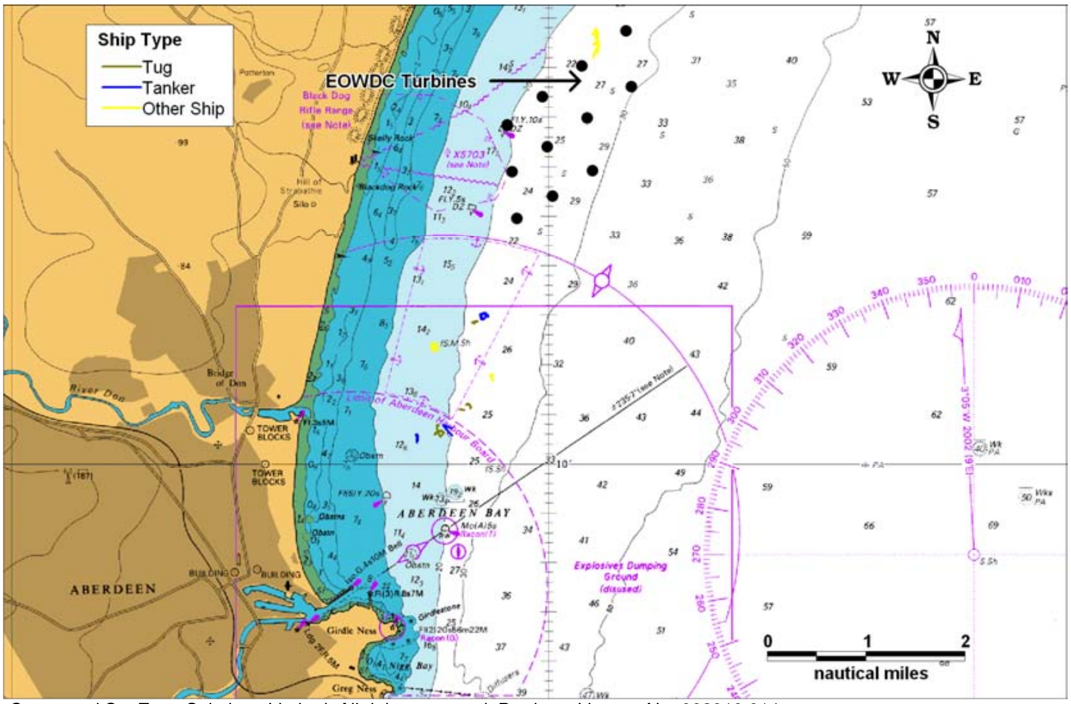

Figure 8.30 Anchored Vessels during Survey 1 (prior to anchorage area being designated)

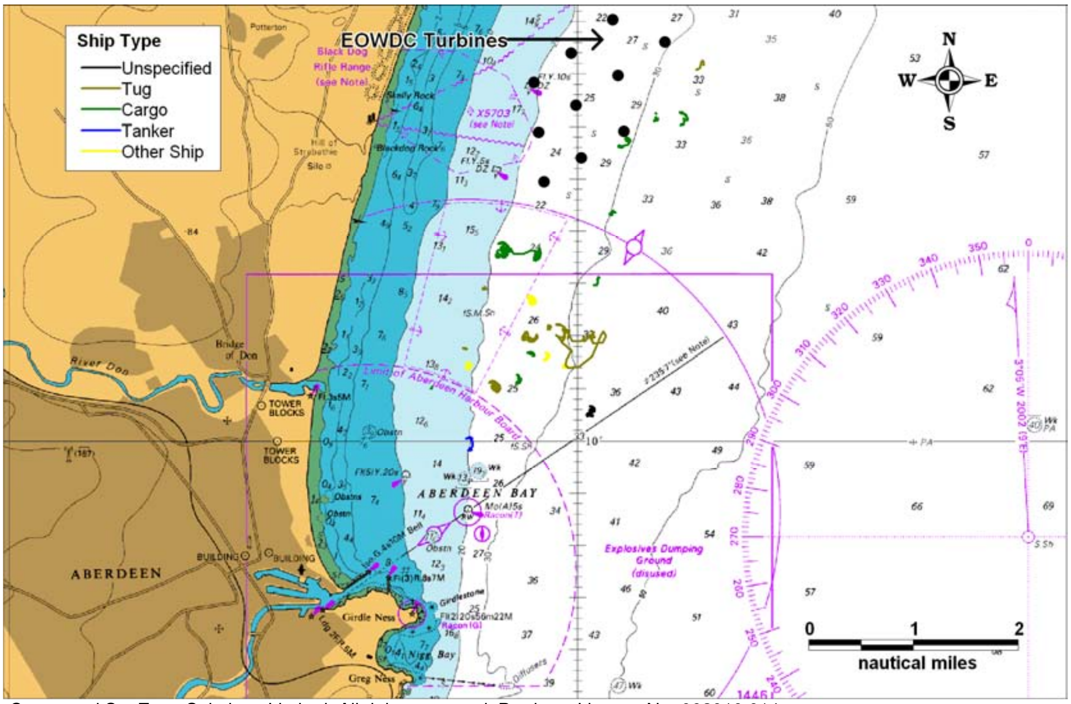

Figure 8.31 Anchored Vessels during Survey 2 (<u>prior to anchorage area being designated)</u>

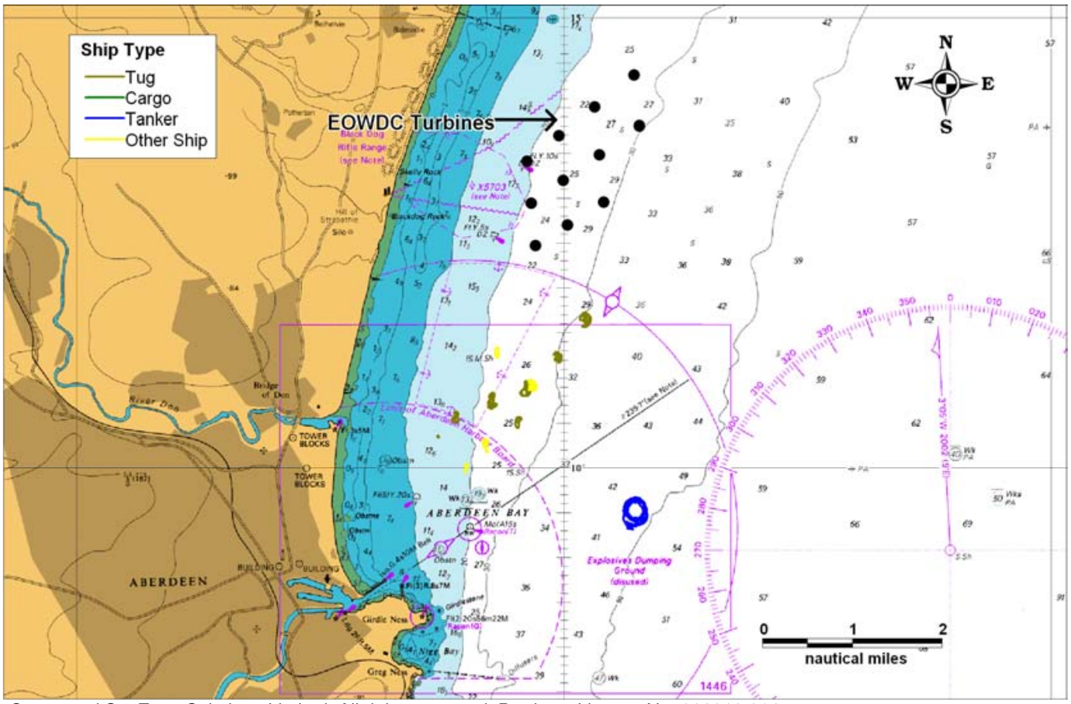

Figure 8.32 Anchored Vessels during Survey 3 (prior to anchorage area being designated)

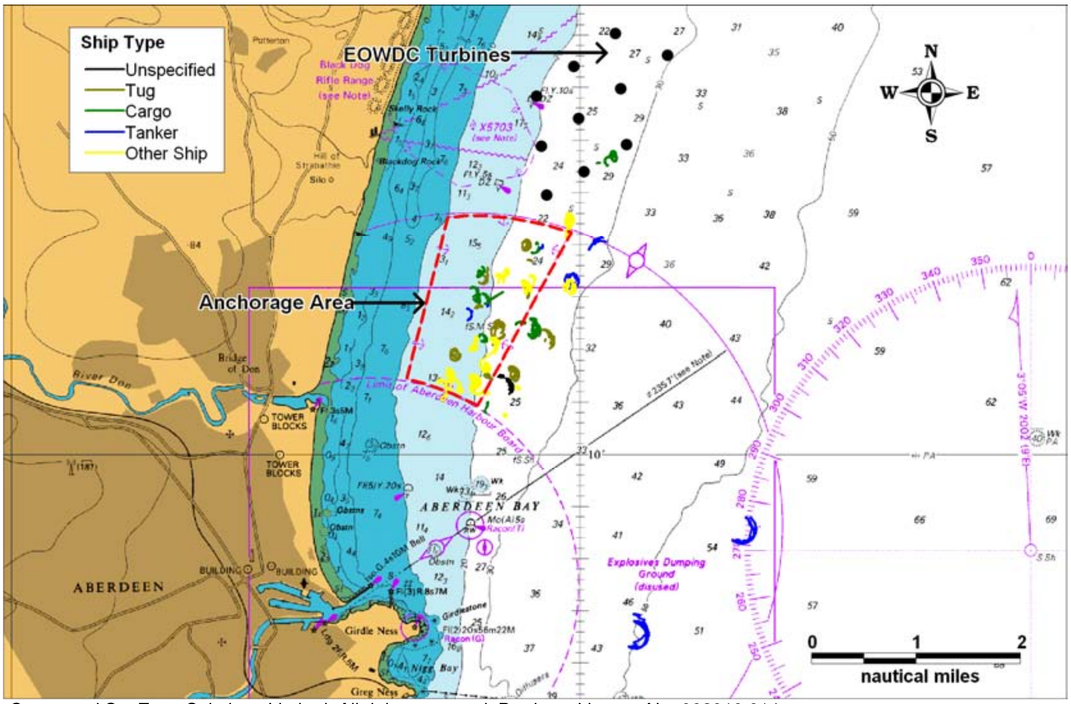

Figure 8.33 Anchored Vessels during Survey 4 (with Charted Anchorage Area shown in red)

There were 10, 29, 20 and 37 vessels observed at anchor during Surveys 1-4, respectively. During part of Survey 4, Aberdeen Harbour was experiencing high winds and pilotage ceased for a period, leading to the higher number of vessels at anchor.

It can be seen from the above figures that most masters have responded to the introduction of the charted anchorage area by anchoring within or close to the designated area. Two cargo vessels anchored for a short time within the EOWDC turbine locations during Survey 4 before entering Aberdeen Harbour. (The fifth survey carried out in 2011 showed most vessels were using the charted anchorage area – see Figure 13.10.)

More detailed analysis of anchoring practices in Aberdeen using long-term data is presented in Appendix C.

9. IMPACT ON COMMERCIAL SHIPPING NAVIGATION

9.1 Passing Ships

Based on the analysis of the shipping survey data presented in Section 8, it is considered that the proposed EOWDC site will not significantly affect passing ships not bound to or from Aberdeen Harbour as they mostly pass well to the east of the proposed EOWDC site (generally at least 3nm away).

In terms of Aberdeen traffic, the majority of traffic also passes well clear of the proposed EOWDC site (i.e., shipping lanes to the east and south of Aberdeen). The only route that will be partly affected is the NE-SW shipping lane to/from Aberdeen. Approximately 12 to 13 vessels per day use this route on average, the majority of which are associated with the oil & gas industry. The current position of this traffic lane is analysed in Section 8.5. A small proportion of tracks currently pass through the site but the vast majority pass to the east, with a Closest Point of Approach (CPA) of approximately 1.1nm from the nearest proposed turbine location. The CPA distribution for these vessels (excluding vessels passing through the turbine perimeter) is presented in Figure 9.1.

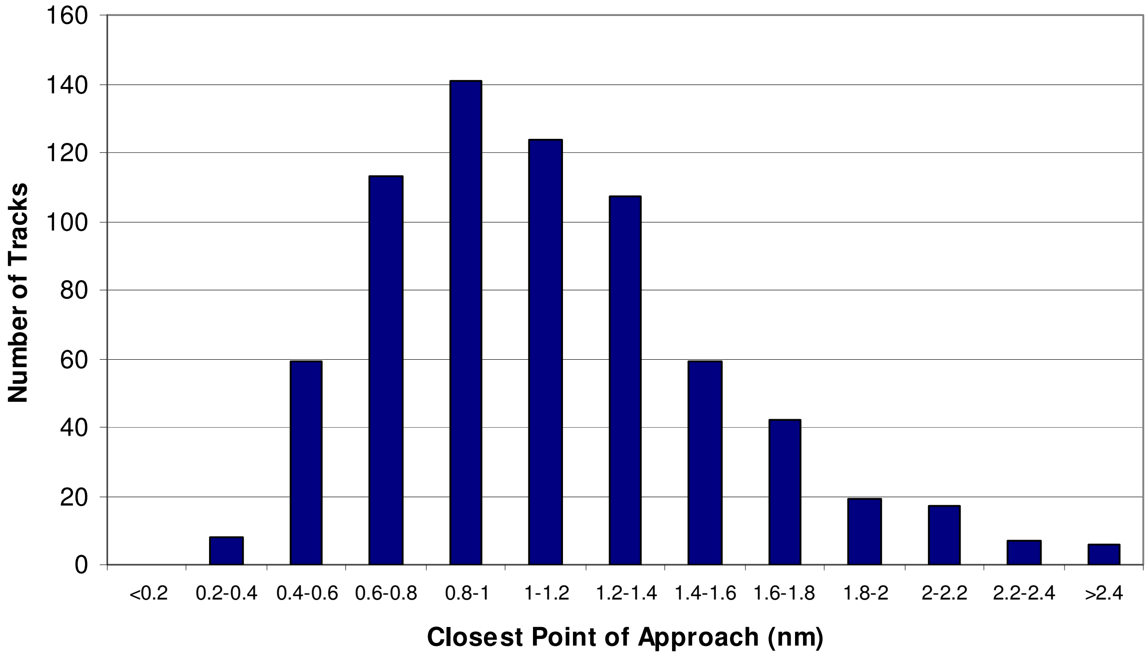

Figure 9.1 CPA Distribution for Vessels travelling on the NE-SW Shipping Lane

The MCA has published draft "Guidance to Mariners Operating in the Vicinity of UK Offshore Renewable Energy Installations (OREIs)". It does not provide guidance on a safe distance at which to pass, as this depends upon individual vessels and conditions, but states that:

> *"In planning a voyage mariners must assess all hazards and associated risks. The proximity of wind farms and turbines should be included in this assessment. "*

Based on experience at other sites, the introduction of the proposed EOWDC is not expected to affect the majority of the NE shipping lane although vessels currently passing near the site are likely to shift to the east, which will result in an increased mean passing distance of approximately 1.5nm. There is sufficient sea room for vessels to make this change. The route is also expected to narrow slightly.

An average track estimated to be taken by a NE/SW vessel prior to the construction of the proposed EOWDC is presented in Figure 9.2. This was calculated by finding the average position of tracks currently using the NE-SW shipping lane. The anticipated deviation is also shown in the chart.

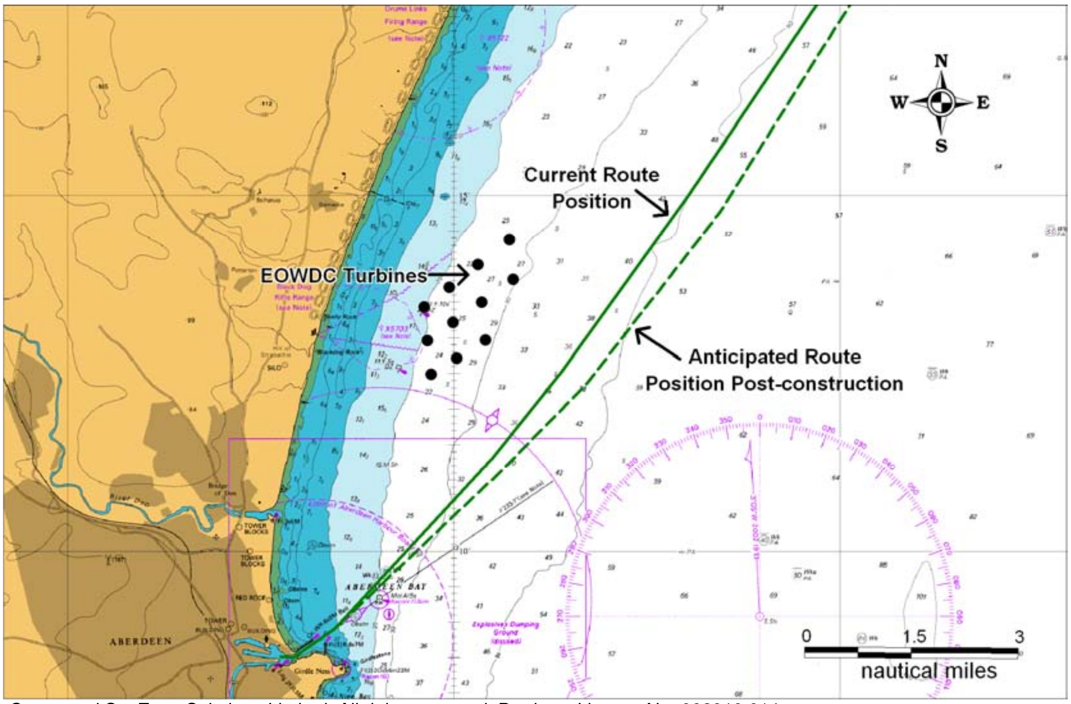

Figure 9.2 Current and Anticipated NE-SW Mean Route Position

The risks associated with the shipping changes anticipated due to the proposed project have been quantified as part of the Formal Safety Assessment (see Sections 12 and 13). The proposed EOWDC may also have an affect on marine radar. This potential impact is discussed in Section 15.

9.2 Anchored Ships

From the maritime surveys it was observed that vessels frequently anchor in Aberdeen Bay. This may be for a number of reasons, such as their intended berth being occupied, awaiting the tide or lack of space in the harbour.

A detailed analysis of anchoring data for Aberdeen Bay, including a review of one-year of AIS data (see Appendix C), was conducted. Following this, discussions with the port and other maritime stakeholders, such as via the MSF, were conducted.

It was identified that the previous turbine locations would have significantly reduced the sea room available for anchored vessels in Aberdeen Bay. Therefore, in consultation with stakeholders, the site has been relocated to the north and reduced in size. Separate to this, an anchorage area has been designated and charted in Aberdeen Bay. This has an area of 1.6nm^2 and its closest limit is 0.25 nautical miles from the nearest turbine (see Section 6.3.4).

Based on these actions, it is considered that following the EOWDC installation there will be sufficient sea room available for the levels of anchoring experienced in the Aberdeen Bay area, as identified in the long-term survey data analysis.

10. RECREATIONAL VESSEL ACTIVITY

10.1 Introduction

This section reviews recreational vessel activity at the EOWDC site based on information published by the Royal Yachting Association (RYA) and radar tracking of recreational vessels during the maritime traffic surveys.

10.2 RYA Data

10.2.1 Introduction

The RYA, supported by the Cruising Association (CA), have identified recreational cruising routes, general sailing and racing areas around the UK in the Coastal Atlas (Ref. xiv). This work was based on extensive consultation and qualitative data collection from RYA and CA members, through the organisations' specialist and regional committees and through the RYA affiliated clubs. The consultation was also sent to berth holder associations and marinas.

10.2.2 Aberdeen Area Recreational Data

A summary plot of the recreational sailing activity and facilities in the Aberdeen area is presented in Figure 10.1.

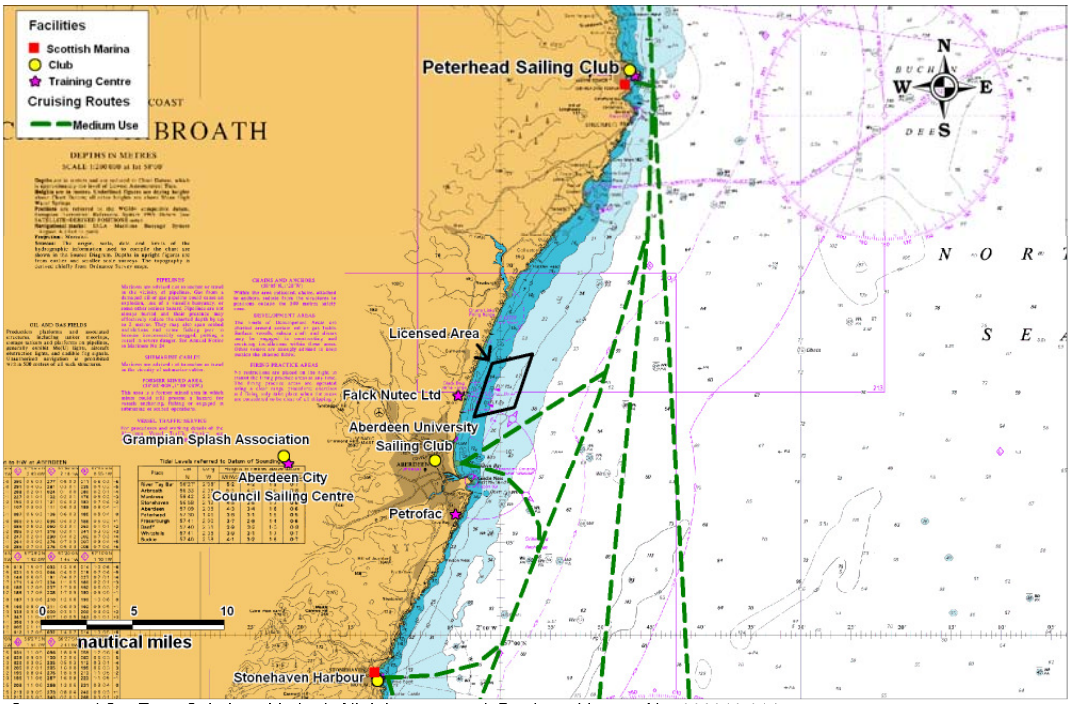

Figure 10.1 Recreational Information for the Aberdeen Area

Based on the RYA published data, the site is close to a few medium-use[1] RYA sailing routes, with the closest indicated route passing approximately 1.7nm to the south of the EOWDC site.

In terms of facilities, there are a few clubs and training centres for recreational vessels located on the coast around Aberdeen. The nearest marina is in Peterhead to the north.

10.3 Survey Data

A total of three recreational vessels (two yachts and one jet ski) were tracked on radar in Survey 1 and three yachts were recorded on radar during Survey 2, as presented in Figure 10.2. There were no recreational vessels tracked on radar during Surveys 3 or 4, although four vessels were manually sighted during Survey 3 - a white sailing boat, a jet ski and two kayaks.

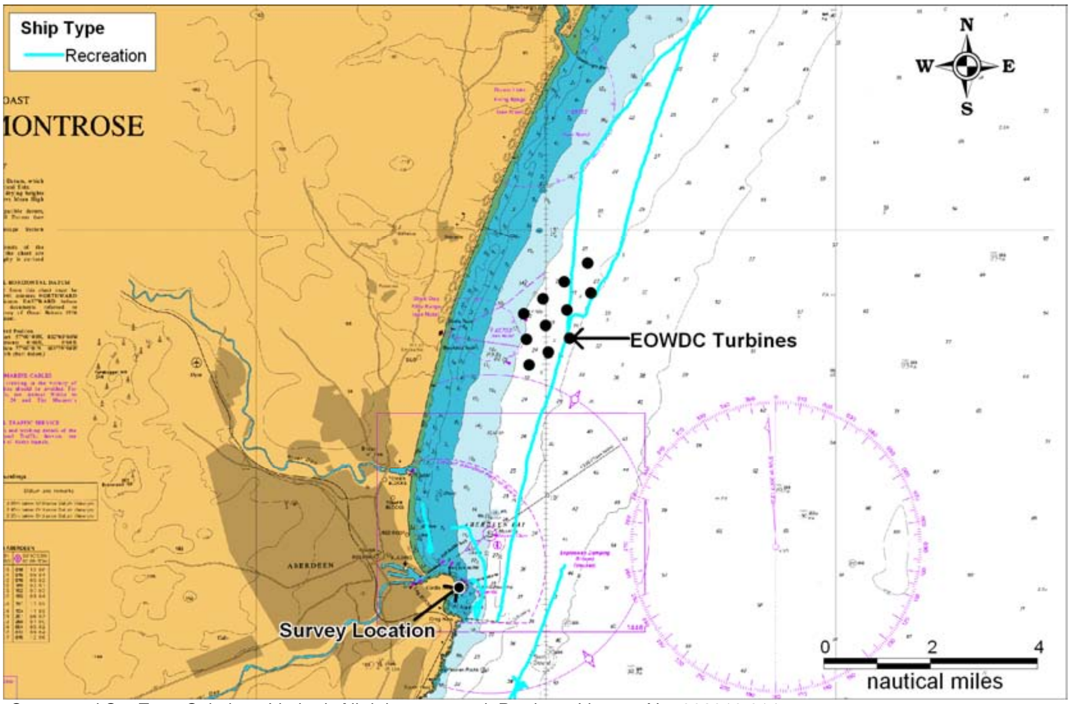

Figure 10.2 Recreational Vessels Tracked during Surveys (56 Days)

Two yachts passed within the proposed turbines and a picture of one of these yachts is shown below.

[1] Popular route on which some recreational craft will be seen at most times during summer daylight hours.

Figure 10.3 Photograph of a Yacht observed on 2nd April 2009 (Survey 1)

10.4 Impact Assessment

The air clearance between turbine rotors and sea level conditions at Mean High Water Springs (MHWS) will not be less than 22m, as recommended by the MCA and RYA. This minimises the risk of interaction between rotor blades and yacht masts.

In terms of vessel routeing, recreational vessels should be able to pass between turbines in suitable conditions, as well as being able to pass inshore and offshore. Based on the activity review, this is not expected to be a frequent event and hence the impact on recreational vessels is considered to be minor.

The Macmillan REEDS Nautical Almanac (Ref. xv) indicates that yachts are generally not encouraged within the busy commercial port of Aberdeen.

11. FISHING VESSEL ACTIVITY

11.1 Introduction

This section reviews the fishing vessel activity at the EOWDC site based on the maritime traffic survey and Commercial Fisheries assessment (Ref. xvi).

11.2 Survey Tracks

The fishing vessels tracked during the combined 56 days maritime traffic survey are plotted in Figure 11.1. Overall, 146 fishing vessels were tracked during the combined survey period, an average of 2 to 3 per day.

The majority of fishing vessels were small trawlers and potters working out of Aberdeen, mainly working south of Girdle Ness, where a number of buoys marking pots were visible from the coastline.

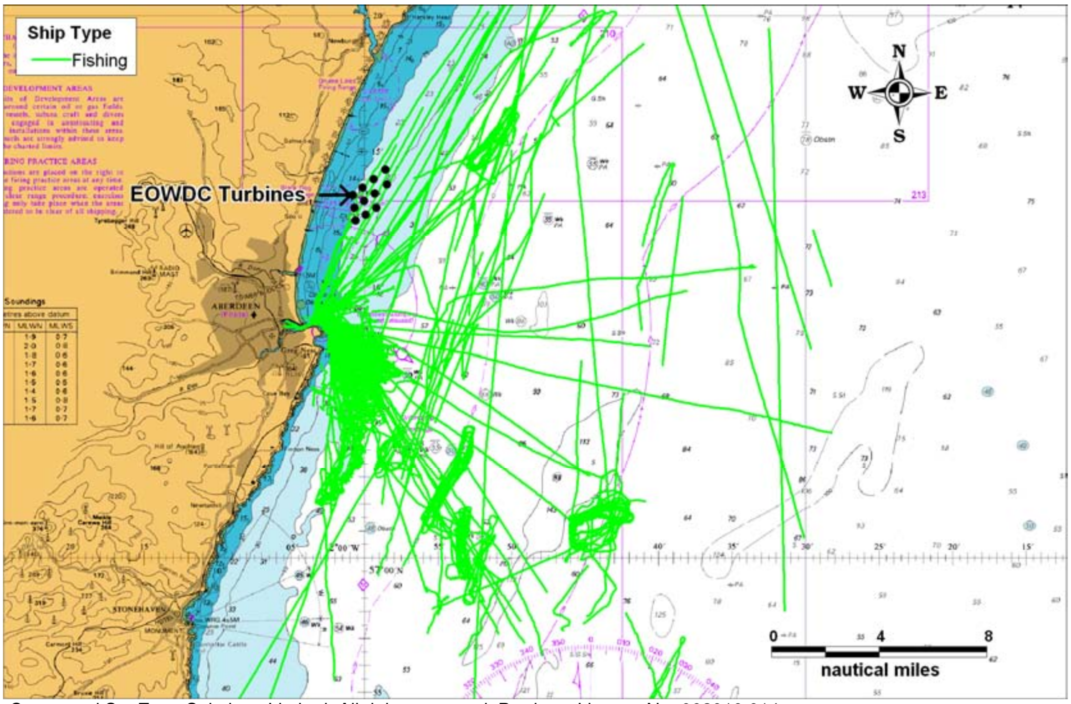

Figure 11.1 All Fishing Vessel Survey Tracks (56 Days)

A total of 4 fishing vessel tracks were logged passing through the proposed EOWDC site during the combined survey period, averaging 1 per fortnight. Details of the vessels are provided in Table 11.1.

Table 11.1 Details of Fishing Vessels Intersecting EOWDC Site during Surveys

Vessel Name	Type	Length (m)	Registered Tonnage	AIS / Radar	Survey
Crystal Tide AH135	Trawler	18.5	75	Radar	1
Boy John INS110	Trawler	20.8	174	Radar	2
Onward BF440	Trawler	21.3	202	AIS	2
Onward BF440	Trawler	21.3	202	AIS	2

Note that all instances of fishing vessels intersecting the proposed site were observed during the first two survey periods in 2009.

Examples of fishing vessels observed during the survey are presented the figures below. It is noted that the photographs are of vessels observed leaving Aberdeen port during the survey. Not all the vessels intersecting the area were photographed due to range and conditions.

Figure 11.2 Photograph of *Fame* A17 during Survey 1

Figure 11.3 Photograph of *Boy Gordon* A441 during Survey 2

Figure 11.4 Photograph of *Crystal Tide* AH135 during Survey 4

11.3 Commercial Fisheries Study

The commercial fishing aspects report (Ref.xvi) carried out for the proposed EOWDC uses the following principal sources of data and information:

- International Council for the Exploration of the Sea (ICES)
- Marine Management Organisation (MMO)
- Marine Scotland, Marine Scotland Science (MS)
- Scottish Fisheries Protection Agency (SFPA)
- European Fisheries Commission (Europa)

Based on the current fishing activity in the area, and the assumption that this will continue after the EOWDC is built, there will be a limited risk of collision between fishing vessels and turbines. In general this is due to the low levels of fishing activity in this area.

There is also potential to impact on the navigation of vessels to and from fishing grounds, for example, increased steaming distances and times. This is mainly an issue during the construction and decommissioning phases when there will be a safety zone and hence there may be some increased steaming distances. During operation there should be sufficient spacing between turbines for vessels to steam through the site if the conditions are considered suitable.

The above was confirmed through consultation with the SFF (Ref. xvii) who indicated there were no major fishing vessel navigational issues associated with the EOWDC proposal.

The risk of interaction between fishing gear and subsea cabling associated with the development is discussed in Section 13.4.

12. FORMAL SAFETY ASSESSMENT

12.1 Introduction

The IMO Formal Safety Assessment process (Ref. xviii) as approved by the IMO in 2002 under SC/Circ.1023/MEPC/Circ392 has been applied within this study. This is a structured and systematic methodology based on risk analysis and cost benefit assessment (if applicable). There are five basic steps within this process:

1. Identification of hazards (a list of all relevant accident scenarios with potential causes and outcomes);
2. Assessment of risks (evaluation of risk factors);
3. Risk control options (devising regulatory measures to control and reduce the identified risks);
4. Cost benefit assessment (determining cost effectiveness of risk control measures); and
5. Recommendations for decision-making (information about the hazards, their associated risks and the cost effectiveness of alternative risk control measures).

Figure 12.1 is a flow diagram of the FSA methodology applied.

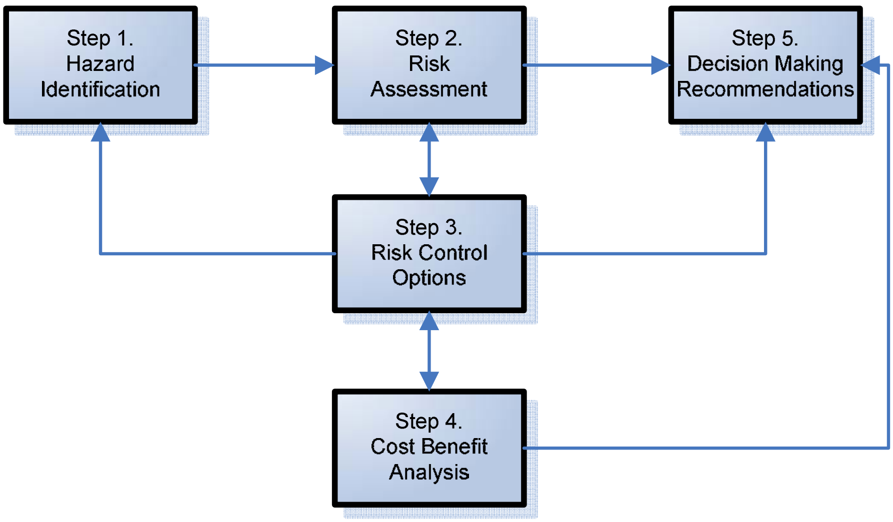

Figure 12.1 Overview of Formal Safety Assessment Methodology

As indicated within the IMO FSA guidelines and the DECC guidance on risk assessment methodology (Ref. i) for offshore renewable projects, the depth of the assessment should be commensurate with the nature and significance of the problem. Within the assessment of proportionality consideration was given to both the scale of the development and the magnitude of the risks/navigational impact.

From review it was concluded that the EOWDC project is a large scale development with the potential to impact navigational safety. As a result, the content and methods of the risk assessment were responsive to this and included the following:

- Comprehensive Hazard Log
- Risk Ranking
- Detailed and quantified Navigational Risk Assessment for selected hazards
- Preliminary search and rescue overview
- Preliminary emergency response overview
- Comprehensive risk control/mitigation measures log

12.2 Hazard Identification

A Hazard Review workshop was held in Aberdeen on 25 August 2010 attended by local stakeholders representing the port and shipping industry, as outlined in Table 12.1. Representatives from MCA, British Chamber of Shipping and NorthLink Ferries were also invited to attend but unfortunately could not make it on the day.

Table 12.1 Hazard Review Workshop Attendees

Name	Organisation
Colin Thomson	James Fisher
Daniel Stroud	Aberdeen Assistant Harbour Master
Brian Turnbull	Marine Safety Forum
David Kenwright	Emergency Response and Rescue Vessel Association
Steve Ferguson*	Marine Safety Forum
Jimmy Chestnutt	Anatec Ltd
Archie Johnstone	Northern Lighthouse Board
Frank Hall	Fisher Offshore
Ray Shaw	Aberdeen Harbour Master
Ian Todd*	AREG
John Sutcliffe	Technip
Nicola Fry	Technip
Liam Dallas-Ross	Anatec Ltd (secretary)
Michael Cain	Anatec Ltd (chairman)

*Attended for part of the meeting

12.3 Key Findings

The focus of the meeting was on shipping navigational hazards and the key findings from the meeting are summarised below:

- It was agreed that all phases of the development need to be appropriately managed to ensure safe navigation:
    - Construction
    - Operation
    - Decommissioning

- Due to the project being a test facility, construction and maintenance activities may be intermittent and would require careful management.

- It was agreed that the construction phase was likely to be prolonged and result in the greatest impact to navigation. This phase was considered as the base case for the Hazard Workshop.

- It was agreed that a project website would provide a useful mechanism for circulating information on the project to the marine industry and keep stakeholders informed about activities associated with the proposed development.

- The main identified impact on shipping was that vessels currently passing close to the East of the site would migrate further east. It was estimated that this displacement of shipping would provide clearance of around 1nm to the turbines. There are no significant sea room restrictions to the East to prevent this happening.

- Concern was expressed that a figure recently circulated showed that the cables could be laid through the anchorage area. This was not acceptable to the marine stakeholders.

- Anatec are to provide more information on the potential effects of wind farms on Marine Radar and other navigational equipment.

- The standard navigational control measures that have been applied to other sites were generally considered the most effective in reducing risks at the site, e.g., marking and lighting.

- Overall the workshop concluded that with the correct mitigation measures in place the navigational risks were likely to be Low.

- It was assessed that although the use of a dedicated support vessel and/or permanent VTS would be beneficial they were not justifiable. It was also agreed that the introduction of a TSS would be unnecessary.

12.4 Risk and Mitigation Measures

The risks involved with the proposed project and the associated mitigation measures are summarised in the following table. In all cases, the competency of mariners has been assumed when assigning the risk of each hazard.

Hazard	Key Points	Mitigation
Commercial ship (powered) collision with turbine.	The vast majority of commercial vessels passing the site tend to naturally avoid it, although it was agreed that shipping will move further to the East passing about 1nm off the turbines. An East Cardinal Mark will result in pushing shipping even further East, and is likely to be swept away. Overall this was not considered necessary. The project are to hold discussions with the Northern Lighthouse Board and UKHO to ensure the project is appropriately marked, lit and depicted on charts, etc. Notices to Mariners to be used to circulate information on the project to stakeholders Competent mariners and the "rules of the road" will contribute to risk reduction. Overall the risks were identified as **LOW**.	Marking and Lighting Sound signal Chart Markings Safety Zones Development Area Notices to Mariners Consultation with Local Users Website
NUC vessel collision	It was highlighted that it was difficult to estimate how often vessels become NUC as this often goes unreported.	Marking and Lighting

Hazard	Key Points	Mitigation
	It was suggested that vessels become NUC most often within 5nm of the port/harbour, when they change engine settings or move from passage to manoeuvring mode. Generally a result of human error. Overall the risks were identified as **LOW** as it was considered unlikely that a vessel would become NUC and drift toward the turbines without sufficient time to drop anchor.	Sound signal Chart Markings (cables) Notices to Mariners Consultation with Local Users Website Cable route away from shipping Appropriate cable protection/burial
Vessel anchoring / dragging anchor	Incident rates of vessels dragging anchor were difficult to quantify for the area. Overall risks were identified as **LOW** as it was considered unlikely that a vessel would drag anchor undetected and drift towards the turbines without starting engines. The main modes of detection were noted as alarm on the bridge, watch keeper/crew detection, and also other vessels at anchor in the anchorage. In addition to this the VTS sets a guard zone with alarm around each vessel when at anchor in the anchorage.	Marking and Lighting Sound signal Chart Markings (cables) Notices to Mariners Consultation with Local Users Website Cable route away from shipping Appropriate cable protection/burial

Hazard	Key Points	Mitigation
Vessel-to vessel-collision due to avoidance of site (includes fishing, recreational and attendant/construction/ maintenance vessels)	An increase in ship-to-ship encounters was identified to be the most likely outcome of the proposed development. However with competent crew/seamanship it was agreed that the risks of ship to ship collision were still likely to be **LOW**. In poor weather it was indicated that vessels are likely to give more sea room to the turbines thereby reducing congestion in periods when visual observation of other vessels was compromised. The vast majority of ships (excluding fishing and recreational) using Aberdeen Harbour have AIS and as a result detection levels will be high so there should be good situational awareness at all times. Radar returns for larger vessels passing 0.7 to 1nm off the turbines are unlikely to be impacted significantly. However smaller vessels exiting the EOWDC site itself have potential to go undetected which could pose difficulty to passing vessels. It was noted that it was extremely unlikely for this event to happen as there was limited small vessel navigation in this area (fishing and recreational) and	Marking and Lighting Sound signal Chart Markings Safety Zones Development Area Notices to Mariners Consultation with Local Users Website Effective Management of Vessels working in site Consultation with fishing and recreational stakeholders.

Hazard	Key Points	Mitigation
	when there was it was very local to Aberdeen so unlikely to exit/enter the site from/to the East. However it was agreed that further discussions should be held with these stakeholders. It is noted that fishing and recreational activity is very limited in the area, however, it is expected that these will both increase within the EOWDC site once it is operational (only small fishing vessels). Further discussions are to be held with both stakeholder groups. A particularly undesirable scenario was recorded as a vessel leaving anchor to go offshore in bad visibility, encountering an inbound vessel. It was agreed that in this instance the vessel leaving anchor would take particular care and that the inbound vessel was likely to pass further off the turbines creating more sea room. In these circumstances most competent mariners would broadcast their intentions to leave the anchorage. With the use of AIS and radar it was concluded that the risks were likely to be well managed by a competent mariner.	

12.5 Risk Analysis

Following identification of the key navigational hazards, risk analyses were carried out to investigate selected hazards in more detail. This allowed more attention to be focused upon the high risk areas to identify and evaluate the factors which influence the level of risk with a view to their effective management. Four risk assessments were carried out as per the DECC guidelines:

1. Base case without wind farm level of risk
2. Base case with wind farm level of risk
3. Future case without wind farm level of risk
4. Future case with wind farm level of risk

The following scenarios were investigated in detail, quantitatively or qualitatively.

Without Wind Farm:

- Vessel-to-vessel collisions

With Wind Farm

- Vessel-to-vessel collisions
- Vessel-to-wind farm collisions (powered and drifting)
- Cable interaction

All the quantified risk assessments were carried out using Anatec's COLLRISK software which conforms to the DECC methodology as outlined in Annex D3 in the Guidance (Ref. i). In line with this, Anatec makes the declaration that the models used within this work have been validated and are appropriate for the intended use. As required the following have been considered and justified:

- Tuning of parameters
- Consistency checks
- Behavioural reasonableness
- Sensitivity analysis
- Comparison with the real world

The results of the detailed risk analyses are presented in Section 13. Where considered appropriate in high risk scenarios, the change in individual and societal risk (based on Potential Loss of Life), as well as the risk of pollution, were calculated and compared to background risk levels in the UK.

12.6 Risk Control Measures

A summary of measures is presented in Section 20.

13. RISK ASSESSMENT

13.1 Introduction

This section assesses the risks identified from the hazard review to require more detailed assessment. This is divided into without EOWDC (pre-installation) and with EOWDC (post-installation) risks.

The base case assessment uses the present day vessel activity level identified from the maritime traffic survey, consultation and other data sources. The future case assessment makes conservative assumptions on shipping traffic growth over the life of the project.

The modelling is based on the current proposed EOWDC set-up, i.e., 11 turbines and assumes the maximum jacket structure (21 m x 21 m (see Section 3.4) (worst case).

13.2 Without Wind Farm Risk

13.2.1 Encounters

An assessment of current ship-to-ship encounters has been carried out by replaying at high-speed two weeks of survey data from Survey 3 in April 2010.

Encounter distances between vessels of 1nm, 0.5nm and 0.25nm were considered. The tracks of vessels during encounters, and heat maps based on the geographical distribution of encounters within a grid of cells, are presented in Figure 13.1 to Figure 13.3. This helps to illustrate where existing shipping congestion is highest and therefore where offshore developments, such as the proposed EOWDC, could potentially exacerbate congestion and hence increase the risk of encounters / collisions.

It can be seen that in all cases, the density of encounters in the vicinity of the proposed EOWDC is minimal.

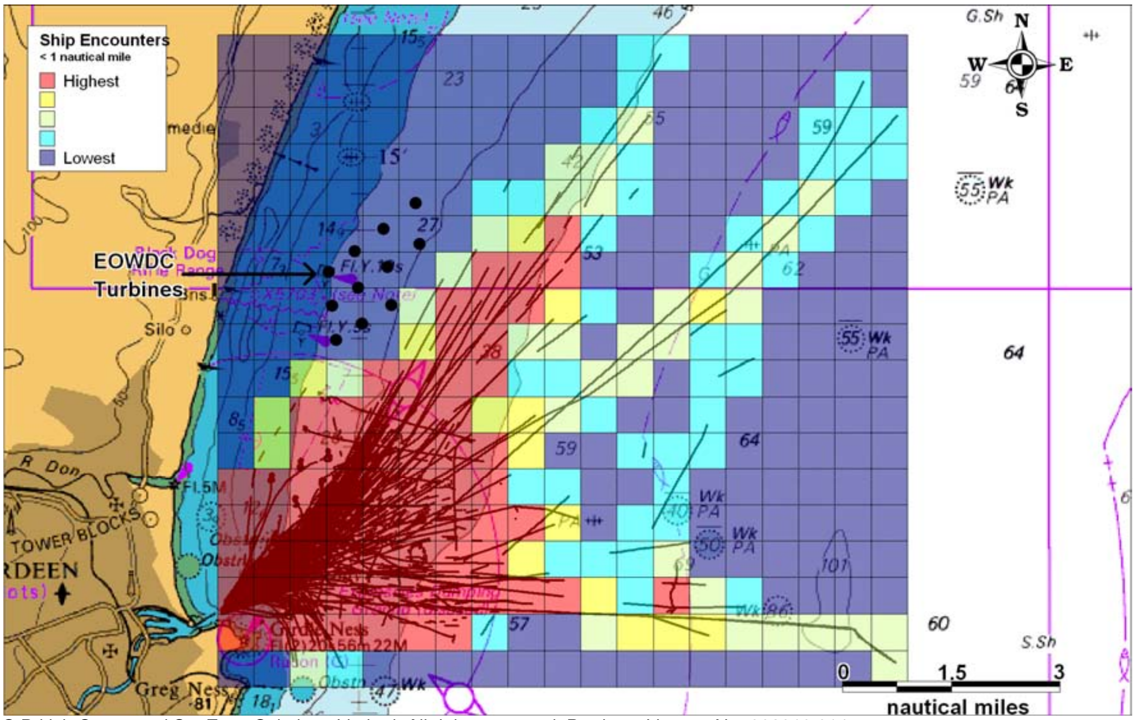

Figure 13.1 Ship Encounters within 1nm

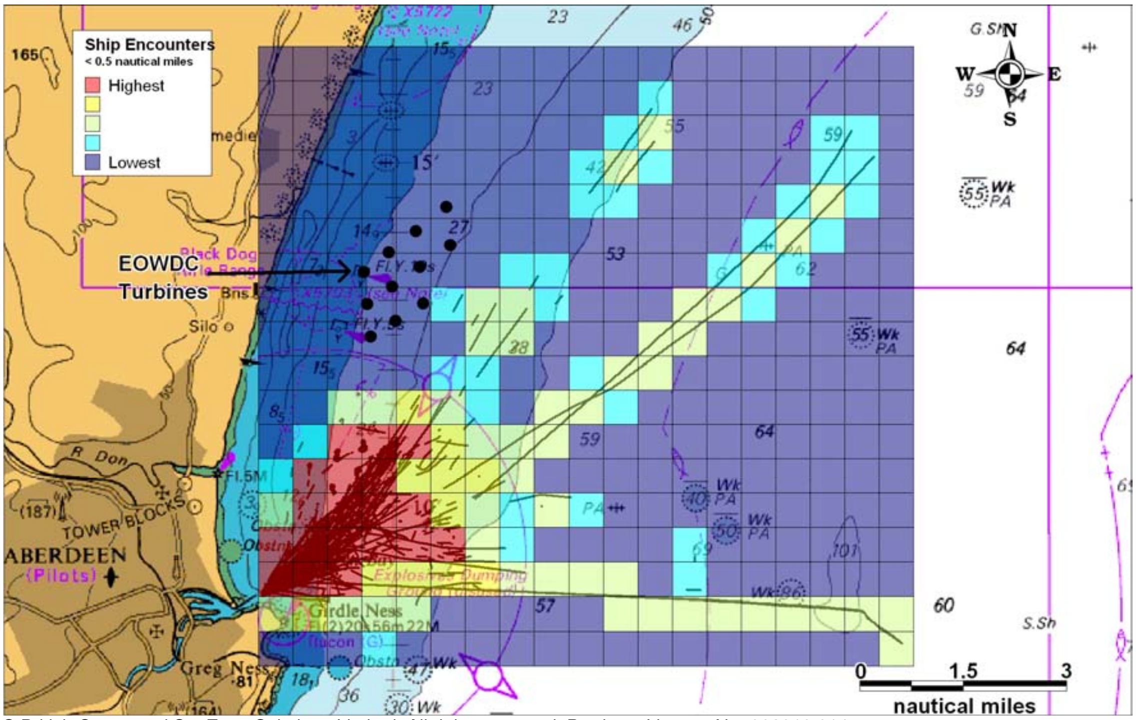

Figure 13.2 Ship Encounters within 0.5nm

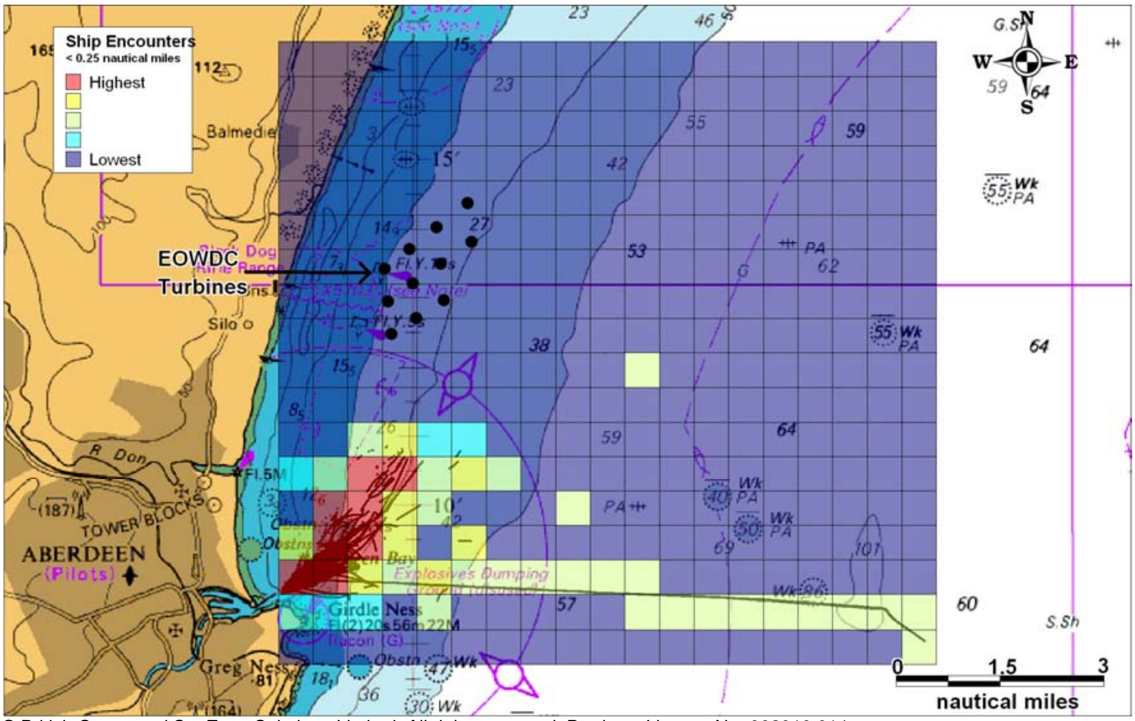

Figure 13.3 Ship Encounters within 0.25nm

Due to the location of the proposed EOWDC site (i.e., near a port), an encounter distance of 0.5nm has been used for further analysing encounters.

There were 789 encounters during the 14-day period. Figure 13.4 presents the number of encounters per day.

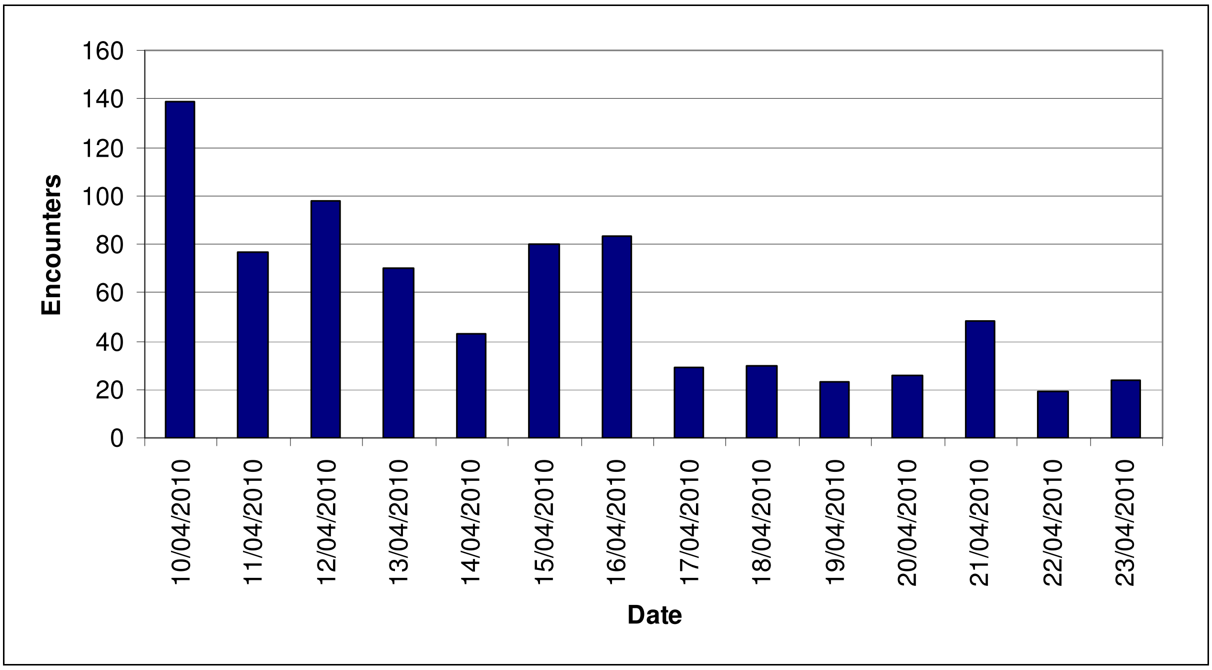

Figure 13.4 Number of Encounters per Day

The average number of encounters was 56 per day, with the highest number (139 encounters) observed on 10 April 2010.

Figure 13.5 presents the distribution of vessel types involved in encounters (excluding unspecified).

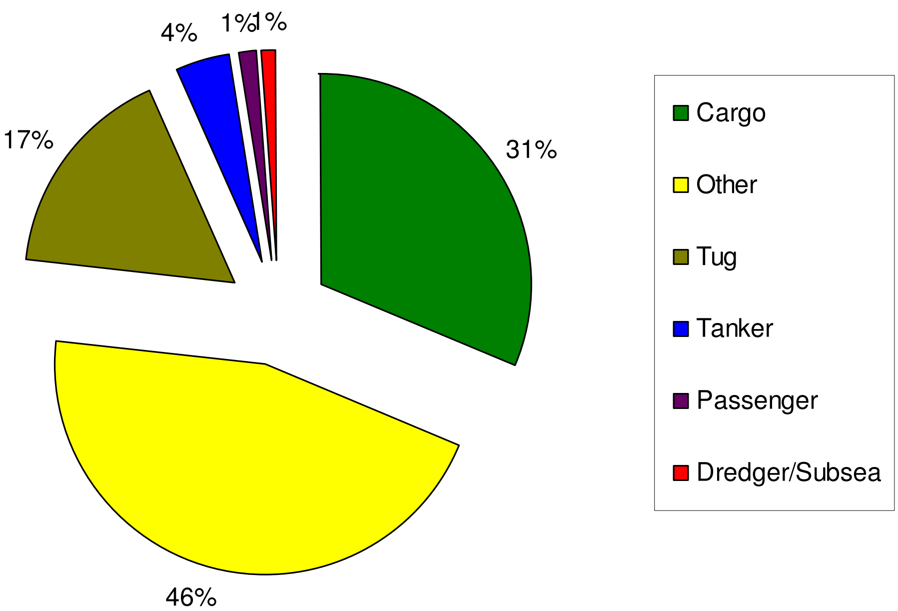

Figure 13.5 Vessel Types Involved in Encounters

It can be seen that the majority of encounters involved 'other ships' (46%) and cargo vessels (31%). The majority of both are offshore industry support vessels.

The locations of encounters during the 14 day period are presented in Figure 13.6. A density map of the encounters is presented in Figure 13.7.

The vast majority of encounters occurred where ships converge on approach to or departure from Aberdeen Harbour to the south of the proposed EOWDC site. There were no encounters recorded within the proposed turbine locations although there were a few close to the eastern boundary of the proposed site.

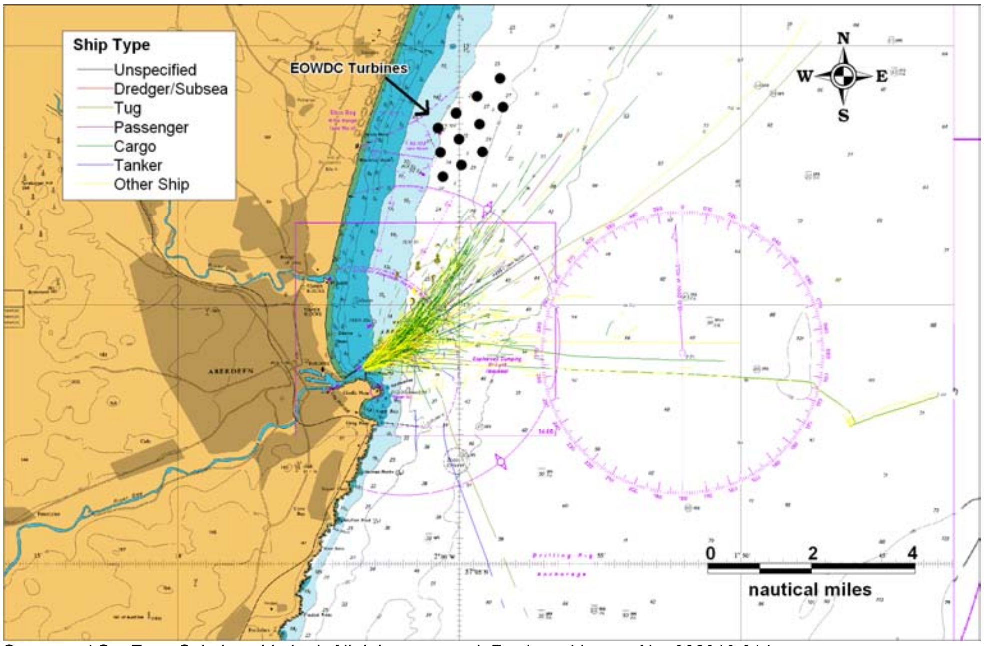

Figure 13.6 Overview of Encounters <0.5nm during 14 Days (AIS)

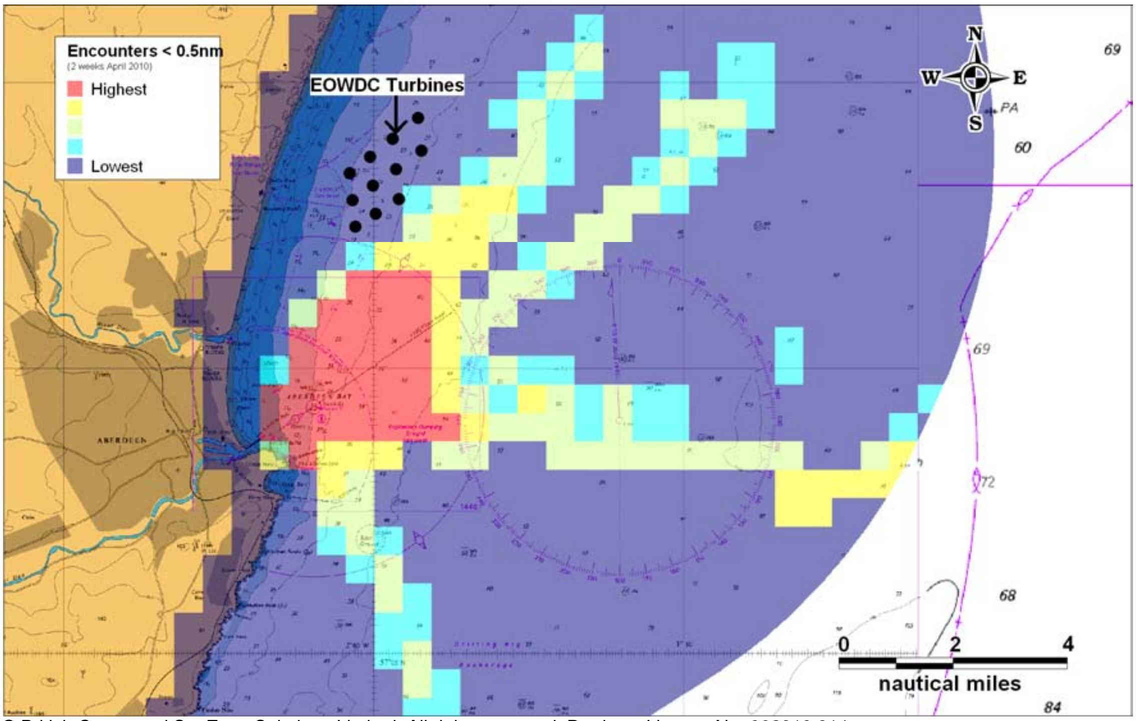

Figure 13.7 Density Distribution of Encounters < 0.5nm

13.2.2 Vessel-to-Vessel Collisions

Based on the existing routeing and encounter levels in the area, Anatec's COLLRISK model has been run to estimate the existing vessel-to-vessel collision risks in the local area around the proposed EOWDC site. The route positions and widths are based on the survey analysis with the annual densities based on port logs and Anatec's ShipRoutes database, which takes seasonal variations into consideration.

Based on the model run for the area, the baseline vessel-to-vessel collision risk level pre-wind farm is in the order of 1 serious collision in just over 153 years[1].

It is emphasised the model is calibrated based on major incident data at sea which allows for benchmarking but does not cover all incidents, such as minor impacts, or incidents occurring within port. Other incident data from RNLI and MAIB is presented in Section 7. This includes other minor incidents including collisions in port (all five collisions reported by MAIB within 10nm of the site were in Aberdeen Harbour).

13.3 With Wind Farm Risk (Base Case)

13.3.1 Vessel-to-Vessel Collisions – Change in Risk

The revised routeing pattern following construction of the proposed EOWDC project has been estimated based on the review of impact on navigation (see Section 8.6). The main change is displacement of ships passing close to the site area on approach/departure from Aberdeen. It is assumed that ships will be able to pre-plan their revised passage in advance of encountering the proposed site due to effective mitigation in the form of information distribution about the development to shipping through Notices to Mariners, updated charts, liaison with ports, etc. Fishing vessels may also be displaced from the site to other areas, which could increase the frequency of encounters.

Based on vessel-to-vessel collision risk modelling of the revised traffic pattern, the collision risk was estimated to increase to 1 major collision in 150 years. The change in collision frequency due to the proposed EOWDC was estimated to be 1.3×10^{-4} per year.

As noted earlier, the model is calibrated based on major incidents at sea which allows for benchmarking but does not cover all incidents, such as minor impacts, or incidents occurring within port.

[1] Note that the models have been calibrated against 'serious' casualty data at sea. This excludes incidents in port, e.g., minor bumps during berthing, requires the incident to be of a defined degree of seriousness in terms of loss of life, environmental damage and/or financial impact. Non-serious casualties are estimated to be in the order of 4 times more frequent than serious casualties. Anatec's models are calibrated against serious casualties as this minimises the probability of under-reporting and provides a benchmark level when comparing the frequency of accidents in different parts of the World.

The following potential effects have not been quantified but may indirectly influence the vessel-to-vessel collision risk:

- Radar interference
- Visual obscuration when ships approach each other

Radar interference is discussed in Section 15. It is noted that any potential impact is only likely to be a problem during bad visibility and this is mitigated to an extent by the widespread adoption of AIS which will assist vessels in discriminating genuine targets (although AIS is not currently mandatory for smaller vessels, e.g., fishing and recreational vessels). Ships may also call Aberdeen VTS if unsure whether a radar target is genuine.

The visual aspect is reviewed in Section 19.2 and is not considered a significant factor for the proposed EOWDC site due to its position and orientation relative to the shipping lanes and the other navigational features in the area.

13.3.2 Ship Collision with Structure

There are two main scenarios for passing ships colliding with offshore structures such as wind turbines:

- Powered Collision:
  - Where the vessel is under power but errant
- Drifting Collision:
  - Where a ship on a passing route experiences propulsion failure and drifts under the influence of the prevailing conditions.

Each scenario is assessed below.

<u>Powered Ship Collision</u>
Based on the ship routeing identified for the area and the anticipated change in routeing due to the site, and assuming effective mitigation in terms of making mariners aware of the site through Notices to Mariners, charts, lights and markings, etc., the frequency of an errant ship under power deviating from its route to the extent that it comes into proximity with the proposed EOWDC site is not considered to be a likely event.

From consultation with the shipping industry it is assumed that merchant ships will not attempt to navigate between turbines due to the restricted sea room and will be directed by the navigational aids in the area.

The main risk of powered collision with a wind farm structure is from human error on the bridge of the ship, however, the proximity to the coastline and Aberdeen port should mean that mariners are already very attentive to their vessel's position and proximity to other vessels and obstructions in this area.

Based on modelling the revised ship routeing pattern estimated with the proposed EOWDC structures in place and using local metocean data, the risk of a passing powered ship collision was estimated to be 1.1 x 10^{-3} per year (approximately 1 in 871 years) for all 11 turbines.

The individual turbine collision frequencies ranged from 4 x 10^{-4} for Turbine 7 to 8.6 x $10^{-6}$for Turbine 3 This compares to the historical average of 5.3 x 10^{-4} per installation-year for offshore installations on the UKCS. A bar chart showing the passing powered collision frequency for each structure relative to the historical benchmark is presented in Figure 13.8. The risk per turbine is below the historical average, which reflects the smaller size of turbines compared to typical North Sea installations, as well as the shipping characteristics of the area.

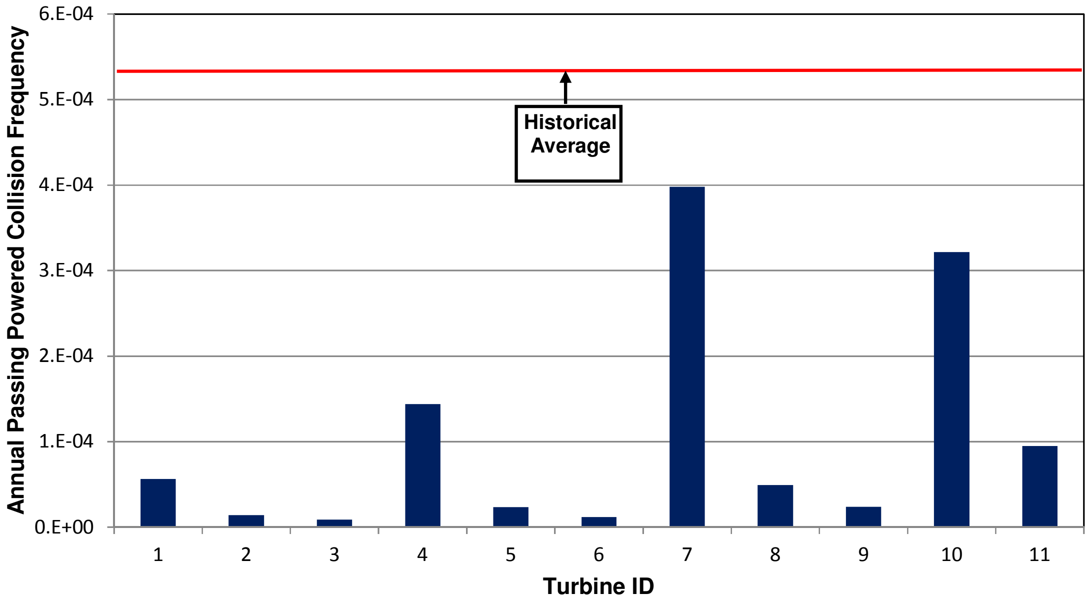

Figure 13.8 Annual Passing Powered Collision Frequency for the 11 Turbines

<u>Drifting Ship Collision</u>
The risk of a ship losing power and drifting into an EOWDC structure was assessed using Anatec's COLLRISK model. This model is based on the premise that propulsion on a vessel must fail before a vessel will drift. The model takes account of the type and size of the vessel, number of engines and average time to repair in different conditions.

The exposure times for a drifting scenario are based on the ship-hours spent in proximity to the proposed EOWDC site (up to 10nm from turbines). These have been estimated based on the traffic levels, speeds and revised routeing pattern. The exposure is divided by vessel type and size to ensure these factors, which based on analysis of historical accident data have been shown to influence accident rates, are taken into account within the modelling.

Using this information the overall rate of breakdown within the area surrounding the project was estimated. The probability of a ship drifting towards a structure and the drift speed are dependent on the prevailing wind, wave and tide conditions at the time of the accident.

The following drift scenarios were modelled:

- Wind
- Peak Spring Flood Tide
- Peak Spring Ebb Tide

The probability of vessel recovery from drift is estimated based on the speed of drift and hence the time available before reaching the wind farm structure. Vessels that do not recover within this time are assumed to collide.

After modelling the three scenarios it was established that wind-dominated drift produced the worst case results for the proposed EOWDC, therefore, this result is presented. This was mainly due to the majority of tidal based drifts being parallel to the site rather than towards it.

The annual drifting ship collision frequency with the Aberdeen structures (all 11 turbines) was estimated to be 5.4 x 10^{-5} per year corresponding to an average of one drifting ship collision in 18,600 years. The low risk levels reflect the fact that a drifting collision is a low probability event. (There have been no reported 'passing' drifting ship collisions with offshore installations on the UKCS in over 6,000 operational-years. Whilst a large number of drifting ships have occurred each year in UK waters, most vessels have been recovered in time, e.g., anchored, restarted engines or taken in tow. There have also been a small number of 'near-misses'.)

The majority of the drifting vessel collision frequency is associated with the more easterly turbines, e.g., Turbines 4, 7 and 10. The westerly turbines tend to be partially shielded from drifting events.

13.3.3 Fishing Vessel Collision

Anatec's COLLRISK fishing vessel risk model has been calibrated using fishing vessel activity data along with offshore installation operating experience in the UK (oil and gas) and the experience of collisions between fishing vessels and UKCS offshore installations (published by HSE).

The two main inputs to the model are the fishing vessel density for the area and the structure details. The fishing vessel density in the area of the proposed EOWDC was based on the number of sightings per patrol in the five-year period 2005-09. The maximum dimensions of the 11 proposed turbines have also been input.

Using the above site-specific data as input to the model, the annual fishing vessel collision frequency with the proposed EOWDC turbines was estimated to be 1.1 x 10^{-3}, which corresponds to an average of 1 collision in 873 years. This collision frequency reflects the relatively low density of fishing vessels operating in the area.

13.3.4 Recreational Vessel Collision

There are two main collision hazards from recreational vessels interacting with wind farms:

1. Turbine Rotor Blade to Yacht Mast Collision
2. Vessel Collision with Main Structures

<u>Blade/Mast Collision:</u>
A collision between a turbine blade and the mast of a yacht could result in structural failure of the yacht.

For a blade/mast collision to occur, the air draught of the yacht (from water-line to top of masthead) must be greater than the available clearance under the area swept by the rotating blade.

The planned minimum rotor blade clearance for the turbines is at least 22m above Mean High Water Springs (MHWS), which matches the MCA minimum requirement and recommendation of RYA. This is the clearance when the blade is in its lowest ('6 o'clock') position. The actual clearance at a given time will depend upon the prevailing tide and wave conditions, i.e., lower clearance at high water and rough seas, greater clearance at low water and calm seas.

To determine the extent to which yacht masts could interact with the rotor blades, details on the air draughts of the IRC fleet are provided in Figure 13.9 based on a fleet size of over 3,000 vessels. IRC is a rating (or 'handicapping' system) used Worldwide which allows boats of different sizes and designs to race on equal terms. The UK IRC fleet, although numerically only a small proportion of the total number of sailing yachts in the UK, is considered representative of the range of modern sailing boats in general use in UK waters.

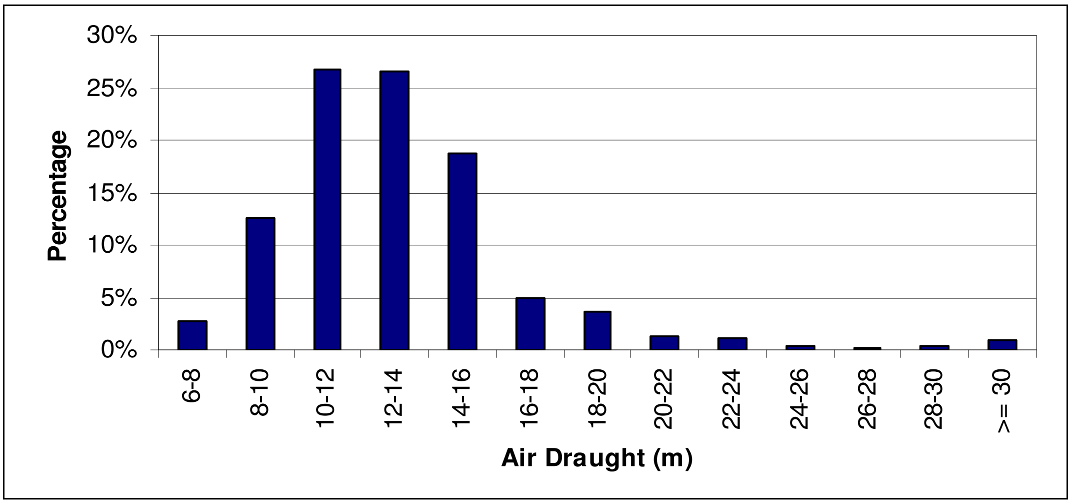

Figure 13.9 Air Draught Data – IRC Fleet (2002)

From this data, just under 3% of boats have air draughts exceeding 22m. Therefore, only a fraction of vessels could potentially be at risk of dismasting if they were directly under a rotating blade in the worst-case conditions. It is also noted that with these larger vessels, crews are likely to be greater in numbers and passage planning will give particular attention to air draught and safe avoidance of potential hazards.

It is further noted that the proposed EOWDC will be designed and constructed to satisfy the requirement of the Maritime & Coastguard Agency in respect of control functions and safety features, as specified in the MCA standards (Ref. ii).

The most likely reason for the Emergency Management System being ineffective is considered to be the mariner failing to alert the Coastguard either directly or indirectly using VHF, mobile phone, flares, etc. It is noted that very large yachts, which are the only boats that could potentially interact with the rotor blades, are also most likely to be equipped with VHF radio and other safety equipment.

Based on the information presented in this section, the risk of the dismasting of a yacht by a rotating blade of an EOWDC turbine is assessed to be minimal, and has not been further quantified.

Vessel/Structure Collision

In good conditions the proposed EOWDC should be visible, especially as most activity occurs during daylight hours. In this case, vessels, if competently skippered, will be able to navigate safely to avoid the structures. Even if a vessel were to get into difficulty, most should be able to keep clear of the structures or anchor or moor if necessary to avoid drifting closer to the proposed EOWDC whilst they fix the problem or call for assistance.

The main risk of collision is considered to be in bad weather, especially poor visibility, where a small craft could fail to see the proposed EOWDC and inadvertently end up closer than intended.

If there were poor visibility combined with adverse weather and/or strong tides, the vessel may not be able to anchor.

The risk of small craft being in the area during bad weather is reduced by the fact that most craft are fitted with radio receivers and VHF so will be able to listen to regular broadcasts of the weather forecast by the BBC and Coastguard. It is also standard practice for local clubs to post weather forecasts on notice boards.

Given the ready availability of weather forecasts and growing use of GPS, the risk of a vessel being in proximity to the proposed EOWDC in bad weather is considered to be low but not negligible. In this scenario, a vessel unable to make way from the proposed EOWDC and at risk of collision may alert Aberdeen VTS and the Coastguard using mobile phone, VHF or flares.

To minimise the risk of collision in this worst case scenario, mitigation in line with regulator guidance will be put in place. It will be ensured, consistent with the requirements of NLB, that the structures are marked in such a way as to enhance the prospect of visual observation by passing recreational craft even in adverse conditions.

The Operator will also ensure notification of the development to the recreational craft community is widespread and effective throughout all phases.

These measures mean that whilst the collision risk cannot be completely eliminated it will be reduced to a level as low as reasonably practicable. In terms of consequences, any collisions with the turbines would be relatively low speed and hence low energy. If the seaworthiness of the recreational craft was threatened by the impact, the turbines will be equipped with access ladders for use in emergency, placed in the optimum position taking into account the prevailing wind, wave and tidal conditions, as required by the MCA. This should provide a place of safety/refuge until such time as the rescue services arrive.

13.4 Cable Interaction – Anchor and Trawl

The following figure provides an overview of the export cable corridor versus the most recent survey data on vessel anchoring (survey 5 from 18th February 2011 to the 4th March 2011).

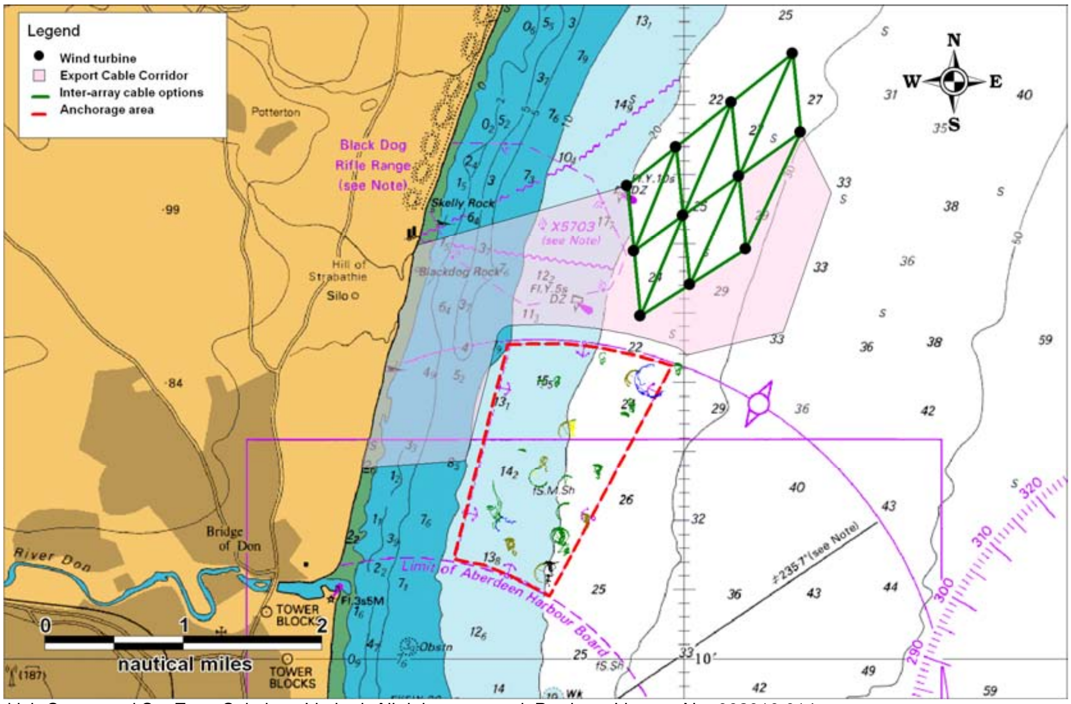

Figure 13.10 Indicative Export Cable Corridor

The main points to note from the figure are:

- There is a 200m buffer between the corridor and the designated anchorage to reduce the risks of interaction between anchoring vessels and the cable.
- Anchored vessels are observed to anchor within the newly designated area thereby staying clear of the cable corridor

There is limited fishing vessel activity in this area (see Section 11) and that the cables are to be buried to a depth between 0.6 and 3m, to reduce the likelihood of interaction.

13.5 Future Case Level of Risk

13.5.1 Shipping

The main factor that is likely to influence the future levels and composition of shipping in the vicinity of the proposed EOWDC is the traffic using Aberdeen Harbour.

Aberdeen Harbour is one of the busiest Trust Ports in the UK. An economic impact assessment of Aberdeen Harbour (Ref. xix), identified its principal activities as follows:

- Marine support for the offshore oil and gas industry in North-west Europe: Aberdeen is well placed to take advantage of the North Sea sector due to its strategic location and comprehensive infrastructure.

- The principal commercial port for North-east Scotland: The Harbour handles a range and scale of general cargo to and from other ports in Europe and has positioned it as the principal commercial port for North-east Scotland, the major mainland port serving the Northern Isles of Orkney and Shetland and as a centre of international trade. Aberdeen Harbour is the nearest port on the UK mainland to Norway, Sweden, Finland, Russia and the Faroe Islands and is the closest Scottish port to the German and Baltic ports. The Harbour is also an international port, with direct, regular connections to around 30 countries including countries in West Africa and the Far East.

- Ferry and cruise services: Aberdeen Harbour has become a principal mainland terminal for ferry services to Norway and to the Northern Islands of Orkney and Shetland. It is also a port of call for cruise ships.

- A gateway for the agriculture industry: Aberdeen Harbour's proximity to rural hinterland makes it ideal for the import and export of agricultural products. In recent years a transit shed has been dedicated for grain export. The Harbour also handles seasonal imports of livestock including sheep and cattle from the Northern Isles.

- A major centre for the import of forest products and the export of finished paper products

Data published by Aberdeen Harbour Board indicates the following changes in ship numbers and goods handled in recent years.

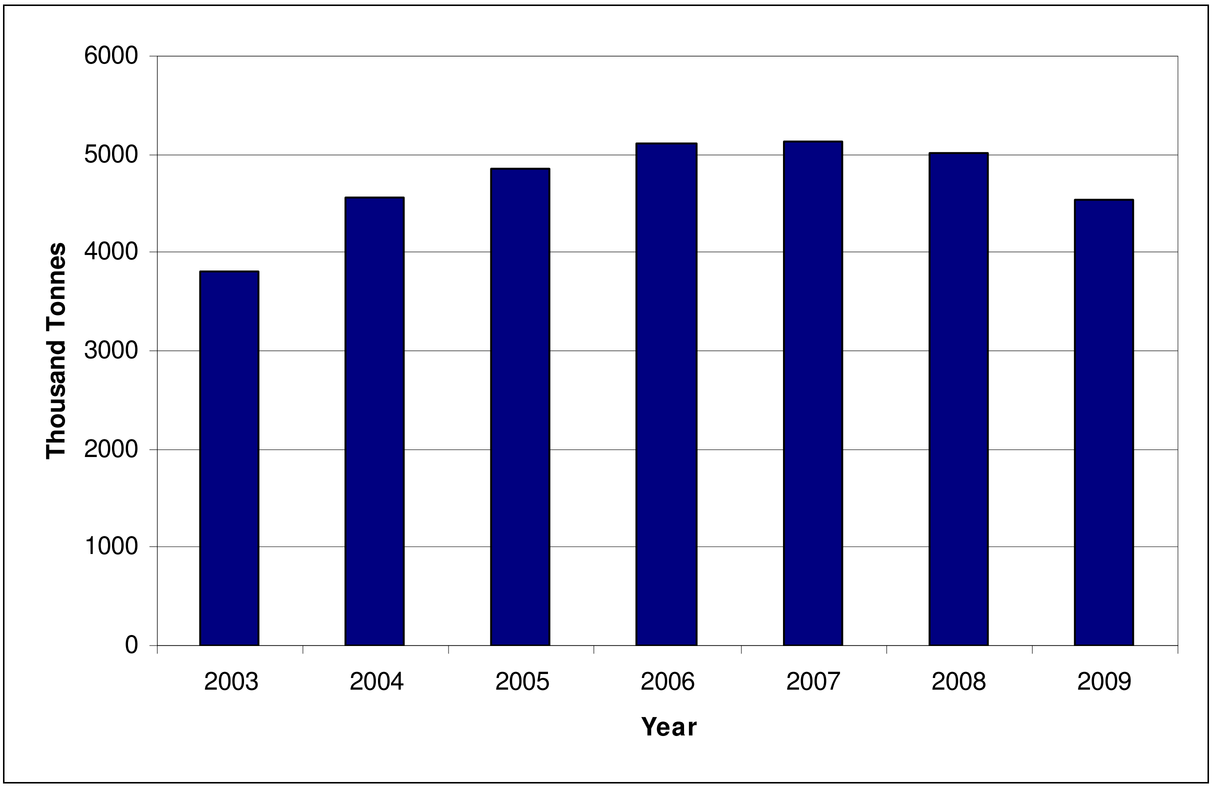

Figure 13.11 Tonnage through Aberdeen Harbour (AHB)

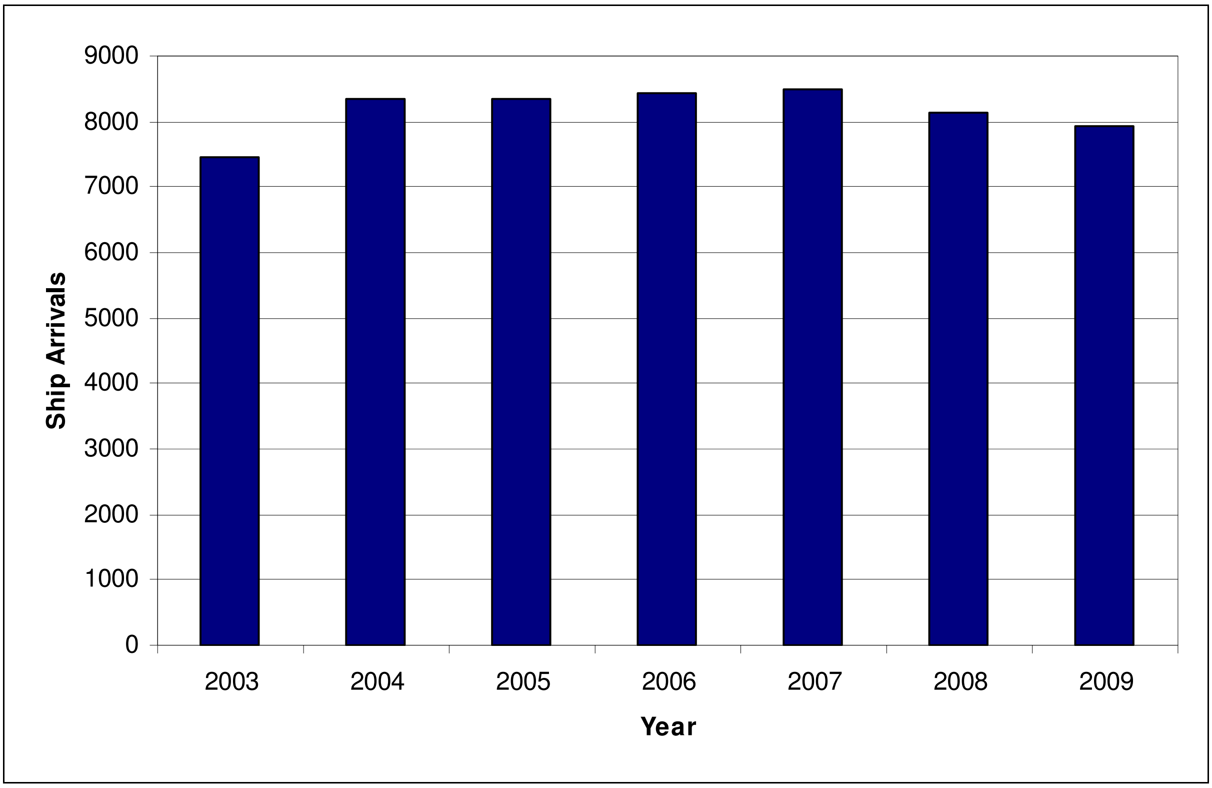

Figure 13.12 Ships through Aberdeen Harbour (AHB)

The number of ships has increased by 6% compared to a tonnage increase of 19% over the period 2003-09. This reflects a general trend in the shipping industry where increased trading tonnages are mainly being achieved through the use of larger vessels as opposed to increased ship movements.

Longer term tonnage data for Aberdeen based on Department for Transport statistics (Ref.xx) are presented in Figure 13.13. (The DfT tonnages for 2003-09 differ slightly from the AHB data but they are reasonably well aligned.)

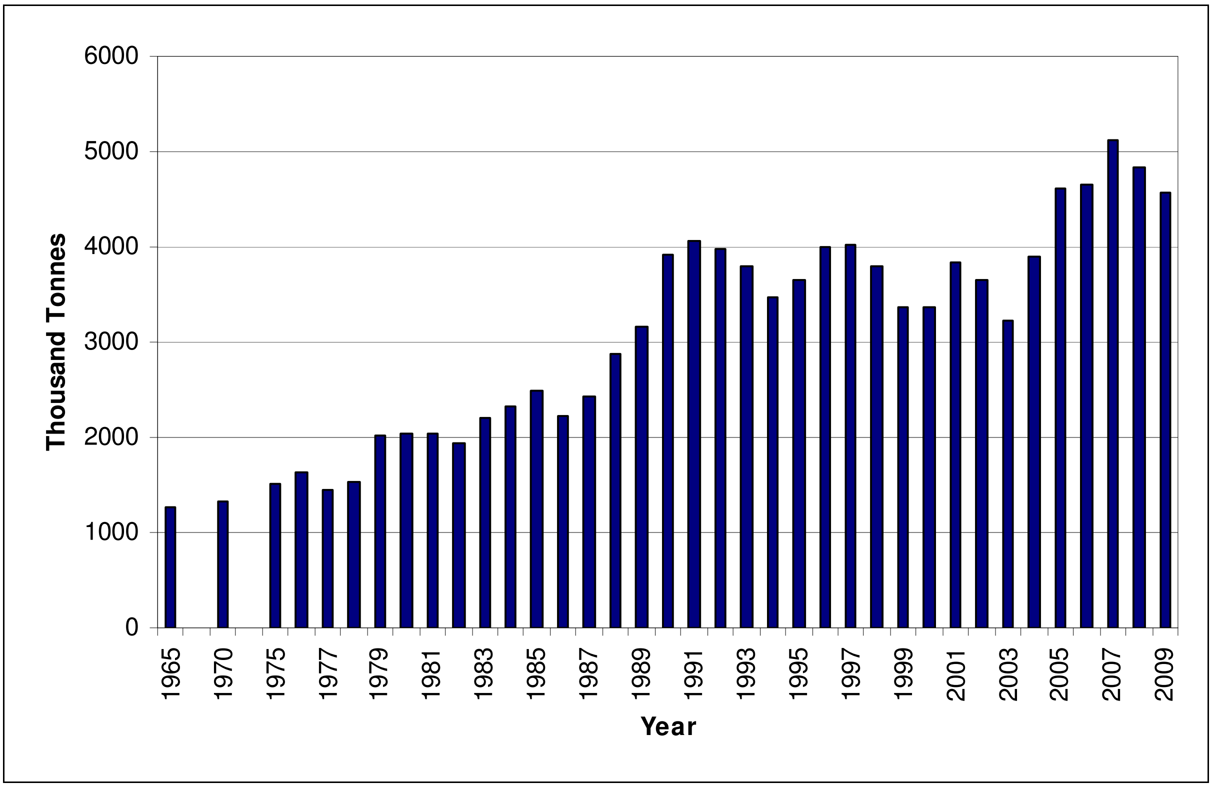

Figure 13.13 Total Tonnage through Aberdeen Harbour (DfT 1965-2009)

Between 1965 and 2009, tonnage has more than trebled. However, in the last 20 years between 1990 and 2009, the overall increase has only been 17%.

Based on the consultation meetings carried out during the project, including several meetings with AHB, no proposals were identified which are likely to have a significant impact on the volume of shipping using the Harbour in the next few years.

The key NW-SW route passing to the east of the proposed EOWDC site is predominantly used by oil & gas industry vessels, and to a lesser extent cargo and passenger ferry services to the Northern Isles. The key factor influencing ship numbers is likely to be the strength of the oil & gas sector in future years. In the long-term, this is expected to decline but the timescale for this is uncertain.

It has been conservatively assumed that over the life of the proposed EOWDC (22 years), there will be a 10% increase in shipping movements.

13.5.2 Fishing

The Commercial Fisheries assessment (Ref.xvi) carried out for the proposed EOWDC Environmental Statement considered the potential changes to the fishing baseline over the life of the development. It is recognised this is a speculative exercise due to numerous unpredictable, direct and indirect factors which can materially affect fisheries.

It stated the following:

> *"At present no new fisheries are foreseen in the area surrounding Aberdeen Bay, and in all probability there is unlikely to be an increase in either fishing effort or vessel numbers. It is also possible that increasing conservation concerns will lead to the implementation of designated protected marine conservation areas which will conceivably have the effect of enforcing further restrictions upon certain commercial fishing activities.*
>
> *There exists the possibility that fishing practices within the proposed EOWDC site could change during its operational life. An example is the appearance of large shoals of squid inshore during the summer in the Moray Firth, providing a valuable fishery which previously did not exist. Furthermore, squid has been recorded at low levels in inshore areas in the proximity of the proposed EOWDC site. It is however considered that this species favours rockier grounds and that the substrate in Aberdeen Bay is not suitable.*
>
> *Finally, future environmental and/or economic constraints may force fishermen to alter or amend current fishing practices. It is possible that vessels may be reconfigured with alternative gear, either to target the same species, or a different fishery."*

The Hazard Review Workshop also indicated that fishing by smaller vessels within the EOWDC site may increase slightly due to the development of the proposed EOWDC.

Based on the discussion presented, the future level of activity has been assumed to increase by 10% over the life of the proposed EOWDC compared to current levels.

13.5.3 Recreational

In terms of recreational vessel activity, there are no major developments known of that will increase the activity of these vessels in the area. There have been suggestions from time to time that a marina for recreational vessels could be established in Aberdeen but there are no known plans for this.

It was suggested at the Hazard Review workshop that the turbines could attract sightseers, given their proximity to the shore.

Based on the discussion presented, the future level of activity has been assumed to increase by 10% over the life of the proposed EOWDC compared to the current, low levels.

13.5.4 Collision Probabilities

The potential increase in vessel activity levels would increase the probability of ship-to-structure collisions (both powered and drifting). Whilst in reality the risk would vary by vessel type, size and route, it is roughly estimated this would lead to a linear 10% increase in the base case collision risks.

The increased activity would also increase the probability of vessel-to-vessel encounters and hence collisions. Whilst this is not a direct result of the proposed project, the increased congestion caused by the site and potential displacement of traffic in the area may have an influence. Again a 10% overall increase is assumed over the life of the proposed EOWDC.

13.6 Risk Results Summary

The base case and future case annual levels of risk without and with the proposed EOWDC site are summarised in Table 13.1 and Figure 13.14. The change in risk is also shown, i.e., the estimated collision risk with the EOWDC minus the baseline collision risk without the EOWDC (which is zero except for vessel-to-vessel collisions).

Table 13.1 Summary of Results

Collision Scenario	Base Case			Future Case		
	Without	With	Change	Without	With	Change
Passing Powered	--	1.1E-03	1.1E-03	--	1.3E-03	1.3E-03
Passing Drifting	--	5.4E-05	5.4E-05	--	5.9E-05	5.9E-05
Vessel-to-Vessel	6.6E-03	6.7E-03	1.3E-04	7.2E-03	7.3E-03	1.4E-04
Fishing	--	1.1E-03	1.1E-03	--	1.3E-03	1.3E-03
Total	6.6E-03	9.0E-03	2.5E-03	7.2E-03	9.9E-03	2.7E-03

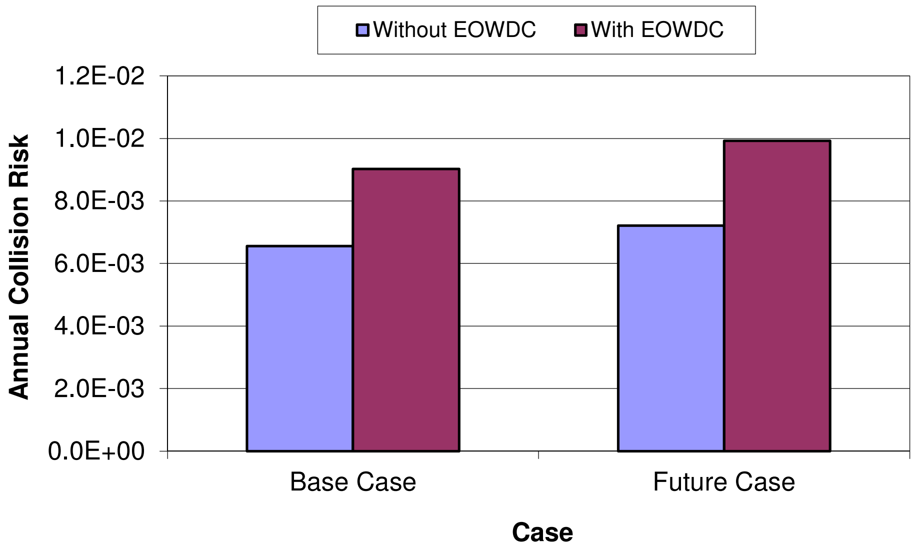

Figure 13.14 Summary of Results

The overall annual level of collision risk is estimated to increase due to the proposed project by approximately 1 in 404 years (base case) and 1 in 367 years (future case). The majority of this risk is from passing powered ship collisions with the turbines on the closest passing route heading in and out of Aberdeen (SSW/NNE), followed by fishing vessel collisions.

The increases are relatively low compared to the existing maritime risks in the area.

13.7 Consequences

The probable outcomes for the majority of hazards are expected to be minor. However, the worst case outcomes could be severe, including events with potentially multiple fatalities.

A collision involving a larger ship is likely to result in collapse of a turbine with limited damage to the ship. Breach of a ship's fuel tank is considered unlikely and in the case of vessels carrying hazardous cargoes, e.g., tanker or gas carrier, the additional safety features associated with these vessels would further mitigate the risk of pollution. Similarly, in a drifting collision the proposed EOWDC structure is likely to absorb the majority of the impact energy, with some energy also being retained by the vessel in terms of rotational movement (glancing blow).

In terms of smaller vessels such as fishing and recreational craft, the worst case scenario would be risk of vessel damage leading to foundering of the vessel and potential loss of life.

A quantitative assessment of the potential consequences of collision due to the proposed EOWDC project is presented in Appendix D. This applies the site-specific collision frequency results presented above with estimated outcomes in terms of fatalities onboard and oil pollution from the vessel based on research into historical collision incidents (MAIB, ITOPF, etc.). The results are summarised in Table 13.2. It is noted that these are based on a conservative approach to give account to the uncertainty surrounding the jacket sub-structure foundation type.

Table 13.2 Annual Predicted Change in Collision Risk due to the proposed EOWDC

Criteria	Base Case	Future Case
Potential Loss of Life (PLL)	1 fatality in 43,000 years	1 fatality in 39,000 years
Oil Spill	0.039 tonnes	0.043 tonnes

Comparing the above estimates with the background marine accident risk levels in the UK (29 fatalities and 16,111 Tonnes of Oil Spilt per annum), the incremental increase in risk to both people and the environment caused by the proposed EOWDC was estimated to be low.

However, it should be noted that this is the localised impact of a single project and there will be additional maritime risks associated with other offshore wind farm projects in Scotland as well as in the UK as a whole.

14. CONSTRUCTION AND DECOMMISIONING IMPACTS

14.1 Introduction

This study has primarily focused on the operational and maintenance phase of the proposed EOWDC, however, it is recognised that there will be additional potential impacts during the construction and decommissioning phases of the project.

In general, whilst the same hazards apply as during the operational and maintenance phase, there are additional hazards which are distinctly associated with these phases of the project and require different risk control measures.

14.2 Hazards during Construction/Decommissioning

During the construction/decommissioning phase there will be an increased level of vessel activity within the proposed EOWDC site and along the cable route.

The presence of construction vessels within the area is likely to pose an additional navigational risk, although such vessels can also provide on-site response and mitigation. The main hazards associated with construction/decommissioning which have been identified over and above those associated with all phases (i.e., where the same risk control measures and emergency response will apply during all phases) are listed below.

- Construction vessel collision with another vessel on-site
- Construction vessel collision with structure
- Construction vessel collision with passing vessel en route to or from site
- Construction vessel encounters (jack-ups or anchors on) underwater obstruction (e.g., cable, pipeline etc).
- Construction vessel jacks-up or anchors onto unexploded ordnance
- Man overboard during personnel transfer operations
- Dropped object during major lifting operations

It is noted that to a large extent the hazards will depend on the vessels and procedures which are to be used for these operations. This will not be known in detail until the structures, construction methods and vessels/contractors have been selected. It is therefore planned that hazard/risk assessment workshops be carried out as part of the project-planning process. The objective of the workshops will be to identify all of the different activities which will be taking place and identify any potential hazards as well as appropriate mitigation measures and operating procedures relevant to the selected vessels and construction methods.

An example measure might be that, wherever possible, construction vessels would follow prescribed transit corridors. These corridors would be defined in consultation with local maritime stakeholders, such as Aberdeen Harbour Board.

The suggested attendees for the workshops are as follows:

- Project Team
- Contractor Representatives (e.g., barges, cable-laying)
- Harbour Representatives
- HM Coastguard (MCA)
- Fishing Representative
- Recreational Vessel Representative
- RNLI Representative

This process will build mutual understanding of the activities and operating constraints of the different parties involved and allow effective procedures to be developed. Separate workshops should be held for each phase of the project as well as for distinct activities.

It is noted that the construction company appointed will have their own internal health and safety procedures that they will adhere to during the work, providing additional security. Experience and lessons learned from the construction of other offshore wind farm projects will be considered prior to the proposed EOWDC being constructed. The same process will apply during the decommissioning phase of the project

14.3 Risk Control/Mitigation during Construction/Decommissioning

Details of risk control/mitigation measures which will apply during these phases of the work are summarised in Section 20.

15. IMPACT ON MARINE RADAR SYSTEMS

15.1 Introduction

In 2004 the MCA conducted trials at the North Hoyle Offshore Wind Farm off North Wales to determine any impact of wind turbines on marine communications and navigations systems (Ref. iii).

The trials indicated that there is minimal impact on VHF radio, Global Positioning Systems (GPS) receivers, cellular telephones and AIS. UHF and other microwave systems suffered from the normal masking effect when turbines were in the line of the transmissions.

This trial identified areas of concern with regard to the potential impact on ship borne and shore based radar systems. This is due to the large vertical extent of the wind turbine generators returning radar responses strong enough to produce interfering side lobe, multiple and reflected echoes (ghosts). This has also been raised as a major concern by the maritime industry with further evidence of the problems being identified by the Port of London Authority around the Kentish Flats Offshore Wind Farm in the Thames Estuary. Based on the results of the North Hoyle trial, the MCA produced a wind farm/shipping route template (see Section 2.2) to give guidance on the distances which should be established between shipping routes and offshore wind farms.

A second trial was conducted at Kentish Flats Offshore Wind Farm on behalf of BWEA (Ref. iv). The project steering group had members from BERR, the MCA and the Port of London Authority (PLA). The trial took place between 30 April and 27 June 2006. This trial was conducted in Pilotage waters and in an area covered by the PLA VTS. It therefore had the benefit of Pilot advice and experience but was also able to assess the impact of the generated effects on VTS radars.

The trial concluded that:

- The phenomena referred to above detected on marine radar displays in the vicinity of wind farms can be produced by other strong echoes close to the observing ship although not necessarily to the same extent.
- Reflections and distortions by ships structures and fittings created many of the effects and that the effects vary from ship to ship and radar to radar.
- VTS scanners static radars can be subject to similar phenomena as above if passing vessels provide a suitable reflecting surface but the effect did not seem to present a significant problem for the PLA VTS.
- Small vessels operating in or near the proposed EOWDC site were detectable by radar on ships operating near the array but were less detectable when the ship was operating within the array.

15.2 Impact on Collision Risk

The potential radar interference is mainly a problem during periods of bad visibility when mariners may not be able to visually confirm the presence of other vessels in the vicinity.

The onset range from the turbines of false returns is about 1.5 nautical miles, with progressive deterioration in the radar display as the range closes. Figure 15.1 presents the combined 56 days of survey tracks relative to the Aberdeen turbine locations, based on the 11 turbine layout. 500m, 1.5nm and 2nm buffers have been applied around each turbine location to illustrate current passing distances.

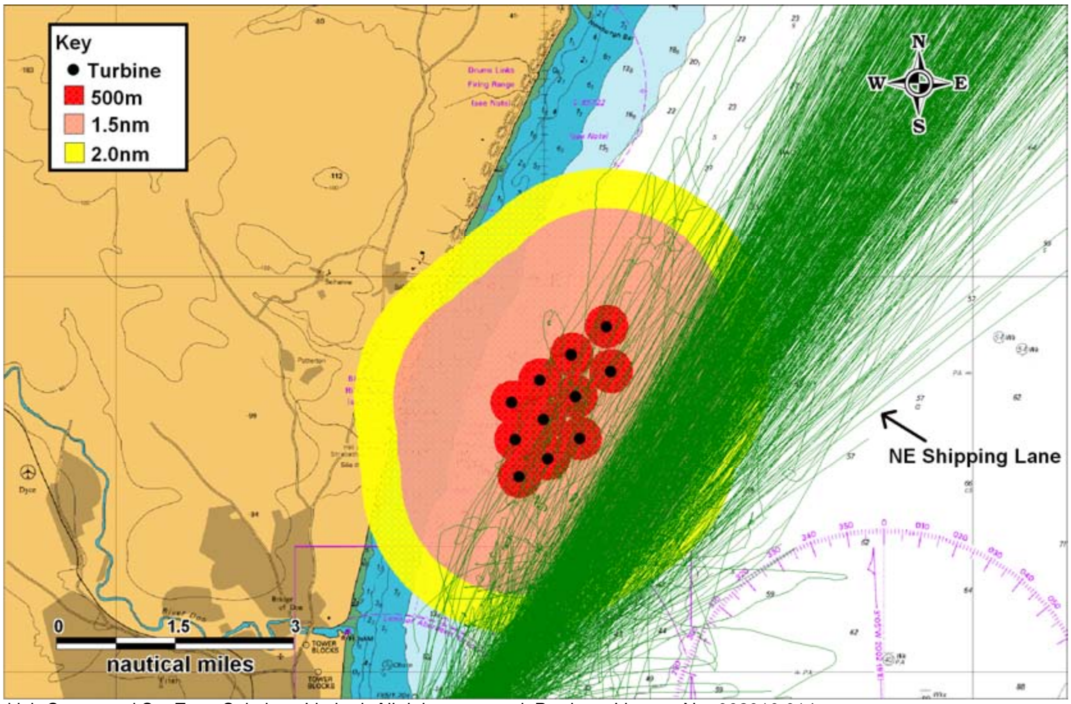

Figure 15.1 Buffer Zones versus Current Shipping Tracks (56 Days Survey Tracks)

It can be seen that, at present, ships pass inside the 1.5nm range from turbines at which radar interference could be experienced.

Assuming an average speed of 11 knots for NE-SW ships based on the survey data, the exposure of a typical ship to the turbines during a 10 mile transit from Aberdeen port travelling northeast is illustrated in Figure 15.2 for the current mean route position and anticipated mean route position (see Figure 9.2).

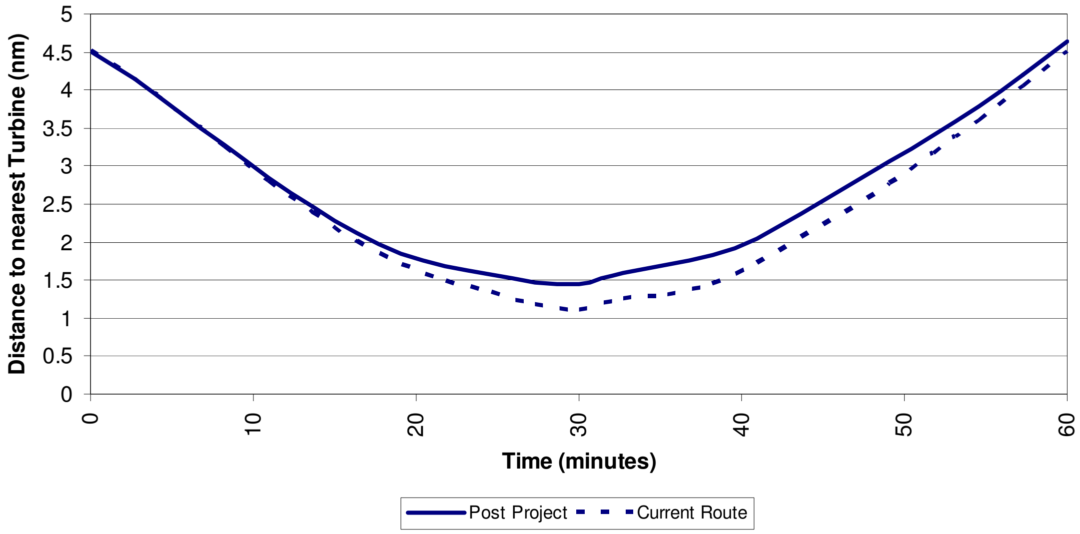

Figure 15.2 Typical Exposure Time versus Distance of Northbound Ship to Turbines

Based on the current transit vessels will be within 1.5nm of the turbines for a total duration of approximately 20 minutes and have a minimum CPA of 1.1nm. Based on the anticipated transit post-project, the typical ship will have a minimum CPA of 1.5nm from the turbines.

Experienced mariners should be able to suppress the observed problems to an extent and for short periods (a few sweeps) by careful adjustment of the receiver amplification (gain), sea clutter and range settings of the radar. However, there is a consequent risk of losing targets with a small radar cross section, which may include buoys or small craft, particularly yachts or GRP constructed craft, therefore due care is needed in making such adjustments. The Kentish Flats Offshore Wind Farm study observed that the use of an easily identifiable reference target (a small buoy) can help the operator select the optimum radar settings.

The performance of a vessel's automatic radar plotting aid (ARPA) could also be affected when tracking targets in or near the wind farm. However, although greater vigilance is required, it appears that during the Kentish Flats Offshore Wind Farm trials, false targets were quickly identified as such by the mariners and then the equipment itself.

Although the evidence from mariners operating in the vicinity of existing wind farms is that they quickly learn to work with and around the effects, it is possible that the radar impacts may result in an increase in the risk of collision. The MCA have produced guidance to mariners operating in the vicinity of UK OREIs which highlights this issue amongst others to be taken into account when planning and undertaking voyages in the vicinity of offshore renewable energy installations (OREIs) off the UK coast (Ref. xxi).

AIS information can be used to verify the targets of larger vessels, generally ships above 300 tonnes. Finally, Aberdeen VTS may be able to assist a vessel if in doubt as to whether a target is genuine during periods of reduced visibility.

The VTS radar may also be affected by the turbines. Discussions are being held with Aberdeen Harbour Board as to how this can be managed / mitigated. At other wind farm sites in the UK, a scanner will be fitted to one of the turbines, linked to the VTS.

16. CUMULATIVE AND IN-COMBINATION EFFECTS

Cumulative impacts with maritime activities (shipping, fishing, recreation and associated facilities) are assessed in the main part of this report.

In terms of other potential cumulative impacts, the only known development in the area was the associated Ocean Laboratory. This is likely to be a Met Mast type structure located in proximity to the proposed EOWDC.

The details available on this development were obtained from the Rochdale Envelope document, as summarised below.

Maximum Height above LAT (m)	120 m
Platform size	20 m x 20 m
Height of platform above LAT	18-20 m
Depth of Platform	Max 4 m including containers and ancillary equipment.
Foundation Type/Size	As per wind turbines
Navigation lighting requirements and colour scheme	The final scheme is to be determined in accordance with British law (IALA requirements) Aviation lighting in accordance with CAA requirements.

There is a potential location identified for this site (see Chapter 3 Description of the Proposed Project) however the final location will be such that it gives full consideration to navigational stakeholders in the area, also allowing for the proposed EOWDC and as a result, cumulative impacts will be negligible.

It is noted that the cumulative assessment also included a review of all Round 1 and 2 offshore wind farms, Round 3 Zones and Scottish Territorial Water sites as presented in Figure 16.1. It can be seen from the figure that the proposed EOWDC is not in close proximity to any other developments. The nearest is the Firth of Forth Round 3 Zone, over 30nm to the south.

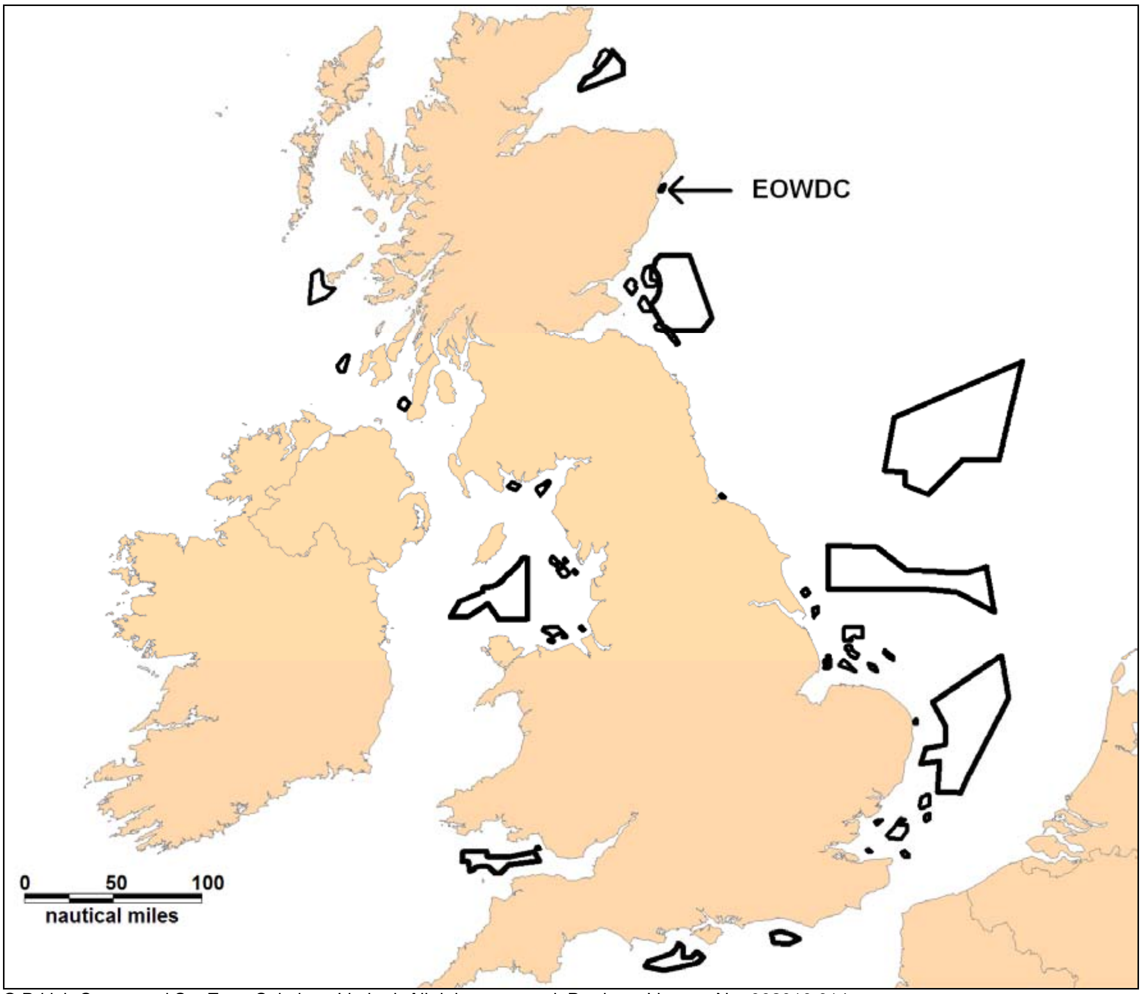

Figure 16.1 Overview of Wind Farm Sites in UK

As mentioned in Section 6.8 there are military practice areas in the vicinity, such as the rifle firing range at Black Dog, but these should not lead to any cumulative navigational impacts.

There are no identified in-combination impacts.

17. SAFETY ZONES

17.1 Construction and Decommissioning Phases

During this phase of the development there will be large construction vessels, working personnel and support craft in operation within and around the proposed EOWDC site area. Further, heavy lifting, piling and cable laying operations will be carried out which have inherent dangers.

In addition the cost of operating construction vessels, and the cost of delay can be significant. A means of controlling 3rd party navigation during these periods of high activity is required. Without this it will not be possible to exclude vessels and carry out their offshore operations in a controlled manner.

Therefore, to ensure the personnel carrying out these activities and those navigating in this sea area are not exposed to unnecessary risk, 500m safety zones may be applied for around each construction activity whilst work is being performed, as indicated by the presence of construction vessels. This will provide a means of regulating the rights of navigation so as to preserve the safety of those working in the proposed EOWDC site and those onboard other vessels that may be navigating in this area. These safety zones will apply to all vessel types not involved in the project operations.

During the construction and decommissioning phases, operational procedures will be implemented for radar and AIS monitoring of vessel activities within the working area, to detect safety zone infringements. Procedures will also be established to ensure that any infringements are formally reported in line with the regulatory requirements.

17.2 Operational Phase

During normal operations the working activities will be limited to general and emergency maintenance work and as such the benefits and requirements for safety zones were reassessed giving account to the working vessels likely to be present within and around the proposed EOWDC site. These vessels will generally be smaller than those involved in the construction phases of the project and therefore smaller safety zones may be applied for during normal operations.

In terms of third-party vessels, it is considered highly unlikely that merchant ships would elect to pass between turbines due to the limited sea room and the fact that the closest routes tend to naturally avoid the location. Therefore, it is only a limited number of fishing and recreational vessels which may choose to pass between turbines.

These vessels were observed in the survey to be mostly heading NE-SW when on passage. It will be up to individual Masters, taking into account the prevailing weather and sea conditions, to decide whether it is safe to navigate, or fish, within the turbine array.

At present 50m safety zones around turbines are planned, which is in-line with other UK offshore wind farm sites. A 200m anchor exclusion is also planned around cables.

17.3 Summary

The safety zones being considered for the project are as follows:

- Construction/Decommissioning:
  - 500m safety zones may be applied for around each construction activity whilst work is being performed.
- Operation:
  - A permanent exclusion zone of 50m around each structure, with a 200m anchor exclusion zone around cables.

The existence of safety zones will be published electronically and via Notices to Mariners.

18. Search and Rescue (SAR)

18.1 Introduction

This section summarises the existing Search & Rescue resources in the region and the issues being considered in relation to the design of the project.

(A detailed review of the historical incidents in the area, including RNLI launches, has been presented in Section 7.)

18.2 SAR Resources

18.2.1 SAR Helicopters

A review of the assets in the area of the proposed EOWDC site indicated that the closest SAR helicopter base is located at Lossiemouth, operated by the RAF, approximately 52nm to the northwest of the proposed EOWDC site. This base has Sea King helicopters with a maximum endurance of 6 hours giving a radius of action of approximately 250nm which is well within the range of the proposed EOWDC site. One helicopter is available at 15 minutes readiness between 0800 and 2200 hours, with another available at 60 minutes readiness between 0800 hours and evening civil twilight (ECT). Between 2200 and 0800 hours, one helicopter is held at 45 minutes readiness.

All RAF SAR helicopters are equipped for full day/night all weather operations over land and sea (some limitations exist with regard to freezing conditions, but in general terms the helicopters are all weather capable) and have a full night vision goggle (NVG) capability. Crews are well practised in NVG operations which is a major enhancement to search capability. In addition, all RAF SAR helicopter rear crew are medically trained, with the winchman trained up to paramedic standard.

Up to 18 persons can be carried, however this is dependent on weather conditions and the distance of the incident from the helicopter’s operating base. All RAF SAR helicopters are equipped with VHF (Marine and Air Band), UHF and HF radios. They are also capable of homing to all international distress frequencies.

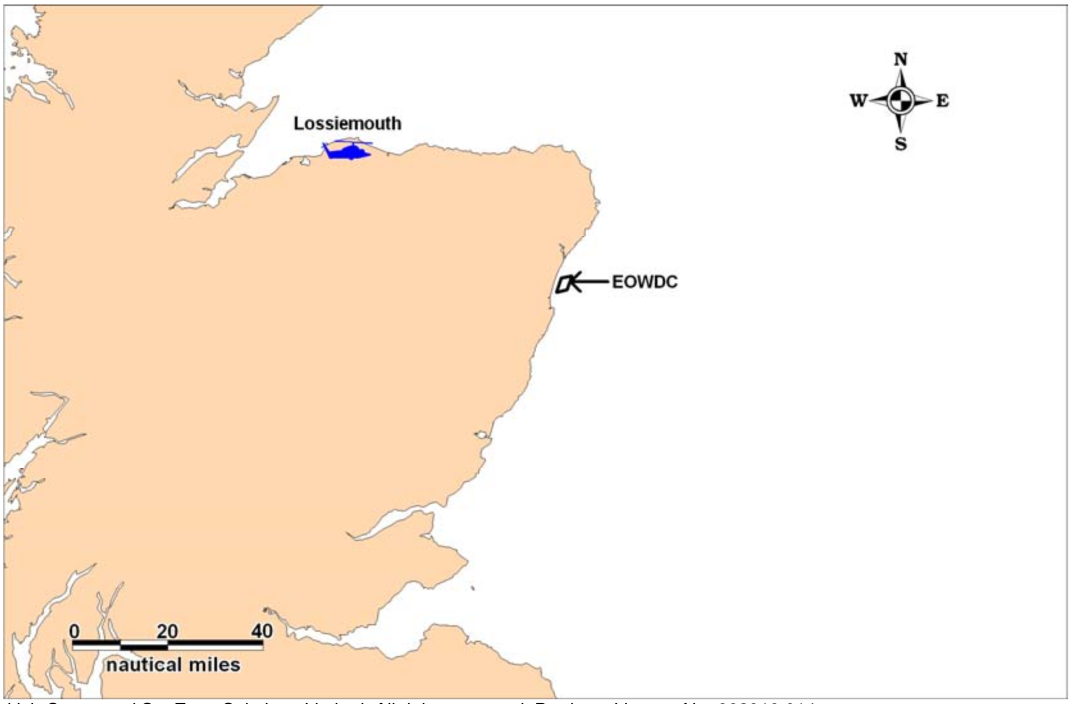

Figure 18.1 SAR Helicopter Bases relative to proposed EOWDC site

Based on the above information, the day-time response to the proposed EOWDC site will be in the order of 1 hour. At night time this will increase by 30 minutes to approximately 1 and a half hours due to the additional response time at the base. It is noted that these calculations are based on still air and will vary depending on the prevailing conditions.

18.2.2 RNLI Lifeboats

The Royal National Lifeboat Institution maintains a fleet of over 400 lifeboats of various types at 235 stations round the coast of the UK and Ireland. The RNLI stations in the vicinity of the proposed EOWDC site are presented in Figure 18.2.

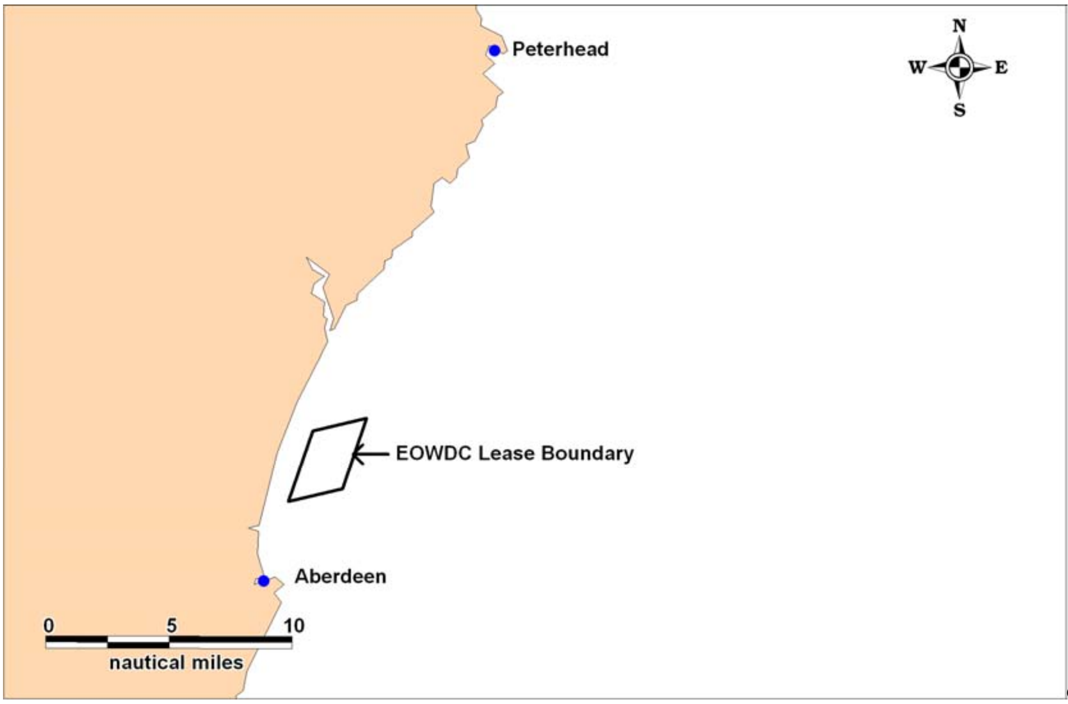

Figure 18.2 RNLI Bases near the proposed EOWDC site

At each of these stations crew and lifeboats are available on a 24-hour basis throughout the year. Table 18.1 provides a summary of the facilities at the stations closest to the proposed EOWDC site.

Table 18.1 Lifeboats held at nearby RNLI Stations

Station	Lifeboats	ALB Spec	ILB Spec	Distance to Site Boundary
Aberdeen	ALB/ILB	Severn	D Class	4.5nm
Peterhead	ALB	Tamar	--	17nm

The Severn class lifeboat has a speed of 25 knots, range of 250nm and can operate in all-weather. The Tamar is also an all weather boat and has a speed of 25 Knots and a 250nm range All-weather lifeboats are fitted with the latest in navigation, location and communication equipment, including electronic chart plotter, VHF radio with direction finder, radar and global positioning systems (GPS).

The D class lifeboat is small and highly manoeuvrable, making it ideal for rescues close to shore in fair to moderate conditions. It has a speed of 25 knots, range of 3 hours at maximum speed and is equipped with VHF radio and GPS.

Response times vary but an average declared by RNLI is 14 minutes for all-weather lifeboats and 7 minutes for inshore lifeboats. This is the time from callout, i.e., first intimation from Coastguard to the lifeboat station to launch. This means the ALB at Aberdeen could be on the scene within 30 minutes.

18.2.3 Coastguard Stations

HM Coastguard is responsible for requesting and tasking SAR resources made available by other authorities and for co-ordinating the subsequent SAR operations (unless they fall within military jurisdiction).

HM Coastguard co-ordinates SAR through its network of 18 Maritime Rescue Co-ordination Centres (MRCC), although this is currently under review. A corps of over 3100 volunteer Auxiliary Coastguards around the UK coast form over 400 local Coastguard Rescue Teams (CRT) involved in coastal rescue, searches and surveillance.

All of the MCA's operations, including SAR, are divided into three geographical regions. The East of England Region covers the East and South Coasts of England from the Scottish border down to the Dorset/Devon border. The Wales and West of England Region extends from Devon and Cornwall to cover the coast of Wales, North West England and the Moray Firth. The Scotland and Northern Ireland Region covers the remainder of the UK coastline including the Western Isles, Orkney and Shetland.

Each region is divided into six districts with its own Maritime Rescue Co-ordination Centre (MRCC), which co-ordinates the Search and Rescue response for maritime and coastal emergencies within its district boundaries (East of England Region includes an additional station, London Coastguard, for co-ordinating Search and Rescue on the River Thames).

The proposed EOWDC site lies within the Scotland and Northern Ireland Region with the nearest rescue coordination centre being Aberdeen. MRCC Aberdeen's area of responsibility provides search and rescue coverage from Cape Wrath to Doonies Point.

MRCC Aberdeen is subdivided into fourteen sectors with the proposed EOWDC site within the Aberdeen sector between Balmedie in the North to Doonies Point in the South.

18.2.4 Salvage

MCA charters four Emergency Towing Vessels (ETVs) to provide emergency towing cover in winter months in the four areas adjudged to pose the highest risk of a marine accident: the Dover Strait, the Minches, the Western Approaches and the Fair Isle Channel.

These are a considerable distance from the proposed EOWDC site; however, each MRCC also holds comprehensive databases of harbour tugs available locally.

Procedures are also in place with Brokers and Lloyd's Casualty Reporting Service to quickly obtain information on towing vessels that may be able to respond to an incident.

MCA has an agreement with the British Tug owners Association (BTA) for emergency chartering arrangements for harbour tugs. The agreement covers activation, contractual arrangements, liabilities and operational procedures, should MCA request assistance from any local harbour tug as part of the response to an incident.

Tugs are available within Aberdeen Harbour through a licensed Tug Operator. An agreement exists which retains one tug permanently in Aberdeen, however in practice there are two tugs most of the time. The tugs *Cultra* and *Carrickfergus* have a bollard pull of 30 tonnes each. A third tug is available with notice. There are also a number of offshore industry vessels with towing capability based in Aberdeen.

18.3 Wind Farm SAR Matters

The proposed EOWDC site will meet the MCA's requirements in terms of standards and procedures for generator shutdown and other operational requirements in the event of a search and rescue, counter pollution or salvage incident in or around the site. These are laid out in Annex 5 of MGN 371 (Ref. ii).

This includes the development of an Emergency Response Co-operation Plan (ERCoP) for the proposed project, which will be in place pre-construction.

Examples of features to be incorporated are as follows:

Design:

- All wind turbine generators (WTGs) and other OREI individual structures will each be marked with clearly visible unique identification characters which can be seen by both vessels at sea level and aircraft (helicopters and fixed wing) from above.

- The identification characters shall each be illuminated by a low-intensity light visible from a vessel thus enabling the structure to be detected at a suitable distance to avoid a collision with it. The size of the identification characters in combination with the lighting will be such that, under normal conditions of visibility and all known tidal conditions, they are clearly readable by an observer, stationed 3 m above sea level, and at a distance of at least 150 m from the turbine.

Operation:

- The Central Control Room, or mutually agreed single contact point, will be manned 24 hours a day.

- All MRCCs will be advised of the contact telephone number of the Central Control Room, or single contact point (and vice versa)

- The control room operator, or single contact point, will immediately initiate the shut-down procedure for WTGs as requested by the MRCC, and maintain the WTG in the appropriate shut-down position, as requested by the MRCC, until receiving notification from the MRCC that it is safe to restart the WTG.

19. ADDITIONAL NAVIGATION ISSUES

19.1 Introduction

There are a number of additional navigational issues identified within MGN 371 (Ref. ii) which require to be addressed by the developer. The following subsections cover additional navigation related issues which have not been covered elsewhere within this report.

19.2 Visual Navigation and Collision Avoidance

19.2.1 Introduction

MGN 371 identifies the potential for visual navigation to be impaired by the location of offshore wind farm structures, based on vessels not being visible to each other (hidden behind structures) and navigational aids and/or landmarks not being visible to shipping.

19.2.2 Visual Impact (Other Vessels)

Based on the position, orientation, number of turbines and spacing between turbines it is not considered there will be any significant issue of visual impact between vessels on the main commercial shipping routes in the area, which should all pass to the east. There is an anchorage area just over 2nm to the south of the proposed EOWDC site, but the vessels using it should also remain visible and will generally be travelling at low speeds when entering or leaving the area.

There is limited small craft activity in the area which limits the likelihood of a small craft emerging from the proposed EOWDC site towards shipping traffic. Even if that were the case, the vessel should be visible for the vast majority of the time due to the small size of the turbines relative to the large spacing between them.

19.2.3 Visual Impact (Navigational Aids and/or Landmarks)

Depending on the approach direction of vessels, the proposed project could hamper the view of existing navigational aids and landmarks, such as the firing range buoys to the west, Girdle Ness Lighthouse, the Fairway Buoy and the lights located on the breakwaters.

However, the proposed EOWDC site itself will form a significant aid to navigation, which will be very visible to shipping with lights on significant peripheral structures as well as selected intermediate structures in accordance with NLB requirements (see Section 4). It is therefore not considered that the EOWDC site will degrade the ability of ships to navigate in the area through visual impairment of navigation aids or landmarks.

19.3 Potential Effects on Waves and Tidal Currents

Based on a specialist study, it was concluded that there will be no significant impact from the proposed project on local tidal currents or waves.

19.4 Impacts of Structures on Wind Masking/Turbulence or Shear

The offshore turbines have the potential to affect vessels under sail when passing through the site from effects such as wind shear, masking and turbulence. From previous studies of offshore wind farms it was concluded that turbines do reduce wind velocity by in the order of 10% downwind of a turbine. The temporary effect is not considered as being significant and similar to that experienced passing a large ship or close to other large structures (e.g., bridges) or the coastline. In addition, practical experience to date from RYA members taking vessels into other sites indicates that this is not likely to be an issue. Finally, it is noted that there is limited sailing activity in the Aberdeen Bay area.

19.5 Sedimentation/Scouring Impacting Navigable Water Depths in Area

There exists the potential for structures in the tidal stream to produce siltation, deposition of sediment or scouring which could affect the navigable water depths in the proposed EOWDC site area or adjacent to the area. The specialist work carried out as part of the ES has shown that no significant impact on navigation will result from the potential effects of the EOWDC development on the physical environment.

19.6 Structures and Generators affecting Sonar Systems in Area

No evidence has been found to date with regard to existing wind farms to suggest that they produce any kind of sonar interference which is detrimental to the fishing industry, or to military systems. No impact is anticipated for the EOWDC project.

19.7 Electromagnetic Interference on Navigation Equipment

Based on the findings of the trials at the North Hoyle Offshore Wind Farm (Ref. iii), the wind turbines and their cabling, inter-turbine and onshore, did not cause any compass deviation during the trials. However, it is stated that as with any ferrous metal structure, caution should be exercised when using magnetic compasses close to turbine towers.

It is noted that all equipment and cables will be rated and in compliance with design codes. In addition the cables associated with the wind farm will be buried to a minimum of 0.6 m and any generated fields will be very weak and will have no impact on navigation or electronic equipment. No impact is anticipated for the EOWDC project.

19.8 Impacts on Communications and Position Fixing

The following summarises the potential impacts of the different communications and position fixing devices used in and around offshore wind farms. The basis for the assessment is the trials carried out by the MCA at North Hoyle Offshore Wind Farm and experience of personnel/vessels operating in and around other offshore wind farm sites.

19.8.1 VHF Communications (including Digital Selective Calling)

Vessels operating in and around offshore wind farms have not noted any noticeable effects on VHF (including voice and DSC communications). No significant impact is anticipated at the proposed EOWDC site.

19.8.2 Navtex

The Navtex system is used for the automatic broadcast of localised Maritime Safety Information (MSI). The system mainly operates in the Medium Frequency radio band just above and below the old 500 kHz Morse Distress frequency. No significant impact has been noted at other sites and none are expected at the proposed EOWDC site.

19.8.3 VHF Direction Finding

During the North Hoyle Offshore Wind Farm trials, the VHF direction equipment carried in the lifeboats did not function correctly when very close to turbines (within about 50 m). This is deemed to be a relatively small scale impact and provided the effect is recognised, it should not be a problem in practical search and rescue.

19.8.4 Automatic Identification System (AIS)

In theory there could be interference when there is a structure located between the transmitting and receiving antennas (i.e., blocking line of sight). This was not evident in the trials carried out at the North Hoyle Offshore Wind Farm site and no significant impact is anticipated for AIS signals being transmitted and received at the proposed EOWDC site.

19.8.5 Global Positioning System (GPS)

No problems with basic GPS reception or positional accuracy were reported during the trials at North Hoyle Offshore Wind Farm and this has been confirmed from other vessels which have been inside offshore wind farms. Consideration will require to be given to any potential degradation of DGPS signals being used to position construction equipment when close to a turbine tower.

19.8.6 LORAN-C

LORAN-C is a low frequency electronic position-fixing system using pulsed transmissions at 100 kHz. The absolute accuracy of Loran-C varies from 0.1 to 0.25 nm. Its use is in steep decline, with GPS being the primary replacement. It is mostly used in ships on and near the US coast, although some GPS receivers have built-in Loran C software.

Attempts were made to test a system during the North Hoyle Offshore Wind Farm trial, but there were difficulties which were probably attributable to operational errors or lack of a nearby transmitter.

Although a position could not be obtained using LORAN-C in the wind farm area, the available signals were received without apparent degradation. The proposed EOWDC is not expected to have a significant impact on LORAN-C. It is noted that the Department for Transport are funding an enhanced LORAN (eLORAN) service in the UK.

19.9 Noise Impact

19.9.1 Acoustic Noise Masking Sound Signals

The concern which must be addressed under MGN 371 is whether acoustic noise from the wind farm could mask prescribed sound signals.

The sound level from a wind farm at a distance of 350m has been predicted to be 51 dB (A) to 54 dB (A) and it should therefore be well below a background sound level which is typically 63-68 dB. A ship's whistle for a vessel of 75m should generate in the order of 138 dB and be audible at a range of 1.5nm, so this should be heard above the background noise of the site. Foghorns will also be audible over the background noise of the project.

Therefore, there is no indication that the sound level of the proposed EOWDC will have any significant influence on marine safety.

19.9.2 Noise Impacting Sonar

Once in operation it is not believed that there will be any subsea acoustic noise generated by the proposed EOWDC that will have any significant impact on sonar systems.

20. RISK MITIGATION MEASURES & MONITORING

20.1 Mitigation

This section summarises the main risk mitigation measures adopted by AOWFL for the proposed EOWDC to reduce the navigational impact of the project.

Table 20.1 Mitigation Measures

Mitigation	Description
Site selection	Site selected to avoid significant navigational impacts, e.g., located away from main anchorage area and navigation lanes to/from Aberdeen following consultation with Aberdeen Harbour, etc.
Marked on Admiralty Charts	EOWDC will be charted by the UK Hydrographic Office using the magenta turbine tower chart symbol found in publication "NP 5011 - Symbols and Abbreviations used in Admiralty Charts". Submarine cables associated with the project will also be charted on the appropriate scale charts.
Information Circulation	Appropriate liaison to ensure information on the wind farm and special activities is circulated in Notices to Mariners, Navigation Information Broadcasts and other appropriate media.
Marking and Lighting	Structures to be marked and lit in-line with NLB and IALA guidance. (See Section 4.)
Turbine Air Draught	Lowest point of rotor sweep at least 22m above Mean High Water Springs as per RYA and MCA recommendations.
Cable Protection	Cables to be buried to suitable depth based on cable protection study taking into account fishing and anchoring practices in Aberdeen Bay. Periodic inspection of the cable to ensure it remains buried. Positions of cable routes notified to Kingfisher Information Services (KIS) for inclusion in cable awareness charts and plotters for the fishing industry.
Compliance with MCA's Marine Guidance Notice (MGN) 371 including Annex 5	Annex 5 specifies "Standards and procedures for generator shutdown and other operational requirements in the event of a search and rescue, counter pollution or salvage incident in or around an OREI."
Formulation of an Emergency Response Cooperation Plan (ERCoP) as per MCA template	AOWFL will use the draft template created by the MCA to formulate an emergency response plan and site Safety Management Systems, in consultation with the MCA.

Discussions on other measures will continue both pre- and post-construction and during the life of the project with the MCA, Aberdeen Harbour Board and other relevant stakeholders.

20.2 Future Monitoring

From a navigation risk perspective, monitoring will take place through the project's Safety Management System (SMS). The Safety Management System will include an incident/accident reporting system which will allow incidents and near misses to be recorded and reviewed to monitor the effectiveness of the risk control measures in place at the site. In addition to this any information gleaned from near misses/accidents at other offshore wind farm sites will be considered with respect to the control measures applied at the proposed EOWDC.

Whilst no radar monitoring of vessel movements has been proposed for the site, AIS monitoring is being considered which can be used to monitor and record the movements of vessels around the proposed EOWDC site and associated export cables to shore, as well as company vessels working at the site.

During maintenance, there will regularly be vessels operating in the site which can monitor any third party vessel activity both visually and on radar, although this will not be their primary function.

The subsea cable routes will be subject to periodic inspection to ensure they remain buried.

Finally, it is noted that the site and cable route are within coverage of Aberdeen VTS, and the VTS will be vigilant to hazardous navigational practices within the general area.

21. CONCLUSIONS

The main conclusions of this work are as follows:

- The proposed EOWDC site has been relocated and reduced in size such that it will not affect the main navigation routes in the area, including the bulk of shipping heading to/from Aberdeen Harbour.

- Moving the site to the north has provided a 0.25 nm separation between the nearest turbine and the designated anchorage area in Aberdeen Bay.

- Consultation with Aberdeen Harbour Board and other users of the area, such as NorthLink Ferries, indicated the site is acceptable.

- There is limited fishing and recreational vessel activity in the area.

- In the hazard review workshop involving local navigational stakeholders, all hazards were identified to be low.

- Following identification of the key navigational hazards, risk analyses were carried out to investigate selected hazards in more detail. The overall annual level of risk was estimated to increase due to the proposed EOWDC by approximately 1 in 404 years (base case) and 1 in 367 years (future case based on traffic growth estimates over the life of the development). The majority of this risk is from passing powered ship collisions with the turbines from the closest passing route headed to/from Aberdeen, followed by fishing vessel collisions.

- The risks associated with recreational craft interaction with the proposed EOWDC structures (blade/mast and vessel/structure collisions) were qualitatively assessed and concluded to be as low as reasonably practicable given the mitigation measures planned.

- A quantitative assessment estimated that, compared to the background marine accident risk levels in the UK, the increase in risk to both people and the environment caused by the proposed EOWDC is low.

TABLE OF CONTENTS

A1. Introduction

This Appendix presents the MCA checklist based on the requirements set out in MGN 371 which was the guidance set by the MCA during the NRA preparation.

Reference notes/remarks are made within the table based on which sections of the NRA, or other documents, address the issue noted in the MGN 371 checklist.

A2. MGN 371 Compliance Checklist

Table 1 MGN 371 Compliance Checklist for the European Offshore Wind Deployment Centre

MGN 371 COMPLIANCE			
Issue	**Yes**	**No**	**Remarks**
Considerations on Site Position, Structures and Safety Zones			
1. Traffic Survey			
All vessel types	✔		Section 8 of NRA.
Four weeks duration, within 12 months prior to submission of the Environmental Statement	✔		Survey period comprised two weeks of data from April 2009, September 2009, April 2010 and November 2010 totalling 56 days.
Seasonal variations	✔		Surveys have been carried out in April, September and November. Other long-term data sets and consultation were used to identify variations in recreational and fishing vessel activity. (Also refer to the Commercial Fisheries study carried out for the ES.)
Recreational and fishing vessel organisations	✔		Sections 10 and 11 of NRA.
Port and navigation authorities	✔		Sections 5, 6 and 8 of NRA.
Assessment			
Proposed OREI site relative to areas used by any type of marine craft.	✔		Sections 8-11 of NRA.
Numbers, types and sizes of vessels presently using such areas	✔		Sections 8-11 of NRA.
Non-transit uses of the areas, e.g. fishing, day cruising of leisure craft, racing, aggregate dredging, etc.	✔		Sections 8-11 of NRA.
Whether these areas contain transit routes used by coastal or deep-draught vessels on passage.	✔		Section 8 of NRA.
Alignment and proximity of the site relative to adjacent shipping lanes	✔		Sections 8 and 9 of NRA.
Whether the nearby area contains prescribed routeing schemes or precautionary areas	✔		Sections 6, 8 and 9 of NRA.
Whether the site lies on or near a prescribed or conventionally accepted separation zone between two opposing routes	✔		Sections 6, 8 and 9 of NRA.
Proximity of the site to areas used for anchorage, safe haven, port approaches	✔		Sections 6, 8 and 9 of NRA.

MGN 371 COMPLIANCE			
Issue	**Yes**	**No**	**Remarks**
and pilot boarding or landing areas.			
Whether the site lies within the limits of jurisdiction of a port and/or navigation authority.	✔		Section 6.2 of NRA.
Proximity of the site to existing fishing grounds, or to routes used by fishing vessels to such grounds.	✔		Section 11 of NRA and Commercial Fisheries study.
Proximity of the site to offshore firing/bombing ranges and areas used for any marine military purposes.	✔		Section 6.8 and Section 16 of NRA.
Proximity of the site to existing or proposed offshore oil / gas platform, marine aggregate dredging, or other exploration/exploitation sites	✔		Section 6.7 and Section 16 of NRA.
Proximity of the site relative to any designated areas for the disposal of dredging spoil	✔		Not applicable.
Proximity of the site to aids to navigation and/or Vessel Traffic Services (VTS) in or adjacent to the area and any impact thereon.	✔		Sections 6 of NRA.
Researched opinion using computer simulation techniques with respect to the displacement of traffic and, in particular, the creation of 'choke points' in areas of high traffic density.	✔		Sections 8, 9 and 13 of NRA.
Type(s) of simulation used in analysis Limitation of system (s)	✔		Sections 8, 9 and 13 of NRA
2. OREI Structures			
Whether any features of the OREI, including auxiliary platforms outside the main generator site and cabling to the shore, could pose any type of difficulty or danger to vessels underway, performing normal operations, or anchoring	✔		Sections 9-15 of NRA. (Note: The final design has not yet been selected therefore the current expected layout has been assumed).
Clearances of wind turbine blades above the sea surface *not less than 22 metres*	✔		Section 3.4 of NRA.
Least depth of current turbine blades	✔		Not applicable.
The burial depth of cabling	✔		0.6m to 3m (Ref Rochdale Envelope Requirements for the European Offshore Wind Development Centre – RE18554-W-02-11)
Whether any feature of the installation could create problems for emergency rescue services, including the use of lifeboats, helicopters and emergency towing vessels (ETVs)	✔		Section 18 of NRA.
How rotor blade rotation and power	✔		Section 18 of NRA.

MGN 371 COMPLIANCE			
Issue	**Yes**	**No**	**Remarks**
transmission, etc., will be controlled by the designated services when this is required in an emergency.			
3. Assessment of Access to and Navigation Within, or Close to , an OREI To determine the extent to which navigation would be feasible within the OREI site itself by assessing whether:			
a. Navigation within the site would be safe:	✔		
i. by all vessels, or ii. by specified vessel types, operations and/or sizes. iii. in all directions or areas, or iv. in specified directions or areas. v. in specified tidal, weather or other conditions			Entire NRA.
b. Navigation in and/or near the site should be:	✔		
i. prohibited by specified vessels types, operations and/or sizes. ii. prohibited in respect of specific activities, iii. prohibited in all areas or directions, or iv. prohibited in specified areas or directions, or v. prohibited in specified tidal or weather conditions, or simply vi. recommended to be avoided.			Entire NRA.
c. Exclusion from the site could cause navigational, safety or routeing problems for vessels operating in the area.	✔		See Sections 8-11 for discussion of likely impacts of site on vessel activity.
Relevant information concerning a decision	✔		Section 17 of NRA.

MGN 371 COMPLIANCE			
Issue	**Yes**	**No**	**Remarks**
to seek a "safety zone" for a particular site during any point in its construction, operation or decommissioning.			
Navigation, collision avoidance and communications			
1. The Effect of Tides and Tidal Streams : It should be determined whether or not:			
Current maritime traffic flows and operations in the general area are affected by the depth of water in which the proposed installation is situated at various states of the tide i.e. whether the installation could pose problems at high water which do not exist at low water conditions, and vice versa.	✔		Sections 3, 6, 8 of NRA
Set and rate of the tidal stream, at any state of the tide, has a significant affect on vessels in the area of the OREI site.	✔		Sections 6,.7, 8 and 13 of NRA
Maximum rate tidal stream runs parallel to the major axis of the proposed site layout, and, if so, its effect.	✔		Section 6.9 of NRA.
The set is across the major axis of the layout at any time, and, if so, at what rate.	✔		Section 6.9 of NRA.
In general, whether engine failure or other circumstance could cause vessels to be set into danger by the tidal stream.	✔		Section 6.9, 9 and 13.3 of NRA. (Tides in the area used to model risk of drifting ship collision.)
Structures themselves could cause changes in the set and rate of the tidal stream.	✔		Section 19.3 of NRA.
Structures in the tidal stream could be such as to produce siltation, deposition of sediment or scouring, affecting navigable water depths in the windfarm area or adjacent to the area	✔		Section 19.5 of NRA.
			.
2. Weather: To determine if:			
The site, in normal, bad weather, or restricted visibility conditions, could present difficulties or dangers to craft, including sailing vessels, which might pass in close proximity to it.	✔		Sections 3, 6.9, 7, 8-13, 15, 19 and 20 of NRA.
The structures could create problems in the area for vessels under sail, such as wind masking, turbulence or sheer.	✔		Section 19.4 of NRA.
In general taking into account the prevailing winds for the area, whether engine failure or other circumstances could cause vessels to drift into danger, particularly if in conjunction with a tidal set.	✔		Section 13.3 of NRA (Drifting collision risk model).

MGN 371 COMPLIANCE			
Issue	**Yes**	**No**	**Remarks**
3. Visual Navigation and Collision Avoidance: To assess the extent to which			
Structures could block or hinder the view of other vessels under way on any route.	✔		Section 19.2 of NRA.
Structures could block or hinder the view of the coastline or of any other navigational feature such as aids to navigation, landmarks, promontories, etc	✔		Section 19.2 of NRA.
4. Communications, Radar and Positioning Systems : To provide researched opinion of a generic and, where appropriate, site specific nature concerning whether or not:			
Structures could produce radio interference such as shadowing, reflections or phase changes, with respect to any frequencies used for marine positioning, navigation or communications, including Automatic Identification Systems (AIS), whether ship borne, ashore or fitted to any of the proposed structures.	✔		Section 15 of NRA.
Structures could produce radar reflections, blind spots, shadow areas or other adverse effects: a. Vessel to vessel; b. Vessel to shore; c. VTS radar to vessel; d. Racon to/from vessel.	✔		Section 15 of NRA.
OREI, in general, would comply with current recommendations concerning electromagnetic interference.	✔		Section 15 of NRA.
Structures and generators might produce sonar interference affecting fishing, industrial or military systems used in the area.	✔		Section 19.6 of NRA.
Site might produce acoustic noise which could mask prescribed sound signals.	✔		Section 19.9 of NRA.
Generators and the seabed cabling within the site and onshore might produce electro-magnetic fields affecting compasses and other navigation systems.	✔		Section 19.7 of NRA.
5. Marine Navigational Marking : To determine:			
How the overall site would be marked by day and by night taking into account that there may be an ongoing requirement for	✔		Section 4 of NRA.

MGN 371 COMPLIANCE			
Issue	**Yes**	**No**	**Remarks**
marking on completion of decommissioning, depending on individual circumstances.			
How individual structures on the perimeter of and within the site, both above and below the sea surface, would be marked by day and by night.	✔		Section 4 of NRA.
If the specific OREI structure would be inherently radar conspicuous from all seawards directions (and for SAR and maritime surveillance aviation purposes) or would require passive enhancers	✔		Section 4 of NRA.
If the site would be marked by one or more racons and/ or,	✔		Section 6.4 of NRA.
If the site would be marked by an Automatic Identification System (AIS) transceiver, and if so, the data it would transmit.	✔		Sections 20 of NRA. (under consideration)
If the site would be fitted with a sound signal, and where the signal or signals would be sited	✔		Section 12.4 of NRA (potential mitigation measure).
If the structure (s) would be fitted with aviation marks, and if so, how these would be screened from mariners or potential confusion with other navigational marks & lights resolved.	✔		Not applicable
Whether the proposed site and/or its individual generators would comply in general with markings for such structures, as required by the relevant General Lighthouse Authority (GLA) or recommended by the Maritime and Coastguard Agency, respectively.	✔		Section 4 of NRA.
The aids to navigation specified by the GLAs are being maintained such that the ‘availability criteria’, as laid down and applied by the GLAs, is met at all times.	✔		Section 4 of NRA.
The procedures that need to be put in place to respond to casualties to the aids to navigation specified by the GLAs, within the timescales laid down and specified by the GLAs.	✔		Section 4 of NRA.
5. Hydrography : In order to establish a baseline, detailed and accurate hydrographic surveys are required to IHO Order 1 standard multibeam bathymetry with final data being supplied as a digital full density data set, and erroneous surrounding flagged as deleted but included in the data set. A full report detailing survey methodology and equipment should accompany the			

MGN 371 COMPLIANCE			
Issue	**Yes**	**No**	**Remarks**
surveys.			
	✔		This was a requirement of the Hydrographic Surveys contract.
Safety and mitigation measures recommended for OREI during construction, operation and decommissioning.			
Mitigation and safety measures will be applied to the OREI development appropriate to the level and type of risk determined during the Environmental Impact Assessment (EIA).The specific measures to be employed will be selected in consultation with the Maritime and Coastguard Agency and will be listed in the developer's Environmental Statement (ES). These will be consistent with international standards contained in, for example, the Safety of Life at Sea (SOLAS) Convention - Chapter V, IMO Resolution A.572 (14)[3] and Resolution A.671(16)[4] and could include any or all of the following:	✔		Sections 18 and 20 of NRA.
Promulgation of information and warnings through notices to mariners and other appropriate media.	✔		Sections 18 and 20 of NRA.
Continuous watch by multi-channel VHF, including Digital Selective Calling (DSC).	✔		Sections 18 and 20 of NRA.
Safety zones of appropriate configuration, extent and application to specified vessels	✔		Section 17 of NRA.
Designation of the site as an area to be avoided (ATBA).	✔		Not applicable.
Implementation of routeing measures within or near to the development.	✔		Not applicable. (See Section 9 of for Impact on Commercial Shipping Navigation).
Monitoring by radar, AIS and/or closed circuit television (CCTV).	✔		Sections 18 and 20 of NRA.
Appropriate means to notify and provide evidence of the infringement of safety zones or ATBA's.	✔		Sections 17, 18 and 20 of NRA.
Any other measures and procedures considered appropriate in consultation with other stakeholders.	✔		Sections 18 and 20 of NRA.
Standards and procedures for wind turbine generator shutdown in the event of a search and rescue, counter pollution or salvage incident in or around a wind farm. The wind farm should be designed and constructed to satisfy the following design requirements for emergency rotor shut-down in the event of a search and rescue (SAR), counter pollution or salvage operation in or around a wind farm:			

MGN 371 COMPLIANCE			
Issue	**Yes**	**No**	**Remarks**
All wind turbine generators (WTGs) will be marked with clearly visible unique identification characters which can be seen by both vessels at sea level and aircraft (helicopters and fixed wing) from above.	✔		Sections 4 and 18 of NRA.
The identification characters shall each be illuminated by a low intensity light visible from a vessel this enabling the structure to be detected at a suitable distance to avoid a collision with it. The size of the identification characters in combination with the lighting should be such that, under normal conditions of visibility and all known tidal conditions, they are clearly readable by an observer, stationed 3 metres above sea levels, and at a distance of at least 150 metres from the turbine. It is recommended that lighting for this purpose be hooded or baffled so as to avoid unnecessary light pollution or confusion with navigation marks. (Precise dimensions to be determined by the height of lights and necessary range of visibility of the identification numbers).	✔		Sections 4 and 18 of NRA
For aviation purposes, OREI structures should be marked with hazard warning lighting in accordance with CAA guidance and also with unique identification numbers (with illumination controlled from the site control centre and activated as required) on the upper works of the OREI structure so that aircraft can identify each installation from a height of 500ft (150 metres) above the highest part of the OREI structure.	✔		Sections 4 and 18 of NRA.
Wind Turbine Generators (WTG) shall have high contrast markings (dots or stripes) placed at 10 metre intervals on both sides of the blades to provide SAR helicopter pilots with a hover reference point.	✔		Section 18 of NRA.
All WTGs should be equipped with control mechanisms that can be operated from the Central Control Room of the wind farm or through a single contact point.	✔		Section 18 of NRA.
Throughout the design process for a wind farm, appropriate assessments and methods for safe shutdown should be established and agreed, through consultation with MCA and other emergency support services.	✔		Sections 18 and 20 of NRA.
The WTG control mechanisms should allow	✔		Sections 18 and 20 of NRA.

MGN 371 COMPLIANCE			
Issue	**Yes**	**No**	**Remarks**
the Control Room Operator to fix and maintain the position of the WTG blades as determined by the Maritime Rescue Co-ordination Centre or Maritime Rescue Sub Centre (MRCC/SC).			
Nacelle hatches should be capable of being opened from the outside. This will allow rescuers (e.g. helicopter winch-man) to gain access to the tower if tower occupants are unable to assist and when sea-borne approach is not possible.	✔		Sections 18 and 20 of NRA.
Access ladders, although designed for entry by trained personnel using specialised equipment and procedures for turbine maintenance in calm weather, could conceivably be used, in an emergency situation, to provide refuge on the turbine structure for distressed mariners. This scenario should therefore be considered when identifying the optimum position of such ladders and take into account the prevailing wind, wave and tidal conditions.	✔		Section 13 of NRA.
Although it may not be feasible for mariners in emergency situations to be able to use wave or tidal generators as places of refuge, consideration should nevertheless be given to the provision of appropriate facilities.	✔		Section 18 of NRA
2. Operational Requirements			
The Central Control Room, or mutually agreed single point of contact, should be manned 24 hours a day.	✔		Sections 18 and 20 of NRA.
The Central Control Room operator, or mutually agreed single point of contact, should have a chart indicating the Global Positioning System (GPS) position and unique identification numbers of each of the WTGs in the wind farm.	✔		Sections 18 and 20 of NRA.
All MRCCs will be advised of the contact telephone number of the Central Control Room, or mutually agreed central point of conatct.	✔		Sections 18 and 20 of NRA.
All MRCCs will have a chart indicating the GPS position and unique identification number of each of the WTGs in all wind farms.	✔		Sections 18 and 20 of NRA.

MGN 371 COMPLIANCE			
Issue	**Yes**	**No**	**Remarks**
3. Operational Procedures			
Upon receiving a distress call or other emergency alert from a vessel which is concerned about a possible collision with a WTG or is already close to or within the wind farm, or when the MRCC receives a report that persons are in actual or possible danger in or near a wind farm and search and rescue aircraft and/or rescue boats or craft are required to operate over or within the wind farm, the MRCC will establish the position of the vessel and the identification numbers of any WTGs which are visible to the vessel. This information will be passed immediately to the Central Control Room, or single contact point, by the MRCC. A similar procedure will be followed when vessels are close to or within other types of OREI site	✔		Sections 18 and 20 of NRA.
The control room operator should immediately initiate the shut-down procedure for those WTGs as requested by the MRCC, and maintain the WTG in the appropriate shut-down position, again as requested by the MRCC, or as agreed with MCA Navigation Safety Branch or Search and Rescue Branch for that particular installation, until receiving notification from the MRCC that it is safe to restart the WTG.	✔		Sections 18 and 20 of NRA.
The appropriate procedure to be followed in respect of other OREI types, designs and configurations will be determined by these MCA branches on a case by case basis, in consultation with appropriate stakeholders, during the Scoping and Environmental Impact Assessment processes.	✔		Section 19 of NRA
Communication and shutdown procedures should be tested satisfactorily at least twice a year. Shutdown and other procedures should be tested as and when mutually agreed with the MCA.	✔		Sections 18 and 20 of NRA.

DECC Ship Type Checklist

European Offshore Wind Deployment Centre

(Appendix B)

TABLE OF CONTENTS

B1. Introduction

The AIS type classification has been converted to the DECC (formerly BERR) Methodology "Vessel Types involved in Navigational Activities - Example Checklist", reproduced below (Ref. i).

H6	Types of Vessel
1	*All*
2a	Large Vessels
	1. Bulk Carriers
	2. Bulk/Oil Carriers
	3. Chemical Tankers
	4. Container Vessels
	5. Cruise Vessels
	6. Liquefied Gas Carriers
	7. Oil Tankers
2b	Medium Vessels
	1. General Cargo
	2. Specialised Carriers
	3. Passenger
	4. Passenger Ferries
2c	High Speed Craft (HSC's)
	1. High speed ferries
	2. Other high speed recreational and commercial craft
3	Fishing Vessels
	1. Fish Processing
	2. Fishing Vessels (Various types and operations)
4	Recreational Vessels
	1. Sailing dinghies and Yachts
	2. Motor Boats
	3. Small Personal Watercraft
	4. Rowing boats
	5. Sports Fishing
	6. Windsurfer
	7. Kite Boards
	8. Tall Ships
	9. Recreational Submarines and dive support craft
5	Anchored Vessels
	All
6	Other Operational Vessels
	1. Barges
	2. Dredgers
	3. Dry Cargo Barge
	4. Offshore Production and Support
	5. Salvage
	6. Tank Barges
	7. Tugs and Tows
7	Military Vessels
	1. Warships
	2. Submarines
	3. Royal Fleet Auxiliaries
8	Other Vessels
	1. Seaplanes
	2. Wing-In-Ground Craft (WIG)
	3. Hovercraft

Figure 1.1 Vessel Types involved in Navigation Activities – Example Checklist

It is noted that the DECC list is not comprehensive, for example, it does not include explicit categories for vessels such as Ro-Ro and Wind Farm Support. Where this is the case, marine knowledge has been used to classify vessels, e.g., Ro-Ro vessels classified as "Medium Vessels – Ro-Ro" and Wind Farm as "Other Operational Vessels – Wind Farm".

The general commercial ship types identified in the traffic survey were:

2a. Large Vessels
2b. Medium Vessels
3. Fishing Vessels
6. Other Operational Vessels
7. Military Vessels
8. Other Vessels

[Note: Anchored Vessels (DECC Type 5) were also recorded in the survey. This reflects navigational status rather than vessel type, as all vessels may anchor at certain times. Therefore, anchored vessels have not been presented as a separate type in the plots but are discernible from the track behaviour.]

B2. Ship Types

The overall percentage distribution of ships passing within 20nm of the proposed European Offshore Wind Deployment Centre (EOWDC) site based on the general (top-level) DECC categorisation (excluding undefined vessels) and is presented below.

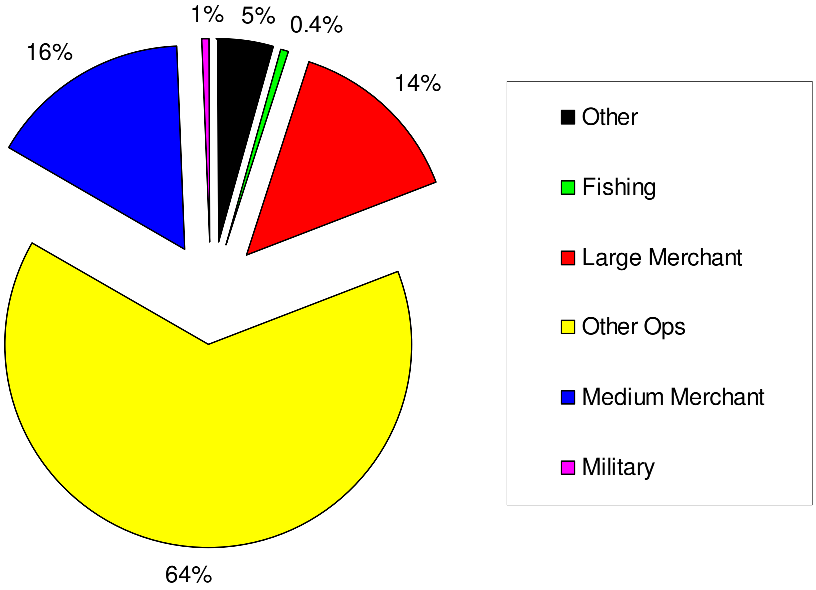

Figure 2.1 DECC General Ship Type Categorisation within 20nm of the Wind Farm

The majority of ships were other operational vessels according to the DECC classification and these are likely to be vessels related to the offshore oil and gas industry. The majority of the remaining vessels were medium and large merchant vessels with a small proportion of fishing vessels, military vessels and 'other' vessels.

A plot of the tracks colour-coded by the DECC general ship type categories is presented in Figure 2.2.

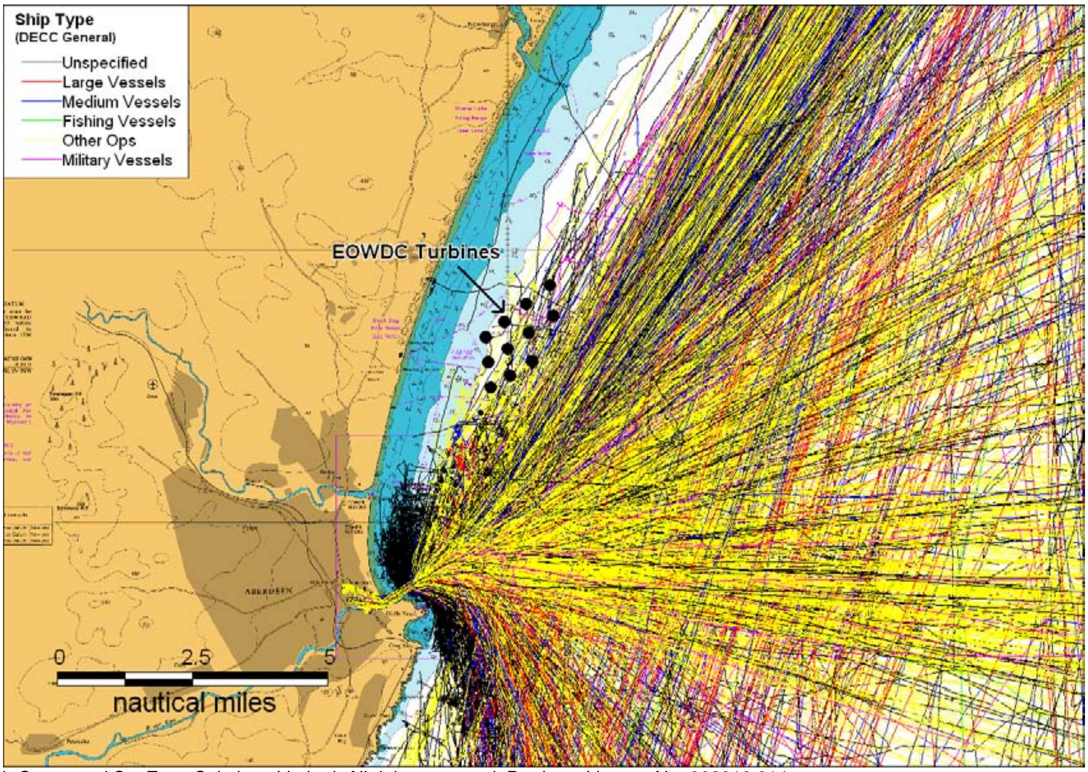

Figure 2.2 Tracks colour-coded by DECC General Ship Types

Dividing the types further using the more detailed (second-level) DECC categories, the distribution within 20nm was as follows:

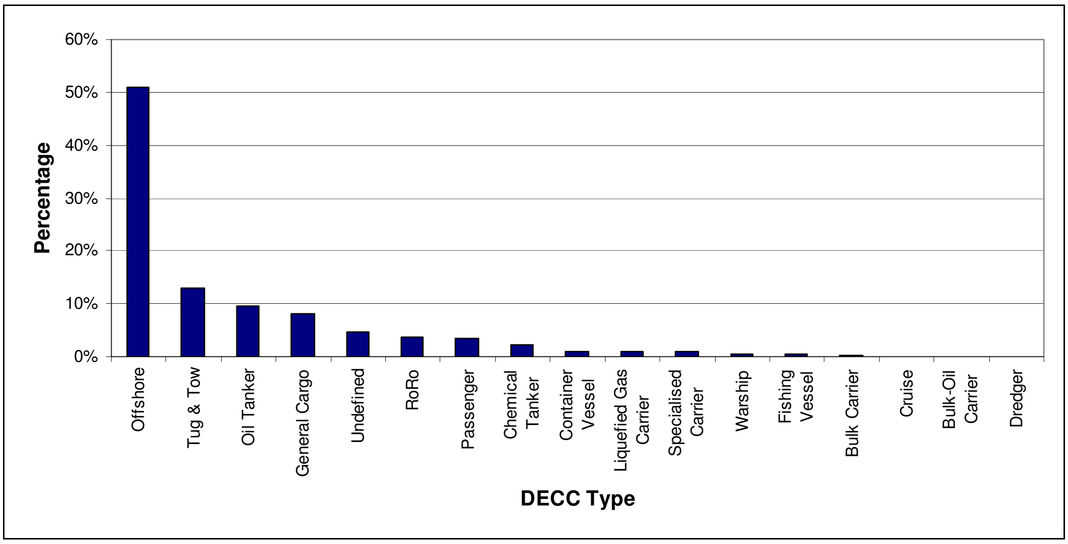

Figure 2.3 Detailed DECC Vessel Types identified within 20nm of the EOWDC Site

The most common category overall was offshore containing just over half of all vessels. There were also a large percentage of tug and tow vessels, oil tankers and general cargo ships.

A plot of the survey data colour-coded by the detailed DECC type classification is presented below.

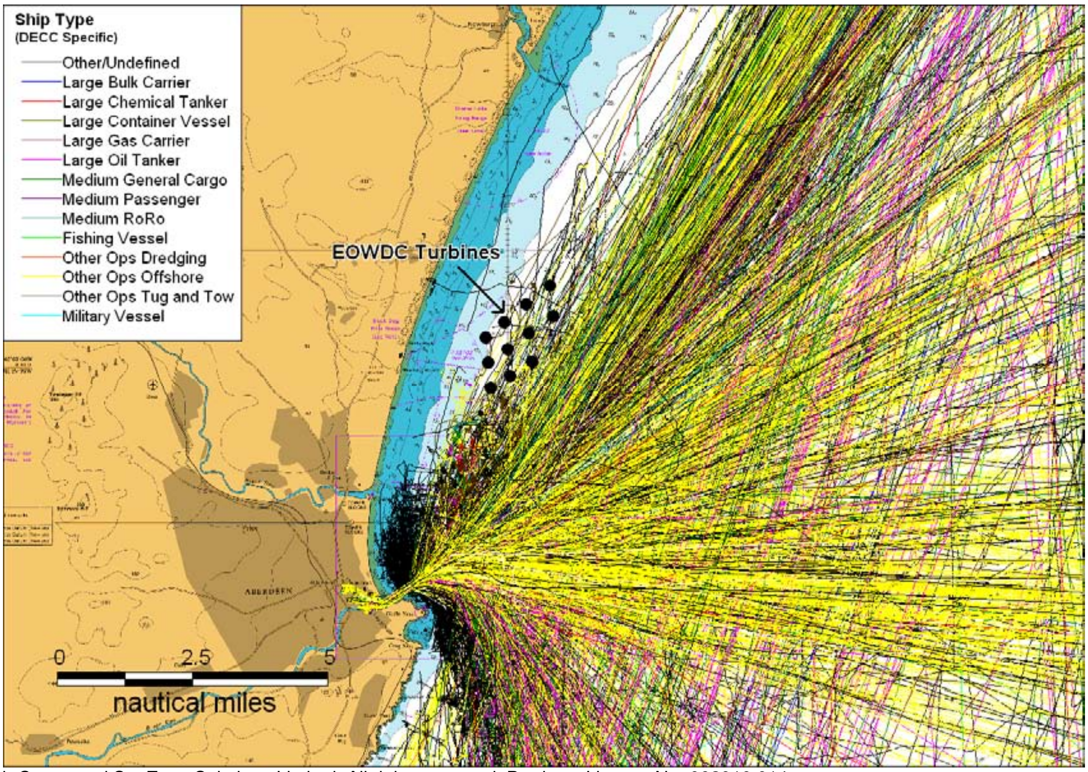

Figure 2.4 Tracks by DECC Detailed Type Categories

The majority of vessels passing between the proposed turbine locations during the surveys were "other operational vessels". This Appendix presents an assessment of the consequences of collision incidents, in terms of people and the environment, due to the impact of the proposed EOWDC.

TABLE OF CONTENTS

C1. Introduction

This Appendix presents an assessment of anchoring by vessels off Aberdeen.

52 weeks of AIS data from October 2008 to October 2009 was examined to gain a broad overview of ships anchoring off Aberdeen. For a more in-depth analysis, 4 weeks of survey data was used which covered two weeks in winter and two weeks in summer. The winter survey took place from 25 March to 7 April 2009 (Survey 1) and the summer survey took place from 21 September to 5 October 2009 (Survey 2).

It should be noted this analysis was carried out before the introduction of an official anchorage area in 2010 to the North of Aberdeen port. With respect to this it is noted that the types and numbers of vessels using the new anchorage are likely to be in line with the information presented within this analysis, and that it is only the anchoring locations that are likely to vary.

To ensure the analysis of the 4 week survey was relevant to Aberdeen Harbour, only those vessels which used the Port were considered. Throughout the report when discussing the number of anchored vessels during the 4 week survey, this refers to those which anchored and visited the Port during this period.

It should be noted that the accuracy regarding the number of anchorings relies on the officers of the ships to manually update their navigation status on their AIS.

C2. Vessel Type

The distribution of vessel type for vessels which anchored off Aberdeen during the 52 week period is presented in Figure 2.1 (excluding 3 % unspecified vessels).

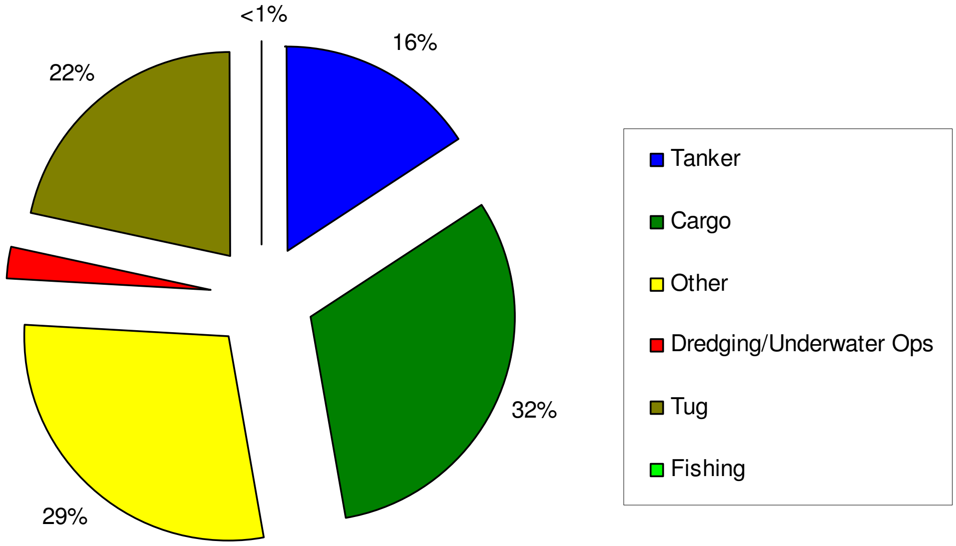

Figure 2.1 Distribution of Anchored Vessels by Type (52 Week Survey)

During this period the type of vessel which anchored most was cargo ships (32%). 'Other' vessels which comprise mainly of offshore support vessels also frequently anchored off Aberdeen (29%). There were no passenger, High Speed Craft (HSC) or military vessels recorded anchoring during the survey.

The distribution of vessel types during the 4 week survey is shown in Figure 2.2 below. There was a total of 36 recorded anchorings during this period.

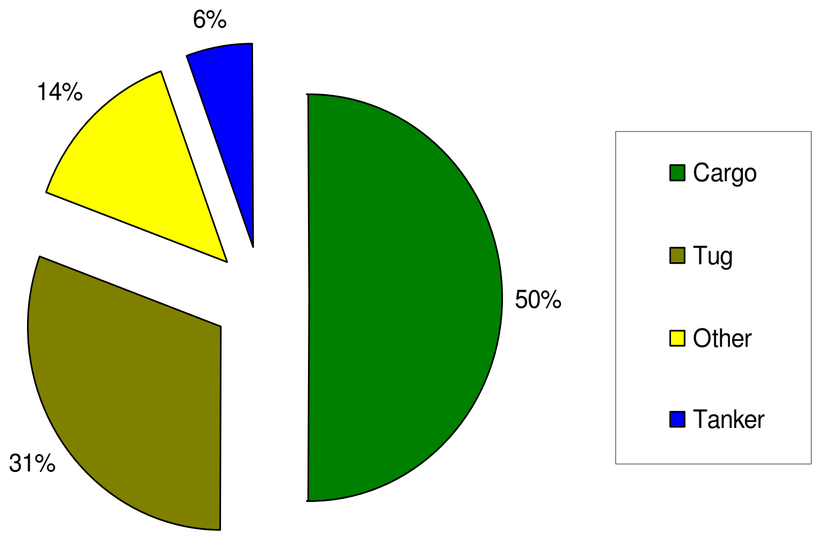

Figure 2.2 Distribution of Anchored Vessels by Type (4 Week Survey)

863 vessels were recorded using the port during the survey. The distribution of these vessels is shown in Figure 2.3 below (excluding 1% unspecified). Pilot vessels and vessels which stayed in the Harbour for the duration of the survey have also been omitted.

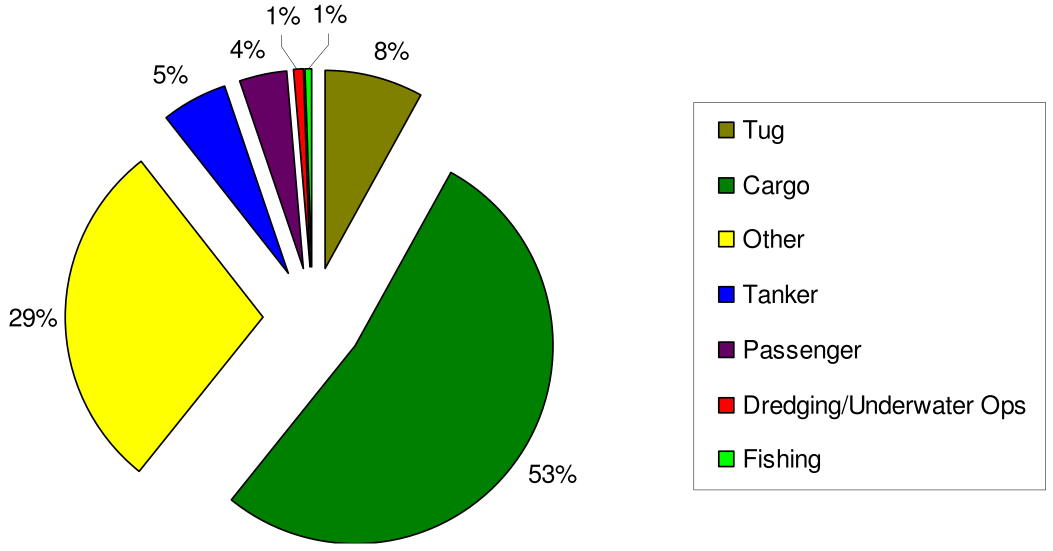

Figure 2.3 Distribution of Vessels using the Port by Type (4 Week Survey)

It can be seen from Figure 2.2 and Figure 2.3 that during the survey approximately half of the vessels using both the anchorage area and the port were cargo ships (50% and 53%, respectively). A bar chart comparing anchoring with port usage is presented in Figure 2.4.

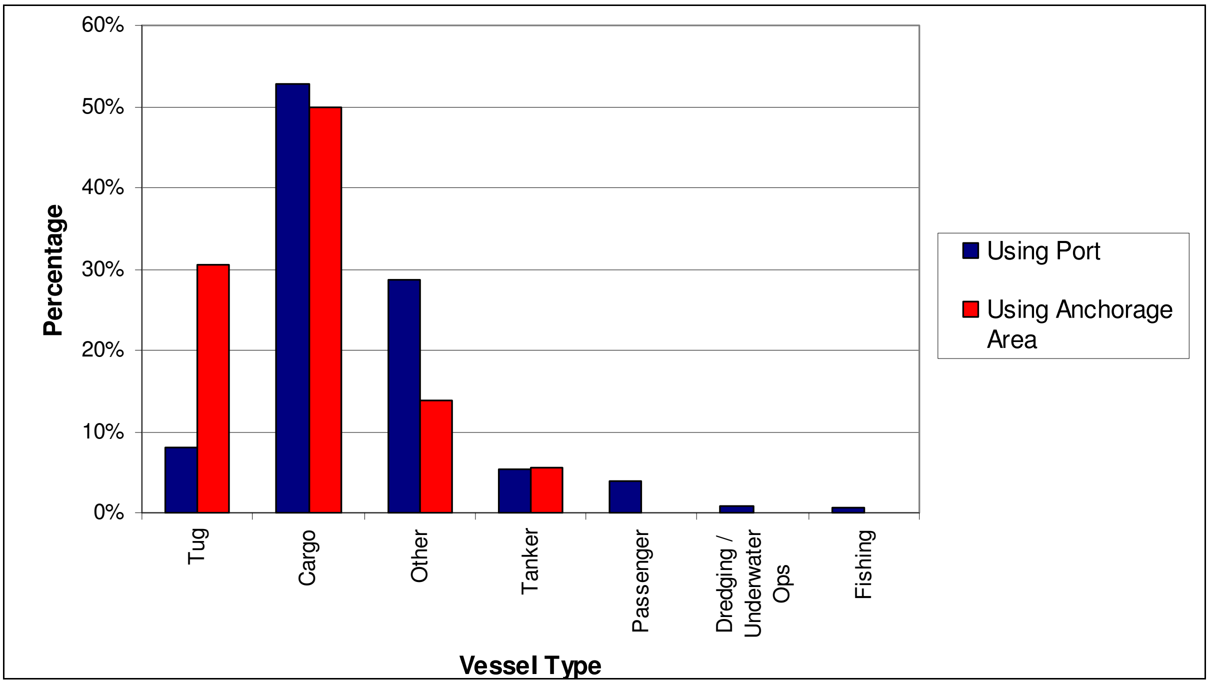

Figure 2.4 Comparison of Port Usage and Anchorage Usage (4-Week Survey)

It can be seen that during the 4 week survey tankers and cargo vessels anchored off Aberdeen in similar proportion to those which used the port. The type of vessel which anchored most frequently relative to how often it used the Port was tugs. With the exception of passenger, dredging/underwater ops and fishing vessels which were all recorded visiting the Port but not anchoring, the type of vessel which anchored least relative to how often it used the Port was 'other' vessels.

The draught distributions of anchored vessels and of those using the Port during the 4 week survey are presented in Figure 2.5.

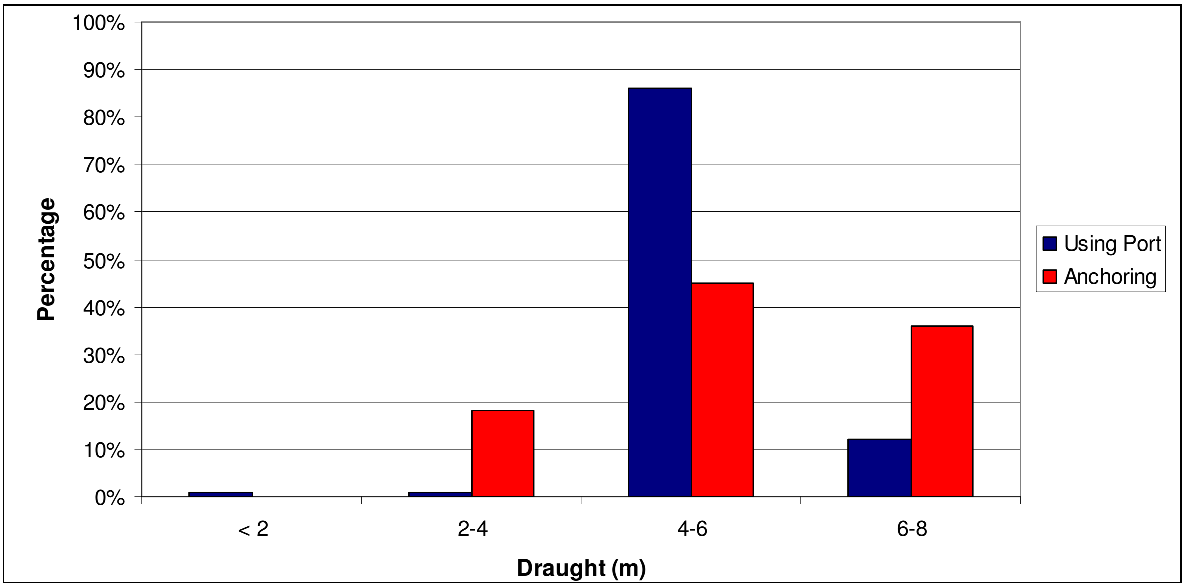

Figure 2.5 Comparison of Draught Distributions (Using Port vs. Anchoring)

In both cases the most common draught size was in the range of 4m to 6m. Vessels with draughts in this size range dominated within those which used the Port (86%) whereas the draughts of those which anchored were more evenly spread. 36% of the anchored vessels had draughts of 6m to 8m whereas only 12% of the vessels using the Port had draughts in this range. This suggests that vessels with a deeper draught are more likely to anchor than vessels with a smaller draught – most likely due to the deeper vessels having to 'wait for tide' before entering the port. It should also be noted that several vessels during the survey with draughts greater than 8m anchored off Aberdeen, but none of these vessels also used the Port.

C3. Anchorage Positions

Taken from the 52-week data set, the tracks of the 5 most common types of vessel to anchor off Aberdeen are shown in the following figures.

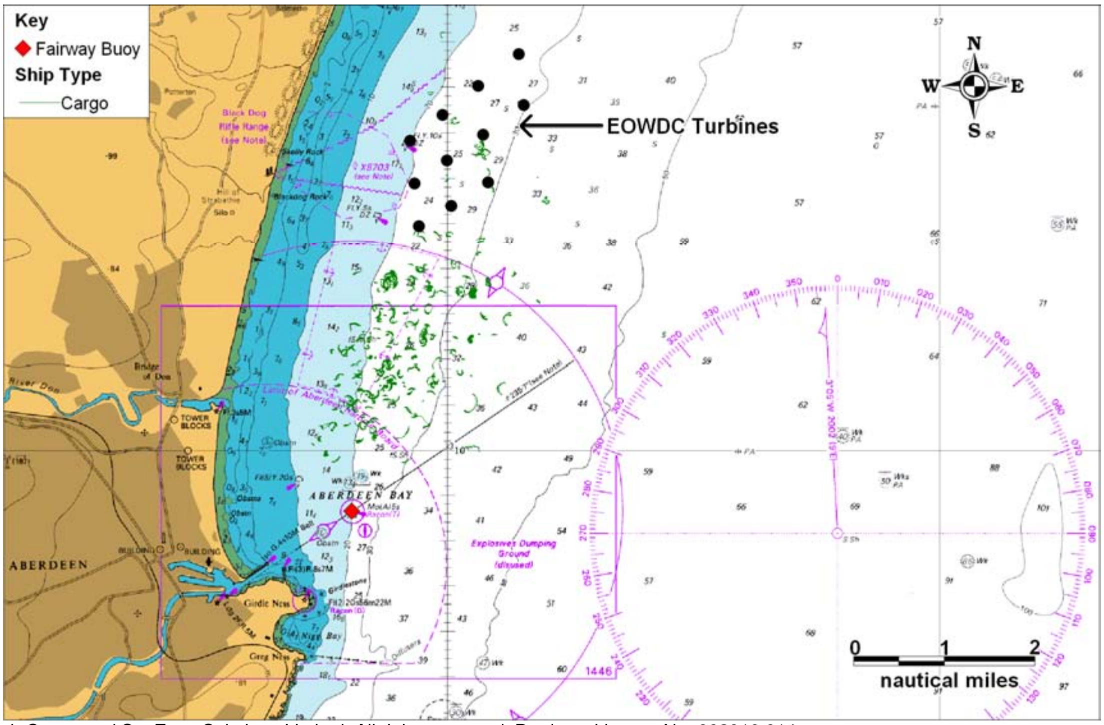

Figure 3.1 Anchored Cargo Vessels during 52 Week Survey (prior to anchorage being designated)

It can be seen that cargo ships were consistent in anchoring to the north, NNE and NE of the Fairway Buoy. Six cargo vessels anchored within the turbine area during the 52 week period.

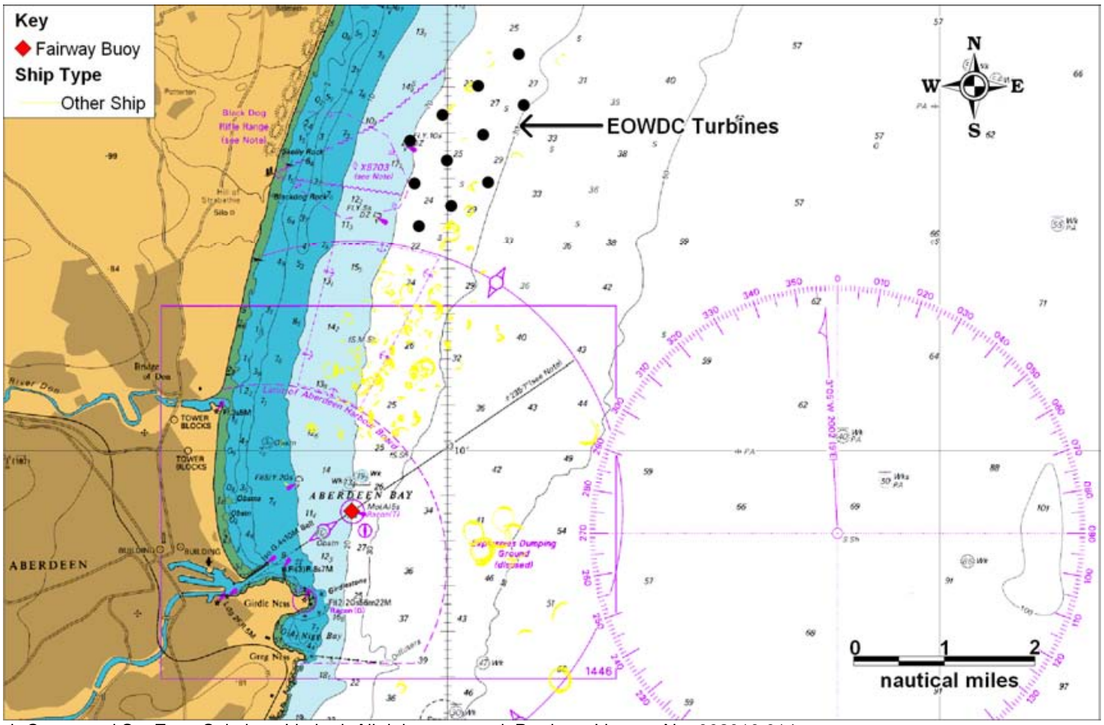

Figure 3.2 Anchored Other Vessels during 52 Week Survey (prior to anchorage being designated)

'Other' vessels generally anchored to the north and NNE of the Fairway Buoy. Almost all of the tracks to the south, SE and east of the Fairway Buoy were made by the shuttle tanker *Navion Fennia* – see discussion below on tankers anchoring in this area. Four 'other' ships anchored within the site during the 52 week period.

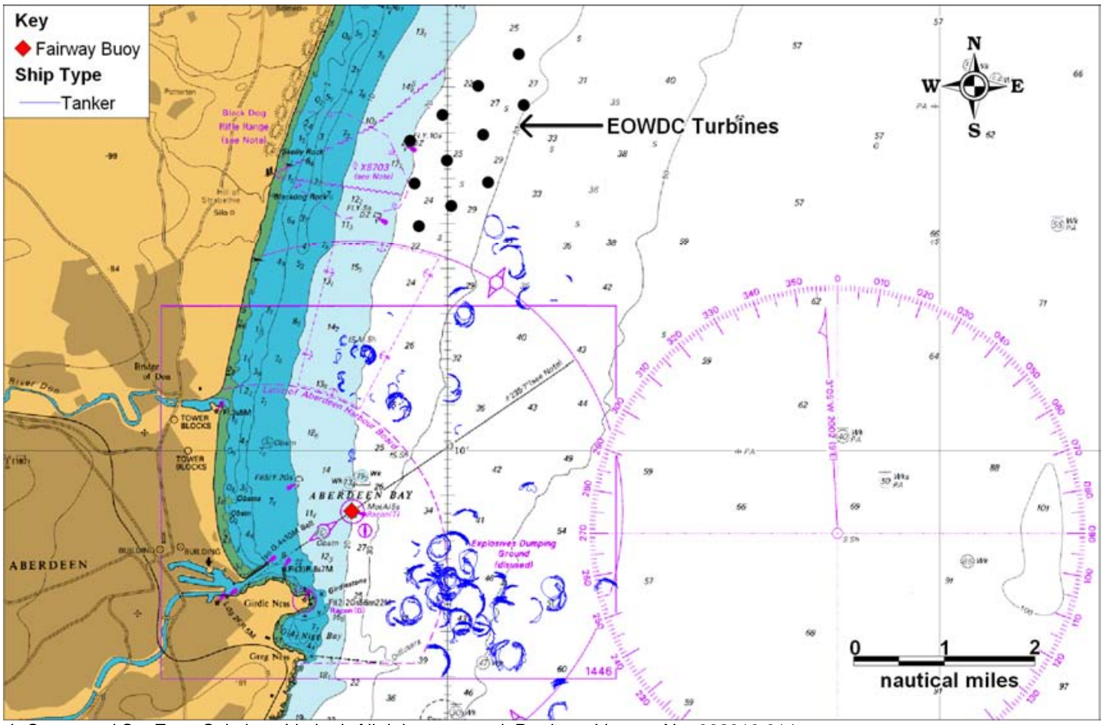

Figure 3.3 Anchored Tankers during 52 Week Survey (prior to anchorage being designated)

The majority of tankers anchored to the SE of the Fairway Buoy but several also anchored to the north and NE. Those to the north and NE and within 2nm of the Fairway Buoy generally had draughts less than 8m and were awaiting entry to Aberdeen Harbour, and the rest generally had draughts greater than 8m and were not visiting the Harbour.

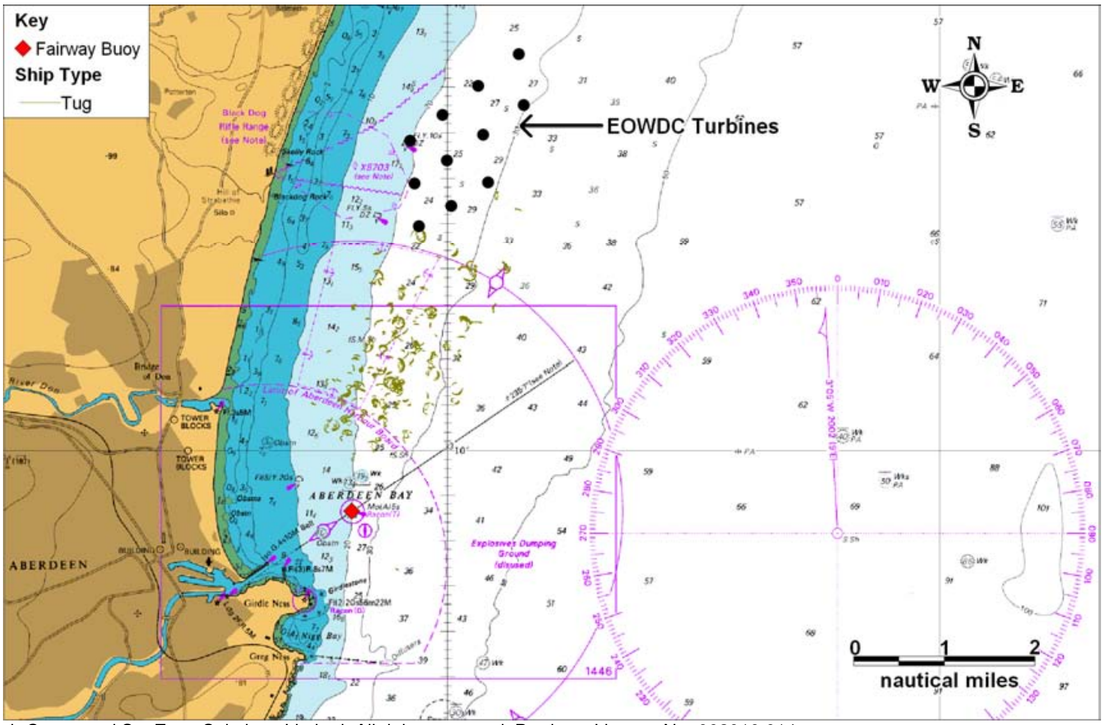

Figure 3.4 Anchored Tugs during 52 Week Survey (prior to anchorage being designated)

Tug vessels were consistent in anchoring to the north and NNE of the Fairway Buoy.

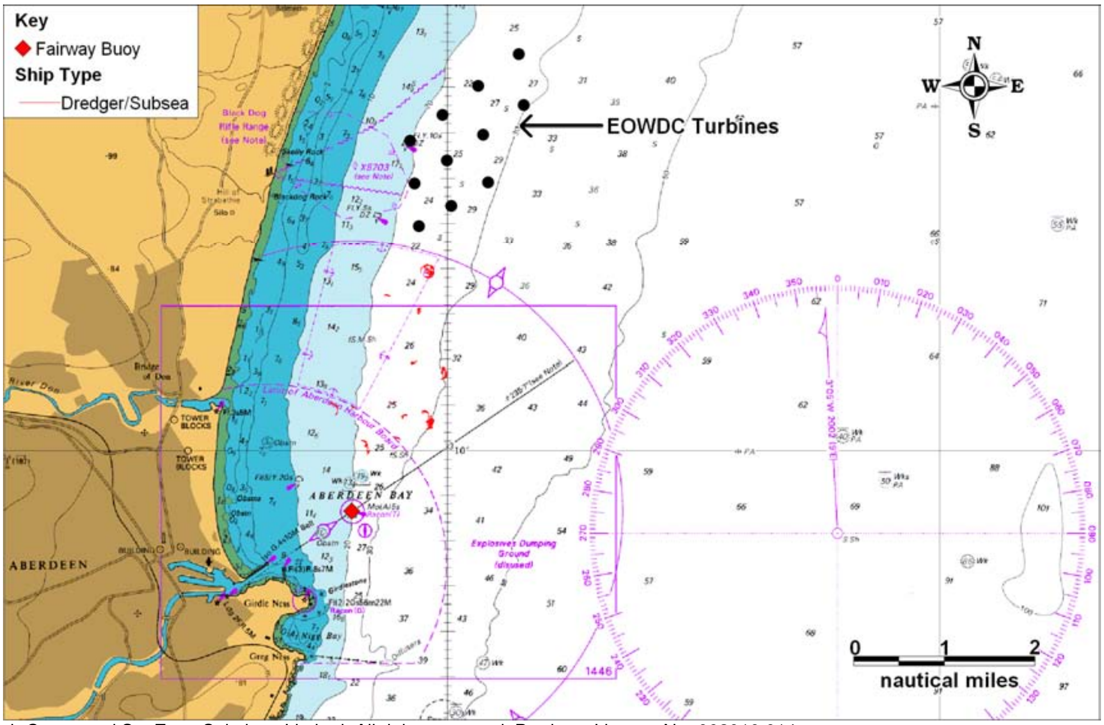

Figure 3.5 Anchored Dredging/Subsea Vessels during 52 Week Survey (prior to anchorage being designated)

Based on the limited data, it is assumed that dredging/subsea vessels tend to anchor to the north and NNE of the Fairway Buoy.

It can be concluded that all vessels visiting Aberdeen Harbour anchor off the Fairway Buoy to the north, NNE and NE, and vessels not visiting (i.e., large tankers) anchor elsewhere.

C4. Weather Analysis

The weather was recorded 4 times a day throughout the 4 week survey. During the winter survey the wind was predominantly from the SW, although for significant periods the wind came from the NE, and then the SE. During the summer survey the wind was predominantly from the west and SW, although for two days the wind came from the NW.

3 vessels were recorded anchoring during the winter survey and 33 during the summer survey. In Figure 4.1 below, each vessel which anchored during the survey periods is represented by a coloured dot, where the colour denotes the wind direction on the day the ship anchored, if wind direction is unknown then the plot has been omitted.

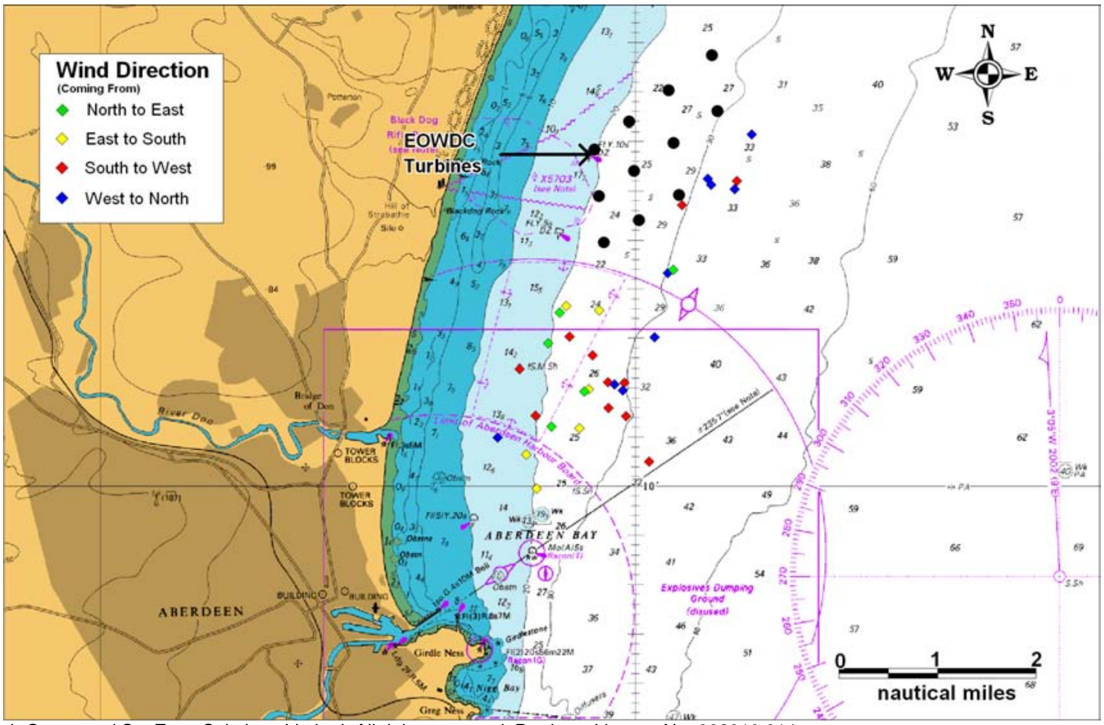

Figure 4.1 Preferred Anchorage Locations with Wind Direction (prior to anchorage being designated)

It should be noted first that in the legend key in the above figure, the second term is not inclusive, i.e., 'North to East' consists of wind coming from the north right through to, but not including, the east. There is no clear relation between the position of the anchored vessels and the wind direction. A more conclusive analysis might be more achievable with the use of further wind data.

C5. Tide Analysis

The tidal variations at Aberdeen during the winter and summer surveys are presented below.

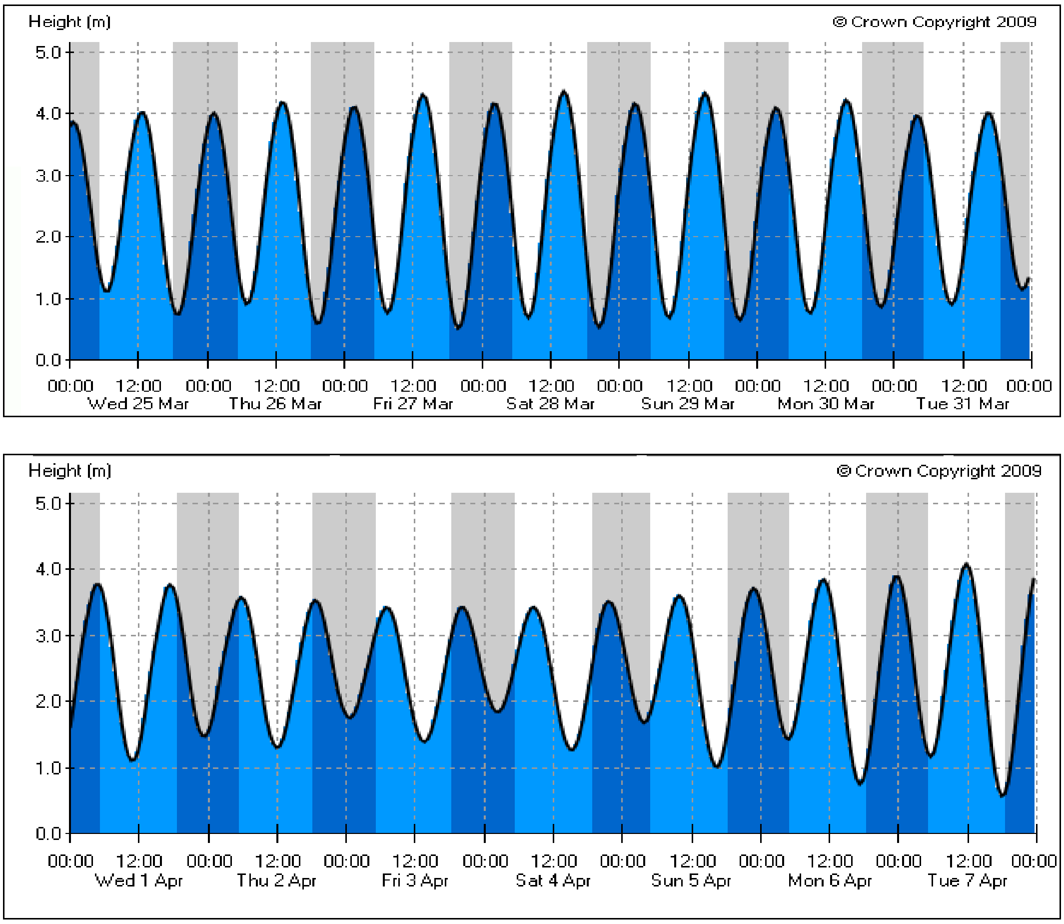

Figure 5.1 Tidal Predictions for Aberdeen during Winter Survey Period (Source: Admiralty Tides, UTC Times)

The 26-30 March has been treated as a spring period and the 1-5 April as a neap period. The remainder of days are considered to be 'neutral'.

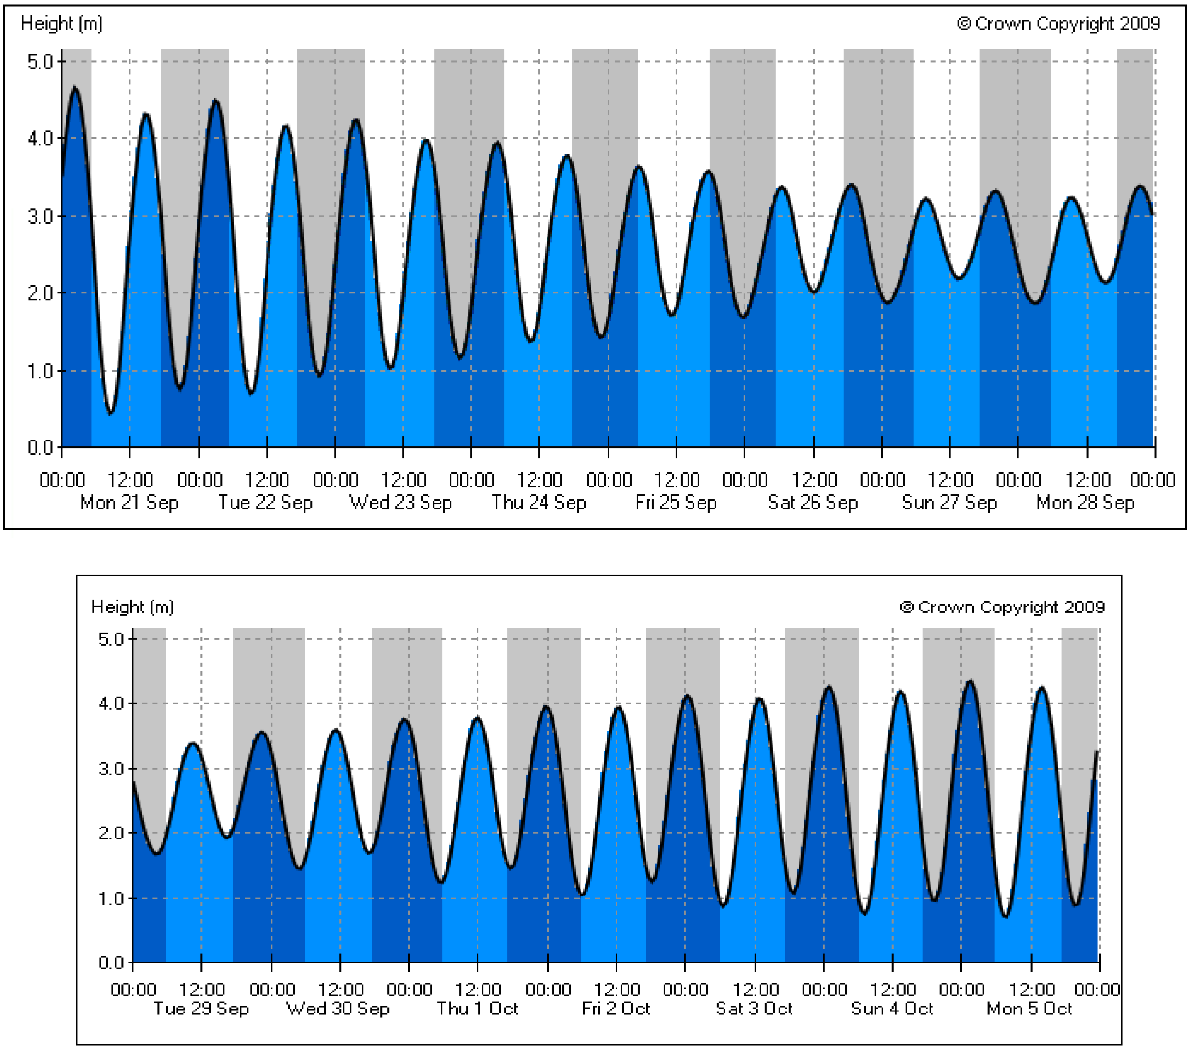

Figure 5.2 Tidal Predictions for Aberdeen during Summer Survey Period (Source: Admiralty Tides, UTC Times)

The periods between 21-22 September and 3-5 October have been classed as spring periods and 25-29 September has been classed as a neap period. Again, the remainder of days have been classed as ‘neutral’.

Of the 28 days that make up the survey, 10 days represent spring tides (36%), 10 represent neap tides (36%) and 8 are ‘neutral’ (29%).

Figure 5.3 below presents the locations of anchored vessels during different tidal conditions.

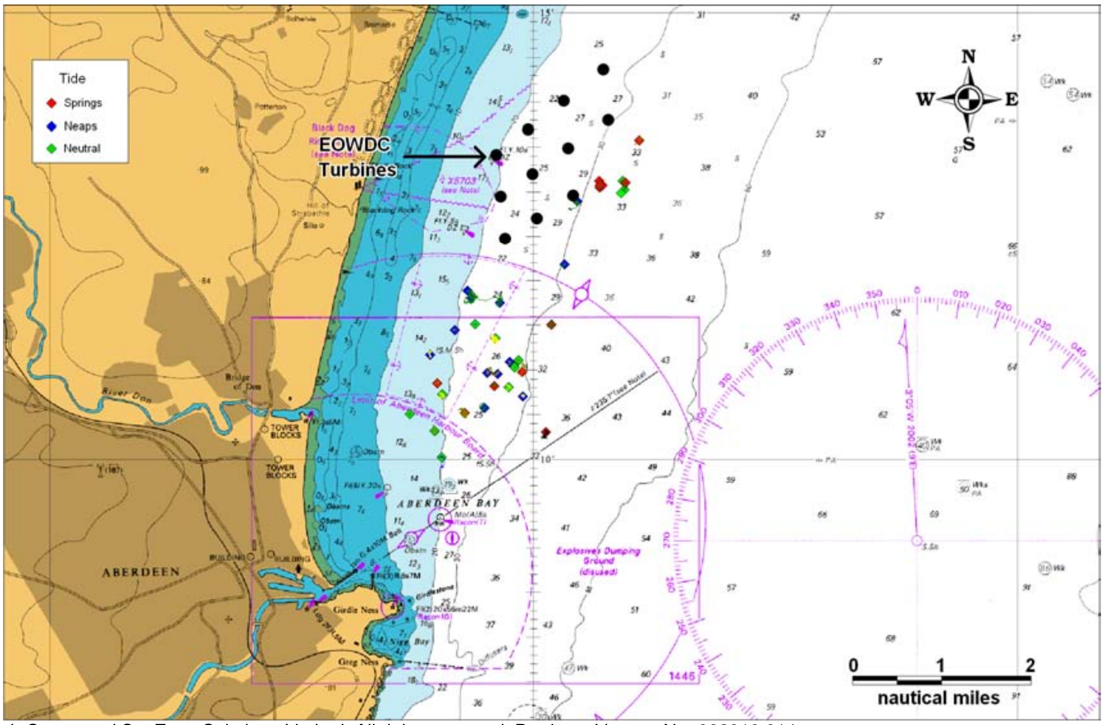

Figure 5.3 Preferred Anchorage Locations during different Tides (prior to anchorage being designated)

There is no clear pattern of anchorage locations by tidal conditions. A more conclusive analysis may be more achievable with the use of more tidal data. The frequency of anchoring during the different tidal conditions was quite equally spread, with 12 ships anchoring during each of the periods. The average numbers of anchorings per day has been calculated for each tidal condition and are presented in Figure 5.4 below.

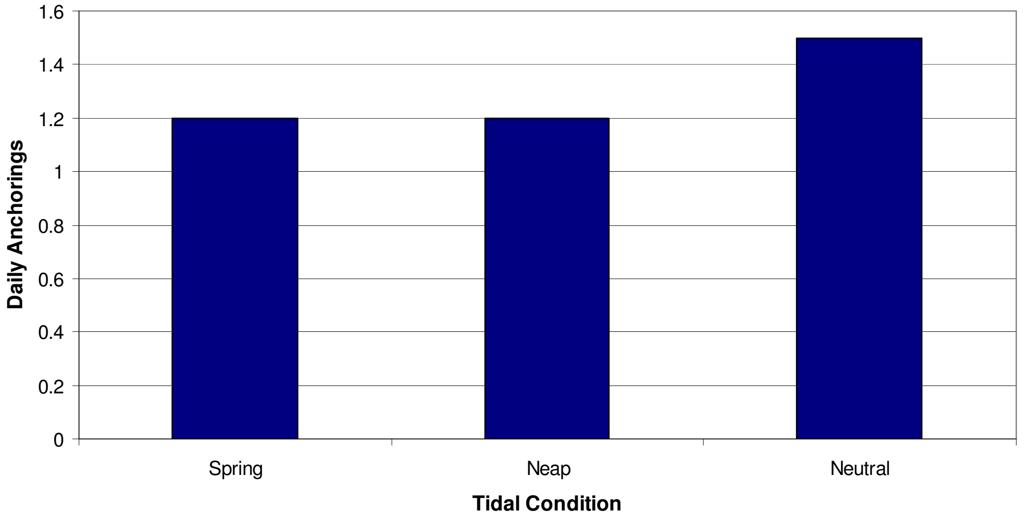

Figure 5.4 Average Number of Daily Anchorings during different Tidal Conditions

The average number of vessels to anchor each day was 1.2 during the spring and neap periods and 1.5 during the 'neutral' periods.

C6. Vessel Movements

The anchored vessels at Aberdeen were analysed visually for one week in September 2009 by replaying the AIS data at high-speed. During this week 22 vessels were observed anchoring off Aberdeen. Figure 6.1 below presents the percentages of these vessels which were in the Port prior to anchoring, and which vessels went on to enter the Port after anchoring.

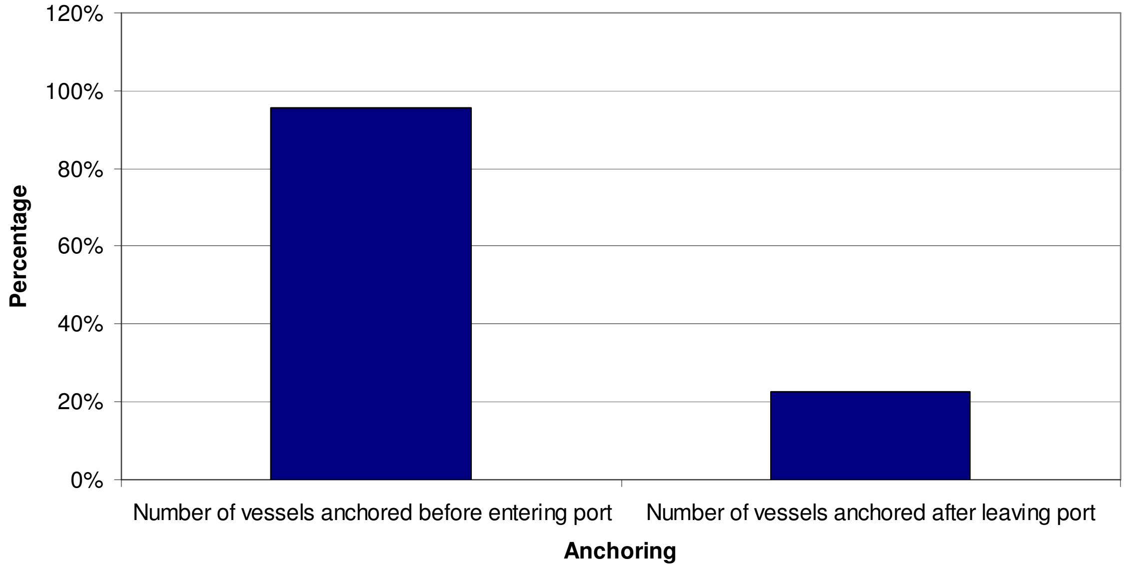

Figure 6.1 Pre- and Post-Anchor Locations

During this 1-week survey 23% of the anchored vessels had come directly from the Harbour with 77% coming from sea. For vessels leaving anchor, 95% went to the Harbour with the remainder going to sea. Of those that entered the Harbour after anchoring, 83% had been out at sea prior to anchoring..

C7. Anchorage Location Preference

Aberdeen bay always contained at least one anchored vessel throughout the summer survey but there were numerous periods during the winter survey when the area was empty. Figure 7.1 shows where vessels opted to anchor when they had the entire bay to choose from.

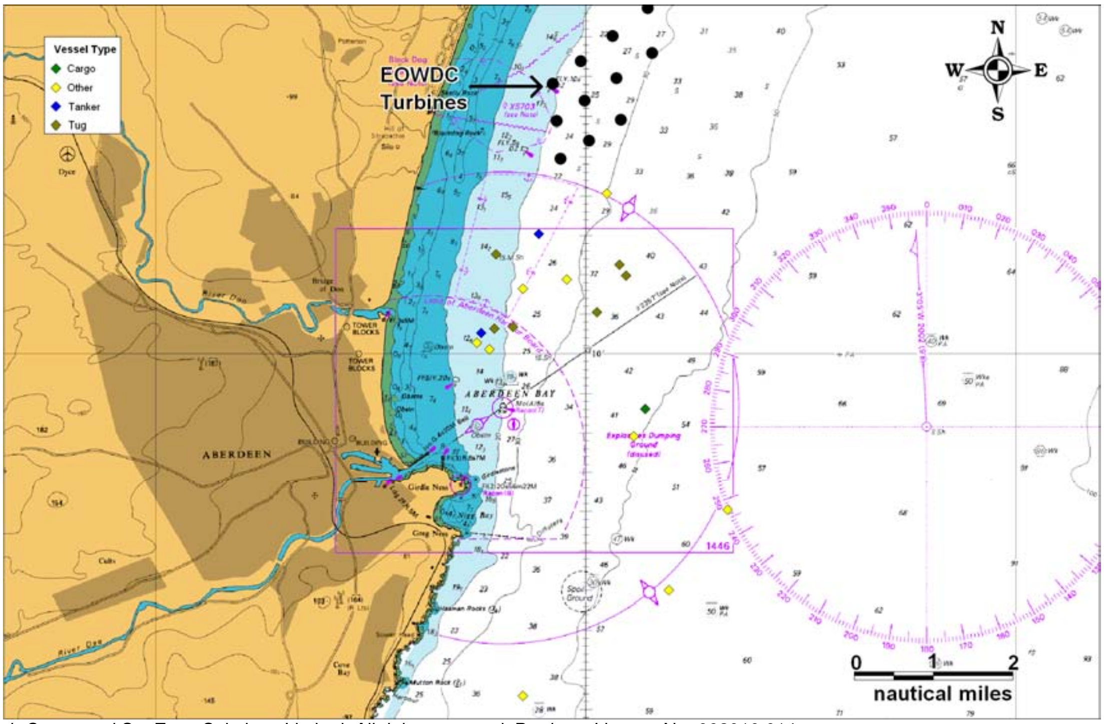

Figure 7.1 First Choice Anchorage Locations (prior to anchorage being designated)

It can be seen that the most common anchorage of choice was in the area to the north, NNE and NE of the Fairway Buoy. It should be noted that not all vessels were definitely visiting the Port and it is assumed that those which anchored to the east, ESE and SE of the Fairway Buoy were not, as comparing with previous figures shows that no ships visiting the Harbour anchored in this area.

C8. Anchorage Duration

The 36 recorded anchorings during the 4 week survey gave a combined anchoring duration of approximately 44 days, which corresponds to an average anchoring duration of 29 hours. The length of time which ships stayed at anchor ranged from under an hour to over 6 days.

Vessels which were not visiting the Port were recorded anchoring for up to 14 days. Figure 8.1 below presents the distribution of the time vessels spent at anchor.

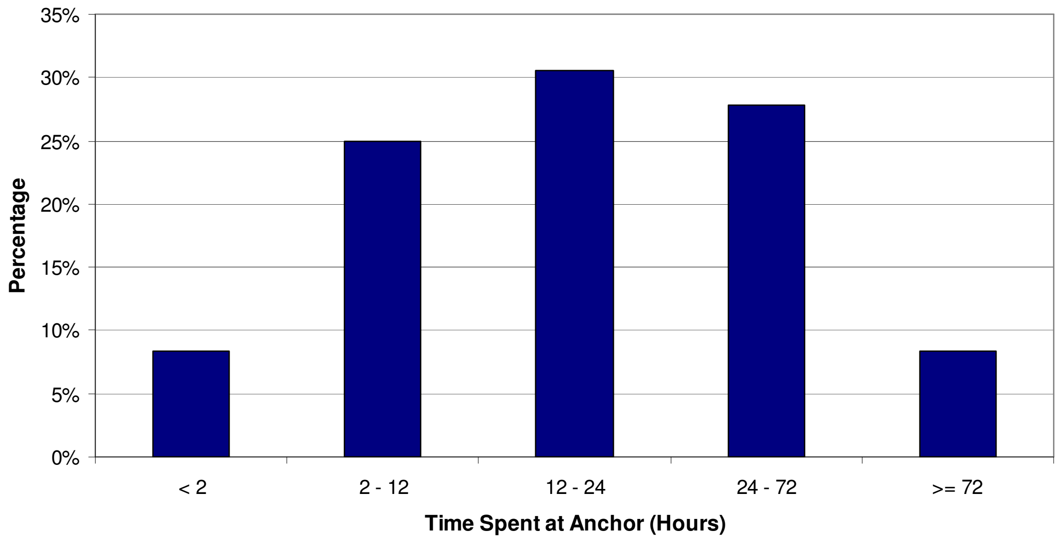

Figure 8.1 Distribution of Time Spent at Anchor

It can be seen that approximately a third of all vessels fall within the category of anchoring for 12 to 24 hours (31%). Another significant point to take from this figure is that 8% of vessels were anchored for less than 2 hours.

The dots in the plot below indicate the locations of the anchored vessels, colour-coded by the length of their stay.

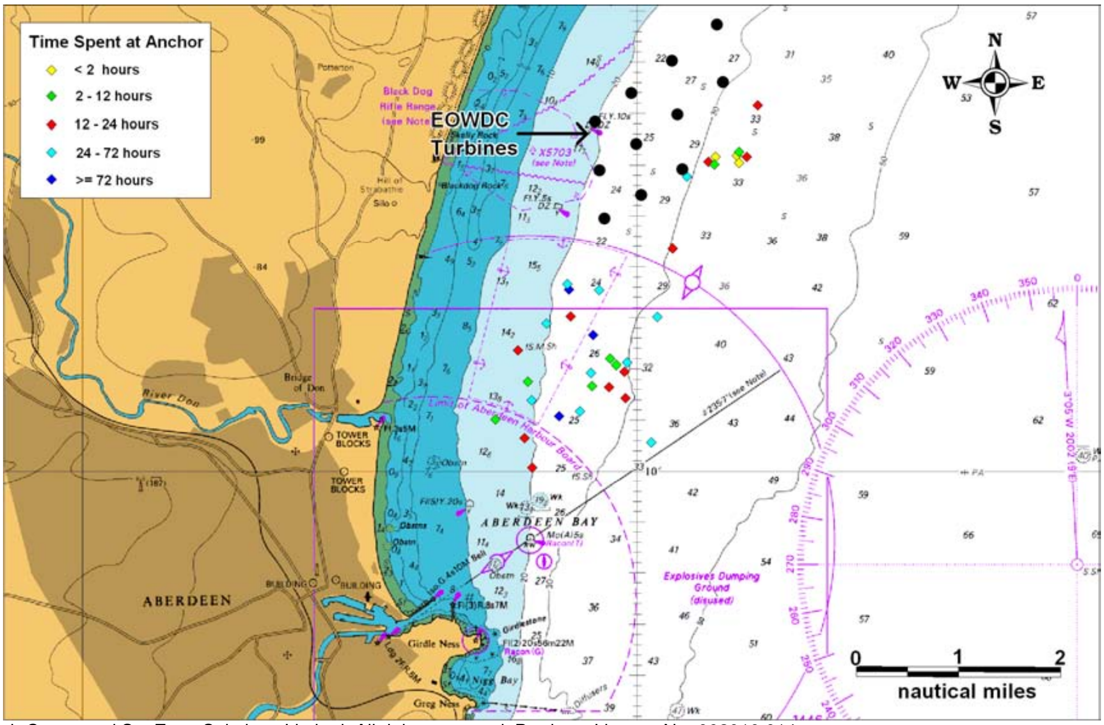

Figure 8.2 Locations of Anchored Vessels with Duration (prior to anchorage being designated)

From the data there is no clear relation between vessels' anchorage location and duration at anchor.

C9. Designation Anchorage

During the course of preparing this navigational impact assessment an anchorage was designated in Aberdeen Bay. The following figure provides an overview of the anchored vessels following this designation (14 day period).

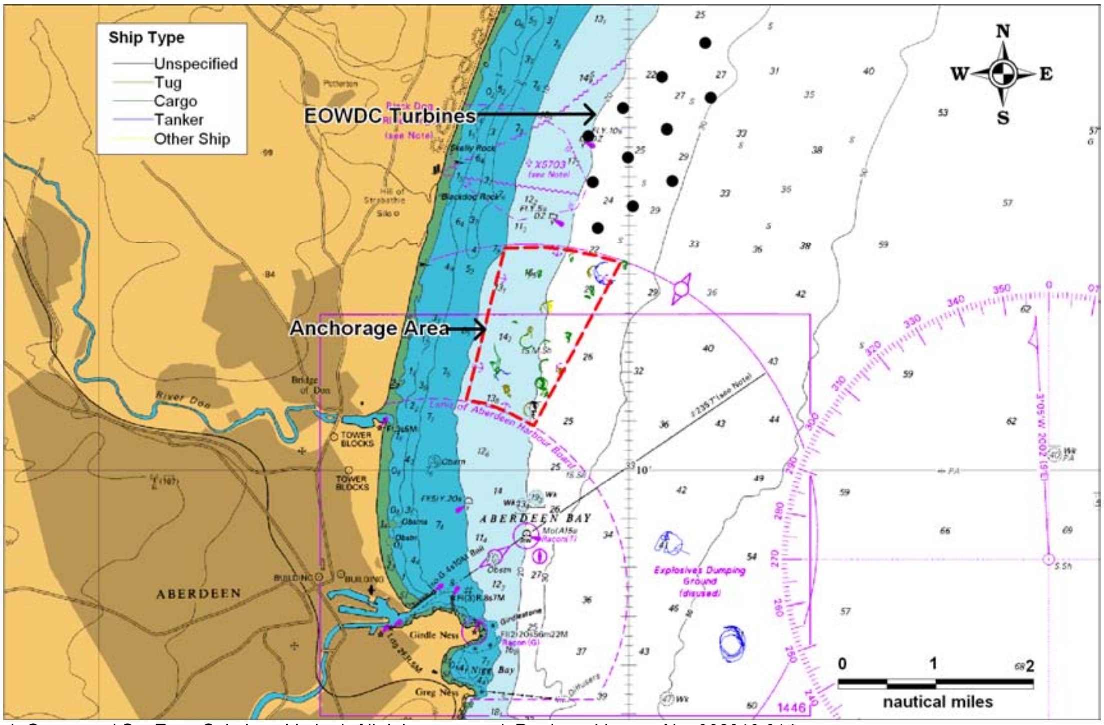

Figure 9-1 Anchored Vessels during Survey 5 (with Charted Anchorage Area shown in red)

Consequences Assessment

TABLE OF CONTENTS

D1. Introduction

This Appendix presents an assessment of the consequences of collision incidents, in terms of people and the environment, due to the impact of the proposed European Offshore Wind Deployment Centre (EOWDC).

The significance of the impact of the proposed EOWDC is also assessed based on risk evaluation criteria and comparison with historical accident data in the UK waters[1].

D2. Risk Evaluation Criteria

2.1 Risk to People

With regard to the assessment of risk to people two measures are considered, namely;

- Individual Risk
- Societal Risk

2.1.1 Individual Risk (per Year)

This measure considers whether the risk from an accident to a particular individual changes significantly due to the wind farm. Individual risk considers not only the frequency of the accident and the consequence (likelihood of death), but also the individual's fractional exposure to that risk, i.e., the probability of the individual of being in the given location at the time of the accident.

The purpose of estimating the Individual Risk is to ensure that individuals, who may be affected by the presence of the wind farm, are not exposed to excessive risks. This is achieved by considering the significance of the change in individual risk resulting from the presence of the wind farm, relative to the background individual risk levels.

Annual individual risk levels to crew (i.e., the annual fatality risk of an average crew member) for different ship types are presented in Figure 2.1 (Ref.i). The figure also highlights the risk acceptance criteria as suggested in IMO MSC 72/16.

[1] In this technical note, UK waters means the UK Exclusive Economic Zone and UK territorial waters means within the 12 nautical miles limit.

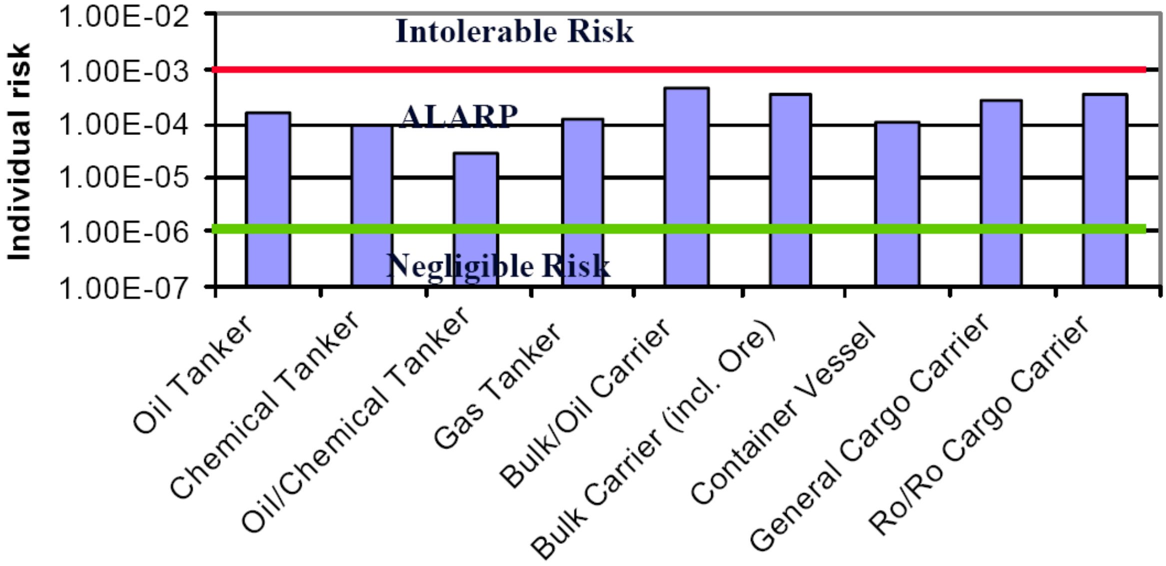

Figure 2.1 Individual Risk Levels and Acceptance Criteria per Ship Type

Typical bounds defining the ALARP regions for decision making within shipping are as follows.

Table 2.1 Individual Risk ALARP Criteria

Individual	Lower Bound for ALARP	Upper Bound for ALARP
To crew member	10^{-6}	10^{-3}
To passenger	10^{-6}	10^{-4}
3rd party	10^{-6}	10^{-4}
New ship target	10^{-6}	Above values reduced by one order of magnitude

On a UK basis, the MCA website presents individual risks for various UK industries based on HSE data for 1987-91 (Ref. ii). The risks for different industries are compared in Figure 2.2.

The individual risk for sea transport of 2.9 x 10^{-4} per year is consistent with the worldwide data presented in Figure 2.1, whilst the individual risk for sea fishing of 1.2 x 10^{-3} per year is the highest across all of the industries listed.

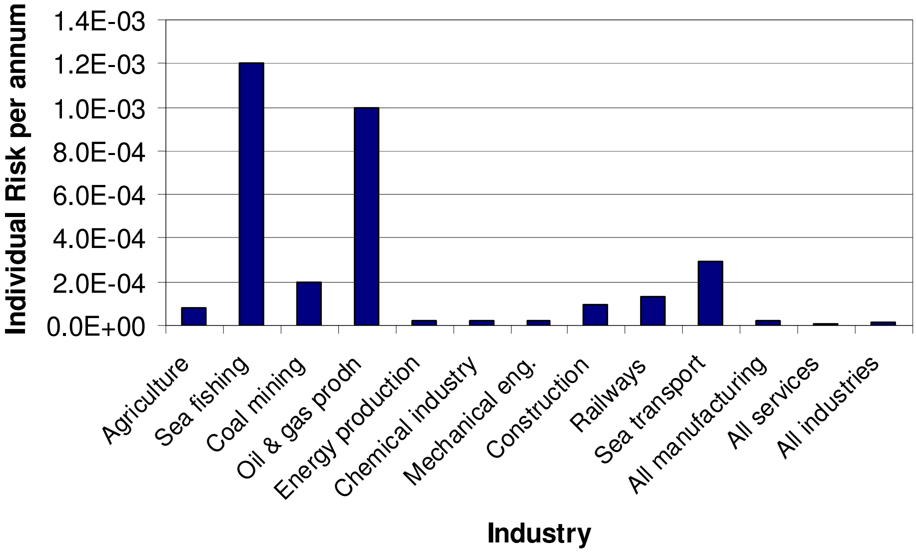

Figure 2.2 Individual Risk per Year for various UK Industries

2.1.2 Societal Risk

Societal Risk is used to estimate risks of accidents affecting many persons, e.g., catastrophes, and acknowledging risk averse or neutral attitudes. Societal Risk includes the risk to every person, even if a person is only exposed on one brief occasion to that risk. For assessing the risk to a large number of affected people, societal risk is desirable because individual risk is insufficient in evaluating risks imposed on large numbers of people.

Within this assessment societal risk (navigational based) can be assessed for the proposed EOWDC giving account to the change in risk associated with each accident scenario caused by the introduction of the structures. Societal risk may be expressed as:

- Annual fatality rate: frequency and fatality are combined into a convenient one-dimensional measure of Societal Risk. This is also known as Potential Loss of Life (PLL).

- FN-diagrams showing explicitly the relationship between the cumulative frequency of an accident and the number of fatalities in a multi-dimensional diagram.

When assessing societal risk this study focuses on PLL, which takes into account the number of people likely to be involved in an incident (which is higher for passenger ferries, for example), and assesses the significance of the change in risk compared to background risk levels for the UK.

2.2 Risk to Environment

For risk to the environment the key criteria considered in terms of the effect of the proposed EOWDC is the potential amount of oil spilled from the vessel involved in an incident.

It is recognised there will be other potential pollution, e.g., hazardous containerised cargoes, however, oil is considered the most likely pollutant and the extent of predicted oil spills will provide an indication of the significance of pollution risk due to the proposed EOWDC compared to background pollution risk levels for the UK.

D3. MAIB Incident Analysis

3.1 All Incidents

All UK commercial vessels are required to report accidents to MAIB. Non-UK vessels do not have to report unless they are in a UK port or are in 12 nautical mile territorial waters and carrying passengers to a UK port. There are no requirements for non-commercial recreational craft to report accidents to MAIB, however, a significant proportion of these incidents are reported and investigated by the MAIB.

A total of 19,130 accidents, injuries and hazardous incidents were reported to MAIB between 1 January 1994 and 27 September 2005 involving 21,140 vessels (some incidents such as collisions involved more than one vessel). 72% of incidents were in UK waters with 28% reported in foreign waters.

The locations[1] of incidents reported in the vicinity of the UK are presented in Figure 3.1, colour-coded by type.

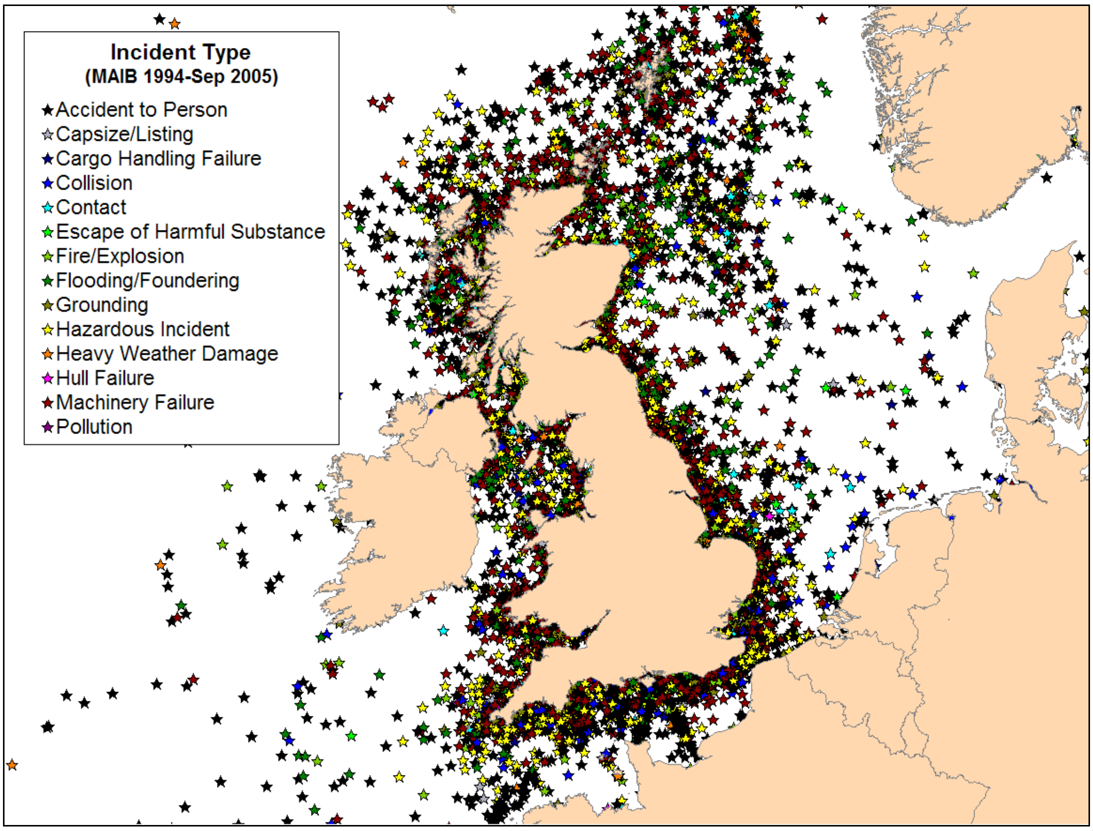

Figure 3.1 Incident Locations by Type (MAIB 1994-Sep 2005)

[1] MAIB aim for 97% accuracy in reporting the locations of incidents.

The distribution of incidents by year is presented in Figure 3.2.

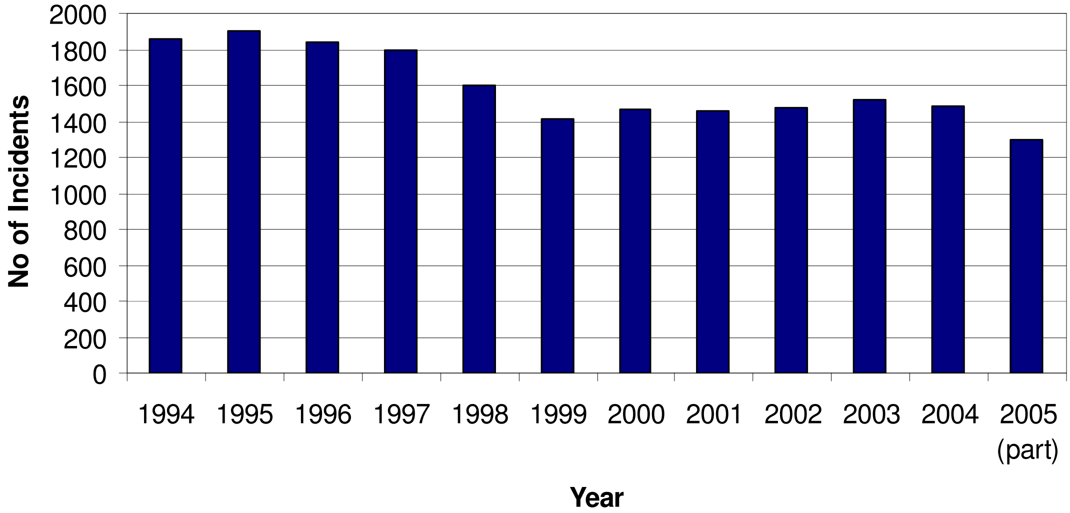

Figure 3.2 Incidents per Year (MAIB 1994-Sep 2005)

The average number of incidents per year, excluding 2005 which is a part-year, was 1,621. There is a declining trend in incidents.

The distribution by incident type is presented in Figure 3.3.

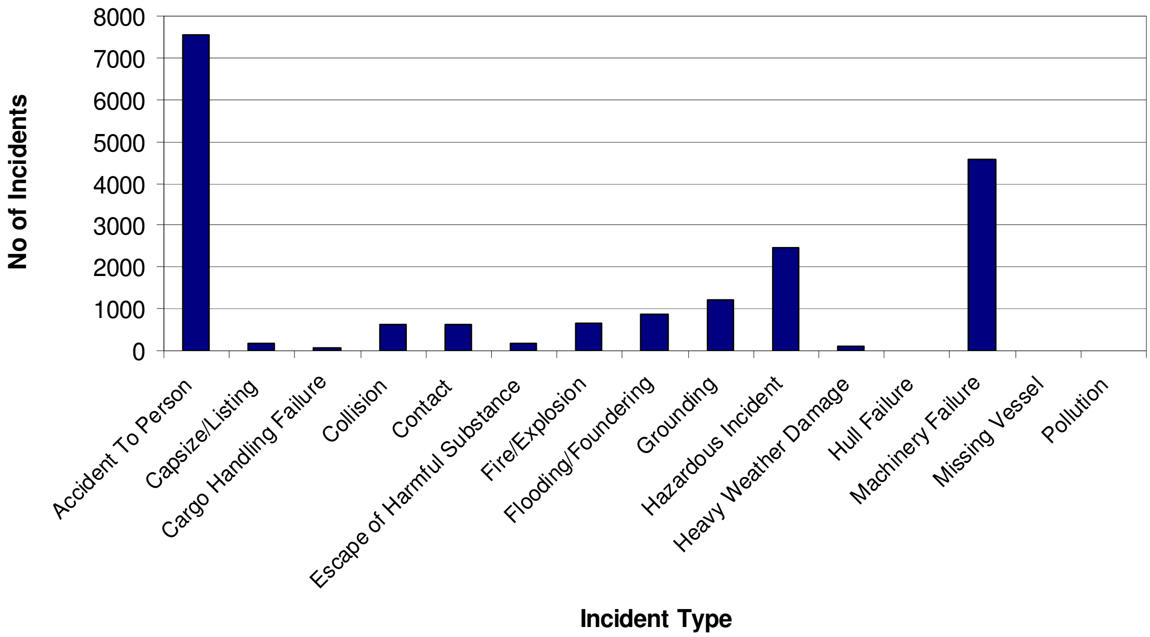

Figure 3.3 Incidents by Incident Type (MAIB 1994-Sep 2005)

Therefore, the most common incident types were Accident to Person[1] (40%), Machinery Failure (24%) and Hazardous Incident (13%). Collisions and Contacts each represented 3% of total incidents.

The distribution of vessel type categories involved in incidents is presented in Figure 3.4.

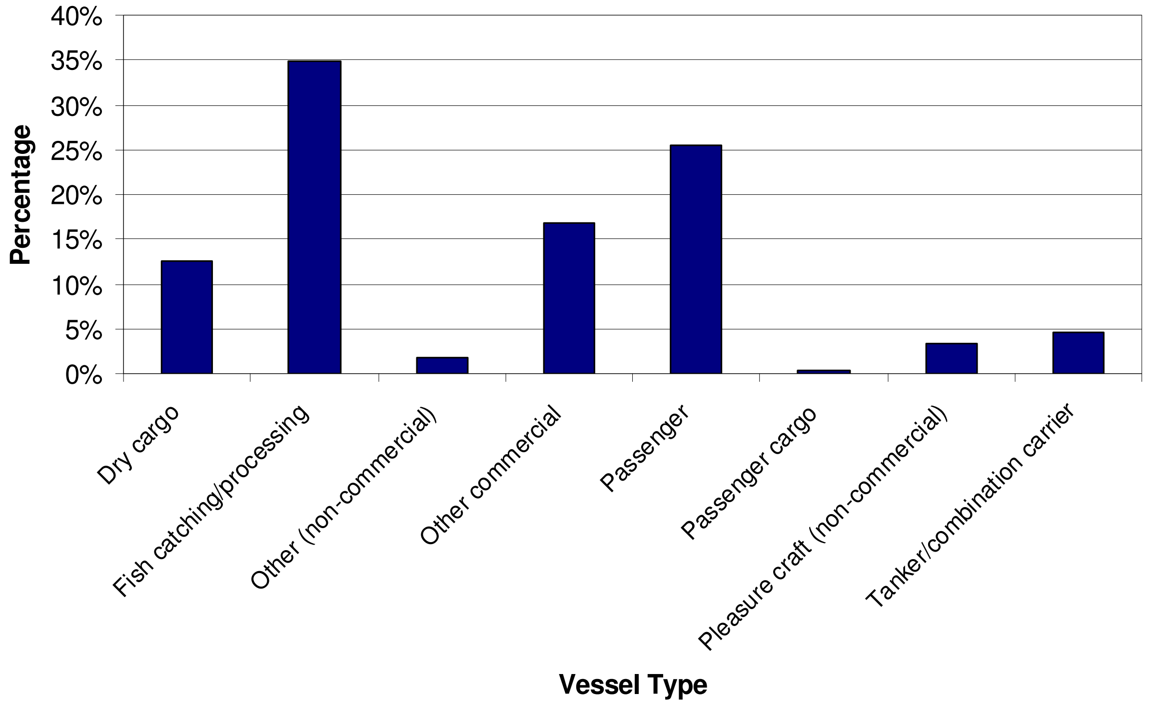

Figure 3.4 Incidents by Vessel Type (MAIB 1994-Sep 2005)

The most common vessel types involved in incidents were fishing vessels (35%), passenger vessels (25%) and other commercial vessels (17%), which includes offshore industry vessels, tugs, workboats and pilot vessels.

The total number of fatalities per year (divided into crew, passenger and other) reported in the MAIB incidents is presented in Figure 3.5.

[1] Where the incident is an accident to a vessel, e.g., collision or machinery failure, it would be reported under this vessel accident category.

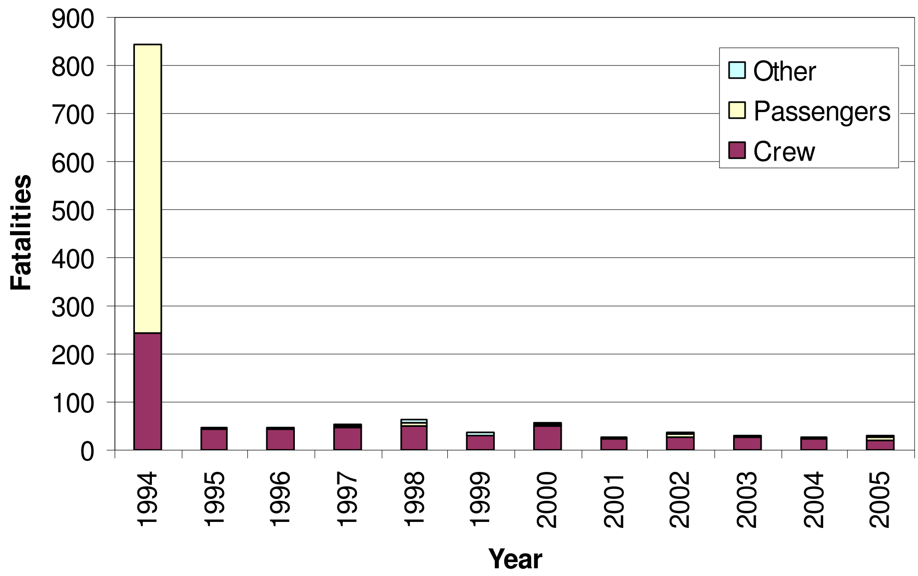

Figure 3.5 Number of Fatalities (MAIB 1994-Sep 2005)

The average number of fatalities per year, excluding 2005 which is a part-year, was 115. The sinking of the 'Estonia' passenger ferry in the Baltic Sea in 1994, which resulted in a reported 852 fatalities, dominates the figures. If 1994 were excluded, the average number of fatalities per year would drop to 42.

Considering only the incidents reported to have occurred in UK territorial waters, the number of fatalities per year is presented in Figure 3.6.

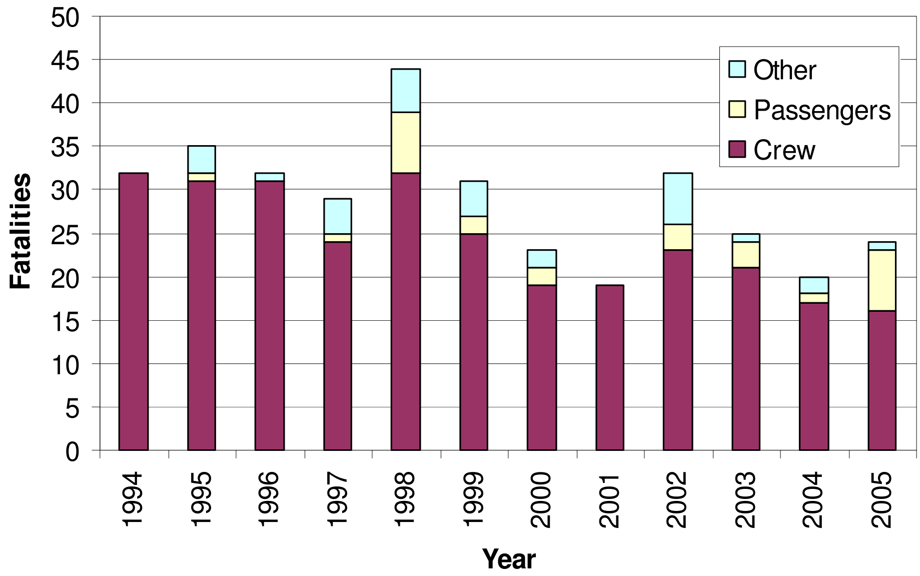

Figure 3.6 Number of Fatalities for Incidents in UK Waters (MAIB 1994-Sep 2005)

Therefore, the average number of fatalities per year in UK territorial waters between 1994 and 2004 was 29.

The distribution of fatalities in UK waters by vessel type and person category is presented in Figure 3.7.

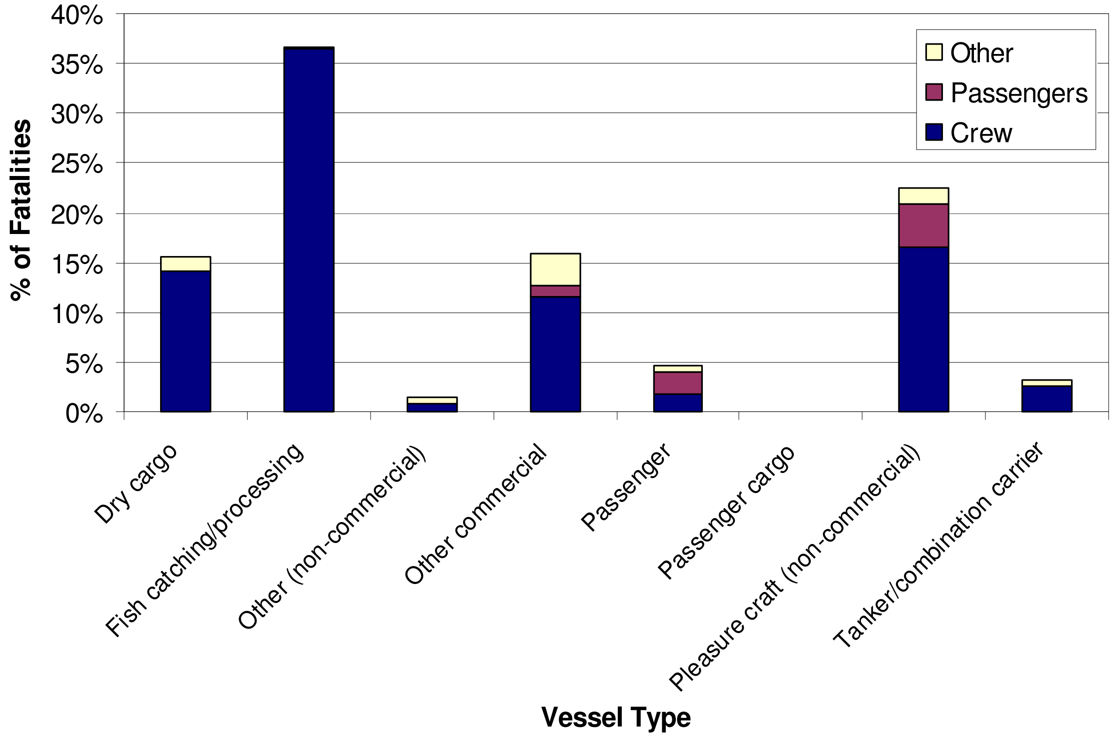

Figure 3.7 Fatalities by Vessel Type for Incidents in UK (MAIB 1994-Sep 2005)

It can be seen that the majority of fatalities in the UK occurred to fishing vessels and pleasure craft, with crew members the main people involved.

3.2 Collision Incidents

MAIB define a collision incident as "vessel hits another vessel that is floating freely or is anchored (as opposed to being tied up alongside)."

A total of 623 collisions were reported to MAIB between 1 January 1994 and 27 September 2005 involving 1,241 vessels (in a handful of cases the other vessel involved was not logged).

The locations of collisions reported in the vicinity of the UK are presented in Figure 3.8, colour-coded by type.

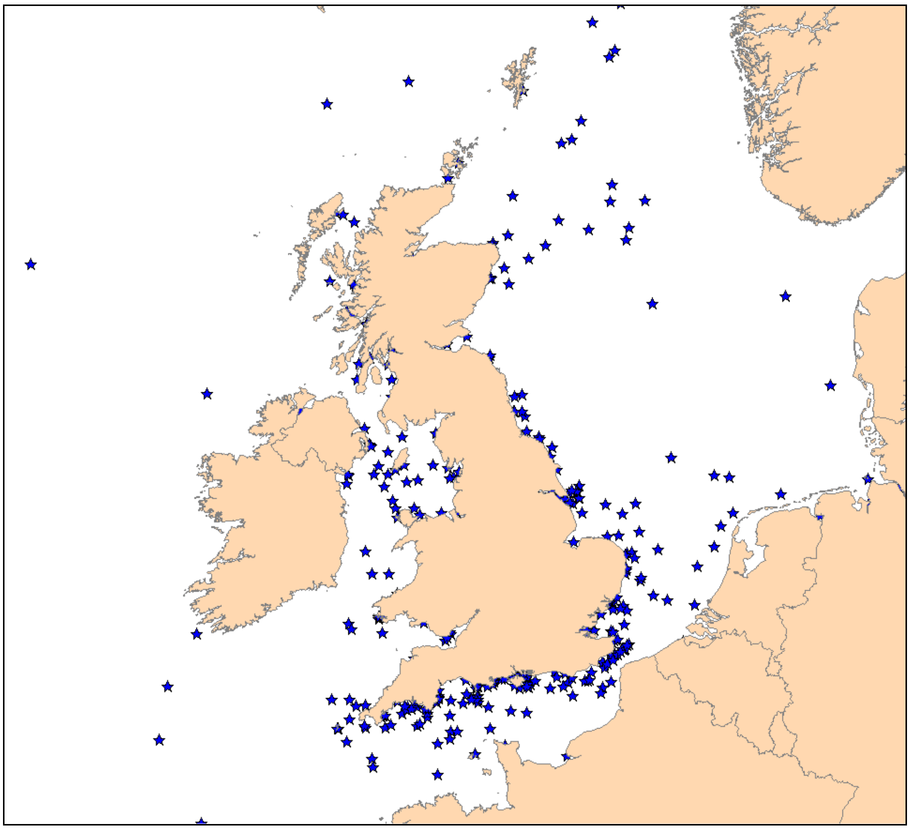

Figure 3.8 Collision Incident Locations (MAIB 1994-Sep 2005)

The distribution of all collision incidents by year is presented in Figure 3.9.

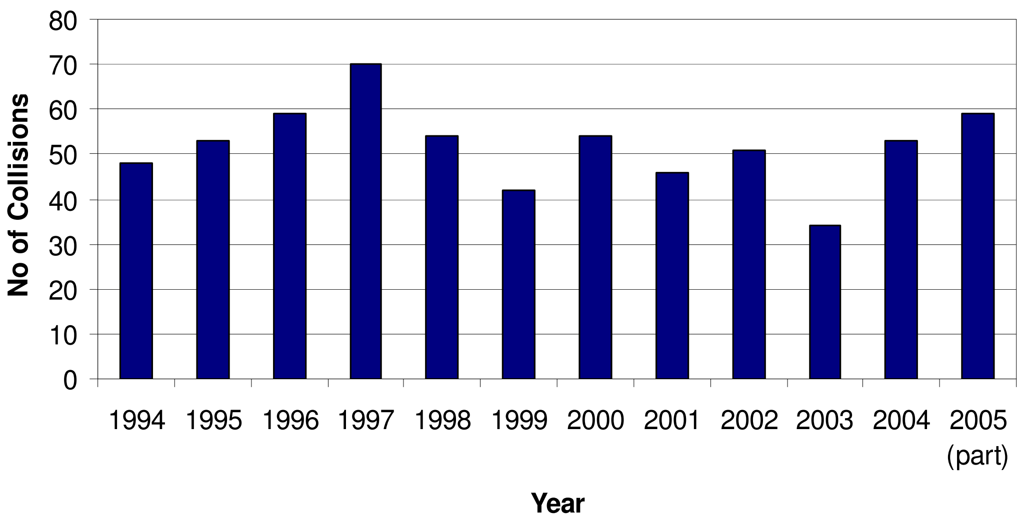

Figure 3.9 Collisions per Year (MAIB 1994-Sep 2005)

The average number of collisions per year, excluding 2005 which is a part-year, was 51.

The distribution of vessel types involved in collisions is presented in Figure 3.10.

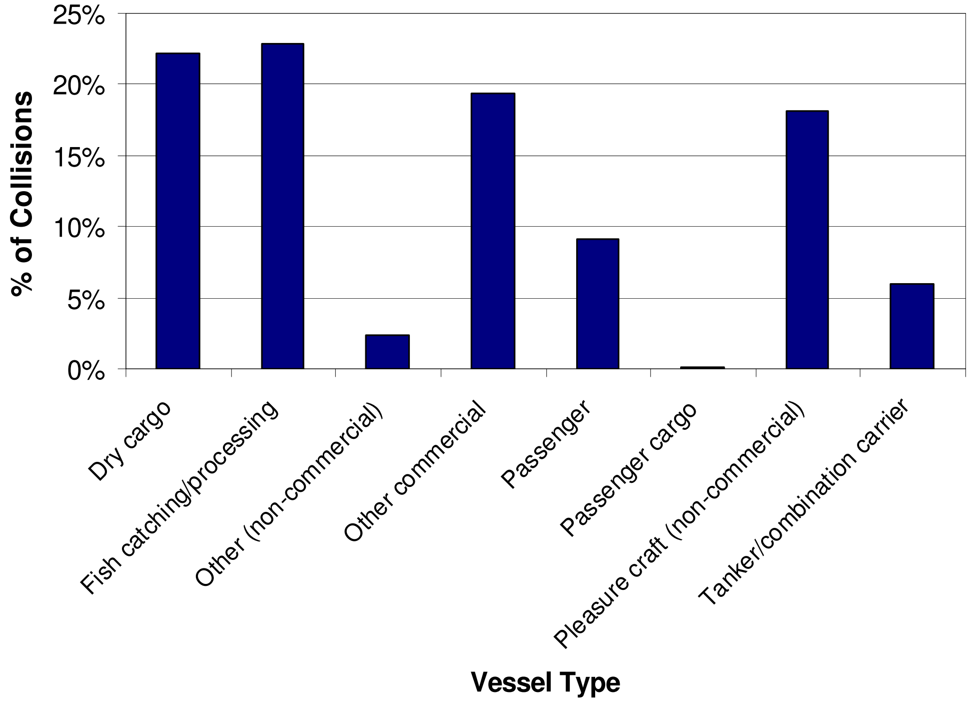

Figure 3.10 Collisions by Vessel Type (MAIB 1994-Sep 2005)

Therefore, the most common vessel type involved in collisions were fishing vessels (25%), dry cargo vessels (22%), other commercial vessels (19%) and non-commercial pleasure craft (18%).

Finally, the total number of fatalities per year (divided into crew and passenger) reported in all MAIB collisions is presented in Figure 3.11.

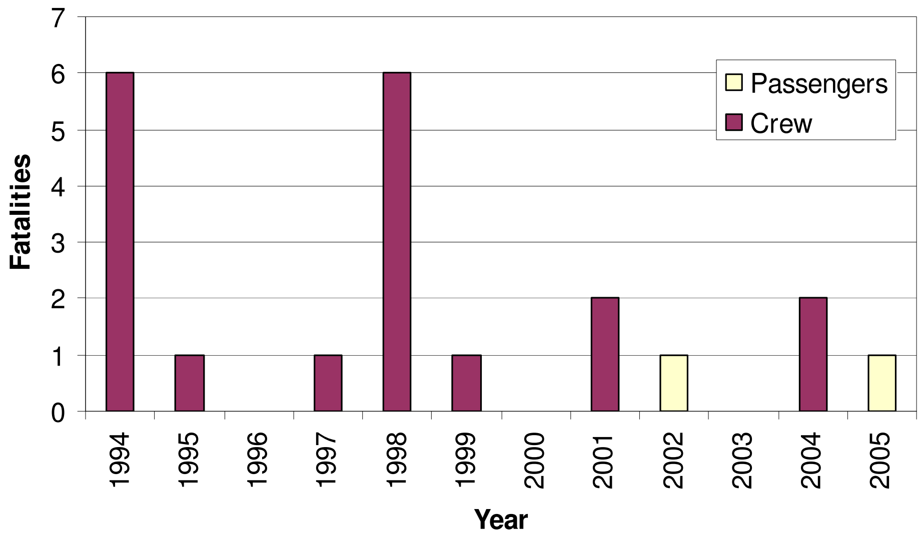

Figure 3.11 Fatalities from Collisions (MAIB 1994-Sep 2005)

The average number of fatalities per year, excluding 2005 which is a part-year, was 1.8.

Details on the 12 incidents reported by MAIB that involved fatalities are presented in Table 3.1. In each case the first vessel listed suffered the losses. It can be seen that most incidents involved fishing vessels and recreational craft.

Table 3.1 Fatal Collision Incidents (MAIB 1994-Sep 2005)

Date	Description	Fatalities
Nov 1994	Beam trawler collision with bulk carrier Foreign waters, high seas, moderate visibility and sea state	6
Jun 1998	Seine netter collision with container ship Foreign waters, high seas, good visibility, moderate seas	5
Feb 1995	Stern trawler collision with supply ship Foreign waters, river/canal, good visibility, moderate seas	1
Mar 1997	Stern trawler collision with other fishing vessel Foreign waters, good visibility, calm seas	1
Jun 1998	RIB collision with other RIB UK territorial waters, river/canal	1
Mar 1999	Fishing vessel collision with container ship Foreign waters, coastal waters, good visibility	1
Aug 2001	Pleasure craft collision with small commercial motor vessel UK territorial waters	1
Oct 2001	General cargo vessel collision with chemical tanker	1

Date	Description	Fatalities
	UK territorial waters, coastal waters, good visibility	
Aug 2002	Speed craft collision with another speed boat UK waters, unspecified location, good visibility, calm seas	1
May 2004	Port service tug collision with passenger ferry (during towing) Foreign waters, coastal waters	1
Jun 2004	Pleasure craft collision with other pleasure craft Foreign waters, river/canal	1
Jul 2005	Pleasure craft collision with (1 passenger fatality) UK territorial waters, coastal waters, good visibility, calm seas	1

A more detailed description of the two incidents which resulted in multiple fatalities is provided below:

- Collision between bulk carrier and beam trawler in eastward lane of Terschelling - German Bight TSS. Both vessels were on passage. Visibility was about 5 miles. Collision caused extensive damage to beam trawler and vessel rapidly flooded and sank with loss of her 6 crew, all of whom were Dutch nationals. Collision was primarily caused by Master of bulk carrier failing to take early and substantial action when complying with his obligation to keep out of the way.

- The fishing vessel was on an easterly course while on passage from Firth of Forth to Esbjerg, and the container ship was on a north-westerly course from Hamburg to Gothenburg. The fishing vessel was the give-way vessel but did not alter course and speed, the cause of which could not be established. The chief officer of the container ship did not alter course until it was too late and the two vessels collided. The fishing vessel foundered so quickly that all hands were trapped inside the accommodation and the container ship was so badly damaged that she had to use Esbjerg as a port of refuge.

3.3 Contact Incidents

MAIB define a contact incident as "vessel hits an object that is immobile and is not subject to the collision regulations e.g. buoy, post, dock (too hard), etc. Also, another ship if it is tied up alongside. Also floating logs, containers etc."

A total of 609 contacts were reported to MAIB between 1 January 1994 and 27 September 2005 involving 663 vessels.

The locations of contacts reported in the vicinity of the UK are presented in Figure 3.12, colour-coded by type.

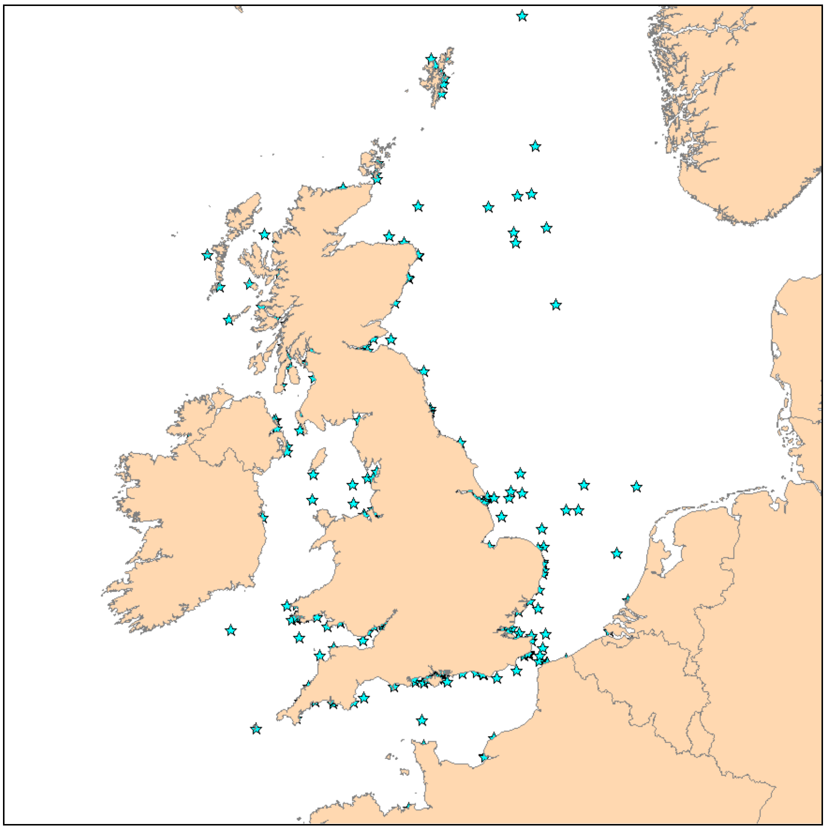

Figure 3.12 Contact Incident Locations (MAIB 1994-Sep 2005)

The distribution of contact incidents by year is presented in Figure 3.13.

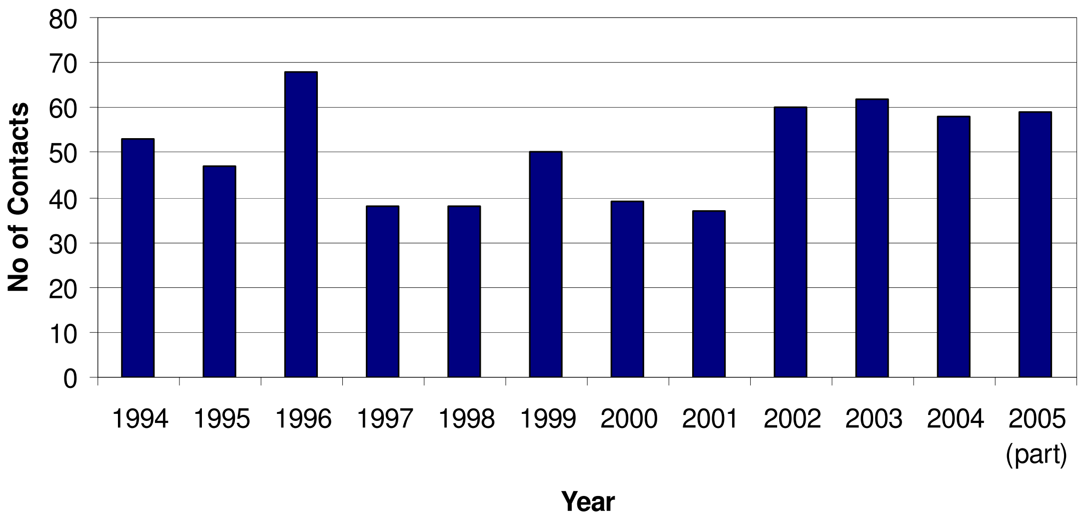

Figure 3.13 Contact Incidents per Year (MAIB 1994-Sep 2005)

The average number of contacts per year, excluding 2005 which is a part-year, was 50.

The distribution of vessel types involved in contacts is presented in Figure 3.14.

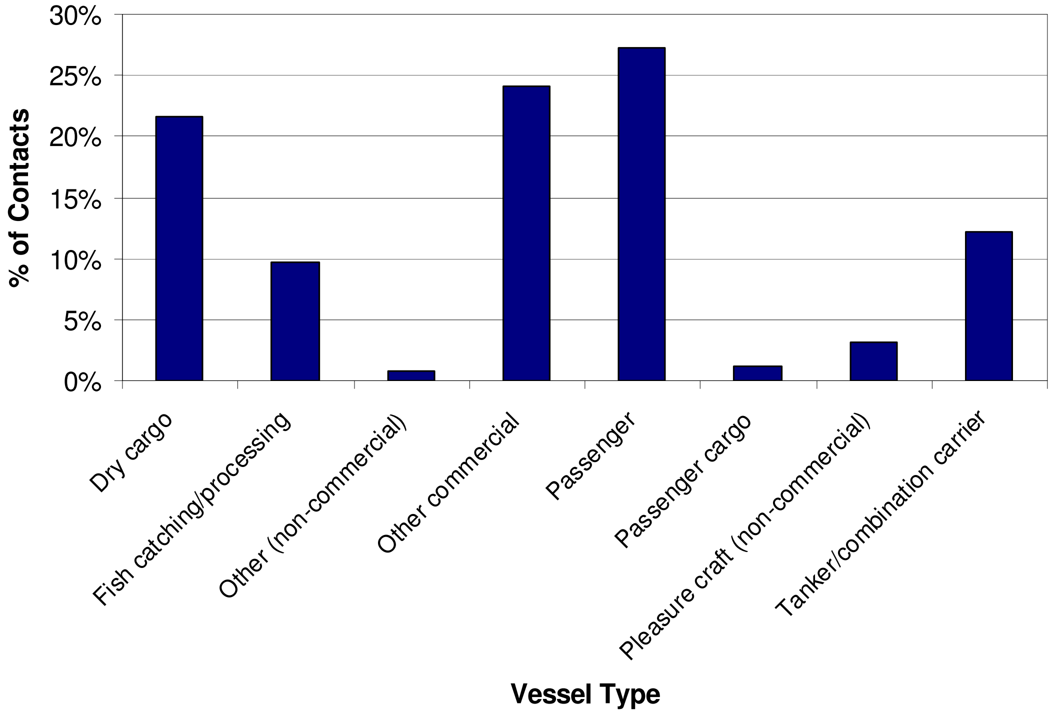

Figure 3.14 Contacts by Vessel Type (MAIB 1994-Sep 2005)

Therefore, the most common vessel type involved in contacts were passenger ferries (27%), other commercial vessels (24%) and dry cargo vessels (22%).

There were no fatalities in any of the contact incidents recorded by MAIB.

D4. Fatality Risk

4.1 Introduction

This section uses the MAIB incident data along with information on average manning levels per vessel type to estimate the probability of fatality in a marine incident associated with the proposed EOWDC development.

The proposed EOWDC is assessed to have the potential to affect the following incidents:

- Passing Powered Collision with Wind Farm Structure
- Passing Drifting Collision with Wind Farm Structure
- Vessel-to-Vessel Collision
- Fishing Vessel Collision with Wind Farm Structure

Of these incidents, only vessel-to-vessel collisions match the MAIB definition of collisions and hence the fatality analysis presented in Section 3.2 is considered to be directly applicable to these types of incidents.

The other scenarios of passing powered, passing drifting and fishing vessel collisions with the wind farm structures are technically contacts, i.e., vessel hits an immobile object in the form of a turbine or substation. From Section 3.3 it can be seen that none of the 609 contact incidents reported by MAIB between 1994 and 2005 resulted in fatalities.

However, as the mechanics involved in a vessel contacting a wind turbine may differ in severity from hitting, for example, a buoy, quayside or moored vessel, the MAIB collision fatality risk rate has also been conservatively applied for these incidents.

4.2 Fatality Probability

Twelve of the 623 collision incidents reported by MAIB resulted in one or more fatalities. This represents a 2% probability that a collision will lead to a fatal accident. A total of 21 fatalities resulted from the collision incidents.

To assess the fatality risk for personnel onboard a vessel, either crew, passenger or other, the number of persons involved in the incidents needs to be estimated. From an ILO survey of seafarers during 1998-99 (Ref. iii), the average commercial vessel had a crew of 17. For other (non-commercial vessels) such as naval craft and RNLI lifeboats the average crew has been estimated to be 20. Onboard fishing vessels and pleasure craft the average crew has been estimated to be 5. Finally, for passenger vessels it is estimated that the average number of passengers carried, in addition to crew, is 300 (based on UK sea passenger movements on principal ferry routes, Ref. iv).

It is recognised these numbers can be substantially higher or lower on an individual vessel basis depending on size, subtype, etc., but applying reasonable averages is considered sufficient for this analysis.

Using the average number of persons carried along with the vessel type information involved in collisions reported by MAIB (see Figure 3.10), gives an estimated 50,000 personnel onboard the ships involved in the collisions.

Based on 21 fatalities, the overall fatality probability in a collision for any individual onboard is approximately 4.3 x 10^{-4} per collision (0.04%).

It is considered inappropriate to apply this rate uniformly as the statistics clearly shown that the majority of fatalities tend be associated with smaller craft, such as fishing vessels and recreational vessels. Therefore, the fatality probability has been subdivided into two categories of vessel as presented in Table 4.1.

Table 4.1 Fatality Probability per Incident per Vessel Category

Vessel Category	Sub Categories	Fatalities	People Involved	Fatality Probability
Commercial	Dry cargo, passenger, tanker, etc.	3	46,200	6.5E-05
Non-Commercial	Fishing, pleasure, etc.	18	3,120	5.8E-03

From the above table it can be seen the risk is approximately two orders of magnitude higher for people onboard non-commercial vessels.

4.3 Fatality Risk due to the Proposed EOWDC

The base case and future case annual collision frequency levels without and with the proposed EOWDC site are summarised below.

Table 4.2 Summary of Annual Collision Frequency Results

Risk Scenario	Base Case			Future Case		
	Without	With	Change	Without	With	Change
Passing Powered	--	1.0E-03	1.0E-03	--	1.1E-03	1.1E-03
Passing Drifting	--	5.5E-05	5.5E-05	--	6.0E-05	6.0E-05
Vessel-to-Vessel	6.6E-03	6.7E-03	1.3E-04	7.2E-03	7.3E-03	1.4E-04
Fishing	--	2.5E-04	2.5E-04	--	2.8E-04	2.8E-04
Total	6.6E-03	8.0E-03	1.4E-03	7.2E-03	8.8E-03	1.6E-03

For the local vessels operating in the area of the site, the average manning has been estimated as follows.

Table 4.3 Vessel Types, Incidents and Average Persons exposed

Vessel Type	Collision Incidents	Average Manning
Cargo/Offshore	Passing powered, passing drifting, vessel-to-vessel.	17
Tanker	Passing powered, passing drifting, vessel-to-vessel.	20
Ferry	Passing powered, passing drifting, vessel-to-vessel.	250
Fishing Vessel	Vessel-to-vessel and fishing.	3
Recreational Vessel	Vessel-to-vessel.	4

From the detailed results of the collision frequency modelling, the distribution of the predicted change in collision frequency by vessel type due to the proposed EOWDC is as follows.

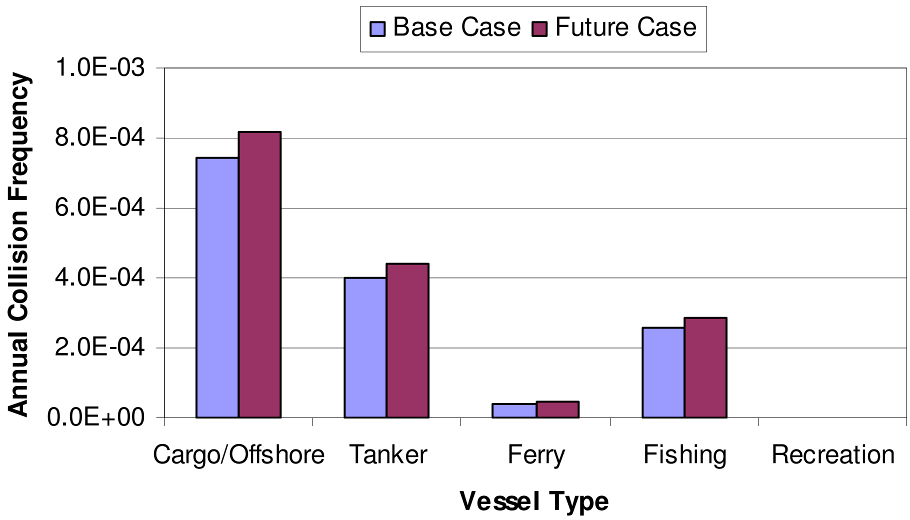

Figure 4.1 Collision Frequency by Vessel Type estimated for the proposed EOWDC

It can be seen the change in collision frequency is highest for cargo/offshore ships and tankers. The change in frequency is lowest for ferries and recreational vessels.

Combining the collision frequency (Table 4.2), the estimated number of persons onboard each vessel type (Table 4.3) and the estimated fatality probability for that vessel category (Table 4.1), the annual increase in Potential Loss of Life (PLL) due to the impact of the proposed EOWDC is estimated to be as follows:

- Base Case PLL: 6.8×10^{-6} fatalities per year
- Future Case PLL: 7.4×10^{-6} fatalities per year

The estimated base case PLL increase equates to an average of one additional fatality in 148,000 years, whilst the future case PLL increase corresponds to an average of one additional fatality in 135,000 years.

The predicted incremental increases in PLL due to the wind farm, distributed by vessel type for the base and future cases, are presented in Figure 4.2.

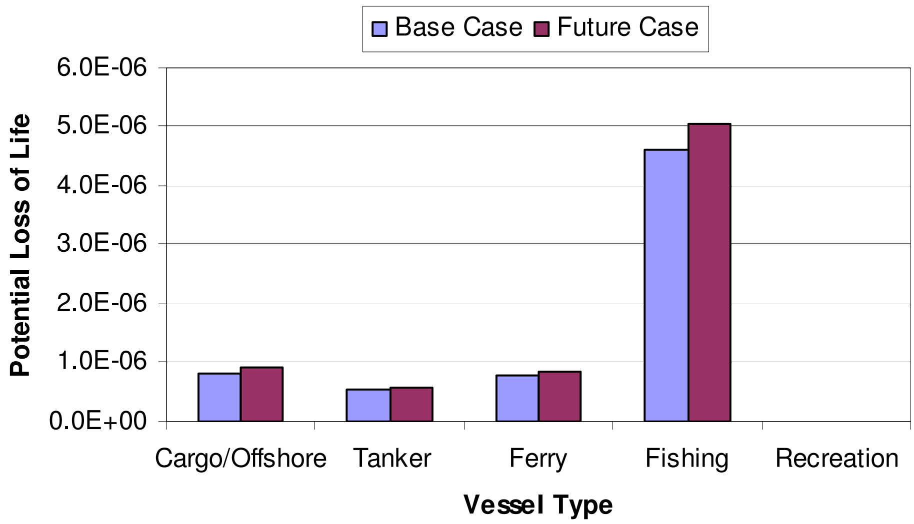

Figure 4.2 Estimated change in Annual PLL by Vessel Type due to the proposed EOWDC

Therefore, it can be seen that the fatality risk is dominated by fishing vessels, which historically have a higher fatality probability per incident than merchant vessels.

Converting the PLL to individual risk based on the average number of people exposed by vessel type, the results are presented in Figure 4.3. (This calculation assumes that the risk is shared between 10 vessels of each type, which is considered to be conservative based on the number of different vessels operating in the vicinity of the site.)

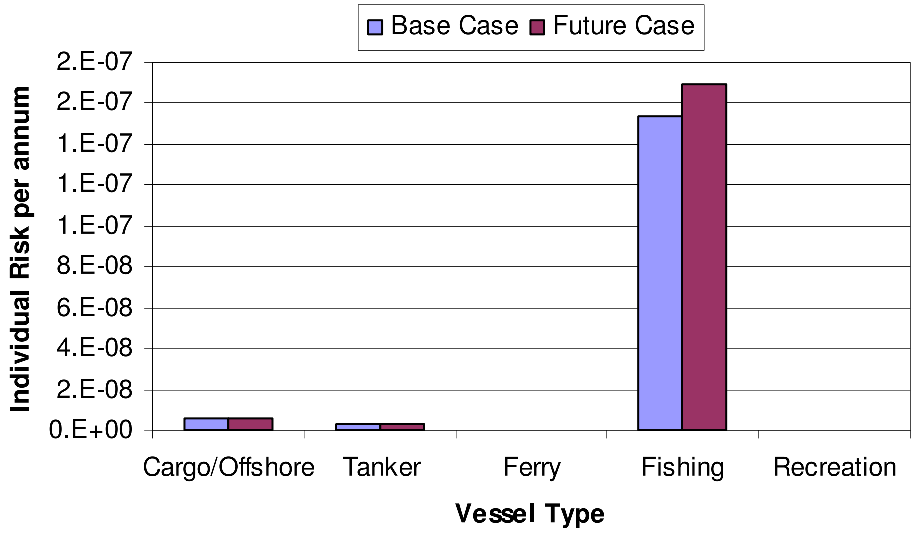

Figure 4.3 Estimated change in Individual Risk by Vessel Type due to the proposed EOWDC

Therefore, individual risk is highest for people on fishing vessels, which is related to the higher probability of fatalities occurring in the event of an incident.

4.4 Significance of Increase in Fatality Risk – Proposed EOWDC

The overall increase in PLL estimated due to the development is 6.8 x 10^{-6} fatalities per year (base case), which equates to one additional fatality in 148,000 years. This is a small change compared to the MAIB statistics which indicate an average of 29 fatalities per year in UK territorial waters.

In terms of individual risk to people, the incremental increase for commercial ships (in the region of 10^{-8}) is very low compared to the background risk level for the UK sea transport industry of 2.9 x 10^{-4} per year.

Similarly, for fishing vessels, whilst the change in individual risk attributed to the development is higher than for commercial vessels (in the region of 10^{-7}), it is very low compared to the background risk level for the UK sea fishing industry of 1.2 x 10^{-3} per year.

D5. Pollution Risk

5.1 Historical Analysis

The pollution consequences of a collision in terms of oil spill depend on the following:

- Spill probability (i.e., likelihood of outflow following an accident)
- Spill size (amount of oil)

Two types of oil spill are considered:

- Fuel oil spills from bunkers (all vessel types)
- Cargo oil spills (laden tankers)

The research undertaken as part of the DfT's MEHRAs project (Ref. v) has been used as it was comprehensive and based on worldwide marine spill data analysis.

From this research, the overall probability of a spill per accident was calculated based on historical accident data for each accident type as presented in Figure 5.1.

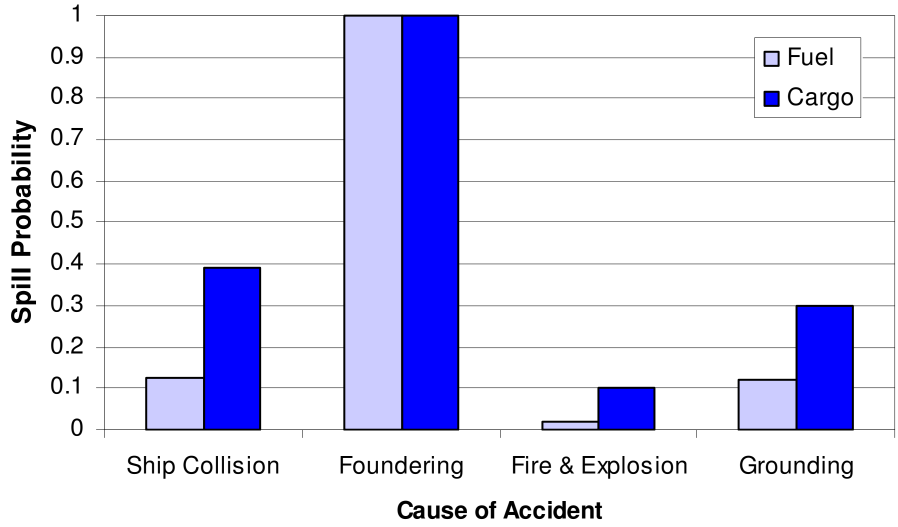

Figure 5.1 Probability of an Oil Spill resulting from an Accident

Therefore, it was estimated that 13% of ship collisions result in a fuel oil spill and 39% of collisions involving a laden tanker result in a cargo oil spill.

In the event of a bunker spill, the potential outflow of oil depends on the bunker capacity of the vessel. Historical bunker spills from ships have generally been limited to a size below 50% of the bunker capacity, and in most incidents much lower. For the types and sizes of ships exposed to the site, an average spill size of 100 tonnes of fuel oil is considered to be a conservative assumption.

For cargo spills from laden tankers, the spill size can vary significantly. ITOPF report the following spill size distribution for tanker collisions between 1974 and 2004.

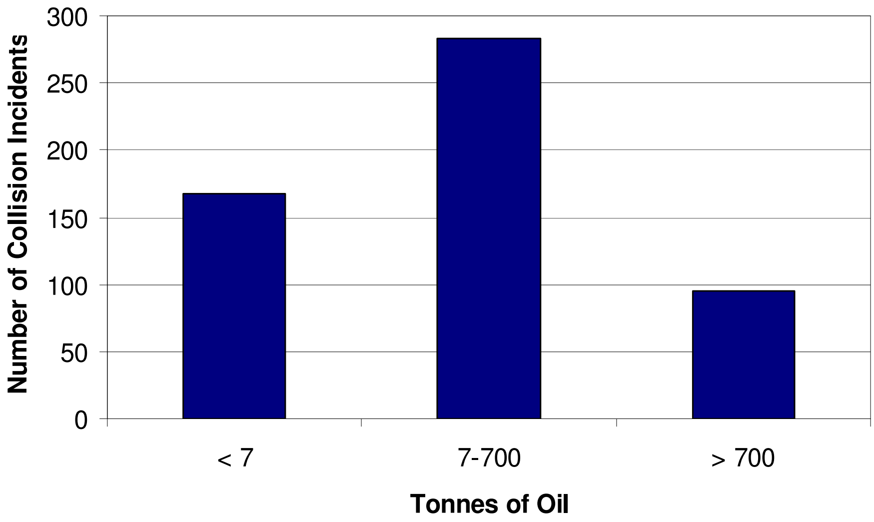

Figure 5.2 Spill Size Distribution in Tanker Collision Incident (ITOPF 1974-2004)

31% of spills are below 7 tonnes, 52% are between 7 and 700 tonnes and 17% are greater than 700 tonnes. Based on this data and the tankers transiting the area in proximity to the proposed EOWDC site, an average spill size of 400 tonnes is considered conservative.

For fishing and recreational vessel collisions, comprehensive statistical data is not available so it is conservatively assumed that 50% of all collisions involving these vessels will lead to oil spill with the quantity spilled being an average of 5 tonnes for fishing vessels and 1 tonne for recreational vessels.

5.2 Pollution Risk – Proposed EOWDC

Applying the above probabilities to the collision frequency by vessel type presented in Figure 4.1 and the average spill size per vessel, the amount of oil spilled per year due to the impact of the development is estimated to be as follows:

- Base Case: 0.07 tonnes of oil per year
- Future Case: 0.08 tonnes of oil per year

The predicted increases in tonnes of oil spilled distributed by vessel type for the base and future cases are presented in Figure 5.3.

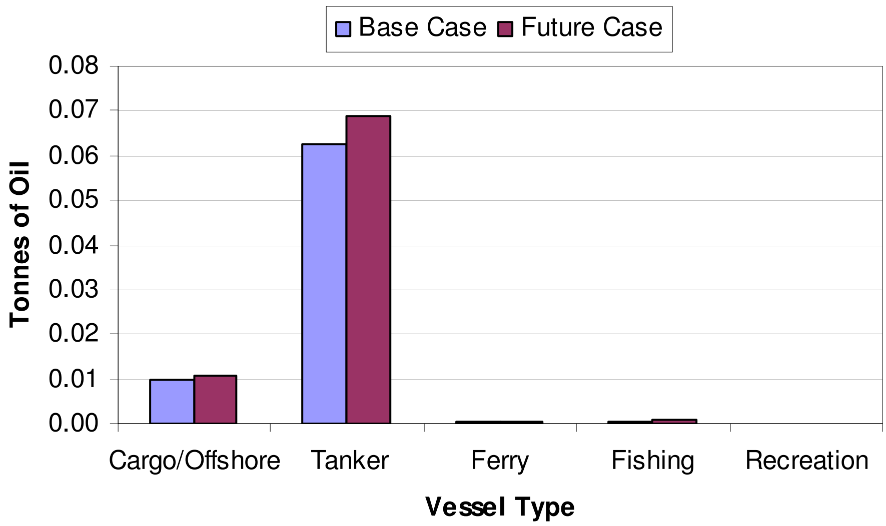

Figure 5.3 Estimated change in Pollution by Vessel Type due to Site

It can be seen that tankers, which can spill both fuel and cargo oils, pose the largest oil spill threat.

5.3 Significance of Increase in Pollution Risk – Proposed EOWDC

To assess the significance of the increased pollution risk from marine vessels caused by the proposed EOWDC, historical oil spill data for the UK has been used as a benchmark.

From the MEHRAs research (Ref. v), the average annual tonnes of oil spilled in the waters around the British Isles due to marine accidents in the 10-year period from 1989-98 1998 was 16,111. This is based on a total of 146 reported oil pollution incidents of greater than 1 tonne (smaller spills are excluded as are incidents which occurred within port and harbour areas or as a result of operational errors or equipment failure). Merchant vessel spills accounted for approximately 99% of the total while fishing vessel incidents accounted for less than 1%.

The overall increase in pollution estimated due to the development is very low compared to the historical average pollution quantities from marine accidents in UK waters (approximately 0.0005%).

D6. Conclusions

The quantitative risk assessment indicates that the impact of the proposed EOWDC on people and the environment is relatively low compared to background risk levels in UK waters.

However, it is recognised that there is a degree of uncertainty associated with numerical modelling. For example, the model does not consider the potential radar interference from turbines which may have an influence on the risk of vessel-to-vessel collisions, especially in reduced visibility where one or both of the vessels involved is not carrying AIS. Therefore, conservative assumptions have been applied in this analysis and the overall project is being carried out based on the principle of ALARP to ensure the risks to people and the environment are managed to a level that is as low as reasonably practicable.

It should also be noted that this is the localised impact of a single project and there will be additional maritime risks associated with other offshore wind farm projects in Scotland and the UK as a whole.

EUROPEAN OFFSHORE WIND DEPLOYMENT CENTRE: BASELINE

TECHNICAL REPORT

65391.04

Acknowledgements

Wessex Archaeology was commissioned by Aberdeen Offshore Wind Power Ltd to undertake a technical archaeological assessment to underpin the environmental impact assessment (EIA) of the known and potential marine and maritime cultural heritage assets associated with the proposed European Offshore Wind Deployment Centre (EOWDC). Gavin Scarff and Edwina Sleightholme at Vattenfall Wind Power Ltd are thanked for their support.

Data was provided by the United Kingdom Hydrographic Office (UKHO), Royal Commission on the Ancient and Historical Monuments of Scotland (RCAHMS) and Aberdeenshire Sites and Monuments Record (SMR). The geophysical data was provided by EMU Ltd (2007) and Osiris Projects (2010).

Wessex Archaeology is grateful to the staff of all the above organisations for their co-operation during the project.

Dr Andrew Bicket produced this report. David Howell and Patrick Dresch processed and reviewed the geophysical data and further contributed to the report. Kitty Brandon prepared the illustrations. Dr Jonathan Benjamin managed the project for Wessex Archaeology, and quality assurance was conducted by John McCarthy and Dr Paul Baggaley.

1 MARINE & MARITIME ARCHAEOLOGY

1.1 Information for the Non-Technical Summary

1 The proposed European Offshore Wind Deployment Centre (EOWDC) comprises 11 wind turbines and inter-turbine and export electrical cables.

2 A total of two cultural heritage assets characterised as A1 – being '*anthropogenic origin of archaeological interest*' (**WA 7071** and **7072**) have been identified within the survey area, approximately 40m apart. Of these, one is a previously uncharted wreck site (**7071**) and the other is a large piece of debris, possibly relating to a wreck (**7072**) (**Table 1**).

3 Wreck **7071** exhibits a magnetometer contact and therefore may be of partly metal construction, with dimensions similar to that of a small trawler or sailing vessel. Identification is not possible with the available evidence.

WA ID	Name / Classification	Easting	Northing	Archaeological Discrimination
7071	Wreck	561077	6342919	**A1**
7072	Debris	561038	6342931	**A1**

Table 1: Summary table of principal features of archaeological interest within assessed geophysical survey area. **N.B. FULL DETAILS CAN BE FOUND IN SECTION A.4.**

4 The shallow geological sequence of much of the survey area represents a prograding shoreline sequence relating to the Forth Formation (**WA 7505**) (**Figure 3**). This type of deposit records changes in sea-level in the area since the Last Glacial Maximum. These deposits are therefore potentially an important palaeogeographical and palaeoenvironmental sequence in relation to local and regional patterns of Mesolithic coastal activity and now-submerged archaeological landscapes. Any cultural heritage assets of early prehistoric origin encountered in an offshore, primary (*in situ*) context would be of national importance.

5 Five small possible cut and fills (**7500**, **7501**, **7502**, **7503** and **7504**) have also been identified in the south-west of the Marine Study Area (MSA). These are shallow, relatively small features and, since it has not been possible to trace them between adjacent geophysical survey lines, they are expected to be isolated depressions and not part of a coherent palaeochannel system. Reworked archaeological material in secondary contexts may be present in the fills of these features.

1.2 Introduction

6 Wessex Archaeology (WA) was commissioned to undertake a technical archaeological assessment for the Environmental Impact Assessment (EIA) of the known and potential marine and maritime cultural heritage assets within the vicinity of the proposed European Offshore Wind Deployment Centre (EOWDC).

1.2.1 Aim & Objectives

1.2.1.1 *Project Aim*

7 The aim of this report is to provide a baseline of the known and potential cultural heritage assets within a defined Marine Study Area (MSA) (see **paragraph 9**). The MSA contains the maximum proposed development area associated with the installation of 11 turbines and inter-turbine cabling in addition to an indicative export cable corridor. The MSA is outlined on **Figure 1**.

1.2.1.2 *Project Objectives*

- To outline and discuss the known cultural heritage assets within the MSA based on existing archaeological records, an assessment of marine geophysical data and secondary sources
- To summarise the potential for the presence of unknown archaeological sites that may be impacted by the proposed development with specific reference to human activity associated with palaeo-shoreline change and submerged prehistoric landscapes, maritime installations and wreck sites (civilian and military) of domestic and foreign origin
- To make an assessment of the importance of known and potential cultural heritage assets
- To present the statutory, planning and policy context relating to the historic environment within the MSA (see **Appendix A.1**)

1.2.2 Methodology Consultation

8 During the preparation of this baseline report stakeholders and organisations have been consulted. These are listed below:

- UK Hydrographic Office (101201) – consulted on source data
- RCAHMS (101201) – consulted on source data
- Ministry of Defence, Third Sector Heritage (110128) – consulted on source data

9 In order to provide adequate spatial context for assessing marine and maritime archaeology the MSA was created by placing a 1km buffer around the combined area of the proposed AOWFL Crown Estate lease boundary and the 2010 geophysical survey area as studied by Osiris Projects Ltd (**Figure 1**). This allowed an assessment of maritime cultural heritage assets preserved on the coast (i.e. wrecks run aground on the beach) as well as wrecks and other features on the seabed.

Point	Easting	Northing
1	558678	6346426
2	560802	6345476

4	561740	6340780
5	560394	6340441
6	560813	6342626
7	557769	6341578
8	557275	6339047
9	556445	6339515
Datum: WGS84 **Projection:** UTM z30N		
To obtain MSA, apply 1km buffer to polygon derived from these points		

Table 2: Vertex coordinates of marine study area.

10 The terrestrial components of the proposed scheme are not considered in this report, except where documented wrecks are present on the beach and to provide qualitative context for submerged landscape features.

11 Sub-bottom profiling surveys have also allowed an investigation of Quaternary sedimentary units permitting an assessment of potential for encountering palaeolandscape features of archaeological significance within the context of published sources.

12 The methodology reflects the requirements of Environmental Impact Assessment arising as set out in European Council Directive 85/337/EEC as amended by Directive 97/11/EC. This follows best practice for archaeological reporting as outlined by the Institute for Archaeologists (IfA) in Standards and Guidance for Archaeological Desk-based Assessment (2008).

13 The approach actively assesses models of past sea-level, palaeo-shorelines and submerged prehistoric landscapes alongside the archaeological record to effectively communicate the relationship of the MSA to the extent of inhabitable land throughout the late Pleistocene and Holocene (i.e. last 18,000 years). The broader geological and geomorphological context of the MSA is also summarised to provide sufficient context to allow an assessment of potential for encountering submerged prehistoric landscapes.

14 A variety of documentary sources have been consulted to provide a gazetteer of recorded maritime assets as well as a contextual baseline. This information underpins an assessment of the archaeological and historic importance of maritime resources identified during the geophysical assessment of survey data.

15 This has partly been undertaken within the context of maritime resources compiled and discussed in a previous desk based assessment (DBA) from an area abutting the south of the MSA (Wessex Archaeology 2007) – where appropriate, this report has incorporated and updated elements of the 2007 report, notably maritime history in the Aberdeen Bay area and gazetteers of known losses (**Appendix A.5**).

1.2.3 Data Information and Sources

- Archaeological records for the MSA available in the maritime section of the CANMORE database held by the Royal Commission for Ancient and

Historic Monuments Scotland (RCAHMS) which constitute the National Monuments Record for Scotland (NMRS), also interrogated via a map interface, CANMAP

- Archaeological records for the MSA held locally in the Aberdeenshire, Moray and Angus Sites and Monuments Record (SMR)
- Records of wrecks and obstructions collated by the UK Hydrographic Office (UKHO)
- Records of Protected Places and Controlled Sites provided by the Ministry of Defence
- SeaZone datasets provided by AOWFL including basemapping and wreck information (derived from UKHO records)
- British Geological Survey (BGS) mapping and UKHO charts
- Various secondary sources relating to the palaeo-environment of the area and to the Palaeolithic and Mesolithic archaeology of Northern Europe (see **section 4**)
- Secondary sources relating to wrecks and the maritime environment and the history and archaeology of Aberdeen and its surrounding area (see **section 4**)

16 Geophysical data that has been archaeologically assessed as part of this report is associated with the following reports:

- Emu Ltd (2008) *Geophysical and Seabed Habitat Assessment of the Proposed Aberdeen Offshore Wind Farm for Aberdeen Offshore Wind Farm Ltd.* Report No. 07/J/1/02/1136/0716
- Osiris Projects (2010) *Aberdeen Offshore Windfarm Geophysical Survey. Volume 1: Operations Report. No. C10023*

1.2.3.1 *Data Management*

17 A Geographical Information System (GIS) using ArcGIS 9.3 has been built to store spatial data for the MSA. Qualitative data without accurate geospatial positions have been compiled in a project archive and used to provide baseline context (e.g. recorded losses).

Feature Numbering System

18 Records of wrecks, casualties and seabed features with sufficient positional data have been mapped in the GIS to determine spatial relationships within the MSA. Duplicate records (i.e. sites and features that appeared in more than one dataset) have been merged where practicable and examined against identified geophysical features and anomalies – reference to original sources are retained in the gazetteer located in section A.2, and highlighted by a Wessex Archaeology identification number (WA_ID) beginning (**WA_2000**).

19 Features identified during the geophysical assessment are numbered with a Wessex Archaeology identification number beginning (WA_6000).

20 Once the documentary records (WA_2000s) and observed geophysical anomalies (WA_6000s) are incorporated into the geophysical assessment the known assets and anomalies on the resulting list have each been given a final unique WA_ID number in a sequence starting at **WA_7000**; reference is retained in the gazetteer to the earlier documented features number system (i.e. WA 2000s – documentary records – and 6000s – geophysical anomalies).

21 A full gazetteer of wrecks, casualties and obstructions within the MSA is presented in Appendices A.2 - A.5.

Data Source Quality

22 The UKHO is considered to be the primary record for wrecks and obstructions on the seabed. Wreck information from the UKHO is incorporated into the SeaZone datasets that were also consulted during this project. The following definitions describe the state of the wreck and obstruction records held by the UKHO (incorporated into the SeaZone datasets), and which have been used to classify some of the sites in the gazetteer:

- ABEY: Previously reported but not detected by survey, leading to doubts about its reported position or existence
- DEAD: Not detected by repeated surveys, therefore considered not to exist
- LIFT: A salvaged wreck
- LIVE: All wrecks and anomalies found by UKHO survey

23 DEAD features may just be buried or obscured during subsequent surveys, and therefore represent potential cultural heritage assets which must be considered. This may apply to ABEY records as well; however, poor positioning of such records may make it difficult to reconcile documentary sources with seabed features.

24 CANMORE/CANMAP provides a mapping interface in which to examine the National Monument Record of Scotland (NMRS). The database assigns the positions of these losses with varying degrees of positional accuracy. Where wreck positions are provided by both the UKHO and CANMORE databases, and positional quality can be accurately assessed, the most accurate positional information has been used. For wrecks discussed in this report, positional information is derived from UKHO records (duplicated in the SeaZone datasets). Wreck records from CANMORE have been integrated into the gazetteer of recorded losses as the positional information was found to be inaccurate (**Appendix A.5**).

25 The Aberdeenshire SMR also provides a map interface allowing the creation of polygons to define the desired search area. The marine and maritime content is relatively scarce, within the MSA some records of beached wrecks are present but with relatively poor positional information. The SMR is also a valuable source for early prehistory, particularly for Mesolithic period sites that provide context for submerged Holocene landscapes, inundated by sea-level rise. These themes are developed in the baseline (see **section 2.3.2.4**, **Table 10**).

26 Many of the records in the CANMORE (RCAHMS) and Aberdeenshire SMR databases and other sources (e.g. literary sources) can be termed ‘recorded losses’. These records refer to maritime casualties for which there are no currently known or confirmed seabed remains. Casualty positions are often based on descriptive definitions or dead reckoning and therefore tend to be much less precise and reliable for older shipwrecks. The records are based on the recording practice of ‘Named Locations’, such as 'off Aberdeen' whereby records are assigned to an arbitrary position not directly related to their point of loss, but within the general area.

27 Casualties that will not have resulted in an archaeological site, such as strandings that were subsequently refloated, have been excluded.

28 A qualitative assessment for the potential for encountering military aircraft crash sites at sea is made in **section 2.5**.

29 Recorded losses 'attached' to the Named Locations that may fall within the MSA have been included in the gazetteer (**Appendix A.5**). However, it should be understood that considerable uncertainty attaches to the actual location of many of the losses records. Therefore the gazetteer is likely to contain records of many losses that have not occurred within the MSA.

1.2.3.2 Mapping and Datums

30 All positions and figures are presented in **UTM zone 30N**, relative to the **WGS 84** datum.

31 Unless otherwise stated, all depths are given in metres and relate either to the Chart Datum (CD) Aberdeen or to the Ordnance Datum (OD), Newlyn. The difference between CD Aberdeen and OD is -2.25m, i.e. CD Aberdeen is 2.25m below OD (Newlyn).

1.2.3.3 Chronology

32 In order to clarify the discussion of submerged landscape potential the chronology of British prehistory currently extending to the last 1 Million years (Ma) is presented in **Figure 2**. Major archaeological industries (characteristic artefacts and technologies of particular periods) and their sea-level context are provided; the fluctuating 'island' palaeogeography of Britain is a critical factor for understanding and assessing the archaeological record.

33 The archaeological dating presented in this report relies on two distinct chronological systems. These are as follows:

- Calendar dates, which are suffixed with BC (Before Christ). Such dates can be considered as part of our present day calendar. Derived from chronological methods that equate directly to calendar years or calibrated radiocarbon dates are either related to our modern calendar as BC (cal.BC) dates, or presented as cal.BP (before present) dates calculated in years before 1950
- BP dates (before 1950) are generally used for geological time and refer to dates derived by means other than radiocarbon dating (which is limited to dating the last 45,000 years

34 Archaeological periods during the Holocene (last 10,000 years BP) are outlined in **Table 3**, based upon the scheme adopted for Scotland by the RCAHMS.

Period	Dates
Mesolithic	8600-4000 BC
Neolithic	4000-2000 BC
Bronze Age	2000-800 BC
Iron Age	800 BC – AD 79
Prehistoric	Pre-AD 79
Roman	AD 79-410
Early Historic	AD 411-700
Early Medieval	AD 700-1100
Medieval	AD 1100-1540
Post-Medieval	AD 1541-1700
Industrial	1700-1899
20th Century	1900-1999

Table 3: Key archaeological periods pertaining to Scotland (RCAHMS).

1.2.3.4 Geophysical Assessment Methodology

35 As part of this technical report WA carried out an archaeological assessment of marine geophysical data previously collected by Emu Ltd. (2007) and Osiris Projects Ltd. (2010) in conjunction with records of historic wreck sites and the archaeological record. This has resulted in an archaeological review of the effects of the proposed development upon sites of archaeological interest within the MSA (Wessex Archaeology 2011b). The objectives were as follows:

- To assess geophysical data in order to identify any material of archaeological interest lying within the limits of the survey area
- To locate, identify and characterise any previously unrecorded archaeological sites, and confirm the presence and condition of any known sites within the survey area
- To identify the presence of any sedimentary deposits of archaeological potential
- To propose future mitigation for material of archaeological interest within the survey area

36 The geophysical data used for this report were assessed for quality and were rated as variable using the following criteria:

Data Quality	Description
Good	Data which are clear and unaffected by weather conditions or sea state. The dataset is suitable for the interpretation of standing and partially buried metal wrecks and their character and associated debris field. These data also provide the highest chance of identifying wooden wrecks and debris.
Average	Data which are affected by weather conditions and sea state to a slight or moderate degree. The dataset is suitable for the identification and partial interpretation of standing and partially buried metal wrecks, and the larger elements of their debris fields. Wooden wrecks may be visible in the data, but their identification as such is likely to be difficult.
Variable	This category contains datasets with the quality of individual lines ranging from good to average to below average. The dataset is suitable for the identification of standing and some partially buried metal wrecks. Detailed interpretation of the wrecks and debris field is likely to be problematic. Wooden wrecks are unlikely to be identified.

Table 4: Geophysical survey data quality categorisation.

37 A particular issue which adversely affected the quality of the data appears to have been variable weather conditions encountered during both of the surveys. This has resulted in a minor to high degree of noise being present on both the sub-bottom profiler and sidescan sonar datasets, though the sidescan sonar appeared more detrimentally affected. As a result of this, it is not possible to guarantee that all the potential archaeological features in the data have been correctly identified during archaeological assessment by WA.

Geophysical Data –Technical Specifications

38 The data were obtained during two separate surveys. The first was conducted by Emu Ltd. (Emu 2008) between the 13th and 18th September 2007 on the *FPV Morven*, and the second by Osiris Projects Ltd. (Osiris 2010) between the 3rd September and 26th October 2010 on the *MV Lia*. Both datasets consisted of sidescan sonar, sub-bottom profiler, multibeam bathymetry and marine magnetometer data.

39 Emu used a Klein 3000 dual frequency (100kHz and 500kHz) sidescan sonar system operated at 100m range, with positioning provided by manual layback applied during processing. Data were recorded digitally using SonarPro software and provided to WA as *.xtf* files. Osiris used a GeoAcoustics 159D dual frequency (110kHz and 410kHz) sidescan sonar towfish operated at 75m range, again with laybacks applied during processing. Data were digitally recorded using a Coda DA2000 acquisition system and provided to WA as *.cod* files.

40 For the sub-bottom profiler data, both Emu and Osiris used a surface-towed Applied Acoustics AA200 Boomer, with either a C-Products (Emu 2008) or Applied Acoustics (Osiris 2010) 8 element trailing hydrophone. The systems were operated at a power of 100J and 250ms firing rate. Data were digitally recorded using a Coda DA2000 acquisition system in both cases, with the data being provided to WA as *.cod* files.

41 The magnetic data for both surveys was acquired using a Geometrics G882 Caesium Vapour magnetometer, with the data being logged directly by the

navigational computer. The data were provided to WA as *.txt* files by Emu and as *.csv* files by Osiris.

42 To acquire the multibeam bathymetry data, Emu used a Reson Seabat 8101 240kHz swathe head and QINSy 8 acquisition software. The data were provided to WA as *.txt* files. Osiris used a GeoAcoustics GeoSwath 250kHz sytem with a Valeport Mini SVS providing real time SVP data. Data were recorded using GeoSwath Plus software, and provided to WA as *.txt* files.

43 For the 2007 survey, positioning was provided by a CS1 Minimax DGPS system, receiving corrections from the EGNOS differential network. For the 2010 survey, primary positioning was provided by C-Nav 3050M system receiving corrections from the EGNOS differential network, whilst secondary positioning was provided by a Leica GX 1230 Smartnet RTK GPS system.

Geophysical Data - Processing

44 The sidescan sonar data were processed by WA using Coda Geosurvey software. This allowed the data to be replayed with various gain settings in order to optimise the quality of the images. The data were initially scanned to give an understanding of the geological nature of the area and were then interpreted for any objects of possible anthropogenic origin. This involves creating a database of anomalies within Coda by tagging individual features of possible archaeological potential, recording their positions and dimensions, and acquiring an image of each anomaly for future reference.

45 A mosaic of the sidescan sonar data is produced during this process to assess the quality of the sonar towfish positioning. The survey lines are smoothed, and the navigation corrected either with CNV files provided by the survey company who acquired the data or individual fixed laybacks as recorded in the survey logs. This allows the position of anomalies to be checked between different survey lines and for the layback values to be further refined if necessary.

46 The form, size, and/or extent of an anomaly is a guide to its potential to be an anthropogenic feature, and therefore of its potential archaeological interest. A single, small, but prominent anomaly may be part of a much more extensive feature that is largely buried. Similarly, a scatter of minor anomalies may define the edges of a buried but intact feature, or it may be all that remains of a feature as a result of past impacts from, for example, dredging or fishing. The application of a ratings system is therefore a means of prioritising sites in order to inform further staged of the interpretation process, and on its own is not definitive.

47 The shallow seismic data were studied in order to detect any in-filled palaeochannels, ravinement surfaces and peat/fine-grained sediment horizons that may have archaeological potential.

48 The shallow seismic data were processed by WA using Coda Seismic+ software. This software allows the data to be visualised with user selected filters and gain settings in order to optimise the appearance of the data for interpretation. The software then allows an interpretation to be applied to the data by identifying and selecting a sedimentary boundary that might be of archaeological interest.

49 The shallow seismic data were interpreted with a two-way travel time (TWTT) along the z-axis. In order to convert from TWTT to depth, the velocity of the seismic waves was estimated to be 1,600ms^{-1}. This is a standard estimate for shallow, unconsolidated sediments.

50 Any small reflectors which appear to be buried material such as a wreck site covered by sediment were also recorded, the position and dimensions of any such objects noted in a gazetteer, and an image of each anomaly acquired. It should be noted that anomalies of this type are rare, as the sensors must pass directly over such an object in order to produce an anomaly.

51 The magnetometer data were processed by WA using Geometrics MagPick software in order to identify any discrete magnetic contacts which could represent buried metallic debris or structures such as wrecks.

52 The software enables both visualisation of individual lines of data and gridding of data to produce a magnetic anomaly map. Smoothed averages of the data were first calculated, and the subtracted from the raw data values in order to reduce the effect of natural variations in the magnetic field such as changes in geology or water depth.

53 The multibeam bathymetry data were used to provide a vertical reference for the sub-bottom profiler data, and were fully analysed to identify any unusual seabed structure that could be shipwrecks or other anthropogenic debris. The data were gridded and analysed using Fledermaus software, which enables 3-D visualisation of the acquired data and geo-picking of seabed anomalies

Geophysical Data – Anomaly Grouping & Discrimination

54 The previous section describes the initial interpretation of all available geophysical datasets, which were conducted independently of each other. This inevitably leads to the possibility of any one object being the cause of numerous anomalies in different datasets and apparently overstating the number of archaeological features in the study area.

55 To address this fact, the anomalies were grouped together along with the results of the desk-based study of known archaeological sites. This allows one ID number to be assigned to a single object for which there may be, for example, a UKHO record, a magnetic anomaly, and multiple sidescan sonar anomalies.

56 Once all the geophysical anomalies and desk-based information have been grouped, a discrimination flag is added to the record in order to discriminate against those which are not thought to be of an archaeological concern. These flags are ascribed as follows:

Non-Archaeological	U1	Not of anthropogenic origin
	U2	Known non-archaeological feature
	U3	Non-archaeological hazard
Archaeological	A1	Anthropogenic origin of archaeological interest
	A2	Uncertain origin of possible archaeological interest
	A3	Historic record of possible archaeological interest with no corresponding geophysical anomaly

Table 5: Criteria discriminating relevance of feature to proposed scheme.

57 All the sites that have been identified within the study areas are presented in **Appendix A.4** and discussed in this report.

58 The grouping and discrimination of information at this stage is based on all available information and is not definitive. It allows for all features of potential archaeological interest to be highlighted, while retaining all the information produced during the course of the geophysical interpretation and desk-based assessment for further evaluation should more information become available.

1.2.4 Key Guidance Documents

59 There is various archaeological guidance applicable to offshore developments, details of which may be found here (see references for full details, **section 4**):

- The Code of Practice for Seabed Developers, Joint Nautical Archaeology Policy Committee 2006 (JNAPC 2006)
- Historic Environment Guidance for the Offshore Renewable Energy Sector, COWRIE 2007 (Wessex Archaeology 2007)
- Guidance for Assessment of Cumulative Impacts on the Historic Environment; from Offshore Renewable Energy, COWRIE 2008 (Oxford Archaeology & George Lambrick Archaeology and Heritage 2008)
- Protocol for Archaeological Discoveries: Offshore Renewables Projects, The Crown Estate, 2010 (Wessex Archaeology 2010)
- Towards a Strategy for Scotland's Marine Historic Environment (Historic Scotland 2009) http://www.historic-scotland.gov.uk/marine-strategy.pdf

2 BASELINE DESCRIPTION

60 In order to assess the existing marine and maritime archaeological record within the MSA and the potential for encountering other cultural heritage assets during the course of future development activity, a baseline is discussed below.

61 The **known cultural heritage assets** are identified primarily through the archaeological assessment of geophysical survey data and integrated where possible with documentary sources.

- Palaeolandscape features visible on sub-bottom profiler (SBP) survey lines are identified and discussed within the regional geological and palaeogeographical literature
- Seabed features identified from sonar and magnetometry survey datasets are then discussed, focusing upon wrecks and obstructions that are preserved on the seabed, where possible, in conjunction with documented losses

62 The potential for encountering further cultural heritage assets within the MSA is then discussed with specific reference to regional records of prehistoric archaeology and submerged Holocene palaeolandscapes preserved at or beneath the modern seabed. This potential is directly focused on the data-led assessment of the geophysical survey reported below where possible. In some cases it is necessary to provide a broader overview in order to highlight the range of issues that may encountered by offshore developments of all kinds.

63 Later prehistory and maritime history are then discussed for the north-east region of Scotland and Aberdeen Bay within an increasing focus upon vessels as rising sea-levels reached modern levels by the Neolithic (*c.* 4000 BC).

2.1 Archaeological Assessment of Geophysical Survey Data

2.1.1 Sub-bottom Profiler (SBP) Assessment

64 Both Emu and Osiris used a surface-towed boomer and trailing hydrophone to acquire the shallow seismic data from the survey area. Of the dataset collected by EMU and Osiris, 20% was archaeologically assessed by WA for the purpose of this report, in line with current practice.

65 The broad geological sequence across the survey area can be summarised as follows (interpreted from the current geophysical data, BGS 1986, Gatliff *et al.* 1994, and Stoker *et al.* 2008):

Unit	Description
1	Recent (Holocene) seabed sediments, silty sand.
2	Late Devensian / Early Holocene fluvio-deltaic and marine sands (**Forth Formation (FH)**, **St. Andrew's Bay Member**)
3	Late Devensian Till (**Wee Bankie Formation**)
4	Devonian Bedrock (**Old Red Sandstone**)

Table 6: General geological sequence from the survey area.

66 Not all of the sequence described above is present across the entire geophysical survey area, with some of the units being absent in places. The geological units are individually described below.

67 **Unit 4** is the oldest unit and forms the basement geology across the MSA. The unit is often very shallow and outcrops at the seabed in places along the western edge of the survey area, though is seen to dip towards the east. BGS reports indicate the sequence is Old Red Sandstone of Devonian age, and is therefore considered too old to be of possible archaeological potential. It is possible that the upper surface of the unit could have once been a land surface upon which archaeological material could have been deposited, though it is expected that any land surfaces which were once present have been subsequently removed by ice erosion during the Devensian glaciation.

68 **Unit 3** directly overlies **Unit 4** across most of the survey area, although it is possibly absent in places. The upper reflector of the unit is irregular and often shows high relief creating a unit of variable thickness. As with Unit 4, it outcrops at seabed towards the west of the survey are and, in general, dips towards the east. The internal structure is generally chaotic. This unit is interpreted as being the Wee Bankie Formation, a glacial till of Late Devensian Age. Due to its glacial nature, this unit is again not considered of possible archaeological potential.

69 **Unit 2** is present across most of the survey area. In the west it fills hollows formed by the irregular relief of **Unit 3** and gradually thickens to the east where it appears as a more uniform blanket deposit. This is interpreted as being the St. Andrew's Bay Member of the Forth Formation (FH, **Figure 3**), a deposit of Late Devensian / Early Holocene fluvio-deltaic and marine sand (Gatcliff *et al.* 1994).

70 Previous work in the wider region (Stoker *et al.* 2008) has suggested that this deposit is part of a prograding shoreline created during periods of relative sea-level change (caused by glacial melting and isostatic rebound) after the last glacial maximum, and that it is divided into four distinct lithozones. A poorly defined reflector (**7505**), observed dipping gently eastwards from a line approximately shore-parallel across the centre of the survey area, could indicate a boundary between two of these lithozones (**Figure 3**).

71 Five small possible cut and fills (**7500**, **7501**, **7502**, **7503** and **7504**) have also been identified in the surface of **Unit 3**. These are shallow, relatively small features and, since it has not been possible to trace them between adjacent lines, they are expected to be isolated depressions and not part of a coherent palaeochannel system.

72 **Unit 2** is potentially of some palaeoenvironmental interest as it contains a record of sea-level change and coastal position since the last glacial maximum. However, the generally sandy nature of the sediments indicate it is unlikely that any organic matter would be preserved within the unit, and it has been previously found that even more inorganic microfossils (e.g. foraminifera) are sparse within this sequence (Stoker *et al.* 2008), reducing its significance from this point of view. Additionally, while there is the potential for some archaeological material to be present within **Unit 2**, this potential is low, and any material that does survive is likely to be re-deposited and not in a primary context.

73 **Unit 1** comprises the Holocene seabed sediment across the study area, and for the most part consists of a thin veneer of silty sand with numerous patches of finer grained sediment. **Unit 1** is not present across the entire site, and is absent in patches towards the west of the study area where **Unit 4** and **Unit 3** outcrop at the

seabed. A curvilinear, roughly shore-parallel sand bank up to approximately 5m high has been identified running along the western edge of the survey area, and represents the thickest localised accumulation of superficial seabed sediment. This is expected to be a Holocene feature, probably comprising older, re-worked sediment.

74 Holocene seabed sediments are not considered archaeologically important in themselves, though where they form large mobile sand waves and banks they can potentially cover archaeological sites including shipwrecks. However, due to the generally thin nature of **Unit 1** in the study area, the potential for this to occur is low.

2.1.2 Seabed Features Assessment

75 A total of 87 sidescan sonar anomalies plus 154 magnetometer anomalies were individually identified within the MSA using data collected by EMU Ltd and Osiris Projects Ltd. These were grouped, together with any recorded wrecks and obstructions as identified by the UKHO within the area covered by the geophysical data, to produce a list of 103 sites of potential archaeological interest. Additionally, 2 of these 103 features are recorded wrecks or obstructions provided by the UKHO and NMR searches. Being located outside of the geophysical survey area in the MSA buffer they are listed as A3 features as they have not been observed. These were all characterised as follows:

Archaeological Discrimination	Number of Anomalies	Interpretation
A1	2	Anthropogenic origin of archaeological interest
A2	97	Uncertain origin of possible archaeological interest
A3	4	Historic record of possible archaeological interest with no corresponding geophysical anomaly
Total:	**103**	

Table 7: Archaeological assessment of identified geophysical anomalies.

76 Furthermore, these anomalies can be classified by probable type, which can further aid in assigning archaeological potential and importance:

Anomaly Classification	Number of Anomalies
Recorded Wreck / Obstruction (*based solely on documentary sources*)	4
Wreck (*features identified solely by geophysical assessment*)	1
Debris	23
Seafloor Disturbance	1
Dark Reflector	13
Rope / chain	3
Magnetic	58
Total	**103**

Table 8: Classification of geophysical anomalies.

77 The individual sites identified in the geophysical survey are discussed below. Further detail can be found in **Appendix A.4** and **Figure 4**.

78 Documented wrecks with accurate positions within the MSA are presented in **Figure 4** (see **Appendix A.2**). Following geophysical assessment it was not possible to identify or confirm the presence of these features as they were either outside of the geophysical survey area (although still within the overall MSA) or their recorded positions were not accurate. See **Figure 4** for details of the dataset used to underpin the conclusions of this report.

79 Only one definite wreck site (**WA 7071**) was identified across the entire survey area, located approximately 60m north-west from the proposed location of Turbine 8 (**Figure 5**). The wreck measures (approximately 25m x 6.5m x 0.7m), and exhibits structure and height suggesting it is upright and relatively intact, though it is possibly partially buried. Multibeam bathymetry data indicate it is located in a very shallow (<0.5m deep) scour, and an associated magnetic anomaly of 58nT (magnetic amplitude (nT)) indicate the structure is at least partially ferrous in composition. The name and history of the structure is unknown, as it was not present in the provided UKHO data, suggesting it is a previously unknown structure. The wreck is illustrated in **Figure 5**.

80 Lavery (2001:78-79) describes steam trawlers of similar dimensions dating to throughout the later 19^{th} and 20^{th} centuries and Aberdeen was a centre for shipbuilding with local vessel types a distinctive aspect of the maritime history of the area as discussed in the maritime baseline (**Section 2.4**). Further information will be required to enable an assessment of the archaeological importance of this wreck.

81 Additionally, four previously documented wrecks or obstructions (**WA 7046**, **7093**, **7102** and **7103**) were not identified by the geophysical survey. **WA 7102** and **7103**, the given locations of the wrecks of the *Sheriffmuir* and the *Coastal Emperor* respectively, were located outside of the geophysical survey area and so their presence/location/current condition cannot be commented upon at this time.

82 **WA 7093** is the given location of the wreck of the SS *Archangel*, which was not identified by any of the survey equipment despite the UKHO records indicating it is a large vessel and probably contains a number of ferrous elements. The last amended survey date is given as 1977, which may indicate that this position is inaccurate and the wreck is actually located elsewhere beyond the boundaries of the survey area.

83 **WA 7046** is recorded as the location of a seabed obstruction, specifically an anchor and shackles abandoned on the seabed. This was not identified by any of the geophysical equipment, and could either be located a short distance away outside of the geophysical survey area, or be buried by seabed sediments at the time of survey.

84 Three sites (**WA 7000**, **7047** and **7051**) comprise curvilinear dark reflectors, with a small acoustic shadow and small magnetic anomaly in the case of **WA 7000**. These are interpreted as possible lengths of rope or chain. Lengths of rope or chain such as this could be pieces of modern debris abandoned on the seabed, or could be all that is visible of mostly buried structures or those that have been damaged by wave action or fishing.

85 23 sites (**WA 7001**, **7006**, **7019**, **7020**, **7023**, **7024**, **7027**, **7029**, **7038**, **7045**, **7049**, **7052**, **7069**, **7072**, **7073**, **7074**, **7076**, **7085**, **7086**, **7087**, **7090**, **7097** and **7100**)

have been classified as possible pieces of anthropogenic debris (A2 - **Table 5**). Of these, **WA 7001**, **7038**, **7045** and **7087** have been found associated with magnetic anomalies and are interpreted as being at least partially ferrous in nature. **WA 7038** in particular, a rounded dark reflector with an acoustic shadow and associated scour, is associated with a magnetic anomaly of 53nT and is possibly highly ferrous in nature.

86 The remainder of the debris sites are interpreted as being non-ferrous. **WA 7006**, **7049**, **7052**, **7074**, **7076**, **7085**, **7086** and **7100** are short, linear reflectors (or linear alignments of individual reflectors) and are possibly the visible portions of partially buried structures **WA 7069** is a longer linear reflector and possibly a length of rope or chain, but the data is unclear. **WA 7090** is a very long, straight dark reflector extending seawards from an outfall pipe observed on the magnetometer data. This is possibly a piece of debris caught on the edge of the outfall pipe, though the pipe itself is not easily visible. **WA 7029** is a curvilinear dark reflector linking a number of small point contacts, and could possibly be fishing gear.

87 **WA 7019** and **7020** are limited areas of small, irregular dark reflectors and are potential small scatters of badly degraded non-ferrous debris. The remainder (**WA 7023**, **7024**, **7027**, **7072**, **7073** and **7097**) are individual, generally isolated features, generally with acoustic shadows, and could be individual large pieces of non-ferrous debris. Site **WA 7072** is of particular note, as it is located close to wreck **WA 7071** and is possibly debris relating to the structure.

88 13 of the sites (**WA 7002**, **7013**, **7022**, **7025**, **7028**, **7030**, **7031**, **7032**, **7033**, **7034**, **7075**, **7098** and **7099**) have been interpreted as dark reflectors. These are all generally isolated, poorly defined contacts without magnetic anomalies which could either be natural features, likely in an area where the bedrock outcrops at seabed periodically, or pieces of non-ferrous anthropogenic debris.

89 One site (**WA 7021**) has been classified as an area of seafloor disturbance, and is characterised by a small area of low seabed reflectivity containing small dark reflectors. Due to the data quality on the survey line where this site was identified, the feature is poorly resolved and so its precise nature is uncertain. It could either be of anthropogenic or natural origin.

90 The remaining 58 sites (see **Appendix A.4** for full list) are magnetic anomalies without any apparent sidescan sonar or multibeam bathymetry contact. Of these, 38 are relatively small in size (<20nT) and could represent either small pieces of buried debris or natural changes in the seabed geology. A further 16 are slightly larger, and are more likely to represent small pieces of buried ferrous debris than natural features.

91 Four sites (**WA 7065**, **7081**, **7091** and **7092**) are significantly larger. **WA 7065** (68nT) is an isolated magnetic anomaly and could possibly represent the presence of a large piece of buried ferrous debris. **WA 7081** (183nT) is the largest magnetic anomaly and is situated on the western edge of the survey area, close to the shoreline. This position indicates it could be an anthropogenic coastal structure (e.g. pipe), though it could be the remains of a now buried beached shipwreck. **WA 7091** (47nT) is located close to the end of an outfall pipe (itself identified by a linear alignment of strong magnetic anomalies) and could be either ferrous debris from a marine context, or terrestrial material introduced into the area via the pipe. **WA 7092** (45nT) is located at the far northern edge of the survey area. It could represent a piece of buried ferrous debris, though its position at the end of a survey

line indicates it could also have been caused by continuing logging of data as the survey equipment was pulled in.

92 Additionally, a large area of very strong magnetic anomalies is present towards the south-west of the survey area (**Figure 4**). This is too large to have been caused by an anthropogenic feature, and is instead interpreted as representing an igneous intrusion at depth, beyond the penetration of the sub-bottom profiler equipment. Such intrusions are known to be present on land in the area (GSGB 1957), and it is conceivable that they continue offshore in the region of the survey area.

2.2 Environmental Baseline – Pertaining to Cultural Heritage Asset Potential

2.2.1 Introduction

93 The potential for the presence of submerged prehistoric archaeology within the region is dependent upon the age and nature of the sedimentary units present at and offshore of the coast, and is closely related to relative sea-level change through time (**Figure 2**). Therefore an outline of the relevant known shallow geological, sea-level, topographical and climate change data relating to the region and the impact that they are likely to have on archaeological potential is given below.

94 An assessment of sea-level is important because at various times during prehistory the sea-level will have been low enough for the offshore areas of eastern Scotland in the North Sea Basin to have been dry land, and therefore available for exploitation by humans. This occurred when water that would otherwise be held in oceans and seas was locked into ice sheets during periods of glaciation.

2.2.1.1 Site formation - Taphonomy

95 The taphonomy (contributory formation processes) of archaeological deposits is of central importance to assessing the nature, development and significance of the archaeological record. Archaeological material can be preserved in primary contexts, where the spatial relationship between finds has not substantially altered since deposition, and in secondary contexts, where artefacts have been 'derived' or moved from their original positions. Secondary context sites can be associated with fluvial re-deposition, glacial processes, marine transgression and other processes of disturbance.

96 The formation, preservation, survival and discovery of submerged prehistoric sites and deposits (in primary and secondary contexts) are dependent on a number of factors. With respect to environmental conditions, they are likely to have been affected by:

- Beach and offshore gradient
- Speed of transgression
- Fetch magnitude, influencing wave amplitude and wavelength
- The degree of cohesiveness of the deposit being submerged
- Local topography, in terms of coastal forms, presence/absence of estuaries, sediment bars and islands
- The presence of frozen ground or permafrost at inundation

2.2.1.2 Geomorphology and Hydrology

97 Dune-backed sandy beaches characterise much of the coast of eastern Scotland at river mouths and sheltered embayments (e.g. Aberdeen Bay), interspersed with rocky coastline. Estuaries and tidal reaches of major rivers are also areas of archaeological interest such as at Montrose, the Tay and Forth. Broadly speaking, nearshore areas off the east Scottish coast slope gently from Mean Low Water (MLW) to an extensive and generally flat offshore platform at a depth of 50-70m.

98 Wave direction along the eastern coast is predominantly from the east or south-east. Significant wave heights of 2m can be expected for 10% of the year (Flemming 2004). Along the Scottish east coast there is a general southern flood and northern ebb tidal flow.

2.2.1.3 Climate

99 The climate during the last 780,000 years (Cromerian Complex stages OIS 13 to 17) alternated between cold and warm phases. At least six distinct temperate phases have been identified, between approximately 450,000 and 780,000 BP (Preece 1995). Since then there has been a similar sequence of alternating cold and relatively warm periods. The cold periods correspond with the glacial advances noted below.

2.2.1.4 Sea-level Change and Glaciation

100 There were at least two glacial phases (MIS 14 and 16) during the Cromerian (**Figure 2**). Since then the Northern European landscape was shaped by a further three major glaciations which are known as the Anglian (480,000-425,000 BP), Wolstonian (380,000-130,000 BP) and Devensian (70,000-12,000 BP). During these glaciations north-eastern Scotland would probably have been covered by ice sheets, though the exact extents of ice sheets during different glaciations and the time of maximum extents at different points on the margins of the ice sheets is still the subject of considerable debate (Merritt *et al.* 1995; Shennan and Horton 2002; Ballantyne 2004).

101 Most of the Scottish continental shelf was covered by these successive ice sheets, although at least six phases of growth and retreat have been identified (Ballantyne 2004). The ice sheets were centred upon the Scottish Highlands and extended as far as the continental shelf to the north and north-west.

102 In northern Scotland the Devensian glacial maximum occurred some time after 26,000 BP, with deglaciation well advanced by 15,000 BP (Ballantyne 2004). By 13,000 BP the ice sheets had completely melted in lowland areas, although there was a brief period of renewed ice cover during the Loch Lomond stadial at about 11-10,000 BP (Ballantyne 2004). Allowing for the uncertainties of isobase mapping, north-east Scotland (Aberdeenshire) probably ceased to be covered by the ice sheet at some point between 18,000 and 14,000 BP (Lambeck 1995) with more southerly areas becoming ice free by the Holocene (10,000 BP) (**Figure 6**).

2.2.1.5 Suitability for Human Occupation

103 Ethnographic evidence shows that human hunting cultures can operate successfully along the margins of ice and sea (Blankholm 2004). That this was the

same in the past is demonstrated by the discovery of a number of sites in the Russian high Arctic (Pitulko *et al.* 2004, Pavlov *et al.* 2001) and observations made of native Inuit populations in the Canadian Arctic by early European explorers strongly suggests that cold was not the principal limiting factor for the spread of early human populations.

104 Suitability for human occupation instead depended upon the availability of food. The nature of available food sources would have varied with climate. There is no evidence for agriculture in Britain prior to the Neolithic and earlier human populations would have been dependent upon a hunter-gatherer mode of subsistence.

105 The region is likely to have been suitable for early human populations whenever it was not covered by ice or submerged (**Figure 6**). During the cooler periods plant resources would have been relatively sparse, and populations would have been largely reliant on animal resources, either marine or terrestrial. Such animals are likely to have been present within the region, during cooler periods perhaps on a migratory basis and during warmer periods on a permanent basis.

2.3 Cultural Heritage Baseline - NE Scotland & Blackdog, Aberdeen Bay

2.3.1 Lower, Middle and Early Upper Palaeolithic (>780,000 – 12,000 BP)

2.3.1.1 Introduction

106 During the Lower and Middle Palaeolithic Britain would have been occupied by a range of hominins, including *Homo heidelbergensis* and *Homo neanderthalensis*. During the Upper Palaeolithic, these populations would have been replaced by modern humans - *Homo sapiens* (**Figure 2**).

107 The dominant palaeogeographic setting of Britain for the majority of the late Pleistocene is that of a peninsula connected directly to mainland Europe across a broad front; from southern Scandinavia to north-west France. The flux of eustatic sea-level during inter-glacial periods has periodically flooded the English Channel and areas of the North Sea to create an island Britain. For the majority of the last 1 million years, especially during glacial periods, lower sea-level meant that Britain and Scotland were, to a greater or lesser extent directly connected to continental Europe (**Figure 2**, **Figure 6**).

2.3.1.2 Evidence of Human Occupation in Scotland

108 No well-provenanced and reliable archaeological evidence of human occupation during the Lower, Middle and Early Upper Palaeolithic is known from Scotland. (Wickham-Jones 1994). The cave site excavated in 1926 at Creag nan Uamh in Sutherland contained an accumulation of reindeer bones dating from between 44,000 and 22,000 BP. It has been interpreted as evidence of early hunting by humans but plausible alternative interpretations are possible (Lawson 1981). Nevertheless, whilst it may not prove the presence of humans, it does prove the presence of suitable prey species (Fleming 2004: 8).

2.3.1.3 *Potential for Submerged Palaeolithic Prehistory at Blackdog*

109 Any assessment of the archaeological potential of the east Scotland coast must take into account the more general records of Lower, Middle and Early Upper Palaeolithic human occupation of Britain, as well as local climatic and geological conditions.

110 Recent work at the terrestrial site of Happisburgh 3, Suffolk, (Parfitt *et al.* 2010) has produced lithic evidence of human activity in an interglacial environment that dates to between 780,000 to 1,000,000 BP (OIS 17 or earlier) (**Figure 2**). It is therefore theoretically possible for a human presence in eastern Scotland from at least this time onwards when climate conditions were cold but potentially favourable and the area was not submerged or covered by ice.

111 As noted above, the region has been subject to considerable glacial action, culminating in the Late Devensian glacial maximum. Although the survival of archaeological material in primary contexts under ice is possible (Cook and Ashton 1991), it is unusual. Therefore any earlier archaeological deposits are likely to have been destroyed or buried under glacial deposits and any surviving artefacts may be some distance from their original site of deposition. The potential for the presence of Palaeolithic material within the region pre-dating the Devensian glaciation is therefore probably extremely low.

112 The principal Quaternary and Holocene geology is defined by the Wee Bankie Formation which is overlain by the Forth Formation. The latter formations are contemporaneous during their early deposition. The modern seabed is generally of sand-sized sediments (**Table 6**) (Gatcliff *et al.* 1994).

113 The Wee Bankie Formation is a diamicton (glacial deposit of poorly sorted sediments i.e. complex mixture ranging from boulders to clay-sized particles) of up to 40m thick probably of basal till from glacial down-wasting during the end of the last glacial period (i.e. Devensian). Diagnostic faunal and floral material is present but reworked (and therefore out of context).

114 The archaeological potential for encountering *in situ* Palaeolithic material from the Wee Bankie Formation (i.e. from offshore of the entire east coast of Scotland) is likely to be reduced as a result of the turbated nature of the formation however it may be possible to encounter artefacts in secondary contexts, although the chances are likely to be low.

115 The Late Glacial age of the deposits suggests there is potential for archaeological sites and material to have been located on the “uneven, ridged upper surface” lying conformably below the Forth Formation; and also within the Forth Formation sediments that subsequently accumulated during the late Glacial and Holocene.

2.3.2 Late Upper Palaeolithic and Mesolithic (12,000 BP – 4,000 BC)

2.3.2.1 *Climate*

116 The Late Devensian ice sheet had completely melted by *c.* 13,000-12,000 BP (Ballantyne 2004). Although there was a temporary return to cooler conditions during the Loch Lomond Stadial between 10,800 and 10,000 BP, the climate would not have precluded human occupation outwith the core glacial and periglacial area. Coasts may have been principal areas of activity as maritime climates are less

extreme. After 10,000 BP temperatures rose quickly and by 8,500 BP appear to have been slightly higher than today (Ballantyne 2004). A general scheme for Holocene climate based on the Blytt and Sernander peat scheme is presented below (**Table 9**). It must be remembered that short-term, high-magnitude events during the early Holocene made the environment, climate and sea-level change very dynamic (e.g. meltwater pulses, the 8200 BP event, **section 124**). The influence upon Mesolithic people's behaviour and subsistence strategies for example is likely to be complex and highly variable between groups and over space and time (Warren 2005, Bailey and Spikins 2008).

Period	Inferred Climate	Evidence	Approximate Age (BP)
Pre-Boreal	Subarctic (cool-dry)	Macrofossils of subarctic plants in peat	10,000 – 9500
Boreal	Warm-dry	Pine stumps in humified peat	9500 – 7000
Atlantic	Warm-wet	Poorly humified Sphagnum peat	7000 – 5000
Sub-Boreal	Warm-dry	Pine stumps in humified peat	5000 – 2500
Sub-Atlantic	Cool-wet	Poorly humified Sphagnum peat	2500 – present

Table 9: General scheme of Holocene climate (Blytt-Sernander) adapted from Lowe & Walker, 1997; Warren 2005).

2.3.2.2 Suitability for Human Occupation

117 Following deglaciation (*c.*18,000-14,000 BP) the climate became increasingly suitable for human occupation (Ballantyne 2004). As conditions became warmer, tundra would have given way to open grassland and then woodland. Ultimately open woodland predominated with birch, hazel, oak and pine (Wickham-Jones 2004). Even at the start of this period, suitable food resources are likely to have been available for hunter-gatherer populations. The recently discovered site at Howburn Farm, South Lanarkshire, is dated on typological grounds to *c*. 12,000 BP and demonstrates the potential for later Upper Palaeolithic sites in Scotland (Ballin *et al.* 2010). Given the probable rate of decay of the Scottish ice sheet it may be speculated that occupation evidence might survive in the north-east from this period, or perhaps even as early as 13,000 BP.

118 The only marine find from the Late Upper Palaeolithic occupation is a single worked flint obtained during vibrocoring close to Viking Bank, 150km north-east of Shetland. Sedimentary deposits below the tool date it to post-11,000 BP (Wickham-Jones and Dawson 2006).

119 The climatic amelioration from 13,000 BP, even allowing for the slight hiatus in the form of the Loch Lomond Stadial (*c.*11,000-10,000 BP), would have driven environmental change, so that while the broad suitability of the region for human occupation would have probably improved over the course of the early to mid Holocene, the nature of the environment that humans would have had to deal with would have changed significantly over this period.

120 Another key form of environmental change would have been changes in hydrological regime associated with marine transgression (rising sea-level

inundating the land). As sea-level rose the effective gradient of local river systems would have lessened, causing channel aggradation and flood plain formation, potentially leading to the formation of wetlands. It has been proposed, for example, that the area where Aberdeen stands would have been an area of wetland during the early Holocene (Warren 2005). Such environments are known to be ecologically diverse and to offer a wide range of resources for human exploitation.

2.3.2.3 Sea-level & Rapid Coastal Change in the early Holocene

121 Modelling of the sea-level history of Scotland during the Holocene (the last 10,000 years) is greatly complicated by the presence and varying thickness of the ice sheet that covered the land during the Late Devensian glaciation and variable rates of glacio-isostatic rebound as a result (**Figure 7**).

122 Glacio-isostatic uplift following deglaciation was greater and more rapid in areas that lay close to the centre of the last ice sheet. This centre was in the area of Rannoch Moor in the Western Grampian Highlands. In areas farther from the centre, such as the east of Scotland, uplift was slower and less pronounced. The figures for relative sea-level change from reconstruction models should therefore be applied with caution – e.g. Funnel (1995:4), Westley, Dix and Quinn (2004:67-80), Holocene sea-levels from Lambeck (1995), Shennan & Horton (2002) and Smith *et al.* (2007).

123 The principal work on late Devensian and Holocene relative sea-level change in the region is based on work on the river valleys of the Ythan and the Philorth (Smith *et al.* 2004), and the Montrose Basin (e.g. Smith, Cullingford & Seymour 1982; Smith, Cullingford & Brooks 2006; Smith and Cullingford 1985). This work suggests that between 18,000 and about 14,000 BP relative sea-level could have been approximately -5m, falling to about -10m by 10,000 BP. From 9,000-8,000 BP relative sea-level rose 8 m and then continued to rise until it was approximately 4 m above present sea-level by c. 5,000 BP, before dropping gradually to current levels (Shennan and Horton 2002). This pattern of relative sea-level rise and then fall reflects the interplay of varying rates eustatic sea-level rise and glacio-isostatic recovery, with eustatic rise initially outpacing but then being overtaken by glacio-isostatic recovery (Ballantyne 2004).

The Storegga Landslide and Tsunami – c. 8100 BP

124 Around 8100 BP, a massive undersea landslide off the coast of north-west Norway caused a tsunami wave. Evidence for the Storegga tsunami has been found along palaeo-shorelines in Scandinavia, north-west Europe and northern and eastern Scotland as a clear sandy horizon. Mesolithic sites at Inverness and Morton, Fife are preserved beneath the Storegga tsunami deposit suggesting human groups on the coast were directly affected (Dawson *et al.* 1990; Weninger *et al.* 2008). The tsunami also had a widespread effect inland, penetrating along major rivers like the Forth (Smith *et al.* 2010). The destruction of camp sites, and disruption to coastal food resources, in addition to a loss of life, would have had a significant effect upon Mesolithic groups' ability to successfully exploit affected coastal, estuarine and riverine environments across eastern and northern Scotland. The tsunami may also have contributed to the final flooding of 'Doggerland' in the southern North Sea (Weninger *et al.* 2008; Gehrels 2010). In conjunction with (and not to be confused with) the so-called 8200 BP event (a rapid and large-magnitude oscillation to cold, regionally arid conditions) (Alley *et al.* 1997; Barber *et al.* 1999), and rapid sea-level rise after *c.*8000 BP, the regional climate was dynamic in the

early Holocene. This may have had significant effects upon human groups in Scotland during this time.

2.3.2.4 Distribution of Evidence

125 There is a degree of geographical bias in the distribution of known, and in particular intensively investigated, sites within Scotland, with much effort expended on the west coast, Inner Hebrides and recently the south-west (Warren 2005). This, unusually in modern British archaeology, probably tends to reflect research effort rather than development impacts: by contrast a number of the Mesolithic sites in the north-east of Scotland have been excavated as a result of development mitigation (e.g. Murray 1982, Suddaby 2007, Murray *et al.* 2009).

126 Findspots and recorded sites along the east coast compiled in the Aberdeenshire SMR suggest that along the modern coast directly adjacent to the proposed EOWDC there are several flint working and lithic scatter sites of prehistoric age, several are Mesolithic age within coastal dune complexes (**Table 10**). Sub-bottom profiling assessed as part of this project has identified geomorphological deposits indicative of a prograding coastline preserved offshore suggesting there is potential for similar Mesolithic sites to be present in submerged contexts.

Name	Aberdeenshire SMR ID	CANMORE ID	Site type	Description	Source
Easter Hatton	NJ91NE0071	NJ91NE58	Findspot	Flint scatter – prehistoric.	http://www.aberdeenshire.gov.uk/smrpub/shire/detail.aspx?refno=NJ91NE0071
Menie	NJ92SE0028	NJ92SE6	Findspot	Site of findspot of microliths and flints; shows evidence of Mesolithic occupation.	http://www.aberdeenshire.gov.uk/smrpub/shire/detail.aspx?refno=NJ92SE0028

Leyton Farm	NJ92SE0004	NJ92SE7	Findspot	Site of findspot of flint artifacts & a stone bead with hour-glass perforation – poss. Neolithic	http://www.aberdeenshire.gov.uk/smrpub/shire/detail.aspx?tab=main&refno=NJ92SE0004

Table 10: Selected sites indicative of Mesolithic & prehistoric findspots contextualising early Holocene coastal palaeogeography in the vicinity of the MSA.

127 Flint scatters, as a class, is very wide ranging from a few lithics to large sites incorporating a variety of lithic materials and forms (Warren 2007). As a class it reflects the durability of stone tools, and any associated working debris, rather than a functional distinction in terms of site use. Lithic material may be associated with any other type of site, such as shelter structures, middens and caves. The ephemeral nature of stone tools scatters will make identification in intertidal and offshore contexts difficult.

2.3.3 Potential for Holocene Submerged Palaeolandscapes

128 At the coast, the Forth Formation outcrops (Gatcliff, *et al.* 1994) (**Figure 3**). The St Andrews Bay member presents a significant target for investigating the perceived potential for encountering submerged Upper Palaeolithic and Mesolithic archaeological and palaeoenvironmental material in primary contexts along much of the east coast of Scotland. The geological sequence, associated with the Forth Formation, is very extensive, extending as far south as St. Andrew's and possibly as far north as Peterhead (Gatcliff, *et al.* 1994).

129 The sandy nature of the Holocene sediments suggests that in conjunction with lower sea-levels, human occupation could have occurred throughout the early Holocene and very late Pleistocene in a transgressive coastal environment (i.e. the shoreline at a given period progressively moves inland as sea-level rises relative to earlier incarnations). Indeed the forms of the deposits have been described as "coastal sand bars created from sediment delivered by rivers flowing from Scotland" (Gatcliff *et al.* 1994: 93). Where encountered, the **St Andrews Bay member** of the **Forth Formation** would be of primary archaeological interest for assessing Upper Palaeolithic and latterly Mesolithic offshore archaeological potential in the east coast of Scotland (**Figure 8**, **Table** 6).

130 Sea-level models suggest that the rate of land uplift and sea – level rise on the east Aberdeenshire coast are generally emerging at a rate of around 0.5 mm/yr relative to Eustatic sea- level rise (Gehrels 2010). This would suggest that nearshore sediments containing submerged prehistoric material could have been uplifted around 2.5m in the last 5000 years; for example, Mesolithic remains may then exist at a shallower depth than could be assumed from general estimates of Holocene sea-level rise alone.

131 Archaeological deposits in the region post-dating 13,000 BP will not have been affected directly by glaciation, although periglacial effects may have occurred. The available archaeological and sea-level data suggests that the potential for the presence of archaeological sites and materials in terrestrial settings in the region exists from about 13-12,000 BP. In lower lying coastal and estuarine settings there may be a hiatus after 7000 to 6500 BP until 5000-3500 BP due to the Main Holocene Transgression (**Figures 6** & **7**).

132 The **St Andrews Bay Member** of the **Forth Formation** which may frequently outcrop at the coast is of primary archaeological interest for late Pleistocene and early Holocene archaeological and palaeoenvironmental investigation. The sands (and clays) in the form of coastal geomorphic structures such as sand bars indicate that coastal bedforms are preserved; and by inference potentially archaeological remains (if any) where local conditions permit.

2.3.4 Regional Archaeological Potential and Wider Relationships

133 The presence of relatively large areas of (now submerged) land to the south should be noted: 'Doggerland' (Coles 1998) would have formed both a relatively near route to Scotland from other regions of Europe, and a population reservoir for colonists moving northwards as climatic conditions ameliorated.

134 There is potential for the presence of submerged late Upper Palaeolithic and Mesolithic archaeology along the coast of the north-east of Scotland. The various reconstructions of landscape around the late Devensian and early Holocene (from 13,000 to 8000 BP) suggest a relatively narrow strip, perhaps in the order of several kilometres of submerged landscape along the coast from eastern Yorkshire to the north-eastern tip of Aberdeenshire, in contrast with the very extensive areas of now-submerged landscape in the southern North Sea and the Moray Firth.

135 The relatively narrow dimensions of the modern offshore area that has the potential for the presence of submerged Late Upper Palaeolithic and Mesolithic remains, together with a presumed preference by early populations for coastal settings for settlement and exploitation, implies that the density of remains may be relatively high if present and preserved but the spatial extent of development activity will be a primary factor in the potential for encountering such remains.

136 The cultural remains of the Later Upper Palaeolithic and Mesolithic tend to be relatively small-scale, ephemeral, and largely lithic in nature. This renders these remains particularly vulnerable to disturbance processes, both cultural and natural. In an offshore environment the factors listed above will largely determine the degree of disturbance such remains undergo. When these factors work against preservation, the effects on primary contexts can be severe. Where these factors favour preservation, primary contexts may be much better preserved than the majority of onshore sites. In particular, long term cultural disturbance will generally have been excluded.

137 The sandy nature of the offshore sediments is similar to the coastal dunes known to contain early prehistoric lithic remains not necessarily in the presence of palaeoenvironmental material. It is currently not possible to assess potential of likely impacts upon these types of cultural heritage assets.

2.4 Potential for Maritime Archaeology

138 The potential exists for archaeological evidence of maritime sites of all periods from the Mesolithic to the present day to be recoverable from within the MSA. Given the offshore location of the MSA, Maritime sites considered shall consist of either vessels (wrecks) or debris accidentally or deliberately lost overboard from a vessel.

139 The potential for evidence of maritime activity within the MSA from the Post–medieval and Modern periods can be expected to be greatest because of the

increasing volume of trade and other marine activities in the area during these periods, and because of the relatively short period of time since its deposition on the seabed. Potential for the survival of evidence of medieval or earlier date is likely to be low, although certain classes of material, such as stone ballast, can be expected to survive for very long periods and the survival of more vulnerable organic material can occur in the right circumstances.

140 Estimates for the density of shipping losses around the coast of the UK estimate eight to 40 wrecks for every mile of coastline. This does not include losses in open water, which are particularly difficult to quantify. Records such as Lloyd's Lists contain many references to ships that are 'overdue' and for which no knowledge of their fate has ever been recovered.

141 As a result, the currently known maritime casualties in UK waters probably only represent a small percentage of actual losses. The positions of losses are often vague or inaccurate, and hence require interpretation. It is perhaps reasonable to assume that post–medieval wreck recording close to important ports such as Aberdeen will be more reliable, but nevertheless it is likely to be incomplete.

142 The nature of the loss record also means that it is heavily weighted towards Industrial and 20^{th} century period wrecks (**Appendix A.5**). Whilst it is undoubtedly the case that there was an increase in vessel numbers traversing the MSA during this period, the record is almost certainly misleading in this respect. The record is also likely to be weighted towards larger vessels, with this bias continuing into the 20th century.

143 There are no protected places or controlled sites, as recorded by the Ministry of Defence that would be subject to statutory protection, within or in the vicinity of the MSA.

2.4.1 Shipping Losses – Causal Factors

144 The North East Scottish coast focused upon Aberdeenshire is characterized by a combination of rugged cliffs interspersed by long sandy shores. Shipping losses along this coast have been caused by a wide range of factors. However the principal causes can be summarised as follows:

- South easterly gales. The shape of the coastline makes shipping that is reliant upon sail power particularly vulnerable and severe storms have historically caused catastrophic losses, such as in 1800 and 1876
- Haar or coastal fog, particularly during the summer months when dense fog could last for days. Prior to the widespread introduction of radar, fog was a significant factor in many shipping losses
- Lack of reliable navigational tools. Although Lindsay's A Rutter of the Scottish Seas was published in 1540 it was not until Grenville Collins' work in the early 17th century that more reliable charting became available
- Enemy action, principally during the two World Wars of the 20th century

145 There are three major concentrations of shipping losses in Scotland: around the major ports of Aberdeen and Wick; and at the extreme north–east coast of Aberdeenshire (Ferguson 1991: 4). Historically shipping losses in the vicinity of the ports of Aberdeen and Wick have mainly been caused by ships being driven ashore whilst trying to lie off or enter the ports in heavy weather (Ferguson 1991:

4). It therefore follows that sailing vessels should have been the principal victims and that the greatest risk was from east and south–easterly gales.

146 Aberdeen harbour entrance, with its long piers has proved to be a hazard in itself. Construction of these piers in the 18th century greatly improved access to the harbour by reducing the impact of the bar at the mouth of the Dee. However, it is clear from the available loss records (**Appendix A.5**) that numerous casualties resulted from vessels either colliding with the piers or missing them altogether.

147 The approach to the harbour is quite confined and difficulties could be experienced in wind against tide conditions, particularly if the wind was blowing strongly from the south–east. Once a vessel missed the harbour entrance it was likely to go aground near the piers or be driven ashore on the beach, unless it was able to escape the threat by bearing away to the north. Several recorded losses and recorded wrecks in the MSA are reported run aground on the beach at Blackdog following difficulties in bad weather trying to navigate the approaches to Aberdeen harbour.

2.4.2 Prehistoric Seafaring (before AD 79)

148 Human settlement patterns in north-west Europe suggest that sea voyages were conducted as early as 7,000 BC, during the Mesolithic. No archaeological remains of vessels that pre – date the Mesolithic have been found in Western Europe. This may reflect the very low probability of organic remains of this type surviving. However, the simple technology required to construct a small boat will almost certainly have existed. The Mesolithic record currently consists exclusively of log boats.

149 Extensive coastal and continental trade and sea fishing increased during the Neolithic, Bronze Age and Iron Age. Small ports or anchorages developed in Britain as the scale of this activity grew. Log boats, hide boats and plank boats were all used and there is evidence of significant advances in technology and vessel size from the Bronze Age onwards.

150 The earliest boat found in Scotland is the log boat found at Catherine Field in Dumfriesshire which dates to the early Bronze Age. A log boat with a separate transom and dating to about 1,500 BC has also been found in Loch Tay. A further late Bronze Age log boat has been found in the Tay Estuary, dating between about 1130 – 970 BC. Other boat finds from Scotland are Iron Age or later. Of the approximately 150 log boats found in Scotland, most are medieval. No Prehistoric boat finds of more complex construction or demonstrably capable of being used in open, maritime water have been found in Scotland.

151 Mesolithic artefacts have been recovered from terrestrial contexts in the Aberdeen area. Although the extent of Mesolithic occupation is not known, this does suggest that there is potential for archaeological evidence of prehistoric seafaring within the MSA from the Mesolithic onwards.

2.4.3 Roman Seafaring (AD 79 – 410)

152 For most of this period, Aberdeen and the surrounding area lay outside the Roman Empire, although not necessarily beyond Roman influence. A Roman military camp has been found at Normandykes on the outskirts of modern Aberdeen and finds of Roman coins and other artefacts have been made in the area. Additionally, the

Alexandrian geographer Ptolemy's map of Scotland of AD 145 shows Devana, 'the town of the two waters' (the Rivers Dee and Don), a town or settlement on the Deva Fluvius. Devana appears to have been within the greater Aberdeen area. Its appearance on Ptolemy's map indicates that it must have been a settlement of some size or importance.

153 Although it is not a safe anchorage, Aberdeen Bay is likely to have been traversed by coastal trading vessels and fishing boats throughout this period. The existence of the riverside Devana settlement somewhere in the area may mean that this activity was at a relatively high level for the north–east coast of Scotland. In addition, the camp at Normandykes may have been supplied by sea, with ships approaching through the Dee Estuary. There is therefore potential for the presence of archaeological evidence of Roman period seafaring within the MSA.

2.4.4 Early Historic (AD 411 – 700) & Early Medieval (AD 700 – 1100) Seafaring

154 The region around modern Aberdeen appears to have been dominated by Pictish tribes during the Early Historic period, a group of indigenous people first referred to in the 3rd century by Roman writers as Picti meaning either 'painted ones' or 'people of the designs' (Foster 2004: 1). The Picts are known to have been seafarers and depictions of their vessels are known, such as from St Orland's Stone from Cossans in Angus (Graham-Campbell and Batey 1998: 8).

155 The estuary of the Dee provides a sheltered anchorage and it is likely that some use was made of it. Vessels, in the form of fishing boats and coastal trading vessels (perhaps capable of long distance voyages) will have traversed the MSA. It is also possible that some use was made of the River Don and the River Ythan to the north.

156 Terrestrial archaeological evidence from the Early Medieval period has been recovered from the Aberdeen area. Given that there is historical evidence that Aberdeen had a significant harbour by 1136, the probability of there being a harbour and therefore maritime activity in the vicinity of the MSA during this period is high. In addition to coastal trade and fishing, trade and other maritime interaction with Scandinavia is also probable.

2.4.5 Medieval Seafaring (AD 1100 – 1540)

157 There is no direct archaeological evidence for medieval maritime activity in the MSA in the form of shipwrecks or seabed debris. However, the historical and terrestrial archaeological evidence is relatively plentiful and documentary evidence becomes available for the first time. The first reference to a shipwreck in the vicinity of the MSA occurs during this period, in 1444.

158 Aberdeen was a significant port during this period and is clearly crucial to the maritime significance of the MSA. By 1136 it was busy enough for David I to grant Bishop Nectan the right to levy a charge on shipping using the harbour (Turner 1986: 3). It was also significant enough to attract hostile attention and in the late 12th century the Norse King Eystein raided 'Apardion'.

159 Aberdeen was also important enough to attract traders from the Continent. King David I is known to have encouraged Scottish merchants to engage in foreign trade in the 12th century. Aberdeen's earliest recorded trade with mainland Europe was with Flanders. This trade, based upon the export of wool, appears to have

been well established by the late 13th century when Philip IV of France ordered Count Guy de Dampierre to allow Scottish merchants freedom to trade in Flanders (Turner 1986: 4). Merchants trading through Aberdeen subsequently appear to have established trading posts on the Continent.

160 Piracy was a problem off the Scottish east coast in the 14th century. This appears to have impacted on the number of vessels trading with Aberdeen. By 1368 the number of vessels entering the port was reduced to ten and by 1398 just six (Turner 1986: 4). Trade recovered in the 15th century, despite disputes with the Hanseatic League and with Flanders in the first half of the century. By the mid – 15th century Aberdeen and Leith held a joint monopoly on the Scottish wool trade with Flanders. Wool, cloth, hides, fur, wood and salmon were exported and wheat, provisions, wine and luxury goods were imported. Mention of other ports is made at this time, including some in Scandinavia, although goods exported from Aberdeen seem to have been largely transhipped from Flanders.

161 There is documentary evidence of a quay on the north side of the Dee by 1453, when the quay is recorded as having been enlarged. Navigation beacons were also established at the mouth of the estuary in 1484. Furthermore in the early 16th century the Town Council commissioned a local pilot to produce a sea chart for the use of Aberdeen ships. Nevertheless Aberdeen does not appear to have been regarded as having good harbour facilities (Turner 1986: 6).

162 During the reign of Alexander II (1241 – 1286), Aberdeen gained a reputation as a fish exporter. Fish curing was a specialism of the town and in 1281 Edward I of England apparently sent agents to obtain salt fish provisions for his campaign in Wales (Turner 1986: 133). In 1290 Aberdeen fish were shipped to Yarmouth, the premier fishing port of England and thence to Norway. However, it seems that during this period fishing was confined to the River Dee and in the immediate environs of the estuary. Salmon would have been the main catch and Robert I (the Bruce) granted rights in this respect to the town in 1319. As a result of the probable increase in maritime activity in the vicinity of the MSA, the probability of wreck – related evidence of maritime activity surviving is greater than for earlier periods.

2.4.6 Post – medieval Seafaring (AD 1540 – 1700)

163 Trade between Aberdeen and the Baltic expanded greatly during the 16th century. Ports to which reference is made at this time include Dantzig, Campveere, Bruges, Middleburg, Antwerp and Stralsund. Substantial numbers of the poor, and refugees from both political and religious strife emigrated through Aberdeen to both the Netherlands and Poland.

164 Competition arose during the 16th century as Peterhead, Newburgh (14 miles north of Aberdeen) and smaller harbours in the area all sought to compete for business. Aberdeen responding with an aggressive enforcement of its rights and by undertaking works to improve the harbour.

165 Navigating the entrance to the harbour had become a serious problem by the mid – 17th century, despite efforts to improve matters, including the building of a bulwark in a failed attempt to defeat the threat of the bar in 1607. In 1656 it was reported that the harbour was “less useful of late than formerly” and it appears that at low tide there was only about two feet (0.61m) of water at the bar (Turner 1986).

2.4.7 *Industrial Seafaring (1700 – 1900)*

166 The Act of Union in 1707 opened up the English market, particularly London and the English colonies to Aberdeen merchants. Trade with the American colonies became particularly important, with woollen and linen goods, salmon, salted herrings and French wine being exported, together with emigrants. A wide variety of raw materials were imported from the Americas, but principally sugar and tobacco. Goods were also exported to Norway, Holland, Portugal, Sweden, Spain, Germany and Italy.

167 By the end of the 18th century Aberdeen was handling 73 inward and 248 outward cargoes annually. Most of the trade was coastwise around the UK, although cargo was exported to 14 different overseas countries and part of the coastwise trade appears to have been of goods destined for export through other ports. Trade with the Low Countries declined as Aberdeen merchants exploited new markets.

168 In 1769 one of the most significant events in the maritime history of the Aberdeen area occurred. The great 18th century engineer John Smeaton was invited to investigate the harbour entrance and suggest remedial measures to deal with the problem of the bar. Smeaton was one of a number of great engineers, including Telford and Rennie, to be involved in the development of the port of Aberdeen. He reported in 1770 and recommended the construction of a pier on the north side of the entrance. The pier was duly built and was successful because it had the effect of enhancing the natural scour of the river. As a result, the number of vessels using the port rose quickly.

169 Smeaton's scheme was subsequently improved, with the north pier being lengthened. A south pier was constructed to prevent swell entering the harbour from the east. In addition, the course of the Dee was altered, allowing for an extensive complex of docks to be built in the 19th century.

170 In the late 18th century the number of ships engaged in foreign trade using the port declined, probably as a result of the wars in Europe, although coastal trade increased. However, during the 19th century Aberdeen's trade increased beyond recognition. Numbers of commercial vessels and total tonnage using the port had increased to 3368 vessels totalling 956,496 tons by 1899, with almost 1.25 million tons of cargo being handled annually (Turner 1986: 43).

171 The first steamship service to Aberdeen commenced in 1821 and by 1855, 16 steamers were operating from the port. By the turn of the century this number had grown to 83 (Turner 1986: 118). The rise of steam reduced the dangers of entry into the harbour and gave vessels which missed the entrance in poor weather a greater chance of avoiding going ashore.

172 This period also saw a dramatic rise in the importance and scale of the fishing and whaling businesses off Aberdeen. The first reference to whaling activity was in 1752 and by 1817 there were 14 Aberdeen whaling vessels (Turner 1986: 136).

2.4.8 *20th Century Maritime Activity*

173 With regard to the fishing industry, whereas it had previously been largely salmon-based and inshore in character, the Aberdeen fleet gradually moved offshore and into trawling. Chief amongst the offshore catch was the herring, and the herring boom from the 1870s and the First World War brought seasonally hectic activity to the port. A large fleet of Aberdeen vessels, mainly small sailing boats or yawls

called ‘Zulus’ and ‘Fifties’, followed the annual migration of these fish south (Edwards 2004: 107).

174 In addition, other fish were pursued in great quantities, with numerous line fishing boats plying the inshore waters of the MSA. Smaller harbours and beaches around Aberdeen were also used by fishing vessels of all types.

175 The first half of the 20th century was the great era of the steam trawlers, which had been gradually introduced in the 19th century. By 1910, 217 of the Scottish fleet of 320 steam trawlers operated out of Aberdeen. In 1888 there were 10,810 arrivals of fishing craft, largely small sailing craft.

176 By the outbreak of the First World War in 1914, Aberdeen was the most important fishing port in the British Isles. 1925 marked the peak of the trade in terms of catch landed. By then 83% of arrivals were steam trawlers and only a small proportion were sailing vessels. Thereafter the fishing fleet declined and by the end of the 20th century the number of fishing vessel arrivals at Aberdeen represented only a very small proportion of that at the turn of the century.

177 The 20th century was an era of other short term changes for the port. The import business of the port became increasingly important. In 1901 coal dominated this trade, but by mid – century this had changed to fuel and other oils. Granite shipments, destined for use as carriageway stones, became a significant export. The early 20th century also saw the last large commercial sailing vessels to use the port. Between the two world wars the pattern of trade did not change significantly. The ferry and, to a lesser extent, liner business built up in the 19th century continued to be important. Following the Second World War import cargoes increased and coastwise traffic declined as a result of the increasing reliance on rail and particularly road transport, and the increasing importance of ferry ports in the southern UK.

2.4.9 Late 20th Century Offshore Activity

178 Undoubtedly the most significant recent development in vessel movements in and around Aberdeen has been the development of the North Sea oil and gas industry. Aberdeen became the major European base for this industry in the 1970s and this caused a dramatic rise in the number of large vessels using the port on a regular basis. Although this is now starting to decline as the industry matures, it is still responsible for a major proportion of vessel movements into or out of the harbour. Several wrecks beached within Aberdeen Bay are rig support vessels highlighting the potential for modern (as well as historic wrecks) to be present.

2.5 Potential for Aviation Archaeology

179 A qualitative assessment of the potential for encountering aircraft crash sites, especially of military origin which may be protected under the Protection of Military Remains Act (PMRA) 1986 was conducted. Air-Sea rescue maps relating to the general locations of rescue missions around the British Isles during World War II and other documentary sources have been compiled by Wessex Archaeology for the Aggregates Levy Sustainability Fund (ALSF) project *Aircraft crash sites at sea* (2008). Positions of specific crash sites and rescue missions are not accurate but relate to the general area of crash reports made at the time. They are useful to provide a means of assessing areas of increased potential.

180 Although no specific aircraft wrecks are noted in the documentary sources consulted for the MSA, there is a moderate concentration of offshore aircraft losses along the north-east coast of Scotland, in the vicinity of Aberdeen. There is potential for encountering unrecorded, unidentified aircraft losses that are buried but this is regarded as low following the geophysical assessment.

3 SUMMARY

3.1 Maritime Cultural Heritage Assets

181 The proposed EOWDC comprises 11 wind turbines, and associated inter-turbine and export electrical cables within the MSA.

182 A total of two sites designated as '*Anthropogenic origin of archaeological interest*' (**WA 7071** and **7072**) have been identified within the marine survey area, the sites are located approximately 40m apart, around 50m north-west of turbine 8. Of these, one is a previously uncharted wreck site (**WA 7071**) and the other is possibly a large piece of debris relating to a wreck (**WA 7072**).

183 It is not currently possible to clearly define the name and type of the unidentified wreck (**WA 7071**) located by the geophysical survey within the MSA, north-west of the proposed position of Turbine 8. The sonar dimensions of the vessel are 25 m long by 6.5 m wide and it is partially buried from the east. The wreck is associated with a small magnetic anomaly suggesting it could be of partly metal construction.

184 Lavery (2001:78-79) describes steam trawlers of similar dimensions dating to throughout the later 19th and 20th centuries and Aberdeen was a centre for shipbuilding with local vessel types a distinctive aspect of the maritime history of the area. Further evidence from the wreck site would be required for a more accurate assessment of archaeological importance to be made.

185 Wreck **WA 7071** exhibits a magnetometer contact and therefore may be of partly metal construction, with dimensions similar to that of a small trawler or sailing vessel. Identification is not possible with the available evidence.

3.2 Submerged Prehistory & Palaeo-landscape Potential

186 The shallow geological sequence of much of the survey area represents a prograding shoreline sequence relating to the Forth Formation (**WA 7505**) (**Figure 3**). This type of deposit records changes in sea-level in the area since the Last Glacial Maximum. These deposits are therefore potentially an important palaeogeographical and palaeoenvironmental sequence in relation to local and regional patterns of Mesolithic coastal activity and now-submerged archaeological landscapes. Any cultural heritage assets of early prehistoric origin encountered in an offshore, primary (*in situ*) context would be of national importance.

187 The nature of the local Mesolithic records of lithic scatters associated with coastal sand dunes directly adjacent to the MSA suggests there may be potential for encountering lithic finds in offshore sediments of appropriate age.

188 Five small possible cut and fills (**7500**, **7501**, **7502**, **7503** and **7504**) have also been identified in the south-west of the MSA. These are shallow, relatively small features and, since it has not been possible to trace them between adjacent lines, they are expected to be isolated depressions and not part of a coherent palaeochannel system. Reworked archaeological material in secondary contexts may be present in the fills of these features.

A APPENDICES

A.1 Legislation Guidance

A.1.1 Summary

189 Description of the domestic, European and international legal framework, including:

- Existing statutory mechanisms relevant to the archaeological heritage
- The application of marine consent and licensing procedures
- The implications of proposed changes associated with the Marine (Scotland) Act 2010 and Marine and Coastal Access Act 2009
- National and regional plans, policies and guidance relating to marine archaeology

A.1.2 Legal and Policy Framework

A.1.2.1 Outline

190 This section presents the legal and policy framework applicable to marine archaeology within the UK Continental Shelf (UKCS), encompassing UK territorial waters and the UKCS itself.

191 The legal framework applicable to marine archaeology is subject to a variety of jurisdictional divisions. It is generally accepted in international law that states have jurisdiction in respect of heritage within their territorial waters (to 12 nautical miles (nm)). Accordingly, the UK exercises authority in respect of marine archaeology to 12nm on the basis of UK-wide legislation. However, as cultural issues are generally devolved, marine archaeology is administered separately by different authorities in each of the home countries, in the case of Scotland, Historic Scotland are the relevant authority.

192 Some aspects of the law relating to marine archaeology, such as the Marine and Coastal Access Act 2009, Protection of Military Remains Act 1986 and the Merchant Shipping Act 1995, are administered by authorities with UK-wide powers.

193 Administration beyond 12nm is not devolved, so that – in principal – marine archaeology on the UKCS is addressed UK-wide. However, in practice the UK-wide authorities with powers relating to archaeology beyond 12nm generally call upon the expertise of the heritage agency responsible for the adjacent territorial waters.

A.1.3 UK-wide

A.1.3.1 Introduction

194 There are two different pieces of legislation under which wrecks of archaeological interest may be designated, namely the Protection of Wrecks

Act 1973 (PWA 1973, which has two relevant sections) and the Protection of Military Remains Act 1986 (PMRA 1986). Designation of wrecks is also possible under a third act, the Ancient Monuments and Archaeological Areas Act 1979 (AMAA 1979), which applies to England, Scotland and Wales, but not Northern Ireland which has its own equivalent legislation.

195 N.B. Scotland's Marine Act (2010; see below), will allow for new Scottish-specific legislation and protection to be implemented.

196 In addition, there are UK-wide provisions applying generally to people who find or take possession of wreck – including wreck of archaeological interest – under the Merchant Shipping Act 1995 (MSA 1985).

197 The Protection of Military Remains Act 1986 and the Merchant Shipping Act 1995 are administered UK-wide by the Ministry of Defence (MOD) and the Maritime and Coastguard Agency (MCA) respectively. Section Two of the Protection of Wrecks Act 1973, which deals with dangerous wrecks, is also administered UK-wide by the MCA. However, Section One of the Protection of Wrecks Act 1973, which deals with wrecks of historic or archaeological importance, is administered by the heritage agencies of each of the home countries. The Ancient Monuments and Archaeological Areas Act 1979 is also administered by the heritage agencies of England, Scotland and Wales.

A.1.3.2 Protection of Wrecks Act 1973: Section One

198 The following paragraphs set out the general provisions and background of Section One of the PWA 1973. Further details relating to its administration in each home country are dealt with subsequently, under the heading for each country.

199 Section One of the Protection of Wrecks Act 1973 enables the Secretary of State to protect wreck sites from unauthorised interference if they are of historic, archaeological or artistic importance.

200 Under the Act it is an offence to carry out certain activities in a defined area surrounding the site, unless a licence for those activities has been obtained from the Government.

201 Section One of the PWA 1973 is administered by each of the home country heritage agencies, largely independently.

202 The relevant Secretary of State (or Scottish Government) must consult appropriate advisors prior to designation, though it is possible to designate a wreck in an emergency without first seeking advice. Advice on designations is provided by the heritage agencies.

203 There are currently a total of 61 sites protected under Section One of the Act http://www.english-heritage.org.uk/daysout/maritime-heritage/map/. The sites range in date and character from dispersed cargoes of Bronze Age metalwork to the largely intact remains of the submarine A1, lost in 1911.

204 Generally, sites are designated following an extended consultation process. However, there have been instances (such as the Swash Channel wreck) where an emergency designation order has been obtained after detection by geophysical investigations in the course of Environmental Impact Assessment

(EIA). The Act does provide for the rapid protection of wrecks at risk, if necessary.

A.1.3.3 *Protection of Wrecks Act 1973: Section Two.*

205 Section Two of the Protection of Wrecks Act 1973 provides protection for wrecks that are designated as dangerous due to their contents and is administered by the Maritime and Coastguard Agency (MCA) through the Receiver of Wreck (ROW).

206 There are currently two wrecks designated as dangerous wrecks under Section Two of the Act: the wreck of the Richard Montgomery off Sheerness; and the wreck of the SS Castilian, East Platters, Anglesey http://www.mcga.gov.uk/c4mca/mcga07-home/emergencyresponse/mcga-receiverofwreck/mcga-protectedwrecks/mcga-protectedwrecks-wrecksact1973_3.htm.

207 Section Two of the PWA 1973 is not used to designate sites because of their archaeological interest, but it is possible that a dangerous wreck designated under this section might also be of archaeological or historic interest.

A.1.3.4 *The Protection of Military Remains Act 1986*

208 Under the Protection of Military Remains Act 1986 the Ministry of Defence has powers to protect vessels that were in military service when they were wrecked. The definition of ‘military service’ has been examined in detail in the course of judicial review and subsequent appeal, such that in some circumstances merchant vessels are eligible for protection (for example http://en.wikipedia.org/wiki/SS_Storaa).

209 The MOD can designate named vessels as Protected Places even if the position of the wreck is not known. In addition, the MOD can designate Controlled Sites around wrecks whose position is known. In the case of Protected Places, the vessel must have been lost after the 4th August 1914, whereas in the case of a wreck protected as Controlled Sites, no more than 200 years must have elapsed since loss (MOD 2001). In neither case is it necessary to demonstrate the presence of human remains.

210 Diving is not prohibited at a Protected Place but it is an offence to tamper with, damage, move or remove sensitive remains. Diving, salvage and excavation are all prohibited on Controlled Sites. Licences to undertake otherwise restricted activities can be sought from the MOD.

211 The provisions of the PMRA 1986 in respect of Protected Places and Controlled Sites are applicable in international waters, which would include the UK Continental Shelf, although they are only enforceable in respect of British-controlled ships, British citizens, and British companies.

212 The MOD is undergoing a rolling programme of identification and assessment that has resulted in several groups of wrecks being designated under the PMRA 1986 http://www.mod.uk/DefenceInternet/AboutDefence/WhatWeDo/Personnel/SPVA/AviationArchaeology.htm%20.

213 The most recent tranche came into effect on 1st May 2008. There are now a total of 12 controlled sites and 55 protected places around the world.

214 Records of vessels lost while in military service do not always give an exact location for the loss. Given the extent of military activity on the UKCS, the potential for wrecks eligible for further designation under the PMRA 1986 is high.

215 Under the Protection of Military Remains Act 1986, all aircraft that have crashed in military service automatically constitute a Protected Place. As such, it is an offence to tamper with, damage, move or remove any remains of military aircraft unless authorised by a licence. The provisions of the PMRA 1986 relating to aircraft are administered by the MOD Joint Casualty and Compassionate Centre.

216 It should also be noted that it is an offence under the PMRA 1986 to carry out unauthorised excavations for the purpose of discovering whether any place in UK waters contains remains of a vessel which has crashed, sunk or been stranded while in military service.

A.1.3.5 Ancient Monuments and Archaeological Areas Act 1979

217 The main legislation used to protect archaeological remains in the UK is the Ancient Monuments and Archaeological Areas Act 1979. This Act primarily deals with terrestrial sites but there is provision to designate sites in territorial waters as Scheduled Monuments.

218 Monuments are defined by the AMAA 1979 as including buildings, structures, works, caves, excavations, vehicles, vessels, aircraft or other movable structures. Monuments can only be scheduled if they are of national importance. Section 53 extends the AMAA 1979 to monuments situated in, on or under the seabed within UK territorial waters.

219 Once a monument has been Scheduled, visiting or diving on the site is not necessarily restricted. It is, however, an offence to demolish, destroy, alter or repair the monument without prior authorisation, in the form of Scheduled Monument Consent.

220 Examples of wreck sites that have been designated as Scheduled Monuments in UK waters (http://www.mcga.gov.uk/c4mca/mcga07-home/emergencyresponse/mcga-receiverofwreck/mcga-protectedwrecks/mcga-protectedwrecks-ancient.htm) include the following:

- The Light Cruisers Brummer, Dresden, Karlsruhe and Koln, along with the Battleships Konig, Kronprinz Wilhelm and Markgraf of the German High Seas Flee. All scuttled at Scapa Flow, Orkney, on 21st June, 1919
- The Kilspindie Hulks Nos.1-8. Examples of 19th to 20th century 'Fifie' sailing fishing vessels, Kilspindie, Aberlady Bay, Lothian
- The Louisa, a 19th century seagoing merchant vessel, Grangetown, Cardiff. This vessel was first protected in 2001 and now forms part of the Cardiff land reclamation scheme

A.1.3.6 Merchant Shipping Act 1995

221 The Merchant Shipping Act 1995 (MSA 1995) http://www.legislation.gov.uk/ukpga/1995/21/contents?view=plain is used to regulate the reporting and disposal of wreck – including wreck of archaeological interest – found or recovered from UK waters, or found or recovered outside UK waters but brought within those waters. Within the context of the MSA 1995, wreck refers to flotsam, jetsam, derelict and lagan found in or on the shores of the sea or any tidal water. It includes ships, aircraft and hovercraft, parts of these, their cargo and equipment.

222 All wreck that is found or taken into possession must be notified to the Receiver of Wreck by the finder. The wreck is then delivered to the Receiver, or, more commonly, held by the finder to the order of the Receiver.

223 The ownership and disposal of wreck is decided according to procedures contained within the MSA 1995. Provision is made for original owners to come forward to claim their property. Ownership of unclaimed wreck from within territorial waters lies with the Crown Estate or in a person to whom rights of wreck have previously been granted by the Crown.

224 The Receiver has a duty to ensure that finders who report their finds according to the legislation, receive an appropriate salvage payment. In the case of material considered to be of historic or archaeological importance, a suitable museum is asked to buy the material at the current valuation and the finder receives the net proceeds of the sale as a salvage payment. If the right to, or the amount of salvage cannot be agreed, either between owner and finder or between competing salvors, the Receiver will hold the wreck until the matter is settled, either through amicable agreement or by court judgement.

A.1.3.7 Archaeological Material other than Wreck

225 The Merchant Shipping Act 1995 applies only to archaeological material that is 'wreck', i.e. material that is derived in some way from a ship or aircraft.

A.1.3.8 Marine & Coastal Access Act 2009

226 The Marine & Coastal Access Act (MCAA) 2009 (http://www.defra.org.uk/environment/marine/legislation/mcaa/index.htm) has fundamentally changed the management of the UKCS, introducing the Marine Management Organisation (MMO), a system of Marine plans for managing coastal activities and development, a revised system licensing marine development, a new system of marine conservation zones (MCZs), and new fisheries management mechanisms.

227 Licensing and enforcement is devolved to Scottish, Welsh and Northern Irish authorities at various levels, to organisations including the Marine Management Organisation in England and Marine Scotland.

228 The Marine Policy Statement (MPS) (http://www.defra.gov.uk/corporate/consult/marine-policy/100721-marine-policy-statement.pdf%20), currently in draft form (Dec 2010), will be the framework for marine planning and decisions affecting the marine area. Marine Plans will set out how the MPS will be implemented in specific areas,

extending to mean high water and overlapping with terrestrial planning schemes. Marine policy guidance and Marine Plans will seek to complement rather than replace terrestrial schemes, recognising that both systems may adapt and evolve over time.

229 The MCAA 2009 itself does not contain specific provisions relating to the historic environment; however the MPS provides the policy context and framework within which all aspects of the historic environment should be managed.

230 The MPS defines the historic environment as including 'all aspects of the environment resulting from the interaction between people and places through time, including all surviving physical remains of past human activity, whether visible, buried or submerged. Those elements of the historic environment – buildings, monuments, sites or landscapes – that hold particular significance due to their historic, archaeological, architectural or artistic interest are called heritage assets'. The MPS uses the term historic environment to include all heritage assets of whether they are afforded statutory protection or not.

231 In relation to the requirements for EIA's under Environmental Impact Assessment (EIA) Directive (Directive 85/337/EEC), the MPS outlines a number of principles to be used, specifically that decisions should:

- Be taken using a risk-based approach that allows for uncertainty, recognising the need to use sound science responsibly
- Be sensitive to potential impacts on sites of particular significance – including designated marine heritage assets
- Look to mitigate negative impacts where possible at various stages of development (in line with legal obligations) in a manner that is proportionate to the potential impacts of the proposal under consideration. Where alternative site selection or design could mitigate effects this should be considered, where appropriate

232 The MPS states that the protection and management of marine cultural heritage should be in a manner appropriate and proportionate to their significance. Significance is defined as 'the value of a heritage asset to this and future generations because of its heritage interests'. It is also highlighted within the MPS that many heritage assets with archaeological interest in coastal and offshore areas are not designated but are of equivalent significance. The MPS states that the 'absence of designation for such assets does not necessarily indicate lower significance' and that the same policy principles should be applied to them as to designated heritage assets.

233 In relation to the management of heritage assets, the MPS identifies the desirability of 'sustaining and enhancing the significance of heritage assets' and a general presumption in favour of the conservation of heritage assets should be adopted. The more significant the asset, the greater the presumption in favour of its conservation. Substantial loss or damage to heritage assets through development activities should be exceptional. Where loss or harm is unavoidable, appropriate mitigation should be considered.

234 In relation to mitigation measures, the MPS requires opportunities for acquiring new information from heritage assets should be taken, and made publicly available, particularly if a heritage asset is to be lost.' It goes further

to state that 'In England and Wales, where development resulting in the loss of a heritage asset's significance is justified, the marine plan authority should require developers to record the asset's significance before it is lost, and to deposit copies of the resulting reports with the relevant local authority planning authority, historic environment record and national heritage agency.'

235 Also of relevance to the historic environment, are the MPS's statements in relation to seascapes, which it defines as 'landscapes with views of the coast or seas, and coasts and the adjacent marine environment with cultural, historical and archaeological links with each other'. The MPS states that the visual, cultural, historical and archaeological impacts on seascapes should be considered for all coastal areas.

A.1.3.9 Other UK Plans, Policies and Guidance

236 Of direct relevance to offshore renewables development is COWRIE's Historic Environment Guidance for the Offshore Renewables Sector (2007) (http://www.offshorewindfarms.co.uk/Assets/archaeo_guidance.pdf). This guidance is UK-wide and provides information on all aspects of dealing with the historic environment in planning and implementing offshore renewable schemes. The guidance is also generally relevant to other forms of marine development, including oil and gas. COWRIE has also published Guidance for Assessment of Cumulative Impacts on the Historic Environment from Offshore Renewable Energy (http://www.offshorewindfarms.co.uk/Assets/cowrie_ciarch%20web.pdf%20) (2008).

237 The Joint Nautical Archaeology Policy Committee (JNAPC) Code of Practice for Seabed Development is a UK-wide code developed in conjunction with key industries. The JNAPC Code is voluntary but provides a framework that can be used in the course of development to ensure that activities are conducted in an archaeologically sensitivity manner (http://www.thecrownestate.co.uk/jnapc_code_of_practice.pdf).

238 The Crown Estate has recently commissioned Wessex Archaeology to prepare a guidance note on assessing, evaluating, mitigating and monitoring the archaeological effects of offshore renewables projects, Protocol for Archaeological Discoveries: Offshore Renewables Projects, (http://www.scribd.com/doc/45787868/The-Crown-Estate-Protocol-for-Archaeological-Discoveries) (The Crown Estate, 2010).

239 As general context for best-practice, English Heritage's general guidance with respect to wind energy is set out in 'Wind Energy and the Historic Environment' (October 2005), which includes a short section on offshore renewables (http://www.english-heritage.org.uk/publications/wind-energy-and-the-historic-environment/).

240 English Heritage has also developed a methodology for Historic Seascape Characterisation, which 'maps a cultural understanding of coastal and marine landscapes' to 'provide area based cultural context our marine management decision-making'. The character areas have no formal legal or planning status, but provide a framework within which seascapes can be understood and managed (http://www.english-heritage.org.uk/professional/advice/advice-by-topic/landscape-and-areas/characterisation/seaschape-character/).

241 English Heritage has recently circulated a consultation document on views, entitled 'Seeing the History in the View: a methodology for assessing heritage significance within views' (April 2008). As implied by the title, the consultation draft sets out a methodology that can be used for 'any view that may have heritage significance', with particular reference to development proposals and environmental impact assessment. English Heritage intends to use the methodology in its own decisions relating to developments affecting views, and also to encourage planning authorities to adopt the same approach. The document includes a methodology for assessing impacts to views in the course of EIA. Although the case studies presented in the document are urban, its potential application to heritage significance within views to and from the coast is apparent (http://www.english-heritage.org.uk/professional/advice/advice-by-topic/setting-and-views/seeing-the-history-in-the-view/).

242 In effect, these principles mean that the historic environment must be a material consideration in development control, that preservation in situ is the preferred approach for heritage assets, that developers are responsible for the recording, publication and dissemination of investigations of heritage assets that cannot be preserved in situ, and that consents are issued subject to sufficient information on archaeological impacts and mitigation.

243 The implications for the historic environment of wind energy developments should be reflected in Regional Spatial Strategies, Local Development Frameworks and Supplementary Planning Documents.

244 The effects of wind energy programmes and projects on the historic environment should be evaluated in all levels of environmental impact assessment.

- Consideration of the historic environment should include World Heritage Sites; marine, coastal and terrestrial archaeology; historic buildings and areas; designed landscapes; and the historic character of the wider landscape

- The significance of internationally and nationally designated sites should be safeguarded, and physical damage to historic sites should be avoided

- The impact of wind energy developments on the setting and visual amenity of historic places should also be considered

- Where wind energy developments affect historic sites, national planning policies on the historic environment should be taken into account

- Consideration should always be given to the reversibility of wind energy projects

A.1.4 Scotland

245 Historic Scotland (HS) carries the responsibilities of Scottish Ministers with regard to nationally important archaeological and built heritage matters, which extend offshore to the 12 nautical mile (nm) territorial limit under the Marine (Scotland) Act 2010. These responsibilities are carried out in collaboration

with other bodies such as Marine Scotland, public authorities and marine planning authorities where appropriate on matters of marine planning or licensing (http://www.scotland.gov.uk/Topics/marine/seamanagement/marineact).

246 There are three relevant pieces of legislation from which direct responsibilities arise: the Marine (Scotland) Act 2010, the Ancient Monuments and Archaeological Areas Act 1979 (http://www.legislation.gov.uk/ukpga/1979/46/contents) and the Planning (Listed Buildings and Conservation Areas) (Scotland) Act 1997. Amendments to the latter two acts, are currently going through the Scottish Parliament as part of the The Ancient Monuments and Listed Buildings (Amendment) (Scotland) Bill (see below).

247 Under the Marine & Coastal Access Act 2009, Scottish Ministers now have powers over marine planning, licensing and conservation over the Scottish Marine Area from 12 - 200 nm offshore. UK Marine Policy Statement and resultant regional marine plans (due by 2012) will outline specific priorities and policy within 12 – 200 nm offshore.

248 Historic Scotland has used the definitions in AMAA 1979 as a basis for designating sites of archaeological interest. Amendments currently being considered in the The Ancient Monuments and Listed Buildings (Amendment) (Scotland) Bill (http://www.historic-scotland.gov.uk/amlb-bill.pdf), (December 2010) clarify what is regarded as a ‘monument’. The proposed change to the definition cites “any site comprising and thing, or group of things, that evidences previous human activity” (p22). This would therefore include artefact scatters, palaeoenvironmentally important sediments containing artefacts, i.e. archaeological material that does not fit under the previous definition that focused upon ‘structure’ or ‘work’. These kinds of archaeological remains are principal components in the archaeological record of submerged prehistoric sites and landscapes and wrecks sites where no vessel has been located. Therefore these proposed amendments are important considerations for the protection of marine archaeology and future guidance.

A.1.4.1 Marine (Scotland) Act 2010

249 The definitions of significance and importance set out in AMAA 1979 have been incorporated into the newly assented Marine (Scotland) Act 2010 and underpin the provisional policies (http://www.scottish.parliament.uk/s3/committees/rae/bills/Marine%20bill/documents/20100110CabSecSGS2Committments-ProvisionalpoliciesforHistoricMPAs-circulationtoparliament.pdf) based upon the Act which replaces the PWA 1973 in Scotland. Under section 4 of the Act, Scottish Ministers have the power to designate an area as an Historic Marine Protected Area (MPA) in order to preserve “a marine historic asset of national importance located, or believed to be located, in the area”.

250 A marine historic asset is defined as:

- a vessel, vehicle or aircraft (or a part of a vessel, vehicle or aircraft)
- the remains of a vessel, vehicle or aircraft (or a part of such remains)
- an object contained in, or formerly contained in, a vessel, vehicle or aircraft

- a building or other structure (or a part of a building or structure)
- a cave or excavation
- a deposit or artefact (whether or not formerly part of a cargo of a ship) or any other thing which evidences, or groups of things which evidence, previous human activity

251 Ministers would also be obliged to consider other environmental characteristics of the marine area with respect to biodiversity and geodiversity policy aims and planning and licensing proposals.

252 Scottish Ministers are required to publish notice and hold a consultation for a proposed Historic MPA designation, however if there is a perceived need to rapidly protect a marine historic asset a designation may be enforced without this process enabling protection for up to 2 years. Specific preservation objectives pertaining to an individual Historic MPA would be defined by Scottish Ministers through Marine Conservation Orders (MCOs) which could prohibit, restrict or regulate a wide range of activities not controlled by other means. The status of designations would be assessed in an ongoing process in relation to the changing state of knowledge and future requirements.

253 Within an MPA it would be an offence to "intentionally or recklessly carry out a prohibited act that significantly hinders or may significantly hinder the achievement of the state preservation objectives for the protected area". Prohibited acts would be to:

- carry out works or activities (or which are likely to) damage or interfere with a marine historic asset or have a significant impact on the protected area
- remove, alter or disturb a marine historic asset
- to contravene an MCO

254 Exceptions may apply when in accordance with a permit or authorisation issued by the Scottish Ministers.

255 Further to powers of protection, marine planning and some licensing powers (under the Marine and Coastal Access Act 2009) would be devolved to Scottish Ministers through the Marine (Scotland) Act 2010 covering the Scottish Marine Area.

A.1.4.2 Planning and the Historic Environment (Scotland)

256 The Planning (Listed Buildings and Conservation Areas) (Scotland) Act 1997 contains the bulk of built heritage conservation planning law for Scotland. It requires Scottish Ministers to compile lists of buildings of archaeological or historic importance and provides for the designation of conservation areas. This Act is currently being discussed in the Scottish Parliament (December 2010) in conjunction with The Ancient Monuments and Listed Buildings (Amendment) (Scotland) Bill which aims to update The Historic Buildings and Ancient Monuments Act 1953, The Ancient Monuments and Archaeological Areas Act 1979 and Planning (Listed Buildings and Conservation Areas) (Scotland) Act 1997 in order to harmonise existing legislation for the management of the historic environment.

257 Under the proposed broader definition of the archaeological record (as per Historic Environment (Amendment) (Scotland) Bill artefact scatters and archaeological important sediments containing evidence of past human activity could be protected once 'cultural significance' and 'national importance' have been discerned under the defined criteria. For example, this type of situation would be well-described by the known submerged prehistoric landscapes and stone tool scatters that define the Mesolithic and Palaeolithic archaeological record in the North Sea.

258 The scope of statutory planning control associated with legislation such as the Planning (Listed Buildings and Conservation Areas) (Scotland) Act 1997 and Town & Country Planning (Scotland) Act 1997 ends at the mean low water mark and it is therefore not possible for buildings or sites that are permanently submerged to be listed. However, it is possible for structures which are sometimes or partly below the sea to be listed, such as ports and harbours. Under the M(S)A 2010 the scope of The Act defines the "Sea" as including the mean high water spring tide, therefore in the case of the intertidal zone, there are overlapping jurisdictions between marine and terrestrial planning legislation and various public bodies including Local Planning authorities and Historic Scotland for example. The resolution of planning decisions in the intertidal zone will be achieved through the national marine plan, and regional marine plans as prepared by Government and regional Marine Planning Partnerships, respectively. The process of producing marine plans (national and regional) is set to take 2 years from the Royal Assent of the M(S)A (10th March 2010).

259 The strategic policies of Scottish Ministers to the historic environment are being set out in a new set of documents entitled Scottish Historic Environment Policies (SHEPs). These documents provide immediate context for advice arising from Historic Scotland, but importantly the SHEPS are effectively cross-governmental and can be expected to guide decisions across the range of authorities responsible to Scottish Ministers. Scotland's Historic Environment (SHEP 1 sets out an overall vision and brings together a broad range of existing guidance and a consolidated volume of the existing SHEPs has recently been prepared (http://www.historic-scotland.gov.uk/shep-july-2009.pdf); however, a document pertaining to the Marine Historic Environment is forthcoming. The consultation period on a draft SHEP on The Marine Historic Environment (http://www.historic-scotland.gov.uk/shep_marine.pdf) has now closed and is likely to be published during 2011-12 (pers. comm. Historic Scotland, December 2010).

260 *Scottish Planning Policy* (SPP) has recently been consolidated to provide a more focused statement of national planning policy (http://www.scotland.gov.uk/Resource/Doc/300760/0093908.pdf), whilst revoking some previous SPP guidance notes, in particular superseding *SPP 23: Planning and the Historic Environment*, Planning Advice Notes (PANs) (pertaining to coastal planning only) and National Planning Policy Guidelines (NPPGs) including *NPPG 18: Planning and the Historic Environment* and *NPPG 5:Archaeology and Planning*.

261 *SPP* sets out policy on how archaeological remains and discoveries should be handled. The guidance is aimed at planning authorities in Scotland, and is also of direct relevance to developers, owners, statutory undertakers, government departments, conservation organisations and others whose actions have a direct physical impact upon the natural or built environment as

it underlines the requirements of development plans to consider the historic environment.

262 The Planning Advice Note: Archaeology 42 - the Planning Process and Scheduled Monument Procedures (PAN 42 - http://www.scotland.gov.uk/Publications/1994/01/17081/21711) gives more detailed advice on planning procedures and the separate controls over scheduled monuments. With the current assessment of the Monuments and Listed Buildings (Amendment) (Scotland) Bill discussed above, this may be updated or changed in the future.

263 Although it is primarily concerned with development on land, a recent document on scoping wind farm proposals in Scotland from Historic Scotland (http://www.historic-scotland.gov.uk/eia_and_gdpo_scoping_setting.pdf) may also be relevant to offshore wind farms.

A.1.5 Local Authority – Aberdeenshire Council Planning

264 The Strategic Development Planning Authority (SDPA, 2010) of Aberdeen City and Shire Council has declared several targets for Quality of the Environment within the 2009 Structure Plan of particular note to archaeology and the historic environment is QE/T1, which is actively monitored during the planning application process:

- To make sure that development improves and does not lead to the loss of, or damage to, built, natural or cultural heritage assets

265 The structure plan highlights "The structure plan area has many sites of significant of built, natural and cultural value. Appropriate monitoring will be developed through 2010 to ensure that development does not have a detrimental effect." (SDPA, 2010:27).

A.1.6 Relevant International Instruments

266 A broader context is provided by international law, represented by customary law and the conventions to which the UK is party. The United Nations Convention on the Law of the Sea 1982 (UNCLOS 1982 - http://www.un.org/Depts/los/convention_agreements/texts/unclos/closindx.htm), the European Convention on the Protection of the Archaeological Heritage (Revised) 1992 (the Valletta Convention), the UNESCO Convention on the Protection of the Underwater Cultural Heritage 2001 (UNESCO 2001 - http://unesdoc.unesco.org/images/0012/001260/12065e.pdf) and the European Landscape Convention 2000 (ELC 2000 - http://conventions.coe.int/Treaty/Commun/QueVoulezVous.asp?NT=176&CM=8&DF=5/19/2009&CL=ENG) are all relevant in this regard, as is the (ICOMOS) Charter on the Protection and Management of Underwater Cultural Heritage 1996.

267 UNCLOS 1982 was ratified by the UK in 1997. Article 303 stipulates that 'states have the duty to protect objects of an archaeological and historical nature found at sea and shall co-operate for this purpose'. Article 303 also provides for coastal states to exert a degree of control over the archaeological heritage to 24 nautical miles, though the UK has not introduced any measures to implement this right.

268 The Valletta Convention was ratified by the UK Government in 2000 and came into force in 2001. The convention binds the UK to implement protective measures for the archaeological heritage within the jurisdiction of each party, including sea areas. Insofar as the UK exerts jurisdiction over the Continental Shelf, then it would appear that the provisions of the Valletta Convention apply to that jurisdiction.

269 The UNESCO Convention 2001 is a comprehensive attempt to codify the law internationally in respect of the underwater archaeological heritage. Although the UK abstained in the vote on the final draft of the Convention, it has stated that it has adopted the Annex of the Convention – which governs the conduct of archaeological investigations – as best practice for archaeology (http://www.unesco.org/new/en/unesco/themes/underwater-cultural-heritage/).

270 The ELC 2000 became binding on the UK from 1 March 2007. Its principal clauses require the Government:

- to recognise landscapes in law as an essential component of people's surroundings, an expression of the diversity of their shared cultural and natural heritage, and a foundation of their identity
- to establish and implement landscape policies aimed at landscape protection, management and planning through the adoption of … specific measures
- to establish procedures for the participation of the general public, local and regional authorities, and other parties with an interest in the definition and implementation of the landscape policies mentioned in paragraph b above
- to integrate landscape into its regional and town planning policies and in its cultural, environmental, agricultural, social and economic policies, as well as in any other policies with possible direct or indirect impact on landscape

271 The Convention applies to the entire territory of the UK and includes land, inland water and marine areas.

272 One further international measure is worth noting, namely the International Council on Monuments and Sites (ICOMOS) Charter on the Protection and Management of Underwater Cultural Heritage 1996 (the Sofia Charter). The Charter includes a series of statements regarding best practice, intending 'to ensure that all investigations are explicit in their aims, methodology and anticipated results so that the intention of each project is transparent to all'. The UK is a member of ICOMOS.

A.2 Gazetteer of Documented Wrecks and Features

(Subsequently compiled into the geophysical assessment of seabed features (section A.4) (co-numbered in Figure 4).

WA_ID (corresponding geophysical feature record)	**RCAHMS ID**	**UKHO ID**	**State**	**Easting**	**Northing**	**Name**	**Type**	**Length (m)**	**Beam (m)**	**Draught (m)**	**Date lost**

A.3 Gazetteer of Sub-bottom Features

WA ID	Name / Classification	Archaeological Discrimination	Description	Sources
7500	Simple Cut and Fill	A2	Small, shallow, possible simple cut and fill in the surface of FH, though could just be an internal reflector. Not definitively observed on adjacent lines, but in the vicinity of 7501 and possibly related. Depth Range: 1.0m - 2.9m BSB.	6500
7501	Simple Cut and Fill	A2	Possible simple cut and fill in the surface of FH, though could just be an internal reflector. Not definitively observed on adjacent lines, but in the vicinity of 7500 and possibly related. Depth Range: 0.4m - 3.7m BSB.	6501
7502	Simple Cut and Fill	A2	Small, shallow, possible simple cut and fill in the surface of FH, though could just be an internal reflector. Not definitively observed on adjacent lines, but in the vicinity of 7503 and 7504 and possibly related. Depth Range: 0.4m - 2.3m BSB.	6502
7503	Simple Cut and Fill	A2	Possible simple cut and fill in the surface of FH, though could just be an internal reflector. Not definitively observed on adjacent lines, but in the vicinity of 7502 and 7504 and possibly related. Depth Range: 1.6m - 6.1m BSB.	6503
7504	Simple Cut and Fill	A2	Possible simple cut and fill in the surface of FH, though could just be an internal reflector. Not definitively observed on adjacent lines, but in the vicinity of 7502 and 7503 and possibly related. Depth Range: 2.3m - 4.7m BSB.	6504
7505	Erosion Surface	A2	Generally fairly poorly defined but laterally continuous reflector within the FH. Appears at seabed just east of the centre of the survey area, in a line running approximately parallel to the shoreline, and dips gently eastwards. Possible erosion surface within FH, possibly representing the internal structure of a prograding palaeoshoreline. Depth Range: 1.4m - 8.3m BSB.	6506

A.4 Gazetteer of Seabed Features

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7000	Rope / Chain	556368	6338517	A2	106.9	0.2	0.1	17	Long, curvilinear dark reflector with a small shadow associated with a small magnetic anomaly. Possible length of rope or chain.	6035	-
7001	Debris	556655	6338337	A2	11.8	1.2	0.4	7	Large dark reflector with large shadow located adjacent to a similar, smaller dark reflector. Associated with a small magnetic anomaly, and possibly both part of the same partially buried piece of ferrous debris.	6036	-
7002	Dark Reflector	556729	6338404	A2	5.7	0.7	0.2	-	Elongate dark reflector with shadow but no associated magnetic anomaly. Could be natural or a piece of non-ferrous debris.	6037	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7003	Magnetic	556721	6338252	A2	-	-	-	12	Small magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contacts. In an area of variable seabed reflectivity and geology and could be due to natural reasons or a piece of buried ferrous debris.	6038	-
7004	Magnetic	557116	6338253	A2	-	-	-	23	Medium magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be a piece of buried ferrous debris, or caused by natural changes in the seabed geology.	6039	-
7005	Magnetic	557167	6338425	A2	-	-	-	23	Medium magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be a piece of buried ferrous debris, or caused by natural changes in the seabed geology.	6040	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7006	Debris	557386	6338562	A2	7.9	0.1	0.0	-	Short but well-defined linear dark reflector without a shadow or associated magnetic anomaly. Possible piece of linear non-ferrous debris.	6041	-
7007	Magnetic	557703	6338644	A2	-	-	-	5	Magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contacts. Anomaly is small but a definite spike compared with the background. Could be caused by natural changes in seabed geology or represent a piece of buried ferrous debris.	6042	-
7008	Magnetic	557447	6338914	A2	-	-	-	24	Medium magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Possibly a piece of buried ferrous debris.	6043	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7009	Magnetic	556700	6338738	A2	-	-	-	28	Medium magnetic anomaly with two positive peaks. No associated sidescan sonar or multibeam bathymetry contact, and possibly a piece of buried ferrous debris.	6044	-
7010	Magnetic	556655	6339020	A2	-	-	-	13	Small magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contacts. In an area of variable seabed reflectivity and could be due to natural geological variations or a piece of buried ferrous debris.	6045	-
7011	Magnetic	556638	6338913	A2	-	-	-	16	Small magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contacts. In an area of variable seabed reflectivity and could be due to natural geological variations or a piece of buried ferrous debris.	6046	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7012	Magnetic	556454	6338955	A2	-	-	-	23	Medium magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contacts. In an area of variable seabed reflectivity and could be due to natural geological variations or a piece of buried ferrous debris.	6047	-
7013	Dark Reflector	556695	6339095	A2	5.7	2.9	0.7	10	Very large dark reflector with very large shadow, possibly associated with a small magnetic anomaly, though the large number of scattered anomalies in the vicinity indicate this could not be the case. Located adjacent to an area of high seabed reflectivity containing numerous similar, but smaller, contacts so could be a natural feature. However is slightly apart from these, so could be a piece of ferrous debris.	6048	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7014	Magnetic	556551	6339186	A2	-	-	-	30	Two adjacent medium magnetic anomalies, probably part of the same broader feature. No associated sidescan sonar or multibeam bathymetry contacts, but is located in an area of variable seabed reflectivity so could be due to natural geological variations or a piece of buried ferrous debris.	6049	-
7015	Magnetic	556557	6339336	A2	-	-	-	27	Medium magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contacts. In an area of variable seabed reflectivity and could be due to natural geological variations or a piece of buried ferrous debris.	6050	-
7016	Magnetic	556896	6339182	A2	-	-	-	6	A linear alignment of three small magnetic anomalies, possibly part of the same broad anomaly though this is uncertain. Could be due to natural changes in seabed geology or represent a piece of elongate, buried ferrous debris (e.g. chain).	6051	-

WA ID	**Name / Class.**	**Easting**	**Northing**	**Arch. Discrim.**	**Length (m)**	**Width (m)**	**Height (m)**	**Magnetic Amplitude (nT)**	**Description**	**Sources**	**External References**
7017	Magnetic	557477	6339608	A2	-	-	-	14	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Possibly represents a small piece of buried ferrous debris.	6053	-
7018	Magnetic	558399	6339593	A2	-	-	-	9	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Possibly represents a small piece of buried ferrous debris.	6054	-
7019	Debris	558823	6339137	A2	20.1	4.1	0.0	-	Group of irregular dark reflectors without a shadow or associated magnetic anomaly. Could be natural or a small scatter of non-ferrous debris.	6055	
7020	Debris	558995	6339921	A2	8.4	4.9	0.3	-	Small area of dark reflectors, some with shadows but without an associated magnetic anomaly. Possible small scatter of non-ferrous debris.	6057	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7021	Seafloor Disturbance	559875	6339635	A2	10.1	4.6	0.0	-	Small area of low seabed reflectivity containing small dark reflectors, possible area of seafloor disturbance. Data is poor and feature is poorly resolved. Not associated with a magnetic anomaly, could be natural or anthropogenic in origin.	6064	-
7022	Dark Reflector	560039	6339560	A2	3.2	0.9	0.5	-	Dark reflector with shadow but no associated magnetic anomaly. Could be natural or a piece of non-ferrous debris.	6065	-
7023	Debris	560261	6339599	A2	2.9	0.6	0.6	-	Small, elongate dark reflector with small shadow but without an associated magnetic anomaly. Feature appears irregular and surround by a small area of disturbed seabed. Possible piece of partially buried non-ferrous debris.	6066	-
7024	Debris	557820	6340910	A2	15.9	1.9	0.0	-	Two adjacent, poorly defined, short linear dark reflectors without shadows or an associated magnetic anomaly. Possibly non-ferrous debris.	6067	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7025	DarkReflector	558423	6340262	A2	7.3	2.3	0.0	-	Poorly defined dark reflector or cluster of small dark reflectors without shadows or associated magnetic anomalies. Could be a natural feature or non-ferrous debris.	6069	-
7026	Magnetic	558680	6340514	A2	-	-	-	18	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Possibly represents a small piece of buried ferrous debris.	6070	-
7027	Debris	558237	6341081	A2	7.6	3.6	0.0	-	Small, irregular dark reflector without a shadow or associated magnetic anomaly. Possible piece of non-ferrous debris.	6071	-
7028	Dark Reflector	558662	6341183	A2	5.4	3.7	0.7	-	Two adjacent large dark reflectors with shadows but no associated magnetic anomaly. Could be natural or a piece of debris.	6076	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7029	Debris	559669	6341721	A2	57.6	0.2	0.0	-	A poorly defined curvilinear dark reflector linking two or three small dark reflectors with shadows. No associated magnetic anomaly, but could be an area of non-ferrous debris.	6088	-
7030	Dark Reflector	560154	6341600	A2	2.4	0.1	0.0	-	Short, indistinct dark reflector without a shadow or associated magnetic anomaly. Located in an area of poor data, and could be a piece of debris or noise.	6092	-
7031	Dark Reflector	560168	6342224	A2	5.3	1.8	0.0	-	Short, indistinct dark reflector without a shadow or associated magnetic anomaly. Located in an area of poor data, and could be a piece of debris or noise.	6093	-
7032	Dark Reflector	560525	6341860	A2	5.2	0.9	0.3	-	Elongate dark reflector with shadow but no associated magnetic anomaly. Could be natural or a piece of non-ferrous debris.	6094	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7033	Dark Reflector	560550	6341691	A2	2.2	0.8	0.1	-	Small dark reflector without a shadow or associated magnetic anomaly. Could be natural or a piece of non-ferrous debris.	6095	-
7034	Dark Reflector	557063	6339094	A2	2.7	0.7	0.3	-	Poorly defined area of dark reflectors forming a rectangular shape. No shadows or associated magnetic anomalies. Possibly a natural feature or an area of non-ferrous debris.	6099	-
7035	Magnetic	556686	6339874	A2	-	-	-	22	Two adjacent medium magnetic anomalies, probably part of the same short linear anomaly. No associated sidescan sonar or multibeam bathymetry contact, but could represent a piece of buried linear ferrous debris.	6102	-
7036	Magnetic	556653	6340003	A2	-	-	-	14	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Possibly represents a small piece of buried ferrous debris.	6103	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7037	Magnetic	557195	6340055	A2	-	-	-	16	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Possibly represents a small piece of buried ferrous debris.	6104	-
7038	Debris	557009	6340182	A2	3.0	2.8	0.5	53	Isolated, rounded dark reflector with small shadow and associated scour. Possibly associated with a medium magnetic anomaly, though this was identified approx 50m away. Possible piece of ferrous debris.	6105	-
7039	Magnetic	556835	6340238	A2	-	-	-	32	Medium magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possible piece of buried ferrous debris.	6106	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7040	Magnetic	557250	6340545	A2	-	-	-	32	Medium magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possible piece of buried ferrous debris. Located in an area of similar contacts at the end of a possible outfall pipe, so could be debris from the pipe.	6107	-
7041	Magnetic	557175	6340485	A2	-	-	-	16	Small magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possible piece of buried ferrous debris. Located in an area of similar contacts at the end of a possible outfall pipe, so could be debris from the pipe.	6108	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7042	Magnetic	557113	6340448	A2	-	-	-	18	Small magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possible piece of buried ferrous debris. Located in an area of similar contacts at the end of a possible outfall pipe, so could be debris from the pipe.	6109	-
7043	Magnetic	557083	6340538	A2	-	-	-	34	Medium magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possible piece of buried ferrous debris. Located in an area of similar contacts at the end of a possible outfall pipe, so could be debris from the pipe.	6110	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7044	Magnetic	557020	6340495	A2	-	-	-	13	Small magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possible piece of buried ferrous debris. Located in an area of similar contacts at the end of a possible outfall pipe, so could be debris from the pipe.	6111	-
7045	Debris	557077	6340342	A2	4.2	1.7	1.3	23	Rectangular dark reflector with shadow, scour and associated medium magnetic anomaly. Possible piece of ferrous debris.	6112	-
7046	Recorded Obstruction	561558	6340796	A3	-	-	-	-	Given location of a seabed obstruction, recorded as an anchor and cable. Not identified by any of the geophysical equipment and could be located elsewhere or currently buried.	6115, 2002	71209 (UKHO)
7047	Rope / Chain	560862	6341169	A2	42.7	1.0	0.0	-	Poorly defined curvilinear dark reflector without a shadow or associated magnetic anomaly. Could be a partially buried length of rope or chain.	6117	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7048	Magnetic	560982	6342050	A2	-	-	-	15	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Possibly represents a small piece of buried ferrous debris.	6118	-
7049	Debris	561746	6341897	A2	14.4	0.5	0.2	-	Short linear dark reflector with small shadow but no associated magnetic anomaly. Possible piece of linear debris.	6119, 6120	-
7051	Rope / Chain	557387	6342034	A2	77.1	0.5	0.0	-	Long, poorly defined curvilinear dark reflector without a shadow or associated magnetic anomaly. Possible length of rope or chain.	6124	-
7052	Debris	557694	6342261	A2	9.7	0.9	0.0	-	Short linear dark reflector without a shadow or associated magnetic anomaly. Possibly a piece of linear non-ferrous debris.	6125	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7053	Magnetic	557806	6343320	A2	-	-	-	8	Two adjacent small but distinct magnetic anomalies, possibly part of the same feature. No associated sidescan sonar or multibeam bathymetry contacts. Could be natural in origin or indicative of a piece of buried ferrous debris.	6129	-
7054	Magnetic	557765	6343110	A2	-	-	-	7	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6131	-
7055	Magnetic	558178	6342835	A2	-	-	-	21	Medium magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possibly indicative of a small piece of buried ferrous debris.	6132	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7056	Magnetic	558523	6342853	A2	-	-	-	8	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6133	-
7057	Magnetic	558325	6342645	A2	-	-	-	9	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6135	-
7058	Magnetic	558185	6342965	A2	-	-	-	6	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6136	-
7059	Magnetic	558545	6343103	A2	-	-	-	6	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6137	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7060	Magnetic	558378	6344343	A2	-	-	-	12	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6141	-
7061	Magnetic	558368	6344145	A2	-	-	-	11	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6142	-
7062	Magnetic	558673	6344048	A2	-	-	-	8	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6143	-
7063	Magnetic	558648	6344283	A2	-	-	-	8	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6144	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7064	Magnetic	558998	6343508	A2	-	-	-	13	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6147	-
7065	Magnetic	559168	6343233	A2	-	-	-	68	Isolated medium magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possibly indicative of a piece of buried ferrous debris.	6148	-
7066	Magnetic	559755	6343090	A2	-	-	-	6	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6149	-
7067	Magnetic	558965	6342600	A2	-	-	-	15	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6151	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7068	Magnetic	559193	6342323	A2	-	-	-	5	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6152	-
7069	Debris	559509	6342605	A2	20.2	5.8	0.1	15	Irregular shaped dark reflector with a small shadow and associated with two small magnetic anomalies. Possible ferrous debris, could be a length of rope or chain but data is unclear.	6153	-
7070	Magnetic	559580	6342703	A2	-	-	-	22	Medium magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Located close to possible ferrous debris 7069, and could be a piece of associated buried ferrous debris.	6154	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7071	Wreck	561077	6342919	A1	25.0	6.5	0.7	58	Wreck not present in the given UKHO or NMR data. Appears upright and fairly intact, still showing structure and height, though is possibly partially buried. No debris field was observed, though one possible piece of discrete debris was located approx. 35m NW. Multibeam bathymetry data indicate the structure is located in a very small (<0.5m deep) scour.	6155	-
7072	Debris	561038	6342931	A1	2.1	1.1	0.2	-	Small dark reflector with a small shadow. Magnetic signature unknown due to the high response created by nearby wreck 7071. Possibly a piece of debris related to the wreck.	6156	-
7073	Debris	562359	6343072	A2	4.8	2.0	0.4	-	Irregular elongate dark reflector with shadow but no associated magnetic anomaly. Possible piece of non-ferrous debris.	6157	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7074	Debris	562363	6343516	A2	4.3	0.4	0.0	-	Short linear dark reflector without a shadow or associated magnetic anomaly. Possible piece of linear non-ferrous debris.	6158	-
7075	Dark Reflector	561821	6343582	A2	3.8	0.9	0.4	-	Isolated dark reflector with shadow but no associated magnetic anomaly. Could be natural or a piece of non-ferrous debris.	6159	-
7076	Debris	561217	6343496	A2	9.8	0.7	0.1	-	Short linear dark reflector or alignment of individual dark reflectors, with a very small shadow but no associated magnetic anomaly. Possible piece of partially buried non-ferrous debris.	6160	-
7077	Magnetic	560093	6344288	A2	-	-	-	7	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6166	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7078	Magnetic	559363	6344785	A2	-	-	-	22	Medium magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possibly indicative of a small piece of buried ferrous debris.	6167	-
7079	Magnetic	559495	6344720	A2	-	-	-	15	Small but definite magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possibly indicative of a small piece of buried ferrous debris.	6168	-
7080	Magnetic	558970	6344655	A2	-	-	-	6	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6169	-
7081	Magnetic	558363	6345125	A2	-	-	-	183	Large magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contacts. No know wrecks or structures in the area, and origin of the anomaly is unknown. Possibly a buried shoreline structure.	6170	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7082	Magnetic	558695	6345140	A2	-	-	-	6	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6171	-
7083	Magnetic	558745	6345160	A2	-	-	-	6	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6172	-
7084	Magnetic	558658	6345208	A2	-	-	-	17	Small but definite magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possibly indicative of a small piece of buried ferrous debris.	6173	-
7085	Debris	558552	6345391	A2	5.1	0.4	0.0	-	Small linear dark reflector without a shadow or associated magnetic anomaly. Possible piece of non-ferrous debris.	6175	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7086	Debris	558530	6345401	A2	5.7	0.4	0.0	-	Small linear dark reflector without a shadow or associated magnetic anomaly. Possible piece of non-ferrous debris.	6176	-
7087	Debris	558468	6345520	A2	11.2	0.4	0.0	18	Small linear dark reflector without a shadow but possibly associated with a small magnetic anomaly. Possible piece of ferrous debris.	6177	-
7088	Magnetic	558763	6346265	A2	-	-	-	22	Two adjacent medium anomalies, possibly part of the same feature. No associated sidescan sonar or multibeam bathymetry contact. Could be a natural feature or indicative of buried ferrous debris.	6179	-
7089	Magnetic	559238	6346023	A2	-	-	-	8	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6180	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7090	Debris	559201	6345459	A2	37.7	2.8	0.2	-	Long, linear dark reflector without a shadow. Extending from the outfall pipe exit away from the shore, and is possibly related debris.	6183	-
7091	Magnetic	559348	6345393	A2	-	-	-	47	Medium magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contacts. Possibly indicative of a buried piece of ferrous debris. Located a short distance from the mouth of an outfall pipe, so could be recent debris washed in from onshore.	6184	-
7092	Magnetic	560063	6345973	A2	-	-	-	45	Medium magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possibly indicative of a small piece of buried ferrous debris.	6185	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7093	Recorded Wreck	560106	6345633	A3	-	-	-	-	Given location of the wreck of the SS *Archangel*, not identified by any of the geophysical equipment. UKHO records show it was last surveyed in 1977, suggesting the positioning may not be accurate and it could lie elsewhere outside of the survey area.	6187, 2000	2145 (UKHO)
7094	Magnetic	560170	6344850	A2	-	-	-	22	Medium magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Possibly indicative of a small piece of buried ferrous debris.	6189	-
7095	Magnetic	560320	6345318	A2	-	-	-	12	Small but definite magnetic anomaly without any associated sidescan sonar or multibeam bathymetry contact. Could be natural or indicative of a small piece of buried ferrous debris.	6190	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7096	Magnetic	560390	6345093	A2	-	-	-	15	Two adjacent small magnetic anomalies, possibly part of the same feature. No associated sidescan sonar or multibeam bathymetry contact. Could be a natural feature or indicative of buried ferrous debris.	6191	-
7097	Debris	561127	6345539	A2	2.3	1.4	0.7	-	Well defined, irregular dark reflector with shadow but no associated magnetic anomaly. Possible piece of non-ferrous debris.	6192	-
7098	DarkRefl ector	561104	6344923	A2	2.0	1.2	0.4	-	Poorly defined rounded dark reflector with shadow and some scour, but no associated magnetic anomaly. Could be natural or a piece of non-ferrous debris.	6194	-
7099	Dark Reflector	560950	6344554	A2	2.7	0.7	0.3	-	Small isolated dark reflector with small shadow but no associated magnetic anomaly. Could be natural or a piece of non-ferrous debris.	6193, 6195	-

WA ID	Name / Class.	Easting	Northing	Arch. Discrim.	Length (m)	Width (m)	Height (m)	Magnetic Amplitude (nT)	Description	Sources	External References
7100	Debris	561855	6345765	A2	15.7	11.0	0.0	-	Collection of short linear dark reflectors without shadows, possible partially buried object/debris. Length of rope or chain possibly extending from one end. No associated magnetic anomaly identified.	6196	-
7101	Magnetic	562015	6345405	A2	-	-	-	8	Medium, complex magnetic anomaly without an associated sidescan sonar or multibeam bathymetry contact. Could be a natural feature or indicative of buried ferrous debris.	6198	-
7102	Recorded Wreck	556542	6340201	A3	-	-	-	-	Given location of the wreck of the *Sheriffmuir*. Located outside of the geophysical survey area, so the current condition of the structure cannot be commented upon.	2003	2144 (UKHO)
7103	Recorded Wreck	557170	6342158	A3	-	-	-	-	Given location of the wreck of the *Coastal Emperor*. Located outside of the geophysical survey area, so the current condition of the structure cannot be commented upon.	2001	2170 (UKHO)

A.5 Gazetteer of Recorded Losses

(Vessels known to have been lost in the vicinity of the MSA, with absent or poor positional information).

Client Approval:	

EUROPEAN OFFSHORE WIND DEPLOYMENT CENTRE: IMPACT ASSESSMENT

TECHNICAL REPORT

65391.15

Acknowledgements

Wessex Archaeology was commissioned by Aberdeen Offshore Wind Power Ltd to undertake a technical archaeological assessment to underpin the environmental impact assessment (EIA) of the known and potential marine and maritime cultural heritage assets associated with the proposed European Offshore Wind Deployment Centre (EOWDC). Gavin Scarff and Edwina Sleightholme at Vattenfall Wind Power Ltd are thanked for their support.

Data was provided by the United Kingdom Hydrographic Office (UKHO), Royal Commission on the Ancient and Historical Monuments of Scotland (RCAHMS) and Aberdeenshire Sites and Monuments Record (SMR). The geophysical data was provided by EMU Ltd (2007) and Osiris Projects (2010).

Wessex Archaeology is grateful to the staff of all the above organisations for their co-operation during the project.

Dr Andrew Bicket produced this report. David Howell and Patrick Dresch processed and reviewed the geophysical data and further contributed to the report. Kitty Brandon prepared the illustrations. Dr Jonathan Benjamin managed the project for Wessex Archaeology, and quality assurance was conducted by Euan McNeill and Candice Hatherley.

1 MARINE & MARITIME ARCHAEOLOGY

1.1 Information for the Non-Technical Summary

1 Impacts to marine and maritime cultural heritage receptors have been assessed for the proposed European Offshore Wind Deployment Centre (EOWDC). Primary direct impacts relate to the construction, operation and decommissioning phases of wind turbine foundations and inter-array and export cable routes. Indirect impacts may derive from changes to the seabed produced by direct impacts. Secondary impacts are likely to be restricted to the seabed footprint of vessels involved in all phases of development.

2 Cultural heritage receptors in the Marine Study Area (MSA) have been grouped under three themes, based on the known and potential cultural heritage resource discussed in the baseline technical report (Wessex Archaeology 2011) – Prehistoric Archaeology; Maritime Archaeology and Aviation Archaeology. Under these themes, several receptors have been identified; these are outlined in Table 1.

3 Each archaeological feature is unique. Importance varies and may not be well understood; although they can still be assessed in terms of the general wreck resource or, in terms of prehistory, the regional potential for prehistoric material and the likely presence of sediments which may contain them.

4 Without mitigation, impacts upon these receptors, especially *known wreck sites*, are likely to be adverse and permanent. With mitigation adverse impacts may be avoided and/or their effects reduced. Adverse impacts relating to the damage and disturbance of heritage assets have been identified primarily with respect to the unidentified wreck (WA 7071) which lies in close proximity to Wind Turbine 8 and with respect to the associated potential inter-array cable routes between wind turbines (Figure 1).

5 Adverse impacts to prehistoric archaeology receptors are likely to be of *moderate* significance. Following mitigation this is likely to be significantly reduced and adverse impacts are likely to be of *minor* significance.

6 Avoidance, where practicable, is the preferred mitigation strategy for known cultural heritage assets (Wessex Archaeology 2007).

7 There is the potential to encounter currently unknown and unidentified cultural heritage assets in the Marine Study Area (MSA) (defined in the archaeological baseline technical report prepared by Wessex Archaeology for Aberdeen Offshore Wind Farm Ltd, 2011). The geophysical survey has identified several anomalies which may be man-made or natural features. Strategies have been proposed to mitigate adverse impacts to these receptors.

8 Research, particularly the geoarchaeological examination of vibrocores and grab samples from sub-seabed sediments taken for engineering purposes provides a cost-effective opportunity to directly investigate the age and archaeological potential of sub-seabed sediments of potential prehistoric archaeological importance. The integration of this kind of geoarchaeological analysis early in the sequence of development activities is advisable to provide the most effective mitigation strategy (Gribble and Leather 2011).

9 Monitoring may be achieved through remote means such as geophysical or ROV surveys. In addition, the Crown Estate has recently published a reporting protocol for finds from offshore renewable developments (The Crown Estate/Wessex Archaeology 2010). Best-practice and effective monitoring may be partly achieved by implementing this protocol. Added value will also be provided to the National Monuments Record.

1.2 Introduction

10 The baseline conditions for the Cultural Heritage Receptors assessed in this report have been reported in the Baseline Technical Report (Wessex Archaeology 2011, report ref: 65391.02).

11 This Impact Assessment should be read in conjunction with the Baseline Technical Report (Wessex Archaeology 2011).

12 The objectives of this impact assessment, in line with existing guidance (Wessex Archaeology 2011, and summarised in section 1.2.1), are to:

- Summarise the adverse and beneficial impacts of the development that are relevant to the submerged archaeology of the area, including
  - Direct
  - Indirect
  - Secondary
  - Cumulative Effects
- Summarise the sensitivity of the archaeological heritage that may be impacted by the development
- Assess the magnitude and scale of impacts on the archaeological heritage of the identified impacts
- Comment on the significance of effects upon the archaeological heritage
- Propose mitigation measures to remove or reduce significant adverse impacts

13 In-combination Effects, in this case, are not applicable to cultural heritage assets, and only apply to European sites associated with the EU Habitats Directive.

1.2.1 Key Guidance Documents

- The Code of Practice for Seabed Developers, Joint Nautical Archaeology Policy Committee 2006 (JNAPC 2006)
- Historic Environment Guidance for the Offshore Renewable Energy Sector, COWRIE 2007 (Wessex Archaeology 2007)
- Guidance for Assessment of Cumulative Impacts on the Historic Environment; from Offshore Renewable Energy, COWRIE 2008 (Oxford Archaeology & George Lambrick Archaeology and Heritage 2008)
- Offshore Geotechnical Investigations and Historic Environment Analysis: Guidance for the Renewable Energy Sector. (Leather & Gribble/COWRIE 2011)
- Protocol for Archaeological Discoveries: Offshore Renewables Projects, The Crown Estate, 2010 (TCE, Wessex Archaeology 2010)

1.2.2 Data Information and Sources

- Archaeological records for the MSA available in the maritime section of the CANMORE database held by the Royal Commission for Ancient and Historic Monuments Scotland (RCAHMS) which constitute the National Monuments Record for Scotland (NMRS), also interrogated via a map interface, CANMAP
- Archaeological records for the MSA held locally in the Aberdeenshire, Moray and Angus Sites and Monuments Record (SMR)
- Records of wrecks and obstructions collated by the UK Hydrographic Office (UKHO)
- Records of Protected Places and Controlled Sites provided by the Ministry of Defence
- SeaZone datasets including basemapping and wreck information (derived from UKHO records)
- British Geological Survey (BGS) mapping and UKHO charts
- Various secondary sources relating to the palaeo-environment of the area and to the Palaeolithic and Mesolithic archaeology of Northern Europe
- Secondary sources relating to wrecks and the maritime environment and the history and archaeology of Aberdeen and its surrounding area
- Other readily available published sources

1.2.3 Impact Assessment Methodology

1.2.3.1 Cultural Heritage Receptors

14 In order to provide a targeted impact assessment, the cultural heritage receptors in the MSA have been grouped under three themes, based on the known and potential cultural heritage resource discussed in the baseline technical report (Wessex Archaeology 2011) – Prehistoric Archaeology; Maritime Archaeology and Aviation Archaeology. Known and potential receptors are outlined in Table 1.

Table 1: Cultural Heritage Receptors Defined for the MSA

Prehistoric Archaeology	Maritime Archaeology	Aviation Archaeology
Post-glacial submerged landscape features & fills	Known wreck sites	Unknown aircraft crash sites
Isolated prehistoric sites & finds	Unknown wreck sites	

15 Each archaeological feature is unique. Importance varies and it may not be possible to accurately assess importance given the available data; although the importance of each receptor can still be assessed in terms of the ‘potential’ for encountering them relative to baseline conditions (Wessex Archaeology 2011). This may be examined in relation to the general wreck resource or, in terms of prehistory, the regional potential for prehistoric material and the likely presence of sediments which may contain them (Wessex Archaeology 2011).

1.2.3.2 Criteria for Assessing Significance of Impact

16 The criteria that will be used in the impact assessment are summarised below:

Spatial Extent of Effect

17 The terms used in the impact assessment are:

- national/international effect
- a regional effect
- a local effect (within 5 km of the site)
- a site-specific effect

Duration of Effect

18 The terms used in the impact assessment are:

- long-term / permanent effect (more than 10 years)
- medium-term effect (existing for 5 to 10 years)
- short-term effect (existing for 1 to 5 years)
- temporary effect (existing for less than a year)

Recoverability of the Receptor

19 Generally impacts have adverse effects upon archaeological materials but some effects can be beneficial. The terms used in the impact assessment for receptor recoverability are:

- High
- Medium
- Low or
- None

20 Cultural heritage receptors are a finite non-renewable resource, they cannot recover following adverse impacts upon them, such as substrate removal and physical damage. The security of the context in which they are found is also a key factor in assessing their value and importance. Therefore against adverse effects, recoverability will be low to none.

Importance of the Receptor

21 Archaeological importance is gauged on the extent, rarity and perceived significance of the resource. For example, finds of Mesolithic and Palaeolithic age are rare compared to material from more recent archaeological periods. As a result they are likely to be of national to international importance (e.g. Parfitt *et al*. 2010; Ballin *et al*. 2010).

22 In contrast, vessels from the 20th century are relatively numerous and well-recorded therefore their archaeological importance may be lower. However, such wrecks may be significant for other reasons such as wartime importance (e.g. protected under the Protection of Military Remains Act (PMRA 1986) or technological advances.

23 There may also be significant local, regional and national importance associated with vessels that were lost with their crew (e.g. the Solway Harvester). http://news.bbc.co.uk/1/hi/scotland/south_of_scotland/8448887.stm

24 The terms used in the impact assessment are summarised within the definitions of Table 2.

1.2.3.3 Assessment of Significance

Sensitivity of the Receptor

25 Assessment of the sensitivity of the cultural heritage receptors is guided by the definitions in Table 2 developed from COWRIE guidance (Wessex Archaeology 2007, COWRIE 2008). Cultural heritage receptors may also be important for other reasons such as wartime history (e.g. protected under PMRA 1986).

26 Where the archaeological importance or sensitivity is unknown or cannot be clearly defined (e.g. for unknown distributions of prehistoric archaeological materials or unidentified wrecks), a precautionary approach is taken and the receptors' archaeological potential is assessed.

Table 2: Sensitivity of Receptors – Definition of terms (adapted from Wessex Archaeology 2007, COWRIE 2008).

Sensitivity	Definition
Very High	Feature of International Importance OR best known example and/or significant potential to contribute to knowledge and understanding and/or outreach
High	Feature of National Importance OR above average example and/or high potential to contribute to knowledge and understanding and/or outreach
Medium	Feature of Regional Importance OR average example and/or moderate potential to contribute to knowledge and understanding and/or outreach
Low	Feature of Local Importance OR below average example and/or low potential to contribute to knowledge and understanding and/or outreach

27 For some cases, a *negligible* significance of impact may be surmised in association with Table 4. In relation to cultural heritage assets this would be defined as a "poor example and/or little or no potential to contribute to knowledge and understanding and/or outreach".

Magnitude of Effect

28 The magnitude of effect is assessed relative to the worst realistic case where possible (see section 1.2.4) and the impact of development upon specific or regional cultural heritage assets relative to baseline conditions. The terms are defined in Table 3.

Table 3: Magnitude of Effect – Definition of terms (adapted from Wessex Archaeology 2007, COWRIE 2008).

Magnitude	Definition
Very High	Total loss or very major alteration to key elements/features of the baseline conditions such that post development character/composition/attributes will be fundamentally changed and may be lost from the site altogether.
High	Major alteration to key elements/features of the baseline (pre-development) conditions such that post development character/composition/attributes will be fundamentally changed.
Medium	Loss or alteration to one of more key elements/features of the baseline conditions such that post development character/composition/attributes of baseline will be partially changed.
Low	Minor shift away from baseline conditions. Change arising from the loss/alteration will be discernible but underlying character/composition/attributes of baseline condition will be similar to pre-development circumstances/patterns.
Negligible	Very slight change from baseline condition. Change barely distinguishable, approximating to the 'no change' situation.

29 Based upon these criteria a judgment on the receptors' sensitivity (Table 2) and the magnitude of effect (Table 3) is made. The significance of impact is guided by the matrix shown in Table 4.

Table 4: Matrix for Significance of Impact

		Sensitivity of Receptor			
		Very High	**High**	**Medium**	**Low**
Magnitude of Effect based on spatial, duration and scale of effect	**Very High**	Major	Major	Major	Moderate
	High	Major	Major	Moderate	Minor
	Medium	Major	Moderate	Moderate	Minor
	Low	Moderate	Minor	Minor	Negligible
	Negligible	Minor	Negligible	Negligible	Negligible

1.2.3.4 Cumulative and In-combination Impact Assessment Methodology

30 Aspects of development activities within the proposed EOWDC in conjunction with other activities and development projects in the region may create cumulative impacts upon cultural heritage receptors.

31 Several offshore activities within the region are considered under cumulative impacts, external or adjacent to the current proposed EOWDC development. A proposed application for an ocean laboratory to the south of Wind Turbine 1 is also discussed. Developments considered include:

- Other offshore wind developments
- Ocean Laboratory, EOWDC
- Maritime and Coastguard Agency designated anchorage area
- Commercial fisheries activity
- Subsea cables
- Port/harbour dredging operations

32 Where possible a brief statement of the nature of the cumulative impacts is made. Recent or future developments are likely to require undertaking EIA and the development of mitigation strategies. These processes in many cases will aid the reduction or avoidance of adverse impacts to cultural heritage assets.

33 In-combination effects, in this case, are not applicable to cultural heritage assets only to European sites associated with the EU Habitats Directive.

1.2.4 Worst Realistic Impact

34 The exact specification of the wind turbines has not been established at this time and a variety may be used. A maximum specification is used to examine the worst case scenario.

35 With respect to cultural heritage receptors within the MSA, the worst realistic impact would derive from activities producing the greatest spatial extent of seabed disturbance and greatest volume of seabed and sub-seabed sediment removal.

Impacts from Cable Trenching

36 As outlined in the Rochdale envelope for the proposed development, cable installation involving ploughing of up to 3 m depth and 10.38 m width would induce the greatest disturbance to the seabed (up to c. 202,500 m^3 depending upon configuration of cable network and method used) and it is considered that the proposed cable trenches have the greatest potential for impacts upon unknown cultural heritage assets.

37 Up to four export cables routes are proposed. Between the designated anchorage and Blackdog rifle range exclusion zones the area for routing these export cable trenches is constrained to a corridor roughly 250 m wide. If all four export cable trenches are excavated the relative area of seabed and sub-seabed sediments under disturbance will be intensified in this area.

38 Not all possible routes for inter-array cabling will be installed. This will enable mitigation through avoidance of cultural heritage assets or micro-siting of wind turbines and therefore the associated inter-array cable routes.

Impacts from Wind Turbine Foundations

39 Depending upon the type of wind turbine foundation used impacts upon the seabed and sub-seabed sediments will vary. The most horizontally-extensive (giving the largest seabed disturbance) wind turbine foundation proposed is a gravity base structure of up to 40 m in diameter. This base can also extend to depths of up to 2 m, so there is a high potential for unknown and buried cultural heritage receptors within this footprint to be adversely affected.

40 Seabed preparation may be required for construction of gravity base foundations which would involve groundworks to the seabed beneath the proposed location by dredging seabed sediments, partly to provide ballast for the gravity bases themselves. Any archaeological or palaeoenvironmental assets within sediment affected by this process would be lost or damaged.

41 In addition, an unknown width of scour protection (dumped aggregates) may also be deposited around the foundation footprint of wind turbine foundations increasing the area of effect further. The volume and extent of this scour protection will ultimately depend on local hydrographic conditions. Cultural heritage assets within

these footprints are likely to be adversely affected by compression under significant volumes of scour-protecting aggregates.

Vessel Footprint

42 Secondary adverse impacts from vessel footprint are also an important consideration, during all phases of the project. If during construction, operation and decommissioning vessels jack-up on legs or anchor to the seabed, either directly onto cultural heritage assets or their protective, sedimentary overburden, then the asset or its archaeological context may be significantly damaged or destroyed within this footprint.

Changes to Seabed Sediment Distribution

43 The prevailing wind and tide directions suggest that cultural heritage receptors in the lee of wind turbine foundations (i.e. sheltered) could be exposed to turbulence and scour produced by water flow around the foundations, removing protective sediment cover and deleteriously affecting the condition of cultural heritage receptors.

1.3 Impact Assessment

44 Cultural heritage receptors are a finite resource, they cannot recover following adverse physical impacts upon them and the security of the context in which they are found is critical to their value and importance. Generally impacts will be adverse in nature upon archaeological materials, but some impacts can be beneficial (Table 5). For example, indirect adverse impacts may manifest as scour around wreck sites created by turbulence induced by changes to water flow around wind turbine foundations leading to adverse effects from erosion (Table 5). In the case of sediment plumes created during trenching for cabling (or other disturbance to the seabed where sediments are entrained in the water column), when they resettle they can provide additional protection to archaeological materials. Clearly this action can not be easily quantified and does not imply direct or comparable mitigation of adverse impacts.

45 With respect to the MSA and cultural heritage receptors in marine contexts, only the impacts to resources on the seabed are considered here, i.e. the specifications of the wind turbine foundations, cable trenching methodologies and secondary impacts from vessels will be the critical factors for assessing impacts, not the above-water configuration of wind turbines.

46 The nature of impacts upon cultural heritage receptors can be seen to derive from two main activities during the lifetime of the proposed development. Impacts will derive from:

- inter-array and export cabling installation; and
- wind turbine foundation installation

47 Impacts from the installation of the inter-array and export cabling, primarily the seabed excavation aspect of the process, are likely occur at shallower depths but more spatially extensive with respect to the distribution of cultural heritage receptors on or beneath the seabed.

48 Impacts from the installation of the wind turbine foundations will be more restricted to the footprint of each wind turbine with respect to the distribution of cultural heritage receptors.

49 Depending upon the wind turbine foundation types ultimately used, pile foundations will have a smaller lateral footprint but will be considerably deeper than a shallower but wider gravity base structure (GBS). GBS foundations are regarded as the worst case scenario and form the focus of the impact assessment (see section 1.2.4). Adverse impacts are likely to be similar within the footprint of pile foundations but penetrate to a greater depth of seabed sediment. As the archaeological importance of the seabed sediment cannot be accurately assessed with the available data, the assessment of pile-driven wind turbine foundations is not developed further and general statements of impact are made within units of sediment of archaeological potential are made.

50 Secondary impacts from the seabed footprint of attending vessels are also likely to occur during construction, operation and decommissioning of the development. Secondary impacts are likely to interact with the seabed and shallow sub-seabed sediments in localised areas by jack-up legs and/or anchoring. Depending upon the methods used, any cultural heritage assets under this footprint are likely to be significantly and adversely impacted. It is not possible to accurately predict exactly where these impacts will affect the seabed at this time.

51 There is also scope for the construction of an Ocean Laboratory to the south-west of Wind Turbine 1. This will be applied for via a separate consent application but this will be considered under cumulative impacts (Figure 1 and 2).

52 The impacts upon cultural heritage receptors considered in this assessment are summarised in Table 5.

Table 5: Summary of the Nature and Type of Impacts

Impact	Nature of Impact	Type of Impact
Direct damage to both *in situ* cultural heritage assets and assets in secondary contexts	Adverse	Direct
Disturbance of relationships between structures, artefacts and their surroundings or contexts	Adverse	Direct
Destabilisation and erosion of sites through changes to seabed characteristics	Adverse	Indirect
Burial of sites due to re-deposited sediment, potentially protecting and promoting the favourable preservation of cultural heritage receptors	Beneficial	Indirect

1.3.1 Impacts on Submerged Prehistoric Archaeology

1.3.1.1 Construction & Decommissioning Phase

Potential Impacts

- Adverse, direct damage to both *in situ* cultural heritage assets and assets in secondary contexts
- Adverse, direct disturbance of relationships between structures, artefacts and their surroundings or contexts
- Adverse, indirect destabilisation and erosion of sites through changes to seabed characteristics
- Beneficial, indirect burial of sites due to re-deposited sediment, potentially protecting and promoting the favourable preservation of cultural heritage receptors

Secondary Impacts

- Produced by vessel footprints; direct, adverse impacts will also affect cultural heritage receptors in association with cable trenching. Jack-up legs and/or anchoring may also impact adversely upon cultural heritage receptors on or shallowly buried under, the seabed through physical damage

53 During decommissioning the cable routes will primarily be buried and/or cut and left *in situ*. In some cases it may be necessary to remove cables which would be done involving excavation of the cable route by similar methods to the construction phase. Assuming that the same area of seabed that was impacted during the laying of the cables in the construction phase was excavated to remove a cable then the impacts to cultural heritage receptors would already have taken place. However, there may be secondary impacts from the vessel footprint from jack-up legs or anchoring in surrounding areas of seabed not previously affected.

54 During decommissioning wind turbine foundations are to be cut and/or craned from the seabed. Assuming that this does not disturb additional areas of seabed out with that affected by construction activities, adverse impacts may be restricted to secondary impacts from vessel footprints.

Post-glacial Submerged Landscape Features & Fills

55 There are currently no known prehistoric artefacts or sites recorded from below Mean Low Water Spring (MLWS) in the MSA (Wessex Archaeology 2011).

56 For clarity, Table 6 from the baseline technical report (Wessex Archaeology 2011) is included here for reference:

Unit	Description
1	Recent (Holocene) seabed sediments, silty sand.
2	Late Devensian / Early Holocene fluvio-deltaic and marine sands (Forth Formation (FH), St. Andrew's Bay Member)
3	Late Devensian Till (Wee Bankie Formation)
4	Devonian Bedrock (Old Red Sandstone)

57 Unit 4 is bedrock and therefore is not considered to be of archaeological interest. There may be potential for encountering older archaeological material of Devensian age in secondary contexts which has been reworked from terrestrial contexts into Unit 3 (Wee Bankie Formation) sediments. However, because the Unit 3 sediments are glacial in origin the potential to encounter archaeological material of Devensian age is regarded as being low to negligible.

58 In general terms the upper, and lower extent of Unit 2 in the region of the proposed wind turbine locations, is in at least 20m of water. The proposed Wind Turbine locations 1 – 3 are located close to the 20 m bathymetric contour, with the rest of the proposed wind turbine locations in progressively deeper water to the east (up to *c.* 30 m bathymetric contour). Groundworks and construction activity required for the installation of the wind turbine foundations will have an additional footprint that may impact the seabed out with the footprint of the wind turbines themselves. Unit 2 sediments will be locally affected by this activity; the magnitude of the impact will be partly dependent upon the method of foundation construction.

59 In the very early Holocene, c. 10,000 BP, the positions of the westernmost wind turbines (1, 2, 3, 5, 6 and 9) may have been in, or close to, the inter-tidal zone, with the remaining wind turbines in increasingly offshore positions moving east. Sub-seabed feature WA_7505 represents a prograding series of sedimentary units. Sea level models from the region suggest that the bathymetry of this feature would have been submerged by around 10,000 BP (Wessex Archaeology 2011: Figure 7) which focuses the potential for archaeological materials roughly landwards of, and in the vicinity of the 20m bathymetric contour. Incorporating estimates of isostatic readjustment from the same sea level dataset suggests that land uplift in north-east Scotland is around 0.5 mm/yr (Gehrels 2010) which is equivalent to sediments undergoing 2.5 m of uplift from their initial position in 5,000 years which would go some way to juxtapose the depth of Unit 2 beneath more recent Unit 1 seabed sediments and using modern bathymetry as a reference point for archaeological palaeo-landscapes potential.

60 This palaeogeographical relationship indicates a reduced potential of directly impacting upon submerged archaeological landscapes that may be preserved in the vicinity of the proposed wind turbine locations within the context of the currently known period of human activity in Scotland. This potential is constrained by Holocene relative sea level modelling, isostatic readjustment and the sediments of Unit 2 and which are comparable to the St Andrews Bay Member of the Forth Formation. In addition, construction, operation and maintenance, and decommissioning impacts from associated activities such

as the footprints of vessels servicing the wind turbines and cable trenching will extend landward into areas of higher potential.

61 Five shallow geological cut and fill features were also identified (WA 7500 – 7504) during the geophysical assessment (Wessex Archaeology 2011). These features are concentrated in the south-west of the MSA and may be small, isolated infilled basins (as they do not appear on adjacent survey lines). There is some potential for archaeological material (perhaps in secondary contexts) to be found within them, but this is likely to be low. Unless directly impacted by export cabling routes, impacts to these palaeolandscape features by the development are likely to be negligible.

62 As Unit 2 deposits underlie much of the MSA and may be adversely affected by the export cables, they are potentially of high value as they form the primary sedimentary resource for preserving *in situ* early prehistoric (of Mesolithic and perhaps Upper Palaeolithic age) archaeological assets. Without further evidence clarifying the age of these sub-seabed sediments and an assessment of their archaeological contents (if present and preserved), a more detailed statement of importance is not currently possible.

63 Locally, the effect of potential sediment removal during cable installation (see section 1.2.4 for worst case) could have a major adverse impact if Unit 2 sediments are affected. However, across the development as a whole, this will be restricted to a relatively small area in the vicinity of development activities.

64 Encountering *post-glacial submerged landscape features and fills* during wind turbine foundation installation is restricted by the potential for the westernmost wind turbines to overly a previously inter-tidal zone as suggested by Holocene sea level models and palaeogeographical literature (Wessex Archaeology 2011). The scale of the impact is judged to be medium for these cases, restricted to a site-specific spatial extent. Importance cannot currently be assessed and is therefore, medium.

65 The redistribution of sediment from development activities is likely to be a beneficial impact as the protective covering of sediment is slightly increased where sediment settles out from the water column.

66 The potential impact has been assessed of **medium** magnitude, **high** sensitivity and of ***moderate*** significance.

Isolated Prehistoric Sites & Finds

67 As discussed in the archaeological baseline report for the proposed EOWDC (Wessex Archaeology 2011), there is potential for encountering isolated, chance finds of lithic scatters and other prehistoric archaeology associated with Unit 2 sediments across the MSA, and also remobilised finds in secondary contexts within the seabed sediments deriving from coastal geomorphology.

68 Within the context of the post-glacial sea-level change and associated palaeo-geography of the MSA, this potential is likely to be focused in the coastal shelf region to the west of the proposed wind turbine locations in less than 20 m of water. The route of the export cabling (a maximum of four export cables are proposed) will therefore be an important factor for assessing the impacts on cultural heritage receptors in the MSA. Unit 2 sediments are

extensively preserved across the MSA in varying thickness, beneath around 1 m of seabed sediment.

69 Although seafloor disturbance is likely to be shallow, if cable trenching and wind turbine bases interacted with Unit 2 sediments there would be a localised, major adverse impact. The depth of the cable would be between 0.6 m and 3 m. Therefore, where cable installation groundworks remove more than *c.* 1 m vertical depth of seabed sediment there is a greater potential that sediments of potential prehistoric archaeological significance will be adversely affected.

70 There is potential for encountering isolated prehistoric finds but the distribution of such material cannot currently be assessed. As a result the scale of impact is described as medium as a precaution. This receptor is primarily associated with Unit 2 sediments (Wessex Archaeology 2011) that may be adversely impacted by wind turbine foundation activities, their spatial extent is across most of the MSA, and is therefore of local-scale.

71 Under current proposals cable routes would be left *in situ* after decommissioning, with maintenance and exposed connections made safe. The significance may be reduced as impacts would already have occurred during the construction phase. Secondary impacts from vessel footprints on the seabed would be the main impact to cultural heritage assets.

72 The redistribution of sediment from development activities is likely to be a beneficial impact as the protective covering of sediment is slightly increased where sediment settles out from the water column.

73 The potential impact has been assessed of **medium** magnitude, **medium** sensitivity and therefore of ***moderate*** significance.

Table 6: Summary of Significance of adverse impacts upon prehistoric archaeology receptors.

Theme	**Receptor**	**Spatial Extent of Effect**	**Duration of Effect**	**Recoverability of the Receptor**	**Importance of the Receptor**	**Sensitivity of the Receptor**	**Magnitude of Effect**	**Significance of Impact**
Prehistoric Archaeology	Post-glacial submerged landscape features & fills	Site-specific to Local	Permanent	None	Medium	Medium	High	**Moderate**
	Isolated prehistoric sites & finds	Local	Permanent	None	Medium	Medium	Medium	**Moderate**

Table 7: Summary of Significance of beneficial impacts upon prehistoric archaeology receptors.

Theme	Receptor	Spatial Extent of Effect	Duration of Effect	Recoverability of the Receptor*	Importance of the Receptor	Sensitivity of Receptor	Magnitude of Effect	Significance of Impact
Prehistoric Archaeology	Post-glacial submerged landscape features & fills	Site-specific to Local	Temporary to long-term	-	Medium	Low	Low	Negligible
	Isolated prehistoric sites & finds	Local	Temporary to long-term	-	Medium	Low	Low	Negligible

* For beneficial impacts such as sediment redeposition settling from the water column onto cultural heritage receptors (Table 5), recoverability is not applicable.

Mitigation

74 Effective mitigation and monitoring during cable trenching and wind turbine installation activities is problematic. Sediment plumes obscure the observation of impacted cultural heritage receptors. The ephemeral nature of potential archaeological materials such as Mesolithic period microliths also precludes ease of monitoring.

75 Avoidance is seen as the primary method of mitigation for offshore developments (Wessex Archaeology 2007) where this is not practicable other methods may be required. Local and national curators may request specific mitigation strategies.

76 Following geotechnical/geoarchaeological assessment of grab samples, vibrocores and other sediment samples it may be possible to gauge the potential for encountering prehistoric archaeology assets further. However, if prehistoric archaeological assets are an important feature of the impacted sub-seabed sediments, then the significance of impact may increase from the scenario described here.

77 A finds reporting protocol should be adopted in order to record any material of potential archaeological interest discovered during all phases of development activity. A protocol for offshore developments has recently been commissioned and published by the Crown Estate (The Crown Estate/Wessex Archaeology 2010). Information from reported finds serves to enhance the National Monuments Record and allows more informed and effective management of offshore cultural heritage assets for the benefit of industry, heritage and the public.

78 The potential for encountering prehistoric archaeology is likely to be restricted to the west of the proposed wind turbine locations, in less than 20m water depth. The impact of export cabling excavated through sub-seabed sediments of archaeological potential could be reduced by geoarchaeological assessment of geotechnical cores taken for engineering purposes (Gribble

and Leather 2011). This would permit a more accurate assessment of the age and archaeological potential of the sub-seabed sediments, particularly Unit 2.

79 Mitigation during construction phase would already apply in relation to the decommissioning phase.

Residual Impacts

80 After mitigation the impacts would likely be restricted to secondary impacts from vessel footprint during the decommissioning phase.

81 After mitigation the impacts would be of ***minor*** significance.

Cumulative Impacts

- **Other Offshore Wind Developments**
    - There are no other existing or planned offshore wind farm developments in the vicinity of the MSA.
- **Maritime and Coastguard Agency Designated Anchorage**
    - Abutting the MSA to the south is the MCA anchorage (Figure 1 and 2). Cumulative impacts from anchoring within this area are unlikely to impact upon buried Prehistoric Archaeology Receptors in conjunction with vessel footprints from the EOWDC project. Consultation with the Aberdeen Harbour Board has already been recommended in Scoping Opinion (Marine Scotland 2011).
- **Commercial Fisheries Activity**
    - There may be cumulative impacts in association with commercial fisheries activities that impact the seabed, such as trawling. However, more likely in this nearshore area would be inshore fisheries activities. Scoping for the development indicates some minor fishing vessel activity in the vicinity of the MSA, partially linked to the designated anchoring area or passage en-route to other areas rather than concentrated fishing activities (AOWF 2010: Figure 14).
    - It is considered that cumulative impacts are likely to be of ***low-negligible*** significance.
- **Subsea Cables**
    - Subsea cables are present within the Blackdog Rifle range exclusion zone but impacts to cultural heritage receptors from that past development are unknown and no assessment can currently be made.
- **Port/harbour Dredging Operations**
    - Dredging activities may be undertaken for the maintenance of Aberdeen Harbour to the south of the MSA. Archaeological assets are likely to have been already be removed and impacted by earlier phases of sediment removal. New areas of dredging will be required to undergo EIA and define mitigation strategies.
- **Proposed Ocean Laboratory, EOWDC**
    - The installation of an Ocean Laboratory to the south-west of Wind Turbine 1 (shown on Figure 1 and 2) would lead to cumulative impacts of a site-specific nature. Following geophysical assessment there appears to be no anomalies or known cultural heritage assets in the given location. Cumulative impacts may be of *minor* significance depending upon the type of the foundation used (spatial extent and volume of seabed sediment disturbed or removed) and cable linkages to other elements of the proposed development. Submerged landscape features associated with Unit 2 sediments

would be most affected in a similar manner to wind turbine foundation installation impacts.
- o The potential impact has been assessed of **medium** magnitude, **high** sensitivity and of ***moderate*** significance.
- o After mitigation the impacts would be of ***minor*** significance.

Monitoring

82 ROV or suitably qualified divers may provide sufficient monitoring of enacted mitigation strategies. Geophysical survey could also be applied to monitor any development in seabed scour and other impacts to prehistoric archaeology receptors.

83 Post-decommissioning, a geophysical survey is recommended to examine the condition of the seabed following the removal of infrastructure, which may largely be the wind turbine foundations as cable routes may be left *in situ*. Geophysical survey data should be reviewed by an archaeological specialist to assess cultural heritage receptors within the development area.

1.3.1.2 Operational Phase

Potential Impacts

84 Operational impacts are likely to be restricted to secondary impacts invoked by vessel footprint. Jack-up legs and/or anchoring may also impact adversely upon cultural heritage receptors on or shallowly buried under, the seabed through physical damage. The significance may be reduced as impacts would already have occurred during the construction phase.

Mitigation

85 Mitigation during construction phase would already apply (see page 16).

Residual Impacts

86 As construction and decommissioning phase (see page 17).

Cumulative Impacts

87 As construction and decommissioning phase (see page 17).

Monitoring

88 Periodic geophysical survey is recommended to review the state of the seabed following development activities. This could be undertaken in conjunction with other development requirements such as for engineering or geotechnical purposes.

1.3.2 Impacts on Maritime Archaeology

1.3.2.1 <u>*Construction & Decommissioning Phase*</u>

Potential Impacts

- Adverse, direct damage to both *in situ* cultural heritage assets and assets in secondary contexts
- Adverse, direct disturbance of relationships between structures, artefacts and their surroundings or contexts
- Adverse, indirect destabilisation and erosion of sites through changes to seabed characteristics
- Beneficial, indirect burial of sites due to re-deposited sediment, potentially protecting and promoting the favourable preservation of cultural heritage receptors

Secondary Impacts

- Produced by vessel footprints; direct, adverse impacts will also affect cultural heritage receptors in association with cable trenching. Jack-up legs and/or anchoring may also impact adversely upon cultural heritage receptors on or shallowly buried under, the seabed through physical damage

89 During decommissioning the cable routes will primarily be buried and/or cut and left *in situ*. In some cases it may be necessary to remove cables which would be done involving excavation of the cable route by similar methods to the construction phase. Assuming that the same area of seabed that was impacted during the laying of the cables in the construction phase was excavated to remove a cable then the impacts to cultural heritage receptors would already have taken place. However, there may be secondary impacts from the vessel footprint from jack-up legs or anchoring in surrounding areas of seabed not previously affected.

90 During decommissioning wind turbine foundations are to be cut and/or craned from the seabed. Assuming that this does not disturb additional areas of seabed out with that affected by construction activities, adverse impacts may be restricted to secondary impacts from vessel footprints.

Known Wreck Sites

91 There is one known wreck site (WA 7071), and one seabed feature (WA 7072) which may be wreck debris in the MSA. Both have been verified by geophysical assessment and characterised as being *Anthropogenic origin of archaeological interest* (Wessex Archaeology 2011).

92 The single known wreck (WA 7071) is unidentified; thus importance cannot be currently assessed. The scale of the impact assessment is therefore site-specific in this case.

93 Cable trenching between wind turbine locations 8 and 9, 8 and 11 and 8 and 5 pass within around 40 m of the wreck location where buried debris may be located. There may also be positional uncertainties associated with both the position of the survey vessel at the time of data capture, and also in the position of the trenching machinery suggesting a cautious approach is advisable with this receptor (Figure 1 and 2).

94 The footprint of a gravity base foundation (40 m diameter) at Wind Turbine 8 would pass within around 40m of the wreck location where buried debris may be located. Once the skirt (up to 2m) and if an unknown width of scour protection is added, the proximity of to the wreck site may ultimately be as little as a few metres (Figure 1). There may also be positional uncertainties associated with both the position of the survey vessel at the time of data capture, and also the position of the installation vessels suggesting a cautious approach is advisable with this cultural heritage asset.

95 Depending upon the particular foundation construction methods and footprint of service vessels during operation, maintenance and decommissioning the likely interaction between this receptor and adverse impacts is likely to be high on a site-specific scale.

96 There may be secondary adverse impacts from the vessel footprint from jack-up legs or anchoring.

97 The redistribution of sediment from development activities is likely to be a beneficial impact as the protective covering of sediment is slightly increased where sediment settles out from the water column.

98 The potential impact has been assessed of **high** magnitude, **high** sensitivity and therefore of ***major*** significance.

Unknown Wreck Sites

99 There are large numbers of *recorded losses* (vessels thought to have been lost in the region, but without accurate recorded locations) in the vicinity of the MSA (Wessex Archaeology 2011). Following geophysical assessment of the seabed, the level of interaction between this receptor and impacts is thought to be low. However, there are significant numbers of magnetic anomalies on the seabed and particularly a medium-sized magnetic anomaly (WA 7070). The importance of this anomaly cannot currently be assessed but it is in close proximity to the proposed location of Wind Turbine 3 and could represent ferrous debris from an unknown wreck site.

100 The redistribution of sediment from development activities is likely to be a beneficial impact as the protective covering of sediment is slightly increased where sediment settles out from the water column.

101 The potential impact has been assessed of **low** magnitude, **high** sensitivity and therefore of ***minor*** significance.

Table 8: Summary of Significance of adverse impacts upon maritime archaeology receptors

Theme	Receptor	Spatial Extent of Effect	Duration of Effect	Recoverability of the Receptor	Importance of the Receptor	Sensitivity of the Receptor	Magnitude of Effect	Significance of Impact
Maritime Archaeology	Known wreck sites	Site-specific	Permanent	None	High	High	High	**Major**
	Unknown wreck sites	Local	Permanent	None	Low	High	Low	**Minor**

Table 9: Summary of Significance of beneficial impacts upon maritime archaeology receptors

Theme	Receptor	Spatial Extent of Effect	Duration of Effect	Recoverability of the Receptor*	Importance of the Receptor	Sensitivity of Receptor	Magnitude of Effect	Significance of Impact
Maritime Archaeology	Known wreck sites	Site specific	Temporary to long-term	-	Medium	Low	Low	Negligible
	Unknown wreck sites	Local	Temporary to long-term	-	Low	Low	Low	Negligible

* For beneficial impacts such as sediment redeposition settling from the water column onto cultural heritage receptors (Table 5), recoverability is not applicable.

Mitigation

102 Avoidance is seen as the primary method of mitigation for offshore developments (Wessex Archaeology 2007) where this is not practicable other methods may be required. Local and national curators may request specific mitigation strategies in line with current planning policies.

103 A finds reporting protocol should be adopted in order to record any material of potential archaeological interest discovered during all phases of development activity. A protocol for offshore developments has recently been commissioned and published by the Crown Estate (The Crown Estate/Wessex Archaeology 2010). Information from reported finds serves to enhance the National Monuments Record and allows more informed and effective management of offshore cultural heritage assets for the benefit of industry, heritage and the public.

104 A precautionary exclusion zone of 50 m around the visible extent of the wreck and debris is proposed in order to avoid inadvertent adverse impact to cultural heritage assets WA 7071 and WA 7072 during all phases of the project before their importance can be determined (Dix *et al*. 2007). As the wreck is

unidentified and importance cannot currently be assigned, importance is classified as **high** as a precautionary approach.

105 These precautionary exclusion zones also provide a buffer in case of positional uncertainties associated with both the position of the survey vessel and towfish at the time of geophysical data capture, and also the position of the trenching machinery.

Inter-array and export cabling

106 The inter-array cable routes between Wind Turbine 8 and 9, 8 and 11 and 8 and 5 intersect the precautionary exclusion zones, passing around 40m from the wreck position (WA 7071) (Figure 1 and 2).

107 The network of inter-array cabling routes indicates there will be repeated direct impacts from these networks of trenches. Mitigation strategies set out above for maritime archaeology receptors may offset repeated adverse impacts form the inter-array cable trenching as known wreck assets have been verified by geophysical survey.

108 Avoidance of the identifiable maritime archaeological receptors could most effectively be achieved by routing the export cabling through the area without geophysical anomalies in the south-west of the MSA (Wessex Archaeology 2011: Figure 4).

109 Further research could be undertaken on the unidentified wreck (WA 7071). The site may be unobtrusively examined by Remotely Operated Vehicle (ROV) or diver survey of the wreck site to ascertain more clearly the type, likely age, identity and importance. Integrating this with other necessary activities such as geotechnical sampling and other early-stage engineering works could provide a cost-effective solution. If the importance of the wreck can be gauged from this kind of survey, further mitigation strategies could be developed or requested by the local or national curators.

110 Up to four export cable routes are proposed passing through the same region of the MSA, but constrained between the Maritime and Coastguard Agency designated anchorage to the south, the proposed wind turbine locations to the north-east and the Blackdog Rifle range and seabed cables within the rifle range exclusion zone. They will be an area roughly 250m wide at the narrowest point. The volume of sediment removed by export cable trenching will be concentrated here, potentially creating increased significance of impact in this area. Known wrecks are absent from this region and the geophysical assessment indicates a lack of seabed anomalies. Sub-seabed palaeolandscape features are also restricted to the south. There is potential for isolated prehistoric finds within the sub-seabed sediments. A geotechnical/geoarchaeological assessment outlined above may serve as a form of mitigation for cumulative impacts to prehistoric archaeology receptors that may be encountered by export cable trenching.

111 Where redeposited sediment volumes may be more significant, such as at the margins of cable trenches, the beneficial impact of protection may reach a level where the added overburden could damage cultural heritage assets, particularly wrecks and aircraft. The suggested mitigation strategies outlined here, especially avoidance and precautionary exclusion zones, would be sufficient to prevent the beneficial impact of sediment redeposition becoming an adverse impact upon cultural heritage assets.

Wind Turbine foundations

112 Mitigation may be achieved by micro-siting the entire footprint of Wind Turbine 8 out with the precautionary exclusion zones around WA 7071 and 7072 and as a result, the inter-wind turbine cabling too. Depending upon the type of foundation and width of scour protection necessary this may be at least 20 m to the east or south-east. The configuration of inter-wind turbine cabling is relatively flexible and not all of the potential connections between wind turbines will be required. Avoidance may effectively be achieved by appropriate configuration of the cable routes outwith the precautionary exclusion zones.

113 Assuming a worst realistic case, a gravity base structure up to 40 m in diameter at the seabed with skirting and an unknown, site-specific width of scour protection would extend close to the wreck site (WA 7071). If damage is likely to occur by entering the precautionary 50 m exclusion zones then a thorough assessment of the wrecks importance is advised.

114 Repeated direct impacts will occur where cable routes and wind turbine foundations are connected. Generally the significance of impact is not thought to increase from those cited for unknown cultural heritage receptors. In site-specific cases where known cultural heritage assets are involved, i.e. wreck site (WA 7071). Both inter-array cable trenching and wind turbine foundation construction in addition to secondary impacts from attending vessel footprints may, without mitigation, repeatedly and significantly adversely impact this unidentified wreck adjacent to Wind Turbine 8 (Figure 1).

Residual Impacts

115 If avoidance of the unidentified wreck (WA 7071) and debris (WA 7072) by micro-siting Wind Turbine 8, and by association the inter-array cabling routes that could be connected to Wind Turbine 8, is undertaken then there should be no direct and likely no indirect adverse impacts upon this cultural heritage receptor.

116 If it is decided to inspect the site under a WSI in order to identify the type, identity and therefore archaeological importance of the wreck then further mitigation strategies will have to be proposed. The wreck represents a physical hazard to trenching machinery and therefore avoidance would appear to be the preferred mitigation strategy as there may be buried debris in the vicinity of the wreck.

117 After mitigation the impacts would be of ***minor-negligible*** significance

Cumulative Impacts

- **Other Offshore Wind Developments**
  - There are no other existing or planned offshore wind farm developments in the vicinity of the MSA.
- **Maritime and Coastguard Agency Designated Anchorage**
  - Abutting the MSA to the south is the MCA Designated Anchorage (Figure 1 and 2). Cumulative impacts from anchoring within this area are unlikely to impact upon Maritime Archaeology Receptors in conjunction with vessel footprints from the EOWDC project if mitigation is undertaken. Consultation with the Aberdeen Harbour Board has already been recommended in Scoping Opinion (Marine Scotland 2011).
- **Commercial Fisheries Activity**

- There may be cumulative impacts in association with commercial fisheries activities that impact the seabed, such as trawling. However, more likely in this nearshore area would be inshore fisheries activities. Scoping for the development indicates some minor fishing vessel activity in the vicinity of the MSA, partially linked to the designated anchoring area or passage en-route to other areas rather than concentrated fishing activities (AOWF 2010: Figure 14).
- It is considered that cumulative impacts are likely to be of ***low*** significance.

- **Subsea Cables**
  - Subsea cables are present within the Blackdog Rifle range exclusion zone but impacts to cultural heritage receptors from that past development are unknown and no assessment can currently be made.
- **Port/harbour Dredging Operations**
  - Dredging activities may be undertaken for the maintenance of Aberdeen Harbour to the south of the MSA. Archaeological assets are likely to have been already be removed and impacted by earlier phases of sediment removal. New areas of dredging will be required to undergo EIA and define mitigation strategies.
- **Proposed Ocean Laboratory, EOWDC**
  - The installation of an Ocean Laboratory to the south-west of Wind Turbine 1 (shown on Figure 1 and 2) would lead to cumulative impacts of a site-specific nature. Following geophysical assessment there appears to be no anomalies or known cultural heritage assets in the given location. Cumulative impacts may be of *minor* significance depending upon the type of the foundation used for the (spatial extent and volume of seabed sediment disturbed or removed) and cable linkages to other elements of the proposed development.
  - There are no known wrecks in the location of the proposed ocean laboratory and therefore no significant impacts.
  - Following geophysical assessment the potential impact upon *unknown wreck sites* has been assessed of **low** magnitude, **high** sensitivity and of ***minor*** significance.
  - After mitigation the impacts would be of ***negligible*** significance.

Monitoring

118 ROV or suitably qualified divers may provide sufficient monitoring of enacted mitigation strategies. Geophysical survey could also be applied to monitor any development in seabed scour and other impacts to known wreck receptors.

1.3.2.2 <u>*Operational Phase*</u>

Potential Impacts

119 Operational impacts are likely to be restricted to secondary impacts invoked by vessel footprint. Jack-up legs and/or anchoring may also impact adversely upon cultural heritage receptors on or shallowly buried under, the seabed through physical damage. The significance may be reduced as impacts would already have occurred during the construction phase.

Mitigation

120 Mitigation during construction phase would already apply (see page 21).

Residual Impacts

121 As construction and decommissioning phase (see page 23).

Cumulative Impacts

122 As construction and decommissioning phase (see page 23).

Monitoring

123 As construction and decommissioning phase (see page 24).

1.3.3 Impacts on Aviation Archaeology

1.3.3.1 Construction & Decommissioning Phase

Potential Impacts

- Adverse, direct damage to both *in situ* cultural heritage assets and assets in secondary contexts
- Adverse, direct disturbance of relationships between structures, artefacts and their surroundings or contexts
- Adverse, indirect destabilisation and erosion of sites through changes to seabed characteristics
- Beneficial, indirect burial of sites due to re-deposited sediment, potentially protecting and promoting the favourable preservation of cultural heritage receptors

Secondary Impacts

- Produced by vessel footprints; direct, adverse impacts will also affect cultural heritage receptors in association with cable trenching. Jack-up legs and/or anchoring may also impact adversely upon cultural heritage receptors on or shallowly buried under, the seabed through physical damage.

124 During decommissioning the cable routes will primarily be buried and/or cut and left *in situ*. In some cases it may be necessary to remove cables which would be done involving excavation of the cable route by similar methods to the construction phase. Assuming that the same area of seabed that was impacted during the laying of the cables in the construction phase was excavated to remove a cable then the impacts to cultural heritage receptors would already have taken place. However, there may be secondary impacts from the vessel footprint from jack-up legs or anchoring in surrounding areas of seabed not previously affected.

125 During decommissioning wind turbine foundations are to be cut and/or craned from the seabed. Assuming that this does not disturb additional areas of seabed out with that affected by construction activities, adverse impacts may be restricted to secondary impacts from vessel footprints.

Unknown Aircraft Crash Sites

126 There are currently no records of aircraft crash sites within the MSA (Wessex Archaeology 2011).

127 There is potential for aircraft crash sites and debris to be present in the MSA (Wessex Archaeology 2008) based on significant numbers of magnetic anomalies on the seabed and particularly WA 7070, adjacent to Wind Turbine 3. Such remains would automatically be protected under the PMRA 1986 (Wessex Archaeology 2011).

128 Importance cannot currently be assessed but the potential for encountering unknown crash sites following the geophysical assessment is gauged to be low.

129 The redistribution of sediment from development activities is likely to be a beneficial impact as the protective covering of sediment is slightly increased where sediment settles out from the water column.

130 The potential impact has been assessed of **low** magnitude, **high** sensitivity and therefore of ***minor*** significance.

Table 10: Summary of Significance of adverse impacts upon aviation archaeology receptors

Theme	Receptor	Spatial Extent of Effect	Duration of Effect	Recoverability of the Receptor	Importance of the Receptor	Sensitivity of the Receptor	Magnitude of Effect	Significance of Impact
Aviation Archaeology	Unknown aircraft crash sites	Regional	Permanent	None	Low	High	Low	**Minor**

Table 11: Summary of Significance of beneficial impacts upon aviation archaeology receptors

Theme	Receptor	Spatial Extent of Effect	Duration of Effect	Recoverability of the Receptor*	Importance of the Receptor	Sensitivity of Receptor	Magnitude of Effect	Significance of Impact
Aviation Archaeology	Unknown aircraft crash sites	Regional	Temporary to long-term	-	Low	Low	Low	Negligible

* For beneficial impacts such as sediment redeposition settling from the water column onto cultural heritage receptors (Table 5), recoverability is not applicable.

Mitigation

131 Avoidance is seen as the primary method of mitigation for offshore developments (Wessex Archaeology 2007) where this is not practicable other methods may be required. Local and national curators may request specific mitigation strategies in line with current planning policies.

132 A finds reporting protocol should be adopted in order to record any material of potential archaeological interest discovered during all phases of development activity. A protocol for offshore developments has recently been commissioned and published by the Crown Estate (The Crown Estate/Wessex Archaeology 2010). Information from reported finds serves to enhance the National Monuments Record and allows more informed and effective management of offshore cultural heritage assets for the benefit of industry, heritage and the public.

Residual Impacts

133 If avoidance of the anomaly WA 7070 is undertaken then there should be no direct and likely no indirect adverse impact upon this feature of possible archaeological interest.

134 If it is decided to inspect the site to attempt identification of the anomaly and therefore archaeological importance of the feature then further mitigation strategies will have to be proposed.

135 After mitigation the impacts would be of ***minor-negligible*** significance.

Cumulative Impacts

- **Other Offshore Wind Developments**
  - There are no other existing or planned offshore wind farm developments in the vicinity of the MSA.
- **Maritime and Coastguard Agency Designated Anchorage**
  - Abutting the MSA to the south is the MCA Designated Anchorage (Figure 1 and 2). Cumulative impacts from anchoring within this area are unlikely to impact upon Aviation Archaeology Receptors in conjunction with vessel footprints from the EOWDC project if mitigation is undertaken. Consultation with the Aberdeen Harbour Board has already been recommended in Scoping Opinion (Marine Scotland 2011).
- **Commercial Fisheries Activity**
  - There may be cumulative impacts in association with commercial fisheries activities that impact the seabed, such as trawling. However, more likely in this nearshore area would be inshore fisheries activities. Scoping for the development indicates some minor fishing vessel activity in the vicinity of the MSA, partially linked to the designated anchoring area or passage en-route to other areas rather than concentrated fishing activities (AOWF 2010: Figure 14).
  - It is considered that cumulative impacts are likely to be of ***low*** significance.
- **Subsea Cables**
  - Subsea cables are present within the Blackdog Rifle range exclusion zone but impacts to cultural heritage receptors from that past development are unknown and no assessment can currently be made.
- **Port/harbour Dredging Operations**
  - Dredging activities may be undertaken for the maintenance of Aberdeen Harbour to the south of the MSA. Archaeological assets are likely to have been already be removed and impacted by earlier phases of sediment removal. New areas of dredging will be required to undergo EIA and define mitigation strategies.
- **Proposed Ocean Laboratory, EOWDC**
  - The installation of an Ocean Laboratory to the south-west of Wind Turbine 1 (shown on Figure 1 and 2) would lead to cumulative impacts of a site-specific nature upon the unknown *aviation crash sites*. Following geophysical assessment there appears to be no anomalies or known cultural heritage assets in the given location. Cumulative impacts may be of minor significance depending upon the type of the foundation used for the (spatial extent and volume of seabed sediment disturbed or removed) and cable linkages to other elements of the proposed development. Assuming a GBS is used under the worst case scenario the magnitude of impact upon *unknown aircraft crash sites*, buried in the GBS footprint would be of high magnitude.
  - The potential impact upon unknown aircraft crash sites has been assessed of **low** magnitude, **high** sensitivity and therefore of ***minor*** significance.

- o Following mitigation outlined above specifically incorporating a finds reporting protocol this impact may be reduced to ***negligible*** significance.

Monitoring

136 ROV or suitably qualified divers may provide sufficient monitoring of enacted mitigation strategies. Geophysical survey could also be applied to monitor any development in seabed scour and other impacts to identified anomalies such as **WA 7070** in the vicinity of Wind Turbine 3.

1.3.3.2 <u>Operational Phase</u>

Potential Impacts

137 Operational impacts are likely to be restricted to secondary impacts invoked by vessel footprint. Jack-up legs and/or anchoring may also impact adversely upon cultural heritage receptors on or shallowly buried under, the seabed through physical damage. The significance may be reduced as impacts would already have occurred during the construction phase.

Mitigation

138 Mitigation during construction phase would already apply (see page 27).

Residual Impacts

139 As construction and decommissioning phase (see page 27).

Cumulative Impacts

140 As construction and decommissioning phase (see page 28).

Monitoring

141 As construction and decommissioning phase (see page 29).

1.3.4 EOWDC Future Research and Monitoring Opportunities

142 There would be beneficial research opportunities for assessing the nature and potential of submerged palaeo-landscapes of archaeological potential from geotechnical samples associated with the wind turbine locations and cable routes. This work would provide added value on local, regional and potentially national scale, to the development through publication in scientific, international journals and dissemination by other types of media to a broad audience of the public and specialists.

143 The unidentified wreck (WA 7071) also provides an opportunity to develop the study of maritime wreck sites where nothing is known about the vessel in question. This work would provide added value to the development through improving the historic environment records, publication in scientific, international journals and dissemination by other types of media to a broad audience of the public and specialists. Additionally, data from ongoing monitoring of the wreck, in conjunction with ecological monitoring for example, would provide ongoing sources of data for research and collaborative projects.

1.3.5 Summary of Impact Assessment

Table 12: Impact Assessment – Adverse Impacts

Potential Impact / Activity	Sensitivity of Receptor	Scale	Duration	Spatial Extent	Magnitude of Effect	Significance	Mitigation	Significance after Mitigation	Monitoring	Cumulative Impacts
Construction – Cable Trenching, Wind Turbine Foundations & Secondary Impacts from Vessel Seabed Footprints										
Post-glacial submerged landscape features	High	Medium	Long-term	Site-specific to Local	Medium	Moderate	Avoidance, Reporting protocol	Minor	Geophysical survey, ROV, finds reporting protocol	Existing subsea cabling, MCA anchorage, inshore fisheries, ocean lab
Isolated prehistoric sites & finds	High	Medium	Long-term	Local	Medium	Moderate	Reporting protocol	Minor	Geophysical survey, ROV, finds reporting protocol	Existing subsea cabling, MCA anchorage, inshore fisheries, ocean lab
Known wreck sites	High	High	Long-term	Site-specific	High	Major	Avoidance, Research, Reporting protocol	Minor	Geophysical survey, ROV, finds reporting protocol	-
Unknown wreck sites	High	Low	Long-term	Local	Low	Minor	Reporting protocol	Minor	Geophysical survey, ROV, finds reporting protocol	Existing subsea cabling, MCA anchorage, inshore fisheries, ocean lab

1.4 Summary

144 Impacts to cultural heritage receptors have been assessed for the proposed EOWDC.

145 The significance of adverse impacts to potential prehistoric archaeology receptors, *isolated prehistoric sites and finds* and *submerged landscape features*, are assessed to be moderate. Following mitigation the significance of impacts is likely to be minor.

146 Adverse impacts relating to the damage and disturbance of known cultural heritage assets have been identified primarily with respect to the unidentified wreck (WA 7071) in close proximity to Wind Turbine 8 and associated inter-array cable routes between Wind Turbines 8 and 9, 8 and 11 and 8 and 5 (Figure 1). Without mitigation adverse impacts to this heritage asset are likely to be major. With mitigation, impacts may be avoided or significantly reduced. Further research and site inspection of this feature may be an effective method for ascertaining the archaeological importance of this unidentified wreck and ultimately the most appropriate methods for impact mitigation.

147 The significance of adverse impacts to potential maritime archaeology and aviation archaeology receptors – *unknown wreck sites* and *unknown aircraft crash sites* – are assessed to be moderate. Following mitigation the significance of impacts is likely to be minor.

148 Avoidance, where practicable, is the preferred mitigation strategy for known cultural heritage assets. Minor amendments to the position of cable trenching and the configuration or placement the foundation of Wind Turbine 8 have been outlined.

149 There is potential for encountering previously unknown archaeology in the MSA (defined in the archaeological baseline technical report prepared by Wessex Archaeology for Aberdeen Offshore Wind Farm Ltd in 2011). Strategies have been proposed to mitigate adverse impacts to these receptors.

150 Research, particularly the geoarchaeological examination of vibrocores and grab samples from sub-seabed sediments, taken for engineering or other development purposes provides a cost-effective mitigation strategy to directly investigate the age and archaeological potential of sub-seabed sediments of potential prehistoric archaeological importance. The integration of this kind of geoarchaeological analysis early in sequence of development activities is advisable to provide the most effective mitigation strategy (Gribble and Leather 2011).

151 Monitoring may be achieved through remote means such as geophysical or ROV survey. In addition, the Crown Estate has recently published a reporting protocol for finds from offshore developments (The Crown Estate/Wessex Archaeology 2010). Best-practice and effective monitoring may be partly achieved by implementing this protocol. Added value will also be provided to the National Monuments Record.

Version: 1.4

Version date: 21st June 2011

Comment FINAL

This document has been prepared and checked in accordance with ISO 9001:2000.

1.0 Introduction

This Baseline Technical Report sets out the existing seascape, landscape, and visual environments within an agreed study area and assesses their sensitivity to the type of change proposed. The EIA Technical Report will then determine the magnitude and significance of any change to the character of the identified regional seascape, landscape, and any areas of designated landscapes, as well as assess the potential effect upon views, visual amenity and receptor groups, and cumulative effects within the overall Zone of Theoretical Visibility (ZTV).

1.1. The Proposed Development

The lease boundary for the proposed European Offshore Wind Deployment Centre (EOWDC) covers an area of up to 20 km^2 and is located approximately 2 km east of the nearest landfall on the Aberdeenshire coast.

The deployment centre will have 11 wind turbines between 4 MW and 10 MW. The scheme has undergone numerous iterations since 2005 in terms of location and number of turbines which are discussed in the Environmental Statement (ES). The nature of the deployment centre is that it will comprise first of run turbines which may result in turbines of different heights. For the purposes of the SLVIA (e.g. ZTV, photomontages) the dimensions of the turbines have been agreed with the consultees to be assessed at the worst case scenario which is eleven 10 MW turbines with a hub height of 120 m and blade tip height of 195 m above lowest astronomical tide (LAT). As with all developments, there will be need to be an allowance for micro-siting which in this case may be up to 100m for each turbine.

It is not envisaged that the final mix of turbine heights will result in a height difference that is greater than 20-35 m between turbines. Any differences may be noticeable at closer distances and the assessment will take this into consideration. Please see Volume 3 of the ES for a figure showing a detailed layout.

An Ocean Laboratory, which could be an offshore structure associated with the deployment centre, would be subject to a separate planning application and will not be assessed as part of this seascape, landscape and visual impact assessment (SLVIA). However, as it is a foreseeable development it has been considered as part of the cumulative assessment.

Whilst the majority of the development is located offshore, the completed scheme will also require various onshore elements, including a cable route and an electricity substation. The assessment of all onshore elements associated with the proposed EOWDC and the respective effects upon the landscape, its character and constituent features and the level of visual effect will be addressed separately within the Onshore Environmental Statement and the supporting Landscape and Visual Assessment technical report. Reference is made to the anticipated effects of the construction of offshore elements in section 6.0 of the SLVIA EIA Technical Report.

1.2. The Study Area

It is accepted practice within seascape, landscape and visual assessment work that the extent of the study area is broadly defined by the visual envelope, or the Zone of Theoretical Visibility (ZTV), of the proposed development. The visual envelope represents the area of land and/or sea from within which it may be possible to see any part of the proposed development.

Within the ZTV, the actual extent of visibility of a proposed development then depends upon a variety of factors including the scale of development, the relationship between the viewpoint and the development itself, the context within which the development is seen and the prevailing weather conditions existing at any one time. To cover all the potentially significant seascape, landscape and visual effects, a 40 km radius study area around the proposed offshore wind deployment centre was agreed with Scottish Natural Heritage (SNH).

In order to undertake a full and robust assessment of the actual effects, and to assess the realistic worst-case scenario for the EOWDC development, the assessment also considers all onshore wind farms (existing, consented and in-planning) within a 60 km radius of the EOWDC. There are no other offshore wind farms within the study area. The sensitivity to change of the seascape, landscape and visual receptors has been assessed on the assumption that the consented wind farms have already been constructed.

1.3. Methodology Consultation

SNH, Aberdeen City Council (ACC), and Aberdeenshire Council (AC) were consulted from the outset with respect to the assessment methodology, study areas, viewpoint locations, and cumulative scope. Table 1.1 below gives a summary of the key consultation stages and dates. Please refer to Appendix 1 for a detailed record of consultation. The agreed methodology used within this assessment is detailed in Appendix 2.

Table 1.1 Summary of Consultation

Key Consultation Dates	Information
24th November 2009	Issue to all consultees of proposed 14 viewpoints, proposed 35km study area, SLVIA methodology including cumulative methodology, proposed cumulative sites and ZTVs.
19th December 2009	SNH response with advice on methodology, viewpoint options and study areas.
14th April 2010	Meeting with AC, ACC and SNH at SNH Offices, Aberdeen.
23rd April 2010	Meeting notes and revised viewpoint list issued incorporating all comments from meeting on 14.04.10.
28th May 2010	Revised Meeting Notes issued.
August 2010	EOWDC Request for Scoping Opinion Seascape, Landscape and Visual section highlighting approach, viewpoints and 35km study area.
29th September 2010	EOWDC Scoping Opinion – SNH response Suggestions on approach including relevant guidance and possible areas for inclusion as viewpoints and part of the study.
19th October 2010	Issue to all consultees of detailed ZTV, large scale 35km study area ZTV and viewpoint list including city centre viewpoints for review following the project layout changes.
29th October 2010	Revised viewpoint list issued to all consultees to include changes following site visit.
9th November 2010	Response from SNH to October 2010 information issued; agreement on viewpoints list with specific comments on cumulative assessment of viewpoints.
13th December 2010	Issue to all consultees of proposed cumulative methodology including sequential cumulative approach and methodology statement covering turbine phasing, turbine heights, and Ocean Laboratory.
24th January 2011	Response from SNH agreeing to the cumulative methodology, querying study area size, agreeing to Bennachie viewpoint as wireframe only due to weather constraints, and suggestion of Menie Estate viewpoint.
25th and 28th January 2011	Discussion emails on study area with SNH.
22nd February 2011	SNH response requesting 40km study area.
25th March 2011	Email to SNH for confirmation of agreement to methodologies and study area.
7th April 2011	SNH response confirming receipt of information and acceptance of 40km study area.

1.4. Key Guidance Documents

Key guidance documents that have informed the SLVIA include:

- Maritime Ireland/Wales Interreg 1994 – 1999 Guidance 'Guide to Best Practice in Seascape Assessment' (GSA, March 2001).
- 'An assessment of the sensitivity and capacity of the Scottish Seascape in relation to wind farms', (SNH commissioned Report 103, 2005).
- Guidance on the Assessment of Effect of Offshore Wind Farms: Seascape and Visual Effect Report (DTI – November 2005).
- Guidelines for Landscape and Visual Effect Assessment (Institute of Environmental Management and Assessment (IEMA) and the Landscape Institute's (LI), second edition 2002).
- Visual Representation of Windfarms Best Practice Guidance (SNH 2006, albeit published in 2007).
- Cumulative Effects on Windfarms, (SNH, 2005).
- Siting and Design of Windfarms, (SNH, December 2009).

1.5. Data Information and Sources

Table 1.2 below records the main survey information and site study data which were used in this baseline assessment.

Table 1.2 Summary of data and sources

Survey/Study	Date of Survey	Description
Seascape/landscape baseline assessment and viewpoint search.	April and October 2010	Land based driving and walking landscape character assessment of study area and establishment of locations of appropriate viewpoints.
Beaches of Northeast Scotland (SNH Commissioned Report)	1977	Environmental inventory of sand beaches, dunes and associated coastal areas of the coastline of the Moray Firth from Inverness eastwards and of the North Sea coast northwards from Inverbervie.
Landscape Character Assessment of Aberdeen (SNH)	1996	Landscape Character Assessment
South and Central Aberdeenshire: Landscape Character Assessment (SNH)	1998	Landscape Character Assessment
Banff & Buchan Landscape Assessment (SNH)	1994	Landscape Character Assessment

2.0 Landscape and Seascape Policy Context

The proposed site is located within offshore coastal waters under the jurisdiction of The Crown Estate. Within the 40 km study area there are only two councils; Aberdeenshire Council and Aberdeen City Council. Please refer to Figure 1 for the site location plan.

This section of the report identifies the relevant national and local planning policy and those statutory and non-statutory designations that apply to the study area that may be relevant to the development and landscape/seascape and visual issues. Refer to Figures 2 and 3 for an illustration of the landscape policy context

2.1. Renewable Energy

The Scottish Government has recently revised its planning statements. Scottish Planning Policy (SPP) is now one document that encompasses all the nationally important land use planning matters, including renewable energy, coastal planning, natural heritage, and historic environment. Relevant to the scheme as a whole, the extracts of the policy document discussed below provide an important overview with reference to more detailed areas pertinent to the SLVIA.

Scottish Planning Policy 'Renewable Energy' (paras. 182 – 192) sets out how the planning system should support the development of renewables and the development of spatial frameworks taking into consideration the many relevant factors including landscape and visual effects. Specifically under the heading Wind Farms, it states that '*Planning authorities should support the development of wind farms in locations where the technology can operate efficiently and environmental and cumulative impacts can be satisfactorily addressed' and 'the design and location of any wind farm development should reflect the scale and character of the landscape. The location of turbines should be considered carefully to ensure that the landscape and visual impact is minimised*'.

At a more local scale, Aberdeen Local Plan (2008) identifies its renewable energy policies under **Policy 22: Energy and Development**:

'Renewable energy development is acceptable in principle provided that …there is no significant impact on the character and amenity of the surrounding landscape or residential properties or on the ecology of the area'

2.2. Green Belt

The purpose of Green Belt allocations is to maintain landscape setting, leisure, recreation and green space. The location of the green belt in relation to Aberdeen and its setting is important, but for the purposes of this assessment it is not a consideration as the EOWDC will have no direct impact upon the green belt nor result in any compromise of its 'openness'.

2.3. Landscape Designations

SPP 'Landscape and Natural Heritage' (paras 125 – 141) gives guidance on how the Government's policies for the conservation and enhancement of Scotland's natural heritage should be reflected in land use planning. It outlines the aims of national and local landscape and natural heritage designations.

'Different landscapes will have a different capacity to accommodate new development, and the siting and design of development should be informed by local landscape character.'

'Landscapes and the natural heritage are sensitive to inappropriate development and planning authorities should ensure that potential effects, including the cumulative effect of incremental changes, are considered when preparing development plans and deciding planning applications. While the protection of the landscape and natural heritage may sometimes impose constraints on development, with careful planning and design the potential for conflict can be minimised and the potential for enhancement maximised.'

Under the above national policy the Aberdeenshire Local Plan (2006) has identified National Scenic Areas and Areas of Landscape Significance with the following policies;

Policy Env 5A, National Scenic Areas

Policy Env 5B states that *'Development that would have an adverse effect on a National Scenic Area will be refused unless the developer demonstrates:*

a) any significant adverse effects on the quality for which the area has been designated are clearly outweighed by social and economic benefits of national importance;

b) the objectives of the designation and overall integrity of the area will not be compromised.'

There are no National Scenic Areas within the study area, but two National Scenic Areas lie just beyond at Deeside & Lochnagar; and the Cairngorm Mountains. These areas are now part of the Cairngorms National Park so will be protected under the National Park designation. The areas are not included within the assessment but they are important to acknowledge with regards to the adjacent Areas of Landscape Significance which lie within the study area.

Policy Env 5B, Areas of Landscape Significance

Policy Env 5B states that *'Development within or adjacent to an Area of Landscape Significance will not be permitted where its scale, location or design will detract from the quality or character of the landscape, either in part or as a whole.'*

The closest Area of Landscape Significance (ALS) to the proposed development is on the coast, extending from Balmedie to south of Peterhead, and extending from Peterhead along the north coast. The coast to the south of Aberdeen, from Findon beyond Stonehaven is also designated as an ALS. Inland there are several ALSs, most of which are concentrated at the western edge of the study area adjacent to the Cairngorms National Park. However, there are some smaller inland ALS closer to the coast such as at Hatton of Fintray, north of Dyce, north west of Methlick, and along Deeside to the south of Aberdeen. To the south west limits of the study area an ALS covers a large area around Drumtochty Forest. The Areas of Landscape Significance within the study area are identified on Figure 2.

Aberdeen Local Plan (2008) Policy 31 – Landscape Protection outlines the objectives for retaining the landscape setting of Aberdeen.

Policy 31: Landscape Protection

Policy 31 states that: '*One of the objectives of planning for future development will be to maintain and manage aspects of Aberdeen's unique landscape setting. Development will not be acceptable unless it avoids:*

1. adversely affecting landscape character and elements which contribute to, or provide, a distinct 'sense of place' which point to being either in or around "Aberdeen" or a particular part of it;

2. obstructing views of the City's townscape, landmarks and features when seen from publicly accessible vantage points such as roads, railways, recreation areas and pathways and particularly from the main city approaches or 'gateways';

3. disturbance, loss or damage to recognised recreation, wildlife or woodland resources or to the physical links between them;

4. sprawling onto green spaces or buffers between places or communities with individual identities, and those which can provide opportunities for countryside activities.

'All developments shall respect the quality of the local landscape character and contribute towards its maintenance and enhancement in terms of siting, scale, massing, colour, design, density, orientation, materials, planting/ landscaping and boundary treatment. They should otherwise be capable of being absorbed within sites without significant adverse impacts upon existing landscape elements, including linear and boundary features or other components, which contribute to local amenity, and provide opportunities for conserving, restoring or enhancing them.'

These are key points relating to any development including the EOWDC and as part of this SLVIA the potential effects that the development may have on the landscape character will be assessed.

2.4. Historic Environment

The scope of this assessment does not cover the effects of the proposed development on individual Conservation Areas and other historic built features or their settings. These are discussed in the Cultural Heritage Assessment of the EOWDC. The general distribution of historic features and landscapes are however considered, as collectively they contribute to informing judgments on the character, historic importance and quality of the landscape. The overall effect of the development on the historic environment in so far as it contributes to defining the character of the landscape resource is also assessed. Coordination with the Cultural Heritage consultants was also undertaken so as to ensure clear separation of areas of responsibility and assessment of effects where relevant.

Conservation Areas and Gardens and Designed Landscapes within Aberdeenshire and Aberdeen are illustrated on Figure 2 and 3.The conservation areas are mostly contained to historic village centres and within Aberdeen, a large part of the town centre, Old Aberdeen, and also coastal areas such as Footdee. There are 19 registered Gardens and Designed Landscapes within the 40 km study area, the majority of which lie beyond 15km from the EOWDC. As discussed above, the Cultural Heritage chapter will assess the potential effects on these areas.

2.5. Summary of Landscape Designations and Planning Context

Table 1.3 below summarises the Areas of Landscape Significance within the 40km radius study area. Please refer to the Cultural Heritage chapter for assessment of the historic environment.

Summary Table 1.3 Landscape Designations

Landscape Designations **Areas of Landscape Significance (Aberdeenshire Policy Env 5B)**	**Approximate closest distance from nearest turbine**	**Sensitivity to proposed change**
Balmedie to Longhaven	3.5 km	High
Peterhead to Inverallochy	33 km	High
Findon to Catterline	15 km	High
River Dee Valley	13 km	High
River Don Valley	7 km	High
West of Inverurie	24 km	High
North West of Methlick	30 km	High
Drumtochty to Torphins and surrounds	36 km	High

3.0 Baseline Description

As set out in the DTI (2005) Seascape and Visual Impact Report, every seascape comprises three components: an area of sea (the marine component), a length of coastline (the coastline component); and an area of land (the landward component). Landscape starts at the coastline and includes all areas inland. The landward component of a seascape is the main factor determining the character of the seascape. Whilst landscape assessments are useful in setting out the character of the hinterland, they concentrate on the characterisation of the landward component only and do not generally address the relationship between landward elements and the sea. The seascape units at national and regional scale are therefore discussed below and show the integration of the marine coastline and the hinterland components. The landscape character areas are also discussed in reference to the wider study area.

3.1. Overview of the Wider Study Area

The study area includes a large part of the North East of Scotland which extends along the coast from Kinneff, south of Stonehaven to Crimond, near Peterhead in the north, and inland west to the Grampian Mountains. The city of Aberdeen is the main settlement within the study area on the North Sea coast approximately 5km south west at its closest point to the proposed turbines. Stonehaven and Peterhead are the main coastal towns within the study area and Ellon, Inverurie and Banchory are the main inland towns.

There are three key rivers within the study area; the Dee, Don, and Ythan. The River Dee descends from the Cairngorms to Strathdee (Deeside), and flows to the south west of Aberdeen before finally reaching the North Sea at Aberdeen Harbour. The mouth of the River Don lies to the north of Aberdeen centre between Old Aberdeen and Bridge of Don settlements. Its source is also in the Cairngorms and it winds down to Inverurie where its main tributary, the River Urie joins it. The Ythan River, a shorter course than the Dee and Don, is well known for its bird populations at its estuary which is located approximately halfway between Aberdeen and Peterhead.

The western extents of the study area consist of the fringes of the Cairngorms. This elevated landscape gradually lowers to a gently undulating topography towards the east coast. Large tracts of commercial forestry lie on the higher land and river valleys to the west and south west of the outer limits of the study area. To the north and north west there is predominantly open gently rolling agricultural land with some areas of woodland along river valleys and around estates.

The coastline varies within the study area. To the south of Aberdeen the coast rises to sea cliffs and rocky beaches. Between Aberdeen and the Ythan estuary there are long sandy beaches and sand dunes. Beyond, to the north, the land rises again to give rocky cliff coastline.

3.2. National Seascape Units

There is one national seascape unit 'Area 4: North East Coast' within the study area as identified by the SNH commissioned report (Scott et al, 2005). This comprises two seascape character types 'Mainland Rocky Coastline with Open Sea Views' and 'Deposition Coastline with Open Sea Views'.

The key characteristics of this national seascape unit are stated as;

- *Long, east-facing generally straight coastline with many small indentations and few significant headlands and with open views out to the North Sea;*
- *Mix of long broad sandy beaches backed by dunes and low cliffs/rocky coastline;*
- *Farmland predominantly backs coast; flat and low lying against deposition coast; gently rolling against rocky headlands/cliffs – some remnant heathland in places;*
- *Frequent fishing villages and harbours and several sizable urban settlements; and*
- *Industry is infrequent but large scale where it occurs.*

The SNH document identifies that the openness of sea in views gives a huge scale which turbines could relate well to. It also states that views are largely focused up and down the coast and out to sea rather than inland. However, the study discusses that although generally not a complex landform, in some localised places turbines could conflict with the natural forms of distinctive coastal features.

In conclusion the study gives the 'North East Coast' seascape unit a Low to Medium sensitivity to wind farms. It states '*Although there are a few large scale industrial features on land and the area has locally distinctive and natural coastal features, the simple landform, relatively linear coastline, general absence of focal features and expansive scale of the sea are key factors in limiting sensitivity to development. Turbines would need to be carefully sited to avoid intrusion on the setting of settlements'*

3.3. Regional Seascape Units

In order to understand the seascape in more detail for the assessment, a regional scale of seascape units is considered appropriate. At a regional scale there are no published seascape units. However, as part of this SLVIA, through a combination of fieldwork and desk based study, six regional seascape units have been identified within the 40km study area. Please refer to Figure 4. These units are primarily dictated by the change in coastal features between a deposition coastline and a rocky cliff coastline. In addition, taking into consideration marine, coastal, and coastal hinterland components, the seascape characteristics were defined and are discussed below for each regional unit as well as the key elements that combine to make the overall character distinctive from adjoining seascapes. The visual characteristics are also defined.

To the south of Aberdeen a rocky coastline extends for approximately 35 km to Inverbervie. The 'Beaches of Northeast Scotland' (SNH 1977) report describes this area as having '*high rock forms…stretches of precipitous rock faces…some of the most spectacular coastal scenery to be found anywhere in Scotland*'. The beaches can be described as '*small sandy inlets and strip beaches… often associated with rock platforms and cliff-foot situations*.'

Geologically this part of the rocky north east coast is divided where the red sandstone cliffs to the south are separated from the granite and quartzite cliffs to the north as a result of the Highland Boundary Fault which lies just north of Stonehaven. This is not easily perceivable along the coastline as it remains as steep rough slopes and cliffs alternating with small shingle bays. However, there is a more distinct change in the landform adjacent to the coast at this point. This also coincides with differing settlement patterns and therefore has divided the coastline south of Aberdeen into two seascape units, which are discussed below.

To the north, the national seascape guidance recognises the area between Girdle Ness and Collieston as deposition landscape. For the purposes of this assessment this section of coastline can be divided into two regional seascape units as the influences of Aberdeen city on the southern extents of the coast separates it from the north. North of Collieston the rocky coastline line begins and extends to Peterhead, where is becomes a deposition coastline once again.

3.3.1. Inverbervie to Stonehaven Regional Seascape Unit

This regional seascape unit lies at the southern extents of the study area, approximately 30 km at its closest point to the nearest turbine of the EOWDC and extends approximately 15 km between the towns of Stonehaven and Inverbervie. The coastline between Stonehaven and Catterline has been designated as an Area of Landscape Significance by Aberdeenshire Council (see Figure 2).

Its character is defined by an intermittently settled and often inaccessible rugged coastal edge, with open agricultural land extending inland from the precarious cliff edges. Villages and isolated houses and farms sit on the cliff tops overlooking small shingle bays. The village of Catterline is one of the few settlements which have access to the sea. The old main north-south road (A92) lies close to the coastline (between 1 km and 500 m), and a network of minor roads extends between this and the coast connecting the scattered farms and hamlets.

Although the agricultural land extends beyond 10 km inland to the slopes of the Mounth, the landward extent of this seascape unit only extends up to 2-3 km inland where the topography becomes more rolling and an increase in woodland cover prevents intervisibility with the coast. As a result the landward extent is characterised more frequently by landscape elements rather than by seascape or coastal elements. The rolling landform contributes to restricting views and intervisibility between landscape, coastal edge and the sea. Wind turbines such as the recently built Tullo Wind Farm are visible in views looking back from the coastline but they are beyond the landward extents of the seascape unit.

The rocky cliff coastline with its roughly convex shape gives exposed expansive views out to sea which gives a vast sense of scale. There are limited areas of more intimate enclosed sea views from the small inlets and bays where access is possible.

On the whole, the open, elevated character is generally harmonious although the intricate craggy cliff coastline contrasts with the relatively simplistic agricultural and settlement pattern. It is considered that, with the generally large scale landscape and expansive seaward views, this seascape unit has a Medium sensitivity to the type of change proposed.

3.3.2. Stonehaven to Girdle Ness Regional Seascape Unit

This regional seascape unit extends approximately 20 km north from Stonehaven to Girdle Ness which is a small headland at the eastern edge of Aberdeen city. Girdle Ness lies approximately 8 km from the nearest turbine of the EOWDC. The coastline within this seascape unit from Findon to Stonehaven has been designated as an Area of Landscape Significance by Aberdeenshire Council (see Figure 2).

This seascape unit has an intricate cliff coast similar to that to the south although as it is north of the Highland Boundary fault the coastal geology consists of granites and quartzite. Stacks and arches are common along the cliffs, more so than to the south of Stonehaven due to the different geology. The cliffs are also in places less severe and have a more gradual slope towards the sea.

Also, differentiating it from the seascape unit to the south, it has a much narrower landward extent and is more heavily influenced by settlement and the edge of Aberdeen. North of Stonehaven the foothills of the Grampians extend almost to the coastline and this topography has influenced the settlement pattern to exist within a narrow corridor of land along the coast, with houses right up to the cliff edges. This rolling topography of the foothills close to the coastline also prevents extensive intervisibility of the coast to considerable distances inland.

The main north-south road (A90) and the railway line lie side by side in close proximity to the coastline offering some spectacular cliff and sea views, albeit intermittent due to the rolling topography. From Stonehaven to Muchalls there are very few developments on the seaward side of this transport corridor. It is a slightly more open, flatter landscape here with connections to the sea extending further inland than elsewhere within this unit. North of Muchalls the main road tracks slightly further inland but the railway line remains along the tops of the cliffs before curving round at Nigg Bay to the centre of Aberdeen. Historic fishing villages such as Portlethen and Newtonhill have expanded in size from the cliff edges to now lie between the railway line and A90.

The northern extent of this seascape unit is considerably urban and industrial in nature and combined with the landform the landward extent is still confined to a relatively narrow area. Quarrying, industrial estates, and golf courses are present between Cove Bay and Girdle Ness. The cliffs gradually decline to an open broad sweeping shingle beach at Nigg Bay. Historic elements such as the remains of St Fittick's Church, Torry Battery, and Girdle Ness Lighthouse sit side by side industry and settlements.

Overall, this seascape unit is a relatively densely settled and urbanised area with a narrow landward element due to topography and also elements such as the railway and main A90 road. The unit gets increasingly chaotic towards the north with the industry and settlement dominating. The elevated settlements on the cliff edges are separated directly from the sea but are connected visually. Although there are no wind farms within this RSU, distant views of wind farms are available. Taking into account all these factors it is judged that this regional seascape unit has a Medium to Low sensitivity to the type of change proposed.

3.3.3. Aberdeen Beach Regional Seascape Unit

The Aberdeen Beach seascape unit extends from Girdle Ness to the mouth of the River Don. It is approximately 5 km at its nearest point to the proposed turbines of the EOWDC.

The coastal component of the seascape unit between Girdle Ness and Bridge of Don is heavily influenced by the city of Aberdeen. The harbour is located at the mouth of the River Dee and is sheltered naturally by the Girdle Ness headland. The headland provides elevated viewpoints looking across Aberdeen Bay. Engineering works across the seafront of Aberdeen such as sea walls and groynes have controlled the beach in contrast to the more natural beach and dune systems beyond the Don mouth. However, Aberdeen beach is still very accessible and used all year round, with a variety of facilities and amusements along the beach esplanade.

Behind Aberdeen beach, the Kings Links and what is left of the Queens Links are remnants of the former dune systems and are now a golf course and recreational area respectively. Between the two links areas there is a ridge called Broad Hill which appears as a grassy knoll, as surrounding settlement has reduced its prominence. However, it does provide elevated views across Aberdeen Beach. The landward extent of this seascape unit is mainly confined to the immediate edges of the city and harbour area where views across the coast are predominantly east except from Girdle Ness.

The seaward extent of this unit is linked to the harbour and as such it is a busy shipping area; commercial, industrial, large and small scale with some recreational uses. Large ships travelling to and from Aberdeen, and also those that lie within the Maritime and Coastguard Agency (MCA) designated anchorage area can be seen across the horizon from many points within the unit. These provide scale and interest to the expansive North Sea. Surfing and Windsurfing are also not uncommon along Aberdeen beach.

It is a dynamic and busy seascape which can't really be separated from the city of Aberdeen. The city influences extend from the shipping channels, groynes along the beach to the tower blocks which overlook the coast. It is judged that due to the city influences and the slightly chaotic nature, but also the visible links with the sea and land, the seascape unit has a Medium sensitivity to the type of change proposed.

3.3.4. Aberdeen Bay Regional Seascape Unit

This regional seascape unit is defined by the large crescent of sandy beaches, dunes and links that lie between the mouths of the rivers Don and Ythan. The unit extends from the mouth of the River Don approximately 18 km to Forvie Sands where the deposition coastline ends. The proposed turbines lie within the southern extents of this seascape unit.

Donmouth represents the end of Aberdeen Beach. This area has been designated as a Local Nature Reserve due to the presence of a range of birds and sea life such as grey seals. To the north, the beach changes from a narrow irregular width at Balgownie to a broad expansive beach area at Balmedie extending approximately 14 km to the Ythan estuary. Dunes and links also change further north and become gradually less modified by development pressures. Examples of development on the links and dunes areas can be found at the Royal Aberdeen and Murcar golf courses, tips, quarries and MOD firing range at Blackdog. The change can also be noted in the designation of the area of coastline from Balmedie to the north as an Area of Landscape Significance.

Visitor access to the beaches is relatively contained to the Bridge of Don, Balmedie and Newburgh areas so there are large stretches of beach and dunes which are rarely used for recreation. Balmedie Country Park is a well-used facility which includes parking, visitor centre, and decked walkways through the dunes to the beach. The dunes and links along this seascape unit generally prevent clear views to the beach from inland except from local high points. On the north side of the Ythan estuary there is an extensive triangular area of complex dune systems called The Sands of Forvie. These are a National Nature Reserve and also have Site of Special Scientific Interest (SSSI) and Special Protection Area (SPA) designations. A dynamic landscape they offer an ever changing place with localised high points offering views across the sea and inland, where there are intermittent views of the Hill of Fiddes Wind Farm.

The landward element of this part of the unit includes the coastal urban residential settlement at Bridge of Don which peters out to the industrial estates and Exhibition facilities which lie either side of the A90. This includes two vertical features; a demonstration oil drilling platform and also an observation tower which is 43 m high. Beyond these buildings to the north, the landscape becomes more open with scattered settlement; however landfill and industrial uses are common. The farmland with an open windswept character encroaches into the sandy coastal fringe where views are available across the sea. The land rises to the west to gently undulating lowlands.

The sea element of the unit is perceived as having some containment to the south and north by the visible headlands at Girdle Ness and Buchan Ness (near Peterhead), although this is beyond the unit extents. The eastern extents extend to the horizon and appear at a vast open scale. The sea within this unit is active with many large fishing vessels, container ships, and ferries travelling through the outer waters.

In contrast to Aberdeen Beach, this Regional Seascape Unit is relatively remote and harmonious, with only the industrial and commercial elements to the south of Balmedie adding a discordant element. The landscape and nature designations also need to be taken into consideration and it is judged that overall the sensitivity to the type of change proposed varies from Medium to the south of Balmedie and High to Medium in the northern extents.

3.3.5. Collieston to Peterhead Regional Seascape Unit

This regional seascape unit is predominantly defined by a rocky cliff coastline which extends from Collieston 18 km north to Peterhead. It lies approximately 15 km from the proposed development.

Its coastal component is similar to the rocky coast to the south of Aberdeen with rugged and sculpted granite cliffs and includes features such as the Bullers of Buchan blowhole. The exception to this is Cruden Bay which is a large sheltered sandy bay which lies in the centre of the unit. There are also some smaller bays such as at Collieston, at the south of the seascape unit. Much of this coastal stretch has been designated as an Area of Landscape Significance.

The landward area reaches to beyond 10 km inland where a high plateau of generally open farmland relates to the coastline. There is an area of high open land surrounding Cruden Bay which gradually declines towards Peterhead. This seascape unit has a larger, consistently open and exposed landward area than the other seascape units to the south.

Settlement is sparse along the immediate coastline and consists of mainly individual farms and hamlets along the roads. The only villages along the coast are at Collieston, Cruden, Whinneyfold and the larger Boddam which lies just south of Peterhead. Transport routes in this area include the A975 and slightly further inland the A90. The Peterhead Power Station at Boddam has two large chimneys the highest of which is 170m high and is visible from a large area, including as far as Girdle Ness. Views of distant wind farms are also possible from the landward elements of the unit. Historic elements such as the remains of Slains Castle just north of Cruden Bay are also a noticeable feature of the landscape.

The sea element to the seascape unit is active with local fishing boats inshore and larger ships and ferries travelling across the outer waters.

This unit is generally a simple, open and large scale seascape with expansive sea views. Strong vertical features such as the Peterhead Power Station, although very visible, do not dominate the whole seascape. Due to the presence of vertical features and the overall simplicity of the seascape, but also the locally designated coastline, it is considered to have a Medium sensitivity to the type of change proposed.

3.3.6. Peterhead to Fraserburgh Regional Seascape Unit

The Peterhead to Fraserburgh seascape unit consists of a stretch of dunes and beaches covering approximately 25 km on the north east corner of Aberdeenshire. The unit extends beyond the 40 km study area.

Descending from the rocky cliff line surrounding Peterhead, the coastal element of this seascape unit consists of over eight separate shallow bays of various lengths broken up by the different directions of tides. Behind the beaches the land consists of huge expanses of vegetated sand dunes. The Loch of Strathbeg, a large water body which lies in the centre of this seascape unit, is enclosed by the sand dunes and therefore quite separate from the sea. The coastal areas north of Peterhead have few if any settlements except for the prominent St Fergus Gas Terminal and the Ron lighthouse. Coastal settlements appear further round the coast at St Combs and Inverallochy near Fraserburgh.

The landward element consists of large coastal plains of farmland which due to the flat nature are not as visually connected to the sea as some of the more elevated areas. The A90 lies inland within the open plains and although the sea is generally not visible, the dune systems behind the beaches can be seen and related to, as also one is aware of the sea by the windswept landscape and exposure to coastal air.

Lying in between two large coastal industrial towns, this seascape unit, whilst having remote sandy stretches and dune systems, is heavily influenced by the industrial developments at St Fergus and the busy A90. It is therefore considered to have a Low sensitivity to the type of change proposed.

Table 1.4: Regional Seascape Unit Baseline

	Regional Seascape Unit	Approximate closest distance of coastline from nearest turbine	Sensitivity to type of change proposed
1	Inverbervie to Stonehaven	30km	Medium
2	Stonehaven to Girdle Ness	8km	Medium to Low
3	Aberdeen Beach	5km	Medium
4	Aberdeen Bay	0km	Medium (south) High to Medium (north)
5	Collieston to Peterhead	15km	Medium
6	Peterhead to Fraserburgh	35km	Low

3.4. Landscape Character

The EOWDC will not have any direct effects on the landscape character areas of the onshore parts of the study area. However, on account of the fact that turbines are tall, vertical and moving features, there is the potential for some landscape character areas to have a visual sensitivity towards them. Given this, the character areas within the study area have been assessed only on the basis of their visual sensitivities towards wind farms and on the extent to which the visual characteristics of a character area contribute to defining that landscape character. This takes into consideration '*the probability of change in the landscape being highly visible, based particularly on the nature of the landform and the extent of tree cover both of which have a major bearing on visibility*' (Countryside Agency and SNH, 2004. Topic Paper 6).

Scottish Natural Heritage commissioned landscape character assessments to cover the whole of Scotland in the early 1990s. Of relevance to this SLVIA are the South and Central Aberdeenshire Landscape Character Assessments (LCA), Aberdeen City LCA, and Banff and Buchan LCA. The following paragraphs discuss the key characteristics of the character areas identified within these assessments that lie within the study area and assesses their visual sensitivity towards the type of change proposed. In cross referencing the ZTV of the proposed development with the landscape character areas it is clear that there are entire areas which do not have any potential intervisibility with the site and therefore these have not been included in the baseline assessment.

Figures 5 and 6 illustrate all the landscape character types within the 40 km radius study area of the proposed development, including those which will not have any intervisibility with the EOWDC.

As the seascape units include the coast and relating landscape, in order to avoid duplication and confusion, the relevant landscape character areas will not be assessed separately. This therefore includes; all Coast landscape types and areas, and Potterton and Murcar landscape character areas. It is acknowledged that parts of the Eastern Agricultural Plain, Formartine Lowlands, and Garvock and Glenbervie landscape character areas also overlap with the seascape units but as these are large character areas covering an area beyond the seascape units they will still be included in the assessment.

South and Central Aberdeenshire LCA

This LCA identifies five landscape types within south and central Aberdeenshire. The 'Coastal Strip' lies closest to the development and the majority of the adjacent area is classified as 'Agricultural Heartlands'. Further to the west and south west the 'Moorland Plateaux' extends into the farmland. 'Farmed Moorland Edge' and 'Straths and Valleys' landscape types lie at the edge of the study area.

Within the 40 km study area, the main landscape type is Agricultural Heartlands which comprise of the Formartine Lowlands, Central Wooded Estates and Kincardine Plateau landscape areas which surround Aberdeen, and also the Ythan Strath Farmland, Northern Rolling Farmlands, Howe of Alford, and Garvock & Glenbervie landscape areas which are at the outer extents of the study area.

The Moorland Plateaux landscape type extends into the Agricultural Heartlands with The Mounth landscape area at the south west of the study area and the Grampian Outliers to the west.

The following paragraphs discuss the key characteristics of the Agricultural Heartland landscape areas and the Moorland Plateaux landscape areas. As only small areas of the Straths & Valleys, and Cromar Uplands landscape character types lie within the study area and when cross referencing them with the ZTV it is clear there is no intervisibility with the EOWDC, they will not be included in the assessment.

3.4.1. **Agricultural Heartlands**

Described as intensive farming on large fertile fields, the Agricultural Heartlands landscape type covers an extensive area between the coast and Grampian Mountains within the study area. The Howe of Alford character area within this type is the only one within the study area which is shown on the ZTV to have no intervisibility with the EOWDC and therefore will not be assessed.

Formartine Lowlands (LCA No.4, Figure 5)

This landscape area lies to the north of Aberdeen, east of the Formartine links and dunes. The character area extends beyond the South and Central Aberdeenshire survey to the Banff and Buchan character assessment which is discussed later.

The gently undulating and open agricultural character of this area gives expansive views across the landscape. However, plans outlined in the LCA to increase woodland cover in this area and also objectives to increase the diversity of landscape features and promote a more coherent landscape structure will reduce this existing openness in places. Existing turbines at Hill of Fiddes and Ardgrain and to a lesser degree the small single turbines at Mains of Bogfechel and Tillymaud combined with transmission lines across the area are strong vertical elements in the otherwise open landscape which lacks any significant landscape features. It is a well settled area including the large town of Ellon and also the main north south road (A90). Taking into account the above, the visual sensitivity of the Formartine Lowlands to the type of change proposed is considered Medium to Low.

Central Wooded Estates (LCA No.5, Figure 5)

This area lies between the Don and Dee valleys at the edge of the suburbs of Aberdeen extending west to the edge of the Grampian hills. As indicated by the character area's name, the wooded estates are a strong feature of this rolling landscape. There are some areas of open farmland which allow long views within the area which contrast with enclosure by woodland. Two Areas of Landscape Significance lie within this character area – one at the north eastern extents of the character area along the River Don valley, and the other to the south along the River Dee. There are a large number of towns and villages and a busy network of roads. The enclosure created by the woodland and rolling landscape and lack of any significant views out of the character area reduce the visual sensitivity to the type of change proposed to Low.

Kincardine Plateau (LCA No.6, Figure 5)

The Kincardine Plateau is an area of land to the south west of Aberdeen which is a transitional landscape between the upland areas of The Mounth and the coastal cliffs around Portlethen and Newtonhill.

This is a landscape area that does not have a strong character; it has a diverse and complex landscape pattern which is often neglected and lacks cohesion. Views out of the character area are not a key characteristic although there are exposed mounds and hills across the landscape which will provide opportunities for wider views. There is strong development pressure extending from the industrial and residential areas of southern Aberdeen. Taking the above into consideration it is judged that the visual sensitivity of the Kincardine Plateau character area to the type of change proposed is Low.

Ythan Strath Farmland (LCA No.7, Figure 5)

This landscape area is a small area which lies to the north of the Formartine Lowlands and to the east of the Northern Rolling Lowlands.

The Ythan Strath Farmland is a rural landscape with exposed hill tops and rocky outcrops contrasting with the more intensely farmed pockets. Settlement is scarce and is mainly scattered farmsteads. The area has a relatively small scale field pattern with diverse vegetation cover which adds to the rural character. The undulating landform, blocks of coniferous woodland and the large areas of estate planting at Haddo give some enclosure to the area .This intricate structure reduces the opportunities and importance of views out to the wider landscape. A three turbine wind farm at Skelmonae and a single turbine at Courtstone lie within the character area. It is judged that the Ythan Strath Farmland will have a Low visual sensitivity to the type of change proposed.

Northern Rolling Lowlands (LCA No.8, Figure 5)

The Northern Rolling Lowlands lie north east of the Formartine Lowlands and extend into the Banff and Buchan Agricultural Heartlands landscape type. It is a simple landscape consisting of a rolling landform covered by large geometric fields and woodland blocks. Settlements and farms lie in the sheltered valleys. A key characteristic is long distance views from the elevated areas out to the wider landscape. This simplistic landscape is now dotted with wind farms varying from single turbines to five turbines. They are a distinctive vertical element seen in the skyline from many areas within and outside the character area, although the undulating landscape curtails some views. The visual sensitivity to the type of change proposed is considered Low as wind farms and views of wind farms are now an established characteristic of this landscape character area.

Garvock and Glenbervie (LCA No.9, Figure 5)

This area lies to the south of the Kincardine Plateau and east of The Mounth. The Garvock and Glenbervie character area is primarily characterised by the large scale sweeping open rolling hills that give distant views across the area to The Mounth and Howe of the Mearns. There is a scattered settlement pattern and radio masts are prominent on high points. The large fields of arable and pasture are divided by fencing and there is a scarcity of hedges and dykes. There are several wind farms in the area both near the coast and in the shelter of The Mounth. The views out to the wider landscape are a key characteristic which may or may not include wind farms and other vertical features. The visual sensitivity is therefore considered to be Medium to Low to the type of change proposed.

3.4.2. **Moorland Plateaux**

The Moorland Plateaux has a 'Highland' character of exposed heather moorland with coniferous plantations. It has been divided into two main areas which are discussed below.

Grampian Outliers (LCA No.12, Figure 5)

The Grampian Outliers consists of several high points to the west of Aberdeenshire at the transition between the high mountains of the Cairngorms and the lower farmland of the north east. The outcrops at Bennachie, Hill of Fare, and the eastern edge of the Ridge of Foudland are included at the extents of the study area.

The Grampian Outliers have a generally high undulating landform with some dramatic outcrops such as at Bennachie. The mountains are mostly covered with conifer plantations with the upper slopes more open with heather moorland giving a rural and wild character. The agricultural lands on the lower slopes provide a distinct edge to the mountains. The few settlements are restricted to the lower sheltered areas. Telecommunication masts are dominant on some of the high points and wind farms lie on some of the areas outside the study area, although views of wind farms are possible to the north. The extensive panoramic views available from the promontories are an important characteristic of these areas. Therefore, these expansive elevated views, moderated by the fact that turbines are already a feature in some views, are judged to give a visual sensitivity to the type of proposed change of High to Medium.

The Mounth (LCA No.13, Figure 5)

The eastern half of The Mounth character area lies within the study area. It is surrounded by the Agricultural Heartland landscape type. The Mounth is a substantial undulating ridge that is a dominant presence in views from the south of Aberdeen. The areas within the study area are heavily forested with some exposed higher areas of heather moorland. The landscape becomes higher and more open towards the south west of the study area. The LCA describes it as having a 'wild and exposed character with commanding views into tranquil farmed lowland'. The Mid Hill Wind Farm lies within a forested part of The Mounth and there are several wind farms in the adjacent lowland areas to the south. Taking into consideration the importance of the views into the 'tranquil farmed lowland' and the presence of wind farms in some views, the visual sensitivity to the type of change proposed can be judged as being High to Medium.

Banff and Buchan Landscape Character Assessment

This LCA covers the northern extents of the study area. Within this area there are four landscape types identified; Coast, Coastal Farmland, Agricultural Heartlands, and River Valleys. The River Valley type and two areas of Agricultural Heartlands are not included as the ZTV shows there is no intervisibility with the site from these areas. The Coast is covered by the seascape units and so will not be assessed separately here.

3.4.3. **Agricultural Heartlands**

This landscape type continues from the Agricultural Heartlands type set out in the South and Central Aberdeenshire LCA. There are three character areas of this type within the study area. Wooded Areas around Old Deer, and Upland Ridges South of the Deveron character areas have not been assessed as the ZTV shows that there will be very limited if any intervisibility with the EOWDC. It is only the Agricultural Heartlands character area which will potentially have intervisibility and is discussed below.

Agricultural Heartland (Landscape Area) (LCA No.18, Figure 5)

The Agricultural Heartland landscape area is a large area of gently rolling farmland which extends to the coastal plains. It has many small settlements and also some larger villages and frequent farmsteads. The large field pattern is defined by a variety of boundary types such as fences, hedges and stone walls. It is also interspersed with small coniferous blocks and broad leaved trees. This relatively simple and large scale landscape contains several small wind farms with many more consented and lodged in the planning process. Open views of the surrounding landscape are a key characteristic of the Agricultural Heartlands. The visual sensitivity to the type of proposed change is considered Low given it is a large scale landscape with existing turbines already a feature in views within and outside of the character area.

3.4.4. **Coastal Farmland**

The Coastal Farmland type extends from the Agricultural Heartlands to the coast. There is just one area identified within our study area which is discussed below.

Eastern Coastal Agricultural Plain (LCA No.21, Figure 5)

This area links with the South and Central Aberdeenshire LCA Formartine Lowlands character area. It is a low coastal plain which gently undulates, but overall it can be described as an open and windswept area. It is predominantly agricultural land with some areas of boggy land at St Fergus Moss, Rora Moss and Moss of Cruden. There are constant views of the sea with only a few intervening conifer blocks and shelterbelts. Several small wind farms exist in this area with several more in planning. It is judged that due to the openness and characteristic views beyond the character area to the sea, the visual sensitivity to the type of proposed change is Medium to Low.

3.5. Aberdeen LCA

The Aberdeen LCA identifies five landscape character types; Major River Valley, Hills, Open Farmland, Wooded Farmland and Coast. These have been divided into 27 character areas, six of which do not have any intervisibility with the site following review of the ZTV. The three coastal areas and Murcar and Potterton areas are not discussed as they are covered by the seascape units. Therefore, the key visual characteristics of the remaining 16 character areas are described below.

3.5.1. Major River Valleys

The river valleys of the Don and the Dee are significant landscape features within the Aberdeen area. The Don valley up to where it is channelled through the city has been divided into three separate character areas, namely; Upper Don Valley, Dyce Plain, and Lower Don Valley. The ZTV shows that there is no intervisibility between the site and the Dee Valley and the Lower Don Valley character areas. The remaining valley areas are discussed below.

The Upper Don Valley (LCA No.23, Figure 6)

This area of the Don valley has a large scale valley landform which is generally enclosed with considerable areas of woodland. There are local confined views along the River Don and also short views east towards the edge of Dyce and Aberdeen. Longer distant views of hills to the west can also be seen. It is a sparsely settled area and pylon lines are dominant through the valley, as well as a large sand extraction site. The visual sensitivity of the Upper Don Valley to the type of proposed change is therefore considered Low due to the inward looking unobtrusive nature of much of the valleys length.

Dyce Plain (LCA No.24, Figure 6)

The Dyce Plain, is a more open part of the river Don valley and affords distant views from higher parts which also feature the extensive industrial estates, airport, and heliport. The visual sensitivity of the Dyce Plain to the type of proposed change is considered Low, as although it is more open, it is a chaotic area with many distracting elements in the foreground such as the airport and industrial estates.

3.5.2. Hills

Gently rounded hills form a distinctive edge to the west of the city and a small section to the south east. There are four specific character areas; Tyrebagger Hill/Kirkhill, Brimmond Hill, Gairnhill and Kincorth & Tullos hills. Gairnhill is not included in the assessment as the ZTV shows that this low hill west of Aberdeen will not have any intervisibility with the EOWDC.

Tyrebagger Hill/Kirkhill (LCA No.27, Figure 6)

Tyrebagger Hill and Kirkhill rise to 233m above ordnance datum(AOD) and lie at the north west limits of Aberdeen. The rounded hill is predominantly covered by coniferous woodland on the hill top and farmland on the lower slopes. The elevation of this area has meant it has become a landmark and it terminates views from many viewpoints from within the city and surrounding areas. Long distant views in all directions are available from the open areas around the woodland. These views include Aberdeen and the sea as well as towards the more rural west. The visual sensitivity to the type of proposed change is therefore considered to be High to Medium, taking on board the diverse elements which will exist with the views.

Brimmond Hill (LCA No.28, Figure 6)

Located to the west of Aberdeen, south of Tyrebagger and Kirkhill, Brimmond Hill rises to 266m AOD and nearby Elrick hill is 200m AOD. Their lower slopes are mostly agricultural land which opens out to moorland on the summit of Brimmond Hill, with some mixed woodland leading up to Elrick Hill's summit. Brimmond Hill has a cluster of masts on its summit which are dominant man-made features in this area and can be seen for some distance. Overall the area forms a strong, visible contrast, especially with the open moorland summits, with the adjacent urban areas. Views from the hilltops are expansive and include the Grampian Outliers to the west and across the city to the sea in the east. Distant existing wind turbines can be seen within these views to the north and north west. The character area's visual sensitivity to the type of proposed change is considered to be Medium given the characteristic hilltop views and presence of large manmade structures within the area.

Kincorth and Tullos hills (LCA No.30, Figure 6)

Kincorth and Tullos hills are a gently rounded ridge line of elevated ground to the southeast of Aberdeen which forms the southern skyline in views from the city. They have an open character dominated by heath vegetation and although predominantly used for recreation there is landfill waste on the northern side of Tullos hill and the hills are surrounding by industrial parks and residential areas. Views across the city are a key characteristic and especially towards the River Dee and Aberdeen Bay. These views take in a variety of natural and manmade elements including the vertical tower blocks at Seaton and Stockethill. Therefore, the visual sensitivity to the type of proposed change is considered Medium.

3.5.3. **Open Farmland**

Broadly corresponding with the adjoining Aberdeenshire LCA's Agricultural Heartland landscape type, the Open Farmland forms much of the immediate hinterland of the city. Murcar and Potterton character areas are not included as they lie within the Aberdeen Bay seascape unit. Also, Clinterty/West Brimmond Farmland and Anguston/Leuchar/Easter Ord character areas are not assessed as the ZTV shows there will be no intervisibility of the EOWDC with these areas.

Perwinnes (LCA No.31, Figure 6)

This area has a gently rolling landform with shallow basins at Perwinnes Moss and Corby Loch which are local nature conservation areas. It is generally higher than adjacent areas so affords distance views across the farmland and to the edges of Aberdeen. The farmland consists of mainly pasture and rough grazing with post and wire fencing with small areas of woodland. Settlement is sparse but manmade elements such as sand extraction and the radar station at Perwinnes are very visible elements within the landscape. It is judged that the visual sensitivity to the type of proposed change is Medium due to the possibility of views outside of the character area but also taking into account dominant elements such as the radar.

East Elrick (LCA No.34, Figure 6)

The East Elrick open farmland character area lies at the edge of the eastern slopes of Brimmond Hill, but is a relatively flat landscape. There are very few distinguishing elements; it is a simple agricultural landscape with sporadic trees, sparse settlement, and a network of minor roads. Extensive views out to the north are a key characteristic but landform and forest cover prevents views to the wider landscape in other directions. In addition, the masts are visible on Brimmond Hill and also the industrial estates at Dyce. Therefore, it is considered the visual sensitivity to the type of proposed change is considered Medium to Low.

Newhills (LCA No.35, Figure 6)

This is a relatively large character area which lies at the western edge of the city and extends to the slopes of Brimmond and Elrick Hills. The landform is 'saucer-shaped' which is predominantly agricultural with marshland in the lower central part. Hedgerows and extensive shelterbelts are a characteristic. Views are enclosed by the rising landform which surrounds the area but the elevation of the area does allow views towards the urban edge, Dyce industrial estate and radar station at Perwinnes. The visual sensitivity of the character area towards the type of proposed change is considered Low due to the generally enclosed nature and dominant manmade features within the long distant views that are available.

Maidencraig (LCA No.36, Figure 6)

This linear character area comprises the shallow valley of the Denburn. The open farmland includes a local nature reserve at Den of Maidencraig which has large areas of woodland planting. The landscape has a more intricate smaller scale than other areas of open farmland and some distinctive lines of trees along the main roads. It is a well settled area with the encroachment of residential developments from the edge of Aberdeen. The landform encloses the area which restricts long distant views to beyond, except for the clock tower of Woodend Hospital which is prominent in views towards the east. Therefore, the visual sensitivity of Maidencraig to the type of proposed change is considered Low.

Kingshill/Bogskeathy (LCA No.37, Figure 6)

Kingshill/Bogskeathy character area is a gently sloping plateau which is enclosed by the higher ground to the north, and coniferous plantations to the west and east. However, views to the south east towards the hills at Kincorth and Tullos are available, and the tower blocks at Stockethill can also be seen. Within the area, it is open pasture/grazing land, with some intervening blocks of coniferous woodland. The few buildings in the area are mostly located along the minor roads or edges of the character area. Taking into account the above it is considered that the visual sensitivity to the type of proposed change is Medium to Low.

Den of Leggart (LCA No.38, Figure 6)

Den of Leggart is a shallow valley landscape located on the western side of the A90 and Kincorth Hill. The open farmland consists of small scale fields bounded by stone dykes often overgrown with scrub and grasses. Views are restricted by the higher valley sides except to the north where views are directed to the western extents of Aberdeen. Long distance views beyond Northfield and Mastrick are limited. Due to the restricted and relatively short distance views, the visual sensitivity to the type of proposed change is considered Low.

Loirston (LCA No.39, Figure 6)

This character area is the southernmost area in the Aberdeen study area. It lies to the east of the A90 and south of Kincorth Hill. It has a gently rising landform which includes a lower area at Loirston Loch. There are industrial and residential areas to the north and east but elsewhere it is open farmland which lies between the A90 and the development. The urban influences are dominant and restrict any views to the wider area. Therefore it is judged the visual sensitivity to the type of proposed change is Low.

3.5.4. **Wooded Farmland**

There are five Wooded Farmland landscape areas identified within the LCA, four of which have potential intervisibility with the proposed development.

Braes of Don (LCA No.42, Figure 6)

The Braes of Don is a gently rolling landscape with a mix of woodland and pasture with distinctive shelterbelts. Grandholme moss is a natural feature on the lower ground. There is some residential development extending into the area from the south. Power lines cross the landscape from north to south and there is a network of roads across the area. Glimpsed views of the edges the Lower Don valley are available but views out are not a characteristic. Therefore the visual sensitivity towards the type of proposed change is considered Low.

Craibstone (LCA No.43, Figure 6)

This is a strongly undulating landscape which forms a distinctive approach to the city from the north west from the A96. It lies on the eastern side of Tyrebagger hill extending towards the urban edge of Dyce. This high ground restricts views towards the west but where woodland allows, views of the sea are possible, and to the city and coast to the east. Settlement is sparse and the Macaulay

Institute buildings are quite dominant. The visual sensitivity towards the type of proposed change is considered Medium given the characteristic views towards the coast.

Kingswells (LCA No.44, Figure 6)

Kingswells wooded farmland landscape area lies around the suburb of Kingswells and on the lower slopes of Brimmond Hill. There are not any large areas of woodland but it is identified as wooded due to the presence of tree clumps, boundary trees and shelterbelts. Since the LCA was written Kingswells has developed significantly and the rural nature has now become more of an urban edge character. Views to the surroundings are limited due to the surrounding higher ground except to the east where they extend further towards the city centre. Also the masts on Brimmond Hill are prominent in views. It is therefore judged that the visual sensitivity to the type of proposed change is Low.

Hazlehead (LCA No.45, Figure 6)

Hazlehead has a gently undulating landform which lies at the western extents of Aberdeen. It consists of Hazlehead woodlands, open areas of golf courses, a public park, recreational areas, school playing fields, garden centre, and also a riding school. There are few buildings and many footpaths, bridleways and minor roads. The woodland encloses the areas and views out to the wider landscape are not a characteristic. Therefore the visual sensitivity to the type of proposed change is considered Low.

Table 1.7: Landscape Character Areas Baseline

Character type	**Character area**	**Approximate closest distance to nearest turbine**	**Visual sensitivity to type of proposed change**
South and Central Aberdeenshire LCA			
Agricultural Heartlands	Formartine Lowlands	3km	Medium to Low
	Central Wooded Estates	7.5km	Low
	Kincardine Plateau	14.5km	Low
	Ythan Strath Farmland	17km	Low
	Northern Rolling Lowlands	22km	Low
	Gavock and Glenbervie	27km	Medium to Low
	Insch Basin	23km	Not within ZTV
	Howe of Alford	37km	Not within ZTV
Moorland Plateaux	Grampian Outliers	27km	High to Medium
	The Mounth	25km	High to Medium
Straths and Valleys	Deeside	30km	Not within ZTV
Farmed Moorland Edge	Cromar Uplands	33km	Not within ZTV
Coastal Strip	Formartine Links and Dunes	3km	Included within Seascape Units
	Kincardine Cliffs	10km	
	Kincardine Links	25km	
Banff and Buchan LCA			
Agricultural Heartlands	Agricultural Heartlands (area)	22.5km	Low

Character type	Character area	Approximate closest distance to nearest turbine	Visual sensitivity to type of proposed change
	Wooded Areas around Old Deer	25km	Not within ZTV
	Upland Ridges South of the Deveron	25km	Not within ZTV
Coastal Farmland	Eastern Agricultural Coastal Plain	17km	Medium to Low
River Valleys	Deveron and Upper Ythan Valley	28km	Not within ZTV
Coast	Dunes and Beaches from Fraserburgh to Peterhead	33km	Included within Seascape Units
	Cliffs of the North and South East Coasts	17km	
Aberdeen LCA			
Major River Valleys	Upper Don Valley	12km	Low
	Dyce Plain	10km	Low
	Lower Don Valley	5km	Not within ZTV
	Dee Valley	12km	Not within ZTV
Hills	Tyrebagger Hill/Kirkhill	12.5km	High to Medium
	Brimmond Hill	14km	Medium
	Gairnhill	15.5km	Not within ZTV
	Kincorth/Tullos Hills	9km	Medium
Open Farmland	Perwinnes	7km	Medium
	Potterton	4.5km	Included within Seascape Units
	Murcar	3km	
	East Elrick	13km	Medium to Low
	Newhills	10km	Low
	Maidencraig	12.5km	Low
	Kingshill/Bogskeathy	14km	Medium to Low
	Den of Leggart	12.5km	Low
	Loirston	12km	Low
	Clinterty/West Brimmond Farmland	16km	Not within ZTV
	Anguston/Leuchar/Easter Ord	17km	Not within ZTV
Wooded Farmland	Braes of Don	7km	Low
	Craibstone	11km	Medium
	Kingswells	13.5km	Low
	Hazlehead	12km	Low
	Countesswells / Milltimber / Kennerty	13km	Not within ZTV

Character type	Character area	Approximate closest distance to nearest turbine	Visual sensitivity to type of proposed change
Coast	Doonies/Cove Coast	9km	Included within Seascape Units
	Girdle Ness/Nigg Bay	8km	
	Aberdeen Links	3km	

3.5.5. **City of Aberdeen**

The heart of Aberdeen lies approximately 8km from the nearest turbine of the proposed development. The character of the landscape surrounding the city has been described above but it is also important to look at the character of the city itself. Again, the proposed development will not have a direct material effect on the city itself but only on those aspects which could potentially have a visual sensitivity. The setting of historic buildings and features within the city is discussed in Chapter 7.6 Cultural Heritage.

The Aberdeen LCA (SNH, 1996) has helpfully assessed the setting of Aberdeen as a city. It has looked at the perception of Aberdeen and its relationship to the surrounding landscape, and the landmarks of the city.

The built-up nature of cities means that long distant views out to the surroundings are often not available except from elevated areas. The LCA identifies that within the city centre there are few, if any views out to the wider area and the main visual sensitivities would be confined to those areas within the outer elevated edges of the city and the coastal edges. It is from these areas that there are opportunities for views across the whole city and the landscape setting can be appreciated. The elevated urban areas include parts of the local areas of Tullos, Kincorth, Torry, and Kaimhill at the south of Aberdeen, and Seafield, Stockethill, Northfield and Hilton to the west and north-west. Within these areas, main roads such as the A96 near Tyrebagger Hill and the A90 near Kincorth Hill allow views across the city within its setting between hills and the sea. These roads give a sense of arrival to the city. The A90 to the north of Aberdeen gives less of an overview of the whole city but the association of the coast to parts of the city is strong when approaching from the north. Other gateways can be found at the city bridges crossing the rivers Dee and Don. The coastal railway route from the south also has a sense of arrival with the contrast of the coastal cliffs to the built up area of southern Aberdeen with views across the River Dee.

Landmarks include the hills which have been discussed in the landscape character above, but also the many historic spires and towers within the city centre and also Girdle Ness lighthouse. Other more modern landmarks include several 1960's and 70's tower blocks, one cluster near the coast at Seaton and another inland at Stockethill and Northfield. These are very prominent in most views of the city. Telecommunication masts at Northfield, Brimmond Hill and radar station at Perwinnes are also features within the views of Aberdeen. Expanding large industrial areas including office developments mostly lie at either the southern side of Aberdeen at Altens and also to the north at the airport and Bridge of Don areas. Also prominent in views of the city, there is a demonstration oil drilling platform which lies on the coastal area beside the Exhibition centre, north of the city.

The visual sensitivity of Aberdeen city to the type of proposed change is judged to vary between negligible and high across the city depending on density and orientation of buildings, elevation, and existing features within open views. Specific areas will be addressed in the visual assessment.

4.0 Meteorological Context

The degree, extent and likelihood of visual effects arising from the proposed development is an amalgam of a variety of different factors, not least the prevailing weather conditions that occur at any one time and can determine changes in character and visibility with varied wind, light, tidal movements and the clarity or otherwise of the atmosphere.

Two visibility data sets were obtained from the MET Office and these are presented in Appendix 2. These show the average distances of visibility over a 30 year period taken from Dyce (Aberdeen Airport) and also offshore locations from ships in the North Sea, east of Aberdeen beyond the 60 km study area. The locations of these data sets provide a good indication of the local conditions but it is acknowledged that they cannot represent the visibility from the whole of the study area. In particular, along the coastline of the North Sea, visibility can be affected by 'haar' between April and September which may not have been picked up in the presented data sets due to their source location. Haar is a sea fog caused when warm continental air is cooled and moistened by the North Sea. These fogs are normally shallow in depth and often lift inland where it is burnt off by the sun. Haar has been recorded as present along the east of Scotland within the spring and summer of up to 14 days per month in exceptional years (North Sea Pilot, 1997; DTI, 2004).

Analysing the data sets presented in Appendix 2, the following tables (4.1 and 4.2) provide a summary of the percentage of time of visibility at the various distances listed. Please note that the offshore ship sourced data and the Dyce data are not recorded with the same distance intervals so there is limited direct comparison that can be made.

Tables 4.1 and 4.2

Dyce Meteorological Station Data	
Kilometres Visible	**% of time**
<10	19
10-15	8
15-20	9
20-25	11
25-30	13
30-35	16
35-40	8
40-45	10
>45	6

Offshore Ship Sourced Data	
Kilometres Visible	**% of time**
<10	13
10-20	22
20-50	61
>50	4

Analysing the data sets shows that there are no noticeably strong trends and, as would be expected, the percentage incidence of visibility decreases to some degree with increasing distance, notably beyond 35 km onshore at Dyce and beyond 50 km offshore, although the offshore data does not provide a detailed breakdown between 20 km and 50 km. At Dyce, 19% of the time visibility is less than 10 km which is not an insignificant period (1 day in 5), and almost 50% of the time visibility is less than 25km (every other day). However, it is acknowledged that visibility is also possible beyond 25km for 50% of the time, albeit to varying distances.

Overall, it is clear that the visibility from these particular points in the study area varies considerably and that the EOWDC will not be seen 100% of the time, even at the closer distances, and this is an important factor that should be taken into account in the assessment of the effects upon land/seascape character and visual amenity.

5.0 Baseline Visual Environment

The inherent visibility of wind farm developments and the resulting effect on the visual environment are often cited as a concern for local residents and visitors alike. The purpose of the visual assessment is to determine the visibility of the proposed development and to establish what the anticipated visual effect of the proposals would be from a range of representative viewpoints within the study area.

5.1. Zone of Theoretical Visibility

The computer generated ZTVs to nacelle and blade tip (Figures 7, 8 and 9) identify key stretches of the coastline and hinterland from which the proposed offshore wind farm development may theoretically be visible. At the baseline stage, reviewing the ZTV is important to understand the potential areas from where the development could be visible, and equally, where it won't be visible. Appendix 4 details the methodology used for creating the ZTVs.

5.2. Key Visual Receptors

A wide variety of visual receptors will be potentially affected by the proposed development. These receptors will vary considerably depending on the intricacies of the coastline and will include local residents, those travelling through the area and those visiting the area for recreational and amenity purposes. Most of these will be onshore receptors, but there is potential for offshore receptors such as those travelling or working on boats or even oil platforms. This report focuses on the following three key categories of visual receptors: local residents, the travelling public and visitors to the area. It is acknowledged that one person can fall into more than one of the three categories. Please also refer to the assessment methodology in Appendix 2.

5.2.1. Residents

Local residents are judged to have a generally High level of sensitivity to the type of change proposed where views of the proposed site are available to them. The ZTVs indicate that residents within the coastal edges and elevated areas of Aberdeen and its suburbs, with coastal villages and towns to the north of Aberdeen, are those most likely to have views of the proposed development. The coastal settlements of Blackdog and Balmedie are the nearest to the development.

5.2.2. The Travelling Public

This category of visual receptors includes both residents/commuters and those who travel to or through the study area, both on land and at sea. It is considered that this group will have an average Medium to Low level of sensitivity to the type of proposed change, depending upon the purpose and objective of the traveller, on account of the transitory nature of views in any one direction.

Roads

There are several main roads throughout the study area. The A90 is the key road which links Aberdeen to the south and also links Fraserburgh and Peterhead in the north. The A90 is the closest road to the EOWDC, running parallel to the coast, 1 km inland. The section of the A90 between Balmedie and Tipperty, to the north of the EOWDC has planning permission to be dualled, although timescales for construction are not known at this time. The A96 is the main road between Aberdeen and Inverness and extends to the north west of the city. Along Deeside, the A93 extends from Aberdeen to Banchory within the study area. The A920, A948, A947 are other main roads within the northern area of the study area and the A944 to the west of the city. There is also a network of many B roads and minor roads which cross the open farmland, becoming slightly sparser towards the western and south western extents of the study area where it is more remote and mountainous.

The proposed Aberdeen Western Periphery Route (AWPR) lies inland from Stonehaven, around the western extents of Aberdeen and turns east at Dyce to join the A90 at Blackdog, directly opposite the EOWDC. Although recently consented is it currently subject to legal challenges and therefore can't be assumed that it will be constructed. It therefore will not be included in the assessment, although reference may be made if appropriate.

Rail

The main east coast railway line terminates at Aberdeen after following the dramatic cliff coastline from Stonehaven to Nigg. At Nigg the line curves inland towards Aberdeen station to the west of the Harbour. Where cuttings and vegetation allow, the stretch of line from Stonehaven to Aberdeen allows extensive eastern views across the North Sea.

Public Paths

There are many accessible public paths and cycle routes around Aberdeenshire and the coast. Aberdeenshire Coastal Path is part of the North Sea Trail which is a route that links parts of the North Sea exposed coasts of Scotland, England, Norway, Sweden, Denmark, Germany and the Netherlands. The trail covers almost the entire Aberdeenshire coast and Aberdeenshire Council has produced 38 separate maps (of which maps 6-23 cover the study area) (The North Sea Train, undated) which detail the route and provide information on features of interest. These have been taken into consideration in the description of the seascape units and also several of the viewpoints are located on the route. The coastal routes include parts of the main roads where walking paths are not available.

Sea Routes

Aberdeen is a busy harbour, as is Peterhead, and many of the other smaller coastal villages also have frequent marine activity. Passenger ferries to Orkney and Shetland are also regular from Aberdeen. The Shipping and Navigation Assessment details the routes across the North Sea.

The Royal Yachting Association (RYA) UK Coastal Atlas of Recreational Boating (RYA, 2009) illustrates the cruising routes in the study area which are all 'medium' recreational use which means that they are '*popular routes on which some recreational craft will be seen at most times during summer daylight hours*.' Within the study area routes are shown between Stonehaven, Aberdeen and Peterhead, with other routes from further afield in the outer waters.

In RYA's response to the scoping opinion request (Aug 2010) they explain that recreational sailing within the study area mainly follows an inshore route from the Firth of Forth to Peterhead, often at night to avoid the busy harbour traffic at Aberdeen and Peterhead.

Also of importance, the RYA Position Statement of Offshore Renewable Energy Developments (RYA, 2005) recognises '*recreational activity is important to the health and wellbeing of the community as well as economic support for the local coastal economies. Retaining the undisturbed remoteness of some waters will be important in terms of its wilderness and amenity value*.' However, with the busy shipping and fishing activities in the surrounding waters of the EOWDC, the terms 'remoteness and wilderness' are not so relevant for the character of the sea in the immediate study area.

Visitors and the Tourism/Amenity Resource

This category embraces a wide variety of individual visual receptor groups whose principal preoccupation is with the enjoyment of the outdoor environment, the open countryside and the tourism / amenity resource the coastline offers. These visual receptor groups will have different objectives, and thus differing levels of sensitivity to any change in the fabric or the character of the seascape units and visual effect arising from the proposed development. On average, the sensitivity of this receptor group is likely to vary between Medium and High.

People in this receptor group include users of footways and cycle routes and visitors to coastal facilities and beaches; golfing; accommodation including hotels, caravan and camp sites; car parking; water sports, boating, and country parks.

5.3. Viewpoint Description

To help define the existing visual baseline environment, it is accepted practice to select and agree upon a number of representative viewpoints within the visual envelope of the development. The representative viewpoint locations as agreed with the consultees are illustrated on Figures 10 and 11.

The character of the existing view from the 20 representative viewpoints is described below (in approximate order of distance from the development) and the sensitivity of the identified visual receptor group to the type of proposed change is described. A synopsis of the baseline sensitivity is also detailed in the summary table at the end of the EIA Technical Report. Photographic panoramas for each viewpoint are shown in Figures WF 01-20.

5.3.1. **Viewpoint 1 – Balmedie Beach**

Balmedie Beach is a popular coastal country park located 3.51 km north west from the nearest turbine of the EOWDC, and lies within the Aberdeen Bay seascape unit. The view is representative of that available to visitors to the beach. A 180 degree view can be seen clockwise from the north round to the south, with the sand dunes precluding any views to the west. The foreground is simply a sand beach with marram grass topped dunes behind. The North Sea is the main feature of the view with often large ships travelling across the horizon which can also be static features in anchorage areas which lie in the vicinity. To the north views include the coastline curving round to the Ythan Estuary and Forvie Sands. This northern view is generally very harmonious with few obvious human influences. Views to the south extend around to the headland at Girdle Ness where the lighthouse is visible in the horizon. Aberdeen city is clear extending to the developments on the beach front. The drilling platform at the Technology Park near Bridge of Don is also visible. Overall the panoramic views from Balmedie Beach offer contrasting views to the north and south. There is a tranquil feel with only the sound of the waves and intermittent noise from helicopters and airplanes flying overhead. The immediate surroundings are unspoilt and the sand dunes shelter views inland. Therefore the sensitivity to the type of proposed change on the key receptor group of visitors to the beach is considered High.

5.3.2. **Viewpoint 2 – A90 (Harehill turn off)**

This viewpoint is 4.44 km south west from the nearest turbine of the EOWDC. It is representative of views available to travellers on the A90 and lies within the Aberdeen Bay seascape unit. The view towards the coast is generally of flat rough grazing land with manmade landfill mounds either side of the A90 breaking up open views of the North Sea. There is quite an industrial presence mostly associated with the landfill. There are scattered houses and farms within the coastal plain which has a gradual descent towards the sea. Although beyond the photographic panorama shown in Figure WF-02 Murcar Golf Club house is visible to the east at the edge of the links course and views towards Aberdeen extend across the sea to Girdle Ness. The Girdle Ness lighthouse is prominent in the skyline as are the drilling platform and tower blocks, and large industrial buildings in the foreground. It is quite a discordant view with the A90 and adjacent landfill and developments dominant in this part of the view. Therefore the sensitivity to the type of proposed change on the key receptor group of travellers on the A90 is considered to be Medium to Low.

It is also noted that the proposed AWPR would join the A90 just north of the Harehill turn off and would potentially be a dominant feature in the area.

5.3.3. **Viewpoint 3 – Jesmond Drive, Middleton Park**

This viewpoint is 7.14 km south west of the nearest turbine of the EOWDC. The viewpoint is on Jesmond Drive, just north of Oldmachar Academy and looks over a recreation ground. The view is representative of that available to local residents within Middleton Park, a residential area to the north of Aberdeen. There are building works at the edge of the recreation ground and large deciduous trees encompassing the area. The high open land at Perwinnes is just visible behind the trees. It is a relatively simple view, but active with the surrounding school, sports pitches and residential area. The sensitivity of the key receptors of local residents to the proposed type of change is therefore judged to be High.

5.3.4. **Viewpoint 4 –Whitecairns (B999)**

This viewpoint is located 8.10 km west of the nearest turbine of the EOWDC. The view is representative of that available to local residents and travellers on the B999. The viewpoint is located on a layby on a minor road at Whitecairns just off the B999, and is within the Formartine

Lowlands character area. Pasture in regular medium sized fields bounded by post and wire fencing lie in the foreground gently sloping towards the B999. The land on the east of the B999 rises considerably to a local high point of 130m AOD. This elevated land has been quarried in one area and is covered by a mix of open pasture, scrub and woodland. Settlement and industrial/farm buildings are visible on the lower enclosed land along the main road with shelterbelts and small areas of woodland. The landscape scale is medium to large with some enclosure given by the undulating land. The view, although relatively simple in components, has a discordant feel. The sensitivity of the key receptors of travellers and local residents to the type of proposed change is judged to be Medium to Low for travellers and High for residents.

5.3.5. **Viewpoint 5 – Aberdeen Beach**

This viewpoint is located on the Beach Boulevard from a point just south of the Codonas Amusement Park and is representative of views available to visitors to the beach and lies within the Aberdeen Beach seascape unit. It is 7.52 km from the nearest turbine of the EOWDC. The development along the beach front lies at a considerable height above the sand and sea. A grass embankment with occasional stepped and ramped access takes the level down from the road to another wide boulevard which lies a few meters above the beach. The beach is accessed at specific points and is divided by timber groynes at regular intervals for the length of beach to the mouth of the Don. There are also some sea defences consisting of large rocks visible at the end of the groynes. Street lighting along the beach road pulls the eye around the curved bay past the Beach Ballroom, Leisure Centre and towards the football stadium. Further around the beach the demonstration drilling platform intersects the skyline beyond the Bridge of Don. Views extend past Balmedie to Peterhead where the power station stack is just visible in the skyline. To the south the view is curtailed by Girdle Ness and the harbour. It is a diverse and active view with expansive views to the north and east. It is a large scale seascape incorporating many elements and long distant views. It is considered that the receptor group of visitors to the beach would have a High sensitivity to the type of change proposed.

5.3.6. **Viewpoint 6 – A90 (West Pitmillan turn off)**

This viewpoint is located just off the A90 at the turn off to West Pitmillan, approximately 9.31 km north west from the nearest turbine of the EOWDC. It is representative of views available to travellers on the A90. This stretch of the A90 is located on a plateau of high, gently rolling land within the Formartine Lowlands character area. There is an exposed feel with views of the sea and sand dunes at the coast available through the gentle undulations. There is a large farm at Pitmillan which is set into the landscape with shelterbelt planting behind. The agricultural land which lies either side of the road consists of large regular fields both arable and grazing with post and wire fencing. There are houses dispersed across the landscape with associated shelterbelts. The landscape here has a large open scale and is relatively uniform. The Hill of Fiddes wind turbines are visible on approach to the viewpoint but at the viewpoint are just hidden behind the hill to the west. The A90 is a busy main road and is a key part of the view, which will become a more significant feature following the planned dualling of this section of the road. The sensitivity of the key receptors of travellers on the A90 to the type of proposed change is judged to be Medium to Low.

5.3.7. **Viewpoint 7 – Torry Battery**

This viewpoint is taken from the public car park at Torry Battery on the headland which overlooks Aberdeen Harbour and the beach beyond. It is located 7.89 km south of the nearest turbine of the EOWDC. It is representative of views available to visitors to the headland and walkers on the coastal path and lies within the Aberdeen Beach seascape unit. The view encompasses the whole of Aberdeen Bay and beyond to the power station stack just visible at Peterhead. In the foreground the view is across the entrance to the Harbour and its associated industrial buildings. Aberdeen Beach is visible behind the harbour entrance wall and the city with the developments along the coast including the tower blocks at Seaton which are very visible. The rolling hills that surround Aberdeen in the west are visible behind the cityscape. As the view moves across to the east, the exhibition centre and demonstration oil drilling platform are visible in the skyline. Balmedie and the dunes can be seen extending eastwards across the horizon where the large expanse of the North

Sea becomes dominant with frequent movement of ships and boats giving some scale to the view. There is a diversity of elements within the view including a very active foreground. Therefore the sensitivity of the key receptors of visitors to the headland and coastal path walkers to the type of proposed change is considered High to Medium.

5.3.8. **Viewpoint 8 – South College Street, Aberdeen**

This city centre viewpoint is located on South College Street which runs parallel to the train station. It is located 9.19 km south west of the nearest turbine of the EOWDC and is representative of views available to workers, shoppers, and travellers. An advertising board lies alongside the footpath. The other side of the road is bounded by a concrete block wall approximately 2 m high. A ten storey office building is the main element in the view, with a red brick multi-storey car park for the Union shopping centre in the middle ground. A tall hotel building stands to the left of the car park. Thereafter, to the left of the view, just the tops of various buildings are visible above the wall. The Salvation Army Citadel granite tower is quite prominent between the tops of the buildings. Also visible is the spire of Kirk of St Nicholas. The view consists of a variety of materials and types of buildings giving a slightly discordant character. It is an active area with constant traffic and train movements. The sensitivity of the key receptors of workers, shoppers and travellers to the type of proposed change is therefore considered Low.

5.3.9. **Viewpoint 9 – Forvie Nature Reserve**

Forvie Nature Reserve is a large expanse of sand dunes on the northern side of the Ythan estuary. There are marked walking routes around and across the dunes. The viewpoint is located within the centre of the dune system on one of the paths and lies within the Aberdeen Bay seascape unit. It is approximately 10.27 km north of the nearest turbine of the EOWDC. The viewpoint is representative of those available to visitors to the nature reserve. The sand dunes are mostly colonised by grasses and in some of the more sheltered areas there are small wind sculpted trees. There is a remoteness and almost bleakness when within the dunes although the noise of the nearby main road is discernable and the helicopter flight path to the airport is directly overhead. The dunes do provide some enclosure which opens out in places and at the viewpoint location the view opens out to the curve of Aberdeen Bay to Girdle Ness and the Seaton tower blocks are visible in the horizon, although detail is hard to discern at this distance. Walking towards the west, to the visitor car park, there are some views of the Hill of Fiddes turbines. Due to the remote and generally unspoilt landscape the sensitivity of the key receptors of visitors to the type of proposed change is considered High.

5.3.10. **Viewpoint 10 – Midstocket Road/North Anderson Drive (A90)**

This viewpoint, which is 10.47 km south west of the nearest turbine of the EOWDC, is located in an area of public open space to the south of housing at Raeden, just south of Woodhill House and the Aberdeen Royal Infirmary. It is representative of the views available to local residents, and travellers on North Anderson Drive (A90). This elevated part of Aberdeen affords intermittent long distant views across Aberdeen to the coast. The foreground of the view is mostly grass with some young tree planting. Four storey housing lies at the edge of the open space and the tower blocks at Stockethill are very prominent in the skyline behind. Some of the hospital buildings are visible behind the trees including a large chimney and the tower blocks of Seaton on the coastline are visible behind. It is an active and noisy area with the main road, schools and hospital in the area. Therefore the sensitivity of the key receptors of local residents and travellers on the A90 to the type of proposed change is considered High for residents and Medium to Low for travellers.

5.3.11. **Viewpoint 11 – Leslie Road (A978), Aberdeen**

Leslie Road is aligned in a north east – south west direction which is in line with the proposed development. There are no views of the coast but the elevated position suggests that the proposed development may be visible. This viewpoint is located 8.07 km from the nearest turbine of the EOWDC and is representative of views available to local residents and travellers on the road. The road is a busy thoroughfare but it is also a well-kept residential street with terraced two storey granite houses and some bungalows. The view looks towards a busy roundabout with commercial granite properties on the other side. It is considered that the sensitivity of the key receptors of local residents and travellers to the type of change proposed is High for residents and Medium for travellers.

5.3.12. **Viewpoint 12 – Kincorth Hill**

This viewpoint is located in a local nature reserve 11.56 km from the nearest turbine of the EOWDC and is representative of the view available to walkers and visitors. It lies within the Kincorth and Tullos Hills character area. It is a local high point at 105m AOD and is surrounded by Kincorth residential area to the north, Altens industrial estate to the east and Cove Bay to the south east. The A90 runs along the western boundary. The paths around Kincorth Hill are mostly enclosed by mixed woodland and scrub with some localised clearings. The viewpoint was taken from one such clearing with a bench on the high point which overlooks Aberdeen and to the north. Trees interrupt clear views but the curve of Aberdeen Bay is visible with Torry, and harbour buildings clear in view. The tower blocks at Seaton and other dominant buildings are just visible behind the trees. The tower of Nigg Kirk unexpectedly rises from the trees into the skyline to the right of view alongside the large office buildings of Altens. The viewpoint is very much influenced by the settlement and noise of traffic from the A90, although the vegetation gives some seclusion. The sensitivity of the key receptors of visitors and walkers to the type of proposed change is therefore considered High to Medium.

5.3.13. **Viewpoint 13 – Udny Station**

This viewpoint is located east of the small village of Udny Station on a local high point. It is 12.63 km north west of the nearest turbine of the EOWDC, and is representative of the views available to local residents. The landscape is characteristic of the Formartine Lowlands agricultural land, and includes wind turbines. The Hill of Fiddes turbines are located within a kilometre of the viewpoint but are partially hidden behind coniferous shelterbelt planting. Although not visible within the photographic panorama in Figure WF-13, distant views to Ardgrain wind farm can also be seen to the north of the viewpoint. Farm buildings and a cottage are visible in the foreground. The view extends across the agricultural lands with dispersed farms and houses and areas of woodland. Wooden telegraph poles lie across the view. It is generally a harmonious view with a large open scale. It is considered that the key receptors of local residents will have a High sensitivity to the type of proposed change.

5.3.14. **Viewpoint 14 –A96 at Kirkhill Forest**

This viewpoint is representative of the views available to travellers approaching Aberdeen from the A96. Due to the lack of a safe place to stop on the carriageway the entrance to Kirkhill Forest provides a comparative view. It is 14.13 km west of the nearest turbine of the EOWDC and lies within the Kirkhill and Tyrebagger Hill landscape character area. The view extends to the North Sea and provides an approximate 90 degree view enclosed by Kirkhill Forest to the north and the embankment planting along the A96. The foreground consists of small undulating rough grazing fields with stone wall and post and wire boundaries. Farm buildings and the tops of the houses at Chapel of Stoneywood appear from behind the undulating field. The woodland at Tyrebagger is visible in the middle ground with views of the taller buildings of Aberdeen city visible in the skyline to the right of view and within the sea in the centre of view. There is a small two blade turbine clear in middle ground. The residential areas on the higher ground north of Bridge of Don are visible to the left of view with agricultural land encroaching. The sea can be seen between the Bridge of Don and Kincorth Hill, and then a short stretch from Blackdog where coniferous trees in the foreground prevent further views. There are many telegraph poles also crossing the view. The mast at Northfield is very visible behind and above the tower blocks at the right of view. It is quite a discordant view with a variety of long and short distance elements. The sensitivity of the key receptors of travellers on the A90 to the type of proposed change is therefore considered Medium to Low.

5.3.15. **Viewpoint 15 – Brimmond Hill**

This elevated viewpoint is 14.41 km west south west of the nearest turbine of the EOWDC. It is representative of the views available to walkers and visitors and is within the Brimmond Hill landscape character area. Brimmond Hill is 266 m AOD and has several telecommunication masts on its summit. There are several paths which traverse around and ascend the hill. The hill is mostly covered by heather, gorse and scrub with some grass clearings. There is a vehicle track to the top to access the masts. There is a 360 degree available view extending to the Cairngorms and the foothills in the west and south west, and the rolling agricultural heartlands to the north. In the foreground, to the north Aberdeen Airport, Tyrebagger and Kirkhill forest are clearly visible. The coastline and boats far off in the North Sea are also visible to the east. The views are far ranging and encompass rural, agricultural and city scenes. Existing wind farms are visible to the north west. Due to the expansive views and diversity of elements within the view the sensitivity of the key receptors of walkers and visitors to the type of proposed change is considered High to Medium.

5.3.16. **Viewpoint 16 – Formartine and Buchan Way nr Quilquox**

The national cycle route runs along local roads in this area. The viewpoint is located on a road near Savoch and Quilquox. It lies on elevated land which affords expansive views across the landscape. The location is 25.98 km north west of the nearest turbine of the EOWDC and is representative of the views available to local residents and cyclists. It is within the Ythan Strath Farmland landscape character area. The view is of a large scale undulating landscape with large fields with stone walls and post and wire fencing. Wind turbines are common in this area and three turbines can be seen in this view. Four turbines lie just behind the viewpoint and three are obscured by the farm in the foreground. Bennachie is clearly visible to the south with other hills in the background. The coast is not visible. There is a uniform and cohesive character to the view with consistent elements across the landscape including wind turbines. The sensitivity of the key receptors of local residents and cyclists to the type of proposed change is considered High for residents and Medium for cyclists.

5.3.17. **Viewpoint 17 –Near Netherley, east of Durris Forest**

This viewpoint is 24.99 km south west from the nearest turbine of the EOWDC. It is located at the southern end of the Kincardine Plateau character area before the land rises to become the 'The Mounth' moorland plateau. It is representative of views available to local residents. The land surrounding the viewpoint is gently undulating. The land use is mainly agricultural with permanent pasture, arable, with some scrub and shelterbelt woodland. Durris Forest lies to the south west of the viewpoint. The fields are irregular, medium to large sized bounded by either stone walls or post and wire fencing. There are many individual farms and houses dispersed across the landscape accessed by a network of minor roads. There are prominent pylons in the skyline which run north south just in front of the viewpoint. The suburbs of Aberdeen are just visible with the tower blocks at Stockethill clear in the skyline, albeit at a distance. Woodland at Maryculter and Banchory Devenick are visible on the rolling hills to the right of view. It is a slightly fragmented landscape with scrub and rough grazing breaking up the medium to large fields, and with large pylons dissecting the scene. The sensitivity to of the key receptors of local residents to the type of proposed change is therefore considered High.

5.3.18. **Viewpoint 18 – A975 near Slains Castle**

This viewpoint is located at a public car park off the A975, north of Cruden Bay. It is representative of views available to visitors to the ruins of Slains Castle. It is located 22.23 km north of the nearest turbine of the EOWDC and lies within the Collieston to Peterhead seascape unit. The view looks across large open fields with the silhouette of the ruins of Slains castle in the skyline. The south of Cruden Bay is just visible within the craggy cliffs. Open large scale fields surround the view to the west and north. There is a simplistic nature to the view but this is punctuated by dramatic elements such as the Slains ruins and the cliff coastline. The key receptors of visitors are considered to have a High sensitivity to the type of proposed change.

5.3.19. **Viewpoint 19 –Mither Tap, Bennachie,**

Bennachie is a hill range in western Aberdeenshire. The distinctive peak of Mither Tap can be seen from the coast on clear days. It is a very popular walking destination in Aberdeenshire and can take as short as an hour to get to the summit. The viewpoint is located at the top of Mither Tap and is representative views available to walkers and visitors to the area. It is 32.02 km west of the nearest turbine of the EOWDC and lies within the Grampian Outliers character area. 360 degrees views are available from this viewpoint. The views extend inland across the top of Bennachie to the Cairngorms. On a clear day it is possible to see the coast and sea, although at some distance, and beyond an expansive view of the agricultural heartlands of Aberdeenshire. There are views of other wind farms dotted around in the surrounding landscape but they appear as small elements within the wider view. The key receptors of walkers are considered to have a High to Medium sensitivity to the type of proposed change due to the elevated nature and expansive views including existing wind farms. Please note that it was not possible to take a photograph panorama from the viewpoint due to adverse weather conditions at the time of the assessment.

5.3.20. **Viewpoint 20 - A92 near Uras**

This viewpoint is 33.58km from the nearest turbine of the EOWDC. The viewpoint was chosen as representative of views available to travellers on the A92, the coastal road. The landscape lies within the 'Inverbervie to Stonehaven' seascape unit. The land is gently undulating arable and pasture which slopes towards the coast and to the extents of the cliff tops. The fields are medium to large scale surrounded by stone walls and post and wire fencing. There is dispersed settlement across the area which includes cottages and a farm within the view. Wooden telegraph poles run across the left of the view. The cliffs north of Stonehaven to Girdle Ness are visible with the farmland and coastal settlements on top. It is, overall, a simple, intact and relatively large scale landscape with expansive views across the North Sea. The sensitivity of the key receptors of travellers on the A92 to the type of proposed change is considered Medium.

Table 1.8 Representative Viewpoint Baseline

	Location	**Grid Ref**	**Distance to Nearest Turbine (EOWDC)**	**Seascape Unit / Landscape Character Area**	**Main Receptors**	**Sensitivity of receptor to the type of change proposed**
1	Balmedie Beach	398035, 818190	3.51km	Aberdeen Bay ALS	Visitors/Walkers Coastal Trail	High
2	A90 (Harehill turn off)	395061, 813041	4.44km	Aberdeen Bay/Murcar Open Farmland	Travellers	Medium to Low
3	Jesmond Drive	392533, 811500	7.14km	(Aberdeen suburbs)	Residents	High
4	Whitecairns (B999)	391988, 818158	8.1km	Formartine Lowlands	Travellers Residents	Medium to Low High
5	Aberdeen Beach	395404, 806706	7.52km	Aberdeen Beach	Visitors/Walkers Coastal Trail	High
6	A90 (West Pitmillen turn off)	397470, 824886	9.31km	Formartine Lowlands	Travellers	Medium to Low
7	Torry Battery	396465,	7.89km	Aberdeen	Visitors/Walkers	High to

	Location	Grid Ref	Distance to Nearest Turbine (EOWDC)	Seascape Unit / Landscape Character Area	Main Receptors	Sensitivity of receptor to the type of change proposed
		805730		Beach	Coastal Trail	Medium
8	South College Street	394113, 805572	9.19km	Aberdeen City	Workers, Shoppers, Travellers	Low
9	Forvie Nature Reserve	401546, 826795	10.27km	Aberdeen Bay ALS	Visitors/Walkers Coastal Trail	High
10	Midstocket Road/North Anderson Drive	391188, 806645	10.47km	(Aberdeen city)	Residents Travellers	High Medium to Low
11	Leslie Road (A978), Aberdeen	392980, 808269	8.07km	(Aberdeen city)	Residents Travellers	High Medium
12	Kincorth Hill	394033, 802824	11.56km	Kincorth and Tullos Hills	Visitors/Walkers	High to Medium
13	Udny Station	391203, 824423	12.63km	Formartine Lowlands	Residents	High
14	A96 at Kirkhill Forest	385467, 811435	14.13km	Tyrebagger Hill/ Kirkhill	Travellers	Medium to Low
15	Brimmond Hill	385634, 809120	14.41km	Brimmond Hill	Visitors/Walkers	High to Medium
16	Formartine and Buchan Way nr Quilquox	391363, 839091	25.98km	Ythan Strath Farmland	Cyclists Residents	Medium High
17	Near Netherley, east of Durris Forest	382565, 794645	24.99km	Kincardine Plateau	Residents	High
18	A975 near Slains Castle	410210, 837001	22.23km	Collieston to Peterhead ALS	Visitors/Walkers Coastal Trail	High
19	Mither Tap, Bennachie	368227, 822362	32.02km	Grampian Outliers ALS	Visitors/Walkers	High to Medium
20	A92, near Uras	387626, 781595	33.58km	Inverbervie to Stonehaven ALS	Travellers Coastal Trail	Medium

6.0 Summary

The baseline landscape, seascape and visual environments within the 40 km study area have been defined and sensitivity to the proposed development assessed.

Within the study area there are no national designated landscapes except for 19 Gardens and Designed Landscapes, two of which are within 15 km of the site. Local designations include Areas of Landscape Significance which cover a large proportion of the coast line and inland areas adjacent to the Cairngorms.

Six seascape units were defined from Inverbervie to Fraserburgh with varying sensitivities towards the proposed development. The north part of Aberdeen Bay at Forvie Sands has the highest sensitivity, assessed at High to Medium due to the remote and unspoilt dune landscape. There are however views from some places within this coastal area of existing onshore turbines and of the developed seafront of Aberdeen which reduce its sensitivity.

The sensitivity of the 38 landscape character areas within the 40 km study area to the proposed development was also assessed with regards to their visual characteristics. Those areas where views out to the sea and coastline are a key characteristic have the highest sensitivity. This includes the higher Moorland Plateau areas at the extents of the study area, and open farmland adjacent to the coastline.

The visual baseline identified key receptors of residents, travelling public (including sea travel), and visitors and tourists. Twenty viewpoints were selected through a consultation process, based on the ZTV plan, to help define the visual environment. The sensitivity to the proposed development of the main identified visual receptor group at each viewpoint was described. Fifteen of the viewpoints are located within 15 km of the site, with seven of these in and around Aberdeen. Those with highest sensitivity to the proposed development are those viewpoints where residents or visitors are the key receptors. This includes the viewpoints at Balmedie Beach, Jesmond Drive, Aberdeen Beach, Forvie Nature Reserve, Udny Station, near Netherley, and near Slains Castle.

7.0 Appendices

Appendix 1. Consultation Record

Aberdeen City Council (Robert Forbes)	
Date of Consultation	**Type and Purpose of Consultation**
24th November 2009	Letter enclosing methodology, viewpoints and ZTV, and cumulative sites for review and agreement.
18th December 2009	Requesting response to earlier letter to agree methodology, viewpoints and cumulative sites.
14th April 2010	Meeting at SNH Offices, Aberdeen to agree approach to assessment.
29th September 2010	Email to advise on upcoming consultation material to be issued shortly.
19th October 2010	Email issuing detailed ZTV, large scale ZTV and viewpoint list for review.
28th October 2010	Email from ACC confirming agreement to viewpoints and requesting a viewpoint at Girdle Ness Lighthouse.
5th November 2010	Phone call with ACC discussing the inclusion of the lighthouse as part of the cultural heritage section and retaining Torry Battery viewpoint within the SLVIA.
13th December 2010	Email issuing proposed cumulative methodology.
13th December 2010	ACC replied querying assessment of land based elements. Reply sent on same day referring to client and informing Mr Forbes we are not involved in the assessment of onshore works.
25th January 2011	Email from ACC in response to SNH comments and requesting additional viewpoints.
25th January 2011	Email to ACC to confirm that requested viewpoints are covered by nearby agreed viewpoints and within the landscape assessment.
28th January 2011	Email from ACC in response to SNH emails stating ACC was not aware of an agreed study area.

Aberdeenshire Council (Peter Fraser)	
Date of Consultation	**Type and Purpose of Consultation**
24th November 2009	Letter enclosing methodology, viewpoints and ZTV and cumulative sites for review and agreement.
14th December 2009.	Letter from AC giving other viewpoint options and further cumulative sites.
23rd December 2009	Email to AC, responding to the earlier assessment suggestions and request to join SNH for a meeting.
14th April 2010	Meeting at SNH Offices, Aberdeen to agree approach to assessment.

Aberdeenshire Council (Peter Fraser)	
Date of Consultation	**Type and Purpose of Consultation**
29th September 2010	Email to AC to advise on upcoming consultation material to be issued shortly.
19th October 2010	Email issue of detailed ZTV, large scale ZTV and viewpoint list for review.
22nd October 2010	Phone Call to AC enquiring as to any feedback to the information previously sent. Mr Fraser replied he was happy to refer to SNH.
29th October 2010	Email issue of revised viewpoint list for information.
13th December 2010	Email issue of proposed cumulative methodology for information.

Scottish Natural Heritage (Sue Lawrence)	
Date of Consultation	**Type and Purpose of Consultation**
24th November 2009	Letter to SNH enclosing methodology, viewpoints and ZTV for agreement.
14th December 2009	Email/letter from SNH giving advice on various parts of the methodology, viewpoint options and study area.
23rd December 2009	Response to SNH letter and request for meeting to discuss issues raised.
14th April 2010	Meeting at SNH Offices, Aberdeen to agree approach to assessment.
29th September 2010	Email to advise on upcoming consultation material to be issued shortly.
19th October 2010	Email issue of detailed ZTV, large scale ZTV and viewpoint list for review.
29th October 2010	Email issue of revised viewpoint list.
9th November 2010	Email response from SNH advising on further cumulative viewpoints and clarity on viewpoint locations.
9th November 2010	Email to SNH confirming viewpoint locations and agreement of including additional cumulative viewpoints.
13th December 2010	Email issue of proposed cumulative methodology
24th January 2011	Email from SNH agreeing to the cumulative methodology, querying study area size, agreeing to Bennachie viewpoint as wireframe only due to weather constraints, and suggestion of Menie Estate viewpoint.
25th and 28th January 2011	Discussion emails on study area.
22nd February 2011	SNH response requesting 40km study area.
March 2011	Phone calls - attempts to discuss requested 40km study area

Scottish Natural Heritage (Sue Lawrence)	
Date of Consultation	**Type and Purpose of Consultation**
25th March 2011	Email to SNH for confirmation of agreement to methodologies and study area.
7th April 2011	SNH response confirming receipt of information and acceptance of 40km study area.

Marine Scotland (Michael Bland)	
Date of Consultation	**Type and Purpose of Consultation**
13th December 2010	Email introduction and enquiry as to any input required from them.
7th January 2011	Email from MS requesting that they would like to see any consultation but input is left to SNH, ACC and AC.
7th January 2011	Email issue of recent consultation material.

Appendix 2. SLVIA Methodology

Introduction

LDA Design has an established methodology for carrying out Seascape, Landscape, and Visual Impact Assessments (SLVIAs) for proposed offshore wind farm developments. The methodology may be varied slightly to address site or development / context specific situations, and the terms used to describe particular levels of effect may be varied (e.g. the use of the word Substantial instead of Major – see below) at the request of the EIA coordinator in order to correlate with other assessments in an ES. The standard methodology, including likely variations, is described below along with any variations specific to this particular assessment.

Overview

The methodology employed has 4 key stages, which are described in more detail in subsequent sections, as follows:

- **Baseline** – includes the gathering of documented information; scoping of the assessment and agreement of that scope with the client, EIA coordinator and local planning authority; site visits; and, initial reports to client and/or EIA coordinator of any issues that may need to be addressed within the design.
- **Design** – where appropriate, review of initial layout/ options, turbine choice(s), and mitigation options.
- **Assessment** – includes an assessment of the seascape, landscape and visual effects of the full scheme, requiring site based work and the completion of a full report and supporting graphics.
- **Cumulative Assessment** – assesses the effects of the proposal in combination with other wind farm developments.

The general assessment methodology draws upon the established Countryside Agency methodology (Landscape Character Assessment Guidance, 2002) and other recognised guidelines, in particular the Institute of Environmental Assessment and the Landscape Institute's Guidelines for Landscape and Visual Impact Assessment, second edition 2002; Scottish Natural Heritage's 'Visual representation of Wind Farms Best Practice Guidance' (2006, albeit published in May 2007); the Guidance on the Assessment of the Impact of Offshore Wind Farms (DTI, 2005); and, the Companion Guide to PPS22 (ODPM, 2004).

Specific methodologies relevant to offshore wind farm developments are particularly relevant and the proposed methodology for the seascape assessment broadly follows the guidance set out in the Maritime Ireland/Wales Interreg 1994 – 1999 Guidance 'Guide to Best Practice in Seascape Assessment', (GSA), published in March 2001. This sets out a clear methodology for undertaking seascape characterisation and for the evaluation process, and subsequent judgements arising. The guidance document is the result of joint pilot studies carried out between Wales and Ireland and sets out a clear process for undertaking a seascape assessment. It also provides practical guidance for undertaking field survey work and the field study forms are utilised during site assessment work.

Scottish Natural Heritage commissioned a report; no.103 'An assessment of the sensitivity and capacity of the Scottish seascape in relation to wind farms' (Scott et al, 2005) to contribute to strategic guidance on identifying the Scottish seascape areas where offshore wind energy development is likely to have least effects. Based largely on the GSA guidance but with some modifications that take in to account the complex seascapes of Scotland, it identifies 33 seascape units in Scotland and describes their character and sensitivity to wind farm development.

These methodologies commonly aim to systematically appraise the existing landscape / seascape condition, to identify all the significant physical and visual characteristics and assess their quality or value as well as the perceived, visual amenity value. These then provide a baseline against which the key Seascape / Landscape and Visual effects can be predicted and evaluated and their magnitude and significance assessed in a logical and well reasoned fashion. The assessment is necessarily iterative, with stages overlapping in parts.

Methodology for Identification of Seascape Units

The Guide to Best Practice in Seascape Assessment (GSA) states clearly that:

'Seascape assessment is an extension of landscape character assessment rather than a specialism in its own right. It does not replace the need for a thorough landscape assessment on land (para 1.6).'

It is therefore important to recognise the interrelationship between, and interdependency of, the sea and land. Identified seascape units will thus, whatever their scale and extent, straddle segments of the coastline with their character being defined by both seaward and landward elements. The GSA then highlights that, whilst some key elements in seascape assessment are common to landscape assessment, there are others that are noticeably different or wholly absent from landscape character assessment work. The key differences are identified as:

- The effects of historic and cultural issues related to the marine environment
- The coastline acting as a clearly defined edge
- Variability and dynamism associated with the marine and coastal components
- Difficulties associated with understanding the scale and distance of elements set within the marine component
- Different principals of visual movement arising from the coastline and marine components
- Amenity functions and uses of the seashore
- Functions and uses of the sea

Paragraphs 2.1 – 2.7 of the GSA, review each of these in turn, in further detail, highlighting key characteristics and issues. All elements, quite correctly, need to be considered during the process of defining the geographical extent of seascape units. Worthy of particular highlight are the issues associated with visibility, both from the land towards the sea, and vice versa. Clarity of visibility is in turn determined by prevailing weather conditions including such aspects as air moisture content and air pressure. Visibility in turn, influences the visual receptor's perception of distance and there are inherent difficulties in judging both scale and distance when looking across expanses of sea. Perspective can often be condensed and misread due to an absence of reference points to provide a sense of scale. Moreover, where the immediate coastline shelves gently, a further dynamic is introduced into the view, varying according to the state of the tide and the resultant extent of exposed foreshore. This both changes the character of local areas on a regular basis and also further alters visual judgments. To accommodate all of these various elements the seascape assessment process requires sufficient time to be spent on site to enable a proper understanding of the local environment.

Chapter 4 of the GSA provides clear guidance on the identification of the spatial extent of seascape units. The GSA proposes three tiers of units, namely: national, regional and local, and notes that the smaller units will effectively 'reside' within the larger regional and national units. Clear guidance is given on both the seaward and landward extent of the various scaled seascape units as well as suggestions as to their likely lateral extent along the coastline. Whilst the landward extent of seascape units can be more readily defined due to the multitude of physical elements and the complexity of landform, it is far more difficult to define a seaward extent. Thus, visibility becomes a key component in defining the seaward extent of the seascape units which can overlap as they 'bleed out' along the coastline.

National Seascape Unit

The GSA advises that national seascape units will cover extensive sections of the coastline where there is an overriding common defining characteristic such as coastal orientation or landform. It suggests that such units will be defined by major headlands of national significance. The units are then defined as extending for up to 24km offshore and inland to the full extent of the Zone of Visual Influence (ZVI). Coastal orientation and the topography of the coastline are identified as key defining characteristics.

Regional Seascape Units

The GSA advises that the most appropriate scale for undertaking seascape characterisation in association with coastal developments, such as offshore wind farms, is the regional unit. It sets out the main recommended parameters for defining regional seascape units, which are noted as generally extending for up to 15 km offshore and inland for up to 10km. It is noted that the landward extent of the regional seascape unit may well include areas of visually dead ground i.e. areas of land that are not intervisible with the sea component of the unit.

Defining Capacity for Change

The Guide to Best Practice in Seascape Assessment defines the evaluation process, and the issues to be considered as seeking to define the capacity of a seascape unit to accommodate the changes arising from the proposed offshore wind farm development. The GSA states that 'Seascape evaluation is defined as the judgement and ranking of seascapes according to their quality, value or capacity to accommodate change'. The GSA provides key guidance as to how quality, value and the capacity to accommodate change should be evaluated and this process has been followed and applied to the identified regional seascape units.

Baseline

The baseline study establishes the planning policy context, the scope of the assessment and the key landscape/seascape and visual receptors. It includes the following key activities:

- A desk study of relevant current national, regional and local planning policy for the site and surrounding areas.
- Agreement of the main study area radius with the local planning authority and SNH. Typically this is 30 - 35km, but in the case of the EOWDC 40km study area has been requested by SNH.
- A desk study of nationally and locally designated landscapes within the agreed study area.
- A desk study of existing landscape and seascape character assessments and capacity and sensitivity studies for the site and surrounding areas, both at national, regional and local level.
- Draft Zone of Theoretical Visibility (ZTV) studies to assist in identifying potential viewpoints and to indicate the potential visibility of the proposed offshore wind farm, and therefore the scope of receptors likely to be affected. The methodology used by LDA Design in the preparation of ZTV studies is described separately within Appendix 4.
- The identification of and agreement upon, through consultation, the scope of assessment for cumulative effects.
- The identification of and agreement upon, through consultation, the number and location of representative viewpoints within the study area.
- Identification of the range of other visual receptors within the study area.
- Site visits to become familiar with the site and surrounding seascape / landscape and to identify viewpoints and receptors.

During this stage, the scheme design may not yet have been finalised and there may be a degree of iteration between this stage (particularly in respect of preparing ZTV studies and consequent changes to likely effects on receptors) whilst the design is finalised.

Design

The degree of 'design fix' for offshore schemes coming forward for assessment can vary. Often there is the need to consider a number of alternative schemes and, through consultation, to reach agreement as to which of the scheme options constitutes the worst case scenario scheme in accordance with the 'Rochdale Envelope' principals. For some sites, the turbine layout may already be fixed, in which case input to the design may be limited to advising on mitigation or an indication that adjustments to particular turbine arrangements would be desirable. In other cases, it may be that no decisions have yet been made, and therefore a range of options by way of turbine numbers, sizes and layouts could be considered, and reviewed with the client and EIA team in order to arrive at an optimum proposal that best addresses the balance between potentially conflicting issues, which will include both beneficial and adverse effects. However, it will be appreciated that

LDĀ DESIGN

proposals located within the more challenging offshore environments cannot always afford a significant degree of fine tuning to turbine layout.

Beyond design changes to the arrangement of turbines, including the number and size of turbines, opportunities for significant mitigation measures are inevitably limited due largely to the nature of the proposed development and the character of the receiving marine environment. The scale of development and distance from the coastline means that there are no real meaningful opportunities for incorporating other mitigation measures. However, within the evident constraints of the proposed development, mitigation measures are considered and, wherever possible, incorporated into the evolving scheme in order to best address potential effects.

The design, siting and mitigation of potential effects of the offshore substations and monitoring mast(s) will also be considered whilst the onshore grid connection routes are usually the subject of a separate application and thus do not form part of the assessment.

The documented assessment will include:

- A description of the proposed wind farm development.
- A description of the design process and any iterations of the design.
- A description of any mitigation measures incorporated within the proposals to help reduce identified potential landscape and visual effects.

Assessment

The assessment of effects includes further desk and site based work, covering the following key activities:

- The preparation of ZTVs based on the finalised design for the development.
- The preparation of computer generated wireframes showing the proposed development from the agreed representative viewpoints
- An assessment of the magnitude and significance of effects upon the seascape regional units, landscape character, landscape designations and the existing visual environment arising from the proposed development during construction, operational and decommissioning stages.
- The production of photomontages from a selection of the agreed viewpoints showing the anticipated view following construction of the proposed wind farm development.

Preparation and use of Visuals

The preparation of the ZTVs, wireframes and photomontages complies with the SNH 'Visual Representation of Wind Farms Best Practice Guidance'. The ZTVs and wireframes are used to inform the field study assessment work, providing additional detail and accuracy to observations made on site. In line with the SNH guidance, photomontages are produced in order to assist readers of the assessment in visualising the proposals, but are not used in reaching judgements of effect.

The following points should be borne in mind in respect of the ZTV study:

1. Areas shown as having potential visibility may have visibility of the development obscured by local features such as trees, hedgerows, embankments or buildings.
2. Since only the turbine hubs and blade tips have been modelled, this may be all that is visible – rather than the turbine tower. This is particularly true of areas near the edges of potential visibility.

A detailed description of the methods by which ZTVs, wireframes and photomontages are prepared is included within appendix 4.

Assessment Terminology and Judgments

The key terms used within assessments are Sensitivity, Magnitude and Significance.

Sensitivity to change is assessed for both seascape/landscape receptors such as regional seascape units, designated areas and landscape character areas, and for visual receptors (people) at agreed viewpoints. It provides an indication of the sensitivity of those receptors to the development proposed and thus gives an indication of the likelihood of unacceptable effects on those receptors.

A description of how sensitivity is assessed for each receptor type is included below. It is rated on the following scale:

- **High** – material effects are likely to arise from a development of this nature.
- **Medium** – material effects may arise from a development of this nature.
- **Low** - material effects are unlikely to arise from a development of this nature.

The Guide to Best Practice in Seascape Assessment (GSA) indicates that the sensitivity of regional seascape units to change is an important factor in assessing the significance of effects upon a particular seascape. For example, a seascape of a grand and generous scale with a limited array of constituent elements may be deemed to have a greater capacity to accommodate change and hence have a lower level of sensitivity to a particular type of development, than a more intimate seascape that might become dwarfed by large-scale development. On the other hand, the GSA also intimates, a more fragmented seascape may have an increased capacity to accommodate change (and hence a lower level of sensitivity) on account of the existence of promontories and/or high landform that assists in intermittently concealing and revealing views of a particular offshore development. There is thus a clear need to consider both the scale of the seascape and its complexity, and the degree to which views towards offshore development change or broadly remain static.

Sensitivity of Regional Seascape Unit/Landscape Character Area

- **High** - Important components or zones of particularly distinctive character susceptible to relatively small change.
- **Medium** - A seascape or landscape of moderately valued characteristics reasonably tolerant of change.
- **Low** - A relatively unimportant seascape or landscape, potentially tolerant of substantial change.

The sensitivity of seascape units, landscape character areas and landscape designations is influenced by factors including their location in relation to the proposed development.

The appraisal also identifies the degree of sensitivity to change in representative views from key receptors and more generally within the 'visual envelope' of the proposed development.

Sensitivity of Representative Visual Receptors

This is primarily a function of the expectations and occupation or activity of the receptor and the importance of the view.

- **High** - Viewers which are highly attuned to their surroundings, with proprietary interest and prolonged viewing opportunities
- **Medium** - Viewers with a moderate awareness of their surroundings
- **Low** - Viewers with a passing awareness of their surroundings

Magnitude of Effect

Magnitude of effect is assessed for all seascape, landscape and visual receptors and identifies the degree of change. It is usually rated on the following scale:

- **High** – Total or major alteration to key elements, features or characteristics, such that post development the baseline situation will be fundamentally changed.
- **Medium** - Partial alteration to key elements, features or characteristics, such that post development the baseline situation will be noticeably changed.

- **Low** – Minor alteration to key elements, features or characteristics, such that post development the baseline situation will be largely unchanged despite discernable differences.
- **Negligible** – Very minor alteration to key elements, features or characteristics, such that post development the baseline situation will be fundamentally unchanged with barely perceptible differences.

Whilst the duration of effects is also a consideration, the normal lifespan of a wind farm, though temporary, is a period of up to 25 years (or less). As this is a reasonable length of time it is not taken into account in determining magnitude. The reversibility of effects is however, a material consideration and will be referred to within the assessment.

Significance of Effect

Significance indicates the importance of the effect, taking into account the sensitivity of the receptor and the magnitude of the effect. It is usually rated on the following scale:

- **Major**– indicates an effect that is very important in the decision making process.
- **Major-Moderate** - indicates an effect that is material in the decision making process.
- **Moderate** – indicates a noticeable effect that is not material in the decision making process.
- **Minor** - indicates an effect that is peripheral in the decision making process.
- **Negligible** - indicates an effect that is akin to no change and is thus not relevant to the decision making process.

Significant effects (in terms of the EIA regulations) are those that are Major-Moderate or Major. As stated within the EIA regulations, if an effect is not significant, it should not be considered as material to the decision making process. It should also be noted that whilst an effect may be significant, and therefore material in coming to a decision, that does not necessarily mean that such an impact would be unacceptable.

Where intermediate ratings are given, e.g. “Moderate-Minor”, this indicates an effect that is both less than Moderate and more than Minor, rather than one which varies across the range. In such cases, the higher rating will always be given first; this does not mean that the impact is closer to that higher rating, but is done to facilitate the identification of the more significant effects within tables.

The process of forming a judgment of significance of effect is based upon the assessments of magnitude of effects and sensitivity of the receptor to come to a professional judgment of how important this effect is in terms of making a decision about whether consent should be granted. This judgment is illustrated by the table below:

	MAGNITUDE			
SENSITIVITY	Negligible	Low	Medium	High
High	Negligible	Moderate	Major-Moderate	Major
Medium	Negligible	Moderate-Slight	Moderate	Major-Moderate
Low	Negligible	Minor	Moderate-Minor	Moderate

Key criteria used in determining the extent of an effect include: the magnitude of the change, the spatial extent of the change, the duration of the change, the degree to which the change is reversible and, related to prevailing weather conditions, the percentage incidence of the change.

Limitations

The nature (or valency) of the effect (Positive, Neutral or Adverse) is not identified. In the case of wind farms, there are difficulties in indicating whether seascape/landscape and visual effects will be positive or adverse. Much depends upon the attitudes and predispositions of the individual. As has been shown in a number of opinion surveys, the attitudes of the general public vary widely from those who think that wind farms blight the landscape to others who feel that they are a beautiful or positive addition, in some instances regardless of the natural beauty/value of the landscape in question. In general terms there appears to be a majority view that is positive towards wind energy generation and its appearance in the seascape / countryside and this is particularly so once a wind farm is built in a particular location. In examining visual effects, it is not realistic to ignore public opinion (nor the likelihood that professionally qualified landscape architects may have differing positions) when discussing the effect upon views perceived by the public and positive/adverse judgments are therefore not made within assessments.

Making positive/adverse judgments for effects of wind farms on landscape character based on current guidance would be of questionable value, particularly if using the conventional interpretation (which is implicit in many local plan policies) that any 'out of character' development should be considered adverse. This would effectively make all wind farm developments result in adverse effects on seascape / landscape character except if they were proposed near to another wind farm. For this reason, such judgments are not included in assessments.

Landscape Character

The European Landscape Convention (2000) provides the following definition:

"*Landscape means an area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors*."

The Landscape Character Assessment – Guidance for England and Scotland, CA/SNH, 2002 defines landscape character as:

"*the distinct, recognisable and consistent pattern of elements in the landscape that makes one area different from another*."

It also notes that (para. 2.1):

"*Character makes each part of the landscape distinct, and gives each its particular sense of place. Whether we value certain landscapes for their distinctiveness, or for other reasons, is a separate question*."

Landscape character assessment is defined as (Natural England website – credited as a quote from the guidance):

"*the tool that is used to help us to understand, and articulate, the character of the landscape. It helps us identify the features that give a locality it's 'sense of place' and pinpoints what makes it different from neighbouring areas*."

The sensitivity of seascape regional units and landscape character areas judged is based on both the attributes of the receiving environment and the characteristics of the proposed development. Thus, the key characteristics of the seascape units / landscape character areas are considered, along with scale, openness, topography; the absence of, or presence, nature and patterns of development, settlement, landcover and land uses in forming the character. The condition of the receiving seascape / landscape, i.e. the intactness of the existing character will also be relevant in determining sensitivity. The likelihood of material effects on the seascape units / landscape character areas can be judged based on the scale and layout of the proposal and how this relates to the characteristics of the receiving seascape / landscape. Thus large-scale seascapes / landscapes are likely to be less sensitive to large scale wind farm developments, whilst some small scale, enclosed seascapes / landscapes may be highly sensitive to all but very small scale proposals.

Wind turbine developments are unusual in their effects upon seascape / landscape character as they primarily involve the addition of elements rather than any alteration to, or removal of, existing features. The introduction of a wind farm into an existing seascape / landscape adds a new feature which strongly affects the "sense of place" in its near vicinity, but with distance, the existing characteristics reassert themselves. At its most basic level, the magnitude of effect can best be understood by considering how one might perceive a particular place post-construction; i.e. If the baseline perception is "I am in a field.", then this may change to: "I am in, or at, a wind farm" (High magnitude); “I am in a field near a wind farm” (Medium); “I am in a field and I can see a wind farm over there” (Low); or remain as “I am in a field” (Negligible).

It is specifically noted within Landscape Character Assessment – Guidance for England and Scotland, CA/SNH, 2002 (para 1.14) that:

“*Landscape Character Assessment is not a tool designed to resist changes that may influence the landscape. Rather it is an aid to decision-making - a tool to help understand what the landscape is like today, how it came to be like that, and how it may change in the future*.”

In para 6.32 it describes the purpose of Key Characteristics in landscape assessment, as follows:

“*Key characteristics are those combinations of elements which help give an area its distinct sense of place. They tend in many cases to be ‘positive’ characteristics but they may also, in some cases, be ‘negative’ features which nevertheless are important to the current character of the landscape. If the key characteristics which are identified were to change or be lost there would be significant consequences for the current character of the landscape. These would usually be negative but sometimes positive where some characteristics currently have a negative influence on the character (e.g. the effects of a busy road corridor). Key characteristics should therefore be the prime targets for monitoring change and for identifying landscape indicators.*”

It follows from the above that in order to assess whether seascape / landscape character is significantly affected by a development, it should be determined how each of the key characteristics would be affected. The judgment of magnitude therefore reflects the degree to which the key characteristics and elements which form those characteristics will be altered by the proposals. Based on recent appeal decisions in relation to onshore wind farm developments, there is a general consensus that significant effects on landscape character arising from wind farms are generally confined to the immediate vicinity, being of High magnitude within up to 1km of turbines (where the turbines may become the dominant characteristic of the landscape), reducing to Medium within up to 4km (where the turbines may become one of the key characteristics of the landscape) and decreasing further thereafter. The scale of the development, the nature and sensitivity of the receiving landscape, and local ‘barriers’ in the landscape (such as breaks of topography, woodlands, settlements, and roads or rivers) will determine the exact extent of effects for each development, but in practice significant landscape effects are unlikely beyond 10km.

Landscape Designations and Value

The sensitivity of designated landscapes is assessed based on their relative value. All landscapes are valued to a greater or lesser extent, and local people generally value open countryside regardless of whether or not it is designated. However, a despoiled or degraded landscape would generally be of Low value (and corresponding Low sensitivity in this respect). Undesignated, ‘everyday’ countryside would tend to be of Medium value. Nationally designated landscapes, which enjoy statutory protection (National Parks and Areas of Outstanding Natural Beauty), have a High value (and thus a high sensitivity in this respect). Locally designated landscapes would have High-Medium value and sensitivity, as would Heritage Coasts, which though nationally designated, are protected only via local plan policy.

In considering the effects on designated areas, a number of factors need to be considered. The effects on the component seascape / landscape character areas and the effects on views from within and towards the designated area need to be understood. These effects are then considered in light of the documented “special qualities” and purposes of the designation; and the proportion of the designated area that is affected, in order to arrive at a judgment of the magnitude of effects on the designated area.

Thus the judgment of the significance of effect on designated areas takes into account the value of the landscape (via the sensitivity rating) and the degree to which the purposes of designation are affected (via the magnitude). Allowing for their lower sensitivity, significant effects on local landscape designations are unlikely to occur beyond 10km from the turbines.

Viewpoints and Visual Receptors

A wide variety of visual receptors can reasonably be anticipated to be affected by a proposed wind farm development. The Guidelines for Landscape and Visual Impact Assessment indicate that the following factors affect the sensitivity of a viewpoint: The location and context of the viewpoint; the expectations and occupation or activity of the receptor and the importance of the view. These are all interlinked considerations, as the location, context and importance of the view will influence the likely activities and expectations of the receptor. The range of visual receptors will include pedestrians, and recreational users of the surrounding landscape such as walkers, cyclists and those otherwise engaged in the pursuit of leisure activities within the visual envelope of the site, local residents, motorists, those working outdoors and other workers. All categories of receptors can potentially be affected to a greater or lesser degree by a wind farm development. The four main visual receptor groups are considered in more detail below under the headings of residents, workers, the travelling public, and visitors.

Residents

Local residents tend to have a higher level of sensitivity to changes in their landscape and visual environment than those passing through. For residents, the most important views are those from their homes, although they will also be sensitive to other views such as those experienced when travelling to work or other local destinations. However, it is these latter views, from public areas nearby houses that are of relevance to the main body of the visual impact assessment (views from private properties are considered under the Residential amenity assessment – see below).

Workers

Workers are generally less sensitive to effects as they are focused on the tasks they are carrying out. Indoor workers generally have a Low sensitivity, and outdoor workers, such as farmers, fishermen and those offering outdoor pursuits are considered to have a Low to Medium sensitivity.

The Travelling Public

This category of visual receptor group overlaps to a degree with the other categories in that it embraces local residents, workers and those who come to visit the area. This group of visual receptors will include the following:

- Motorists - For major trunk routes and motorways, the sensitivity of users will be Low, as they will be travelling at speed and will be primarily focused on achieving their destination. Users of other A-roads will have a Low to Medium sensitivity, unless these are particularly scenic or slow routes, in which case the sensitivity may be assessed as Medium. The users of local roads will have a Medium sensitivity.
- Cyclists and footpath users – These groups are addressed under the heading of visitors as they are generally less concerned with the object of reaching their destination than with the enjoyment of being outside and enjoying the landscape and available views.
- Ferry Passengers – For regular services, ferry passengers will have a Low to Medium sensitivity as they will be travelling at a relatively fast speed and may or may not have an interest in their surroundings.

Users of the roads and ferries identified above will vary in their level of sensitivity to the proposed development depending primarily upon the purpose for which they are travelling. For example, local residents and those on business will be more preoccupied with achieving their destination than in enjoying the scenery and the views available along their route. In contrast, day trippers and longer term visitors to the area are likely to be more concerned with the views they enjoy as they travel, but the speed and direction of travel and the fact that they are in a vehicle or ferry will reduce their sensitivity compared to, for example, walkers or scenic boat trips.

Visitors

This category includes several visual receptor groups, each with different objectives and levels of sensitivity to any change in the fabric or character of the landscape and views arising from the proposed development. This group includes those who are mainly concerned with enjoyment of the outdoor environment but also those who may pursue indoor recreational pursuits and is anticipated to include the following (arranged in decreasing sensitivity):

- Those whose main preoccupation is the enjoyment of scenery (High sensitivity).
- Recreational walkers and equestrians (High sensitivity)
- Those visitors engaged in cultural pursuits (High-Medium sensitivity)
- Cyclists (High-Medium sensitivity)

Residential amenity

Views from private property are not a material consideration in determining planning applications unless the proposed change is sufficiently unpleasant or intrusive to cause unacceptable harm to residential amenity. For this reason, bearing in mind the distance from the coastline of offshore wind farm developments, the effects upon individual residential properties is not assessed.

Public Footpaths

Where applicable, the effects on the visual amenity on public footpaths in the vicinity of the site are assessed. Particular reference is made to effects on National and Regional Trails and Cycle routes. Assessments are informed by viewpoints which are located on public paths and by site visits and reference to aerial photography to ascertain the likely extent and nature of views available from the routes.

Settlements

The effects on settlements are not rated in terms of their magnitude or significance as there is no proper basis for forming such a judgement as each settlement will encompass a range of visual receptors which will be affected in different ways, which might vary from no view of the turbines to very clear, close views. Therefore, effects on settlements within 5km of the site are generally described in such a way as to identify where views towards the turbines are likely to arise and what the nature of those views are likely to be. In some cases this will be further informed by a nearby viewpoint and in others it will be informed with reference to the ZTVs, aerial photography and site visits.

Cumulative Assessment

The purpose of the cumulative effect assessment is to consider the potential effects upon the seascape and visual environments in relation to the existing wind farm developments and other known consented and proposed wind farm developments in the area. It raises questions over thresholds of acceptable change (spatial and temporal) and the landscape/seascape's capacity to accept change.

The Guidelines for Landscape and Visual Effect Assessment (IEMA, 2002, 2nd edition) advises that:

'*cumulative landscape and visual effects result from additional changes to the landscape or visual amenity caused by the proposed development in conjunction with other developments (associated with or separate to it), or actions that occurred in the past, present or are likely to occur in the foreseeable future.*'

A search area from the proposed offshore wind farm site is agreed with the local authority and statutory bodies. Within the agreed radius, all relevant local planning authorities and appropriate statutory consultees are contacted to identify existing and consented wind turbine developments, both on and offshore, as well as applications yet to be determined.

The cumulative assessment does not address the magnitude or significance of the effects arising from the individual developments themselves included within the cumulative assessment, but looks at the seascape and visual effects arising from the combination of turbines at proposed offshore wind farm with one or more other wind farm developments within the parameters identified.

The cumulative assessment examines the same groups of seascape / landscape and visual receptors as the assessment for the main scheme, though different viewpoints may be used in order to better represent the likely range of effects arising from the combination of schemes. The assessment is informed by cumulative ZTVs, showing the extent of visual effects of the schemes in different colours to illustrate where visibility of more than one development is likely to arise. Cumulative wireframes are prepared which show each of the developments in different colours so that they are each readily identifiable. Cumulative photomontages are also prepared.

Cumulative Landscape and Seascape Effects

As set out above in the methodology for landscape and seascape effects, the magnitude and significance of cumulative effects on the identified landscape designations, landscape features and seascape character units are a function of the baseline sensitivity of each receptor, the number and scale of the proposed wind farms in that area and the overall size and shape of the receptor / character area. Cumulative Landscape and Seascape effects will be assessed for each receptor / character unit where they are affected by more than one of the proposed wind farms.

Cumulative Visual Effects

There are two types of cumulative effects on visual amenity, namely effects arising from combined and sequential views. In accordance with the Scottish Natural Heritage publication Cumulative Effect of Wind Farms version 2 (April 2005) these comprise:

- Combined views which 'occur where the observer is able to see two or more developments from one viewpoint. Combined visibility may either be in combination (where several wind farms are within the observer's arc of vision at the same time) or in succession (where the observer has to turn to see the various wind farms).'
- Sequential views which 'occur when the observer has to move to another viewpoint to see different developments.'

Cumulative visual effects will vary in degree depending on

- the number and sensitivity of visual receptors;
- the duration, frequency and nature of views;
- the relative effect of each individual wind farm with regard to visual amenity;

Distances

Where distances are given in the assessment, these are approximate distances between the nearest turbine and the nearest part of the receptor in question, unless explicitly stated otherwise.

Appendix 4. ZTV and Visuals Methodology

ZTV Studies

ZTV studies are prepared using the ESRI ArcGIS Viewshed routine. This creates a raster image that indicates the visibility (or not) of the points modelled. Each turbine is analysed at hub and blade tip height. Two studies are carried out, with the first using a topographic model alone, in accordance with SNH guidance. A second study is also prepared including settlements (generally mapped in at an assumed average of 7.5m above ground level) and woodlands (generally mapped in at an assumed average of 15m high above ground level). If significant deviations from these assumed heights are noted during site visits, for example young or felled areas of woodland, or significant areas of single storey development, the features concerned will be adjusted within the model. The areas of settlement and woodlands are based on the Ordnance Survey Vectormap District alpha version dataset (this equates to urban areas on a 1:25,000 Ordnance Survey plan and woodlands from the Ordnance Survey streetview 1:10,000 product).

The visibility is modelled taking into account both the curvature of the earth and light refraction, and an observer height of 2m, in accordance with SNH guidance. The ZTV also begins at 1m from the observation feature (for example the wind turbine) and will work outwards in a grid of the set resolution (generally 12.4 sq. m for Ordnance Survey Opendata Landform Panorama) until it reaches the end of the terrain map for the project.

For all plan production LDA Design will produce a ZTV that has a base and overlay of the 1:50,000 Ordnance Survey Raster mapping. The ZTV will be reproduced at a suitable recommended scale on an A1 template to encompass the study area. For printing purposes all A1 figures will be produced at 600 dpi to allow interpretation of the base map.

Ground model accuracy

Depending on the project and level of detail required, different height datasets may be used. Ordnance Survey Landform Profile (roughly linked to quality of 10K mapping) and Ordnance Survey Opendata Landform Panorama (roughly linked to the quality of 50K mapping) are supplied as raster dataset. Below is listed the different data products and their specifications:

Product	Distance Between Points	Vertical Error	Horizontal Error
LiDAR	50cm – 2m	up to +/- 10Cm	up to +/- 1cm
Derived Aerial Photography Heights	1m – 5m	up to +/- 25cm	up to +/-15cm
Ordnance Survey Landform Profile	10m	+/- 1.8m	+/- 1m
Ordnance Survey Opendata Landform Panorama	49.6m	+/- 5m	+/- 3m

For most purposes, the Ordnance Survey Opendata Landform Panorama data will be used, but on certain occasions more detailed analysis of areas close to the site may be required, in which case, ZTVs based on Ordnance Survey Landform Profile data with areas of vegetation and building footprints taken from the Ordnance Survey 1:10,000 mapping may be used. Similarly, where actual heights from obstructions and hedgerows might need to be assessed more detailed surface mapping products such as Derived Aerial Photography Heights (from Infoterra or Bluesky) or LiDAR can be used.

Wireframes

Wireframes are produced in 6 key stages:

1) Photography is undertaken by a professional photographer using a digital SLR camera and 50mm equivalent lens. A tripod (usually 1.6m high) is used to take overlapping (50%)

landscape format photographs which are joined together using Adobe Photoshop software to create a single panoramic image for each viewpoint. These are then saved at a fixed height and resolution to enable correct sizing when reproduced in the final images. The photographer also notes the GPS location of the viewpoint and takes bearings to visible landmarks whilst at the viewpoint.

2) Creation of a ground model and 3D Mesh to illustrate that model - This is created using OS landform panorama point data and KEY Terrafirma ground modelling software.

3) The addition of the turbine wireframes to the 3D model using AutoCAD- The turbines are correctly proportioned to match the nacelle height and blade lengths proposed for the development. They are also modelled to closely resemble the turbines proposed. The turbines are then inserted into the 3D model at the proposed locations, facing into the prevailing wind direction.

4) Wireframe generation – The viewpoints are added within the 3D AutoCAD model with each observer point being inserted at 2m above the modelled ground plane. The location of the landmarks identified by the photographer may also be included in the model. The view from the viewpoint is then generated using the AutoCAD camera function, creating a number of single frame images, which also include bearing markers. For cumulative wireframes, each wind farm will be shown in a different colour. As with the photographs, these single frame images are joined together using Adobe Photoshop software to create a single panoramic image for each viewpoint. These are then saved at a fixed height and resolution to ensure that they are the same size as the photographs.

5) Wireframe matching – The wireframes are matched to the photographs using a combination of the visible topography; bearings taken on site and the bearing markers; and the landmarks which have been included in the 3D model.

6) Reproduction – the wireframe images are presented on sheets which are 297mm high and the length needed to show the view. The photographs are shown at 140mm high (a viewing distance of 300mm) with the wireframes below. Data required by the SNH guidance and a location plan is also included on each sheet. Where very wide panoramas (more than 180 degrees) are required to show all of the schemes within a cumulative study, the view will be split across two sheets.

Photomontages

Photomontages are produced in 4 key stages:

1) Wireframe preparation, up to stage 5 above.

2) 3D Studio Max is used to produce a rendered 3D view of the turbines from the viewpoint. The rendering uses a pale grey colour (similar to that used for many turbines) and lighting conditions according to the time of day for the viewpoint photograph. These images are then saved at a fixed height and resolution to ensure that they are the same size as the photographs.

3) The rendered turbines are then added to the photographs in the positions identified by the wireframe (using Adobe Photoshop to overlay the photograph with both the wireframe and rendered turbines to ensure accuracy). The images are then layered to ensure that the turbines appear in front of and behind the correct elements visible within the photograph.

Reproduction – the photomontage images are presented on sheets which are 297mm high and the length needed to show the view which is usually cropped to 90 degrees of the wireframe view, focussed on the wind farm location. The photographs are shown at 200mm high (a viewing distance of 435mm). Data required by the SNH guidance and a location plan is also included on each sheet. Where very wide panoramas (more than 135 degrees) are required to show all of the schemes within a cumulative study, the view will be split across two or more sheets.

Version date: 21st June 2011

Comment FINAL

This document has been prepared and checked in accordance with ISO 9001:2000.

1.0 Introduction

The Seascape, Landscape and Visual Impact Assessment (SLVIA) considers the potential effects that the EOWDC will have on the existing seascape, landscape, and visual environment. The purpose of the assessment is to determine the sensitivity, magnitude, and therefore significance of any change to the character of the regional seascape, landscape, and any areas of designated landscapes, as well as the potential effect upon views, visual amenity and receptor groups within the overall Zone of Theoretical Visibility (ZTV).

The Baseline Report (see Appendix xxx) sets out the existing seascape, landscape and visual baseline environment and identified its sensitivity to the type of change proposed. This impact assessment section describes the nature of the anticipated change upon the regional seascape units, landscape character areas and landscape designations within the study area and upon a number of agreed representative visual receptors and assesses the magnitude and significance of the anticipated changes.

The cumulative seascape, landscape, and visual effects of the proposed development with the existing, consented and in-planning wind farms are assessed for the study area. The 'in-planning' wind farms are those that have had a planning application submitted which has not yet been determined at the time of writing the assessment (18th March). The report also discusses the cumulative effects of the potential Ocean Laboratory structure, although this would be subject to a separate planning application.

1.1. Consultation

Consultation to agree upon the assessment methodology and a number of other important parameters regarding the scope of the SLVIA took place with Scottish Natural Heritage, Aberdeen City Council, and Aberdeenshire Council. The Baseline Report and its Appendix 1 provides a summary of the key stages of consultation and also provides a detailed record of all consultation which took place on the SLVIA throughout the project.

1.2. Key Guidance Documents

Key guidance documents that have informed the SLVIA include:

- Maritime Ireland/Wales Interreg 1994 – 1999 Guidance 'Guide to Best Practice in Seascape Assessment' (GSA), published in March 2001.
- 'An assessment of the sensitivity and capacity of the Scottish Seascape in relation to wind farms', (SNH commissioned Report 103, 2005).
- Guidance on the Assessment of Effect of Offshore Wind Farms: Seascape and Visual Effect Report (DTI – November 2005).
- Guidelines for Landscape and Visual Effect Assessment (Institute of Environmental Management and Assessment (IEMA) and the Landscape Institute's (LI), second edition 2002).
- Visual Representation of Windfarms Best Practice Guidance (SNH 2006, albeit published in 2007).
- Cumulative Effects on Windfarms, (SNH, 2005).
- Siting and Designing Windfarms in the Landscape (SNH, December 2009).

1.3. Data Information and Sources

Table 1.1 below records the main survey information and site study data that were used in this assessment. Please also see the Baseline Report for additional baseline assessment survey information.

Table 1.1 Summary of data and sources

Survey/Study	Date of Survey	Description
Seascape/landscape and visual receptor assessment work	February 2011	Land based driving and walking seascape and landscape receptors and viewpoints assessment
Beaches of Northeast Scotland (SNH Commissioned Report)	1977	Environmental inventory of sand beaches, dunes and associated coastal areas of the coastline of the Moray Firth from Inverness eastwards and of the North Sea coast northwards from Inverbervie.
Landscape Character Assessment of Aberdeen (SNH)	1996	Landscape Character Assessment
South and Central Aberdeenshire: Landscape Character Assessment (SNH)	1998	Landscape Character Assessment
Banff and Buchan Landscape Assessment (SNH)	1994	Landscape Character Assessment

2.0 Impact Methodology

The full assessment methodology is set out in the Appendix 2 of the Baseline Report and a summary of the methods used to assess impacts is discussed below.

2.1. Sensitivity

The sensitivity to the proposed change was assessed in the baseline report for both seascape and landscape receptors such as regional seascape units, landscape character areas, landscape designations and for visual receptors (people) at agreed viewpoints. It identified the sensitivity of those receptors to the type of development proposed and thus gives an indication of the likelihood of unacceptable effects on those receptors.

2.2. Magnitude

The magnitude of effect is assessed for all seascape, landscape and visual receptors and identifies the degree of change arising as a result of the proposed development. It is rated on the following scale;

- High – Total or major alteration to key elements, features or characteristics, such that post development the baseline situation will be fundamentally changed;
- Medium - Partial alteration to key elements, features or characteristics, such that post development the baseline situation will be noticeably changed;
- Low – Minor alteration to key elements, features or characteristics, such that post development the baseline situation will be largely unchanged despite discernable differences; and
- Negligible – Very minor alteration to key elements, features or characteristics, such that post development the baseline situation will be fundamentally unchanged with barely perceptible differences.

The spatial extent of the effect for the purposes of the SLVIA is assessed at a regional scale for seascape and landscape effects, and local effects for specific viewpoints.

The duration of effects is also a consideration, and the lease for the EOWDC site is for 22 years. Given this, the lifespan is not taken into account in determining the magnitude of any effects within the SLVIA. The reversibility of effects is, however, a material consideration and will be referred to within the assessment.

2.3. Significance

The process of forming a judgment regarding the significance of effect is based upon the assessments of magnitude of effects and the sensitivity of the receptor. Professional judgment of how the importance is then used to assess the importance of the impact is informed by Table 2.1.

Table 2.1 Matrix for Significance of Effect

	MAGNITUDE			
SENSITIVITY	Negligible	Low	Medium	High
High	Negligible	Moderate	Major-Moderate	Major
Medium	Negligible	Moderate-Minor	Moderate	Major-Moderate
Low	Negligible	Minor	Moderate-Minor	Moderate

2.3.1. Implications of Significance

The Significant effects (in terms of the EIA (Scotland) Regulations 1999) are those that are Major or Major-Moderate. As stated within the EIA Regulations, if an effect is not significant, it should not be considered as material to the decision making process. It should also be noted that whilst an effect may be significant, and therefore material in coming to a decision, that does not necessarily mean that such an effect would be unacceptable.

Where intermediate ratings are given, e.g. "Moderate-Minor", this indicates an effect that is both less than Moderate and more than Minor, rather than one which varies across the range. In such cases, the higher rating will always be given first; this does not mean that the impact is closer to that higher rating, but is done to facilitate the identification of the more significant effects within tables.

2.4. Cumulative and In-combination

As set out in Appendix 2 of the Baseline Report, there are two types of cumulative effects on visual amenity, namely effects arising from combined and sequential views. In accordance with the Scottish Natural Heritage publication Cumulative Effect of Wind Farms version 2 (April 2005) these comprise:

- Combined views which 'occur where the observer is able to see two or more developments from one viewpoint. Combined visibility may either be in combination (where several wind farms are within the observer's arc of vision at the same time) or in succession (where the observer has to turn to see the various wind farms).'
- Sequential views which 'occur when the observer has to move to another viewpoint to see different developments.'

The assessment of cumulative effects for the SLVIA of the EOWDC takes into consideration the large number of other wind farms (existing, consented or in-planning) within a 60 km radius study area. As of March 18th 2011, there are 48 existing or consented and 24 in-planning wind farms or single turbines (over 50 m hub height) within the study area. Please see Appendix 1 which lists the name, number of turbines and height of each wind farm considered in the cumulative assessment. Figure 12 shows the wind farm locations.

Cumulative landscape and seascape effects will be assessed for each receptor/character unit where there is potential for more than one wind farm to have an effect. As set out in the methodology for landscape and seascape effects, the magnitude and significance of cumulative effects on the identified landscape designations, landscape features and seascape character units are a function of the baseline sensitivity of each receptor, the number and scale of the wind farms in that area and the overall size and shape of the receptor/character area.

Please refer to Appendix 2 of the Baseline Report which details the agreed methodology for the assessment of cumulative effects of EOWDC with one or more turbines.

Due to the large number of wind farms within the study area (none of which are closer than 10km to the EOWDC), the process for producing the ZTVs has undergone much research and development for this project. The ZTVs of all 72 wind farms have been processed and overlaid with the EOWDC ZTV. The resulting images are shown in Figures 13 to 18. Figures 13 and 14 show the existing and consented wind farms overlaid with the in-planning wind farms and EOWDC. Figures 15 to 18 show a more detailed analysis by illustrating the number of sites or the number of turbines visible with the EOWDC. Through colour grading of the number of turbines or number of sites visible (on separate figures) a clearer picture is given of the main areas of 'in combination' effects with the EOWDC. To increase the legibility of this information the ZTVs of the other wind farms are only shown where they overlap with the EOWDC ZTV and the other areas without EOWDC are shown as a beige colour. Due to the number of sites and as they are all further than 10km away from the EOWDC it is not practical to identify individual site ZTVs but the locations of wind farms are identified on the plans for reference.

The potential sequential cumulative effects upon receptors along the main roads within the study area are illustrated using diagrammatic graphs which show the distance to each relevant wind farm and the length of road from which these wind farms will be theoretically visible. Please refer to section 4.3 in this report, Figure 19 and Appendix 2 of this report.

2.5. Worst Realistic Case

For the purposes of the SLVIA it was agreed with the consultees that the worst case scenario dimensions of the turbines would be eleven 10 MW turbines with a hub height of 120 m and blade tip height of 195 m above the lowest astronomical tide (LAT). The nature of the deployment centre is that it will be used to test first of run wind turbines which may result in turbines of different heights. It is not envisaged that any final mix of turbine heights will result in height difference that is greater than 20-35 m between turbines. This difference, however, may be potentially noticeable at specific locations and the assessment will take this into consideration through the production of wireframes modelled with the different turbine heights from a selection of viewpoints. Please see section 5.1 of this report.

3.0 Seascape and Landscape Effects

Whilst it also considers construction and decommissioning effects, the SLVIA is primarily concerned with the operational effects as these will have the most potentially significant effects due to the duration of this stage. The potential impacts during operational phases on the seascape and landscape are discussed below. Each impact has been assessed in its own subsection taking into consideration direct and indirect impacts as well as cumulative impacts.

Please refer to section 6.0 of this report for discussion on the seascape, landscape and visual effects during construction and decommissioning.

For the purposes of establishing intervisibility of the EOWDC with the seascape units and landscape character areas the Zone of Theoretical Visibility (ZTV) plans were reviewed. Please refer to Figures 7, 8, and 9 for the EOWDC ZTVs and also Figures 12 to 18 for the cumulative ZTVs.

The magnitude and subsequent significance of any effects arising from the proposed EOWDC upon the existing seascape and landscape resource is related to the capacity of the regional seascape unit or landscape character area to accommodate the type of change proposed and its sensitivity to the proposed change. As explained in section 2 of this report and Appendix 2 of the Baseline Report, this is assessed using the recognised Landscape Institute / Institute of Environmental Management and Assessment evaluation process, which looks at the physical form and attributes of the seascape, its quality, its sensitivity and the range of visual receptor groups that characterise the individual seascape units or character areas. The magnitude of effect upon seascape and landscape character takes into account the scale, extent and duration of the effect. Please refer to Figures 4, 5, and 6 which shows the seascape unit locations and landscape character areas.

3.1. Seascape Effects

3.1.1. Inverbervie to Stonehaven Regional Seascape Unit

This regional seascape unit (RSU) embraces the rocky coastline from Stonehaven to Inverbervie which lies just beyond the study area. It lies approximately 30 km at its closest point to the nearest turbine of the EOWDC. The ZTVs indicate that the theoretical extent of visual exposure to the proposed development is limited to the sea and a short coastal stretch from Stonehaven to Crawton. There are also limited areas of intervisibility on local high ground. The convex curve of the coastline beyond Crawton prevents any intervisibility with the coast or inshore waters.

The coastal area south of Stonehaven with intervisibility has the characteristic large scale agricultural land sloping towards the tops of the cliffs with a few isolated farms and houses. At this specific point the ground opens out towards the north and east and views of the coastline to Girdle Ness can be seen. Elsewhere in the RSU, the expansive sea views are generally focussed towards the east. Within the sea element, the EOWDC will be seen more clearly than on land, but with a backdrop of the Aberdeen Bay coastline and rolling farmland.

Taking account of the distance to the EOWDC development, the limited intervisibility from the majority of the landward element, the open and large scale character including existing onshore wind farms, this will reduce the potential for the EOWDC to affect the character of the seascape unit. Where visible it will only be a minor indistinct and distant element.

As a result the magnitude of impact upon the Inverbervie to Stonehaven RSU is considered to be Negligible. When combined with a Medium sensitivity to the proposed change, the overall significance of effect is assessed to be Negligible, with no direct effects upon the attributes of this seascape unit, and only a limited effect upon distant views from a short stretch of coastline and sea area.

Cumulative Impacts

The cumulative ZTVs show that visibility of wind farms is a baseline characteristic of this seascape unit. St John's Hill and Tullo Wind Farm, as closest to the RSU, will be dominant in views inland. There are only minor areas on land from where the EOWDC will be seen in combination with other wind farms which as shown on Figure 17 could be up to 10 existing or consented wind farms. There are no in-planning wind farms visible from this RSU. The majority of these other wind farms are closer in proximity to the seascape unit than the EOWDC and they will be only potentially seen together from a few areas on land and to a larger extent at sea. However, the EOWDC will continue to be a minor, indistinct element in these views and therefore the significance of cumulative effects on the Inverbervie to Stonehaven RSU will be Negligible.

3.1.2. Stonehaven to Girdle Ness Regional Seascape Unit

Extending approximately 20 km north of Stonehaven to Girdle Ness, this regional seascape unit is at closest 8 km from the nearest turbine of the EOWDC. The ZTVs indicate that the shape of the coastline and also the landform around Kincorth and Tullos Hills prevent much of the land and coastal elements of the RSU having intervisibility with the proposed development. Visibility is therefore limited on land to the local high points along the coast and at the edge of Aberdeen, including Girdle Ness. Due to the slight curve in the coastline between Stonehaven and Girdle Ness most of the inner shore area will not have any intervisibility but further offshore the vast open sea will afford views back to land with the EOWDC in views to the north.

At the south of the RSU, the areas of intervisibility on land are limited to sporadic, high, open agricultural land which will predominantly have views toward the east. Moving closer to Aberdeen, the coast and land element of the RSU becomes more densely settled and it is only from the open Tullos Hill and Girdle Ness that views of the development will be clearly visible.

Any visibility of the proposed development would be seen in context with the heavily built up settlement and transport corridors which lie inland from the RSU. Effects on the sea element of the RSU will potentially be greater nearer the northern extents of the unit. However, overall intervisibility from the sea with the EOWDC will not alter the perception of scale and the key characteristics of this seascape unit, which already include distant views of existing wind farms.

It is therefore assessed that there will be a Low magnitude of effect on the character of this regional seascape unit. As the level of sensitivity to the proposed change is judged to be Medium to Low, the significance of effect on this RSU is assessed as Moderate-Minor to Minor with no direct effects upon the attributes of this seascape unit, and only a limited effect upon views from the northern extents.

Cumulative Impacts

The existing baseline of this RSU includes views of wind farms, with the recently consented Meikle Carewe wind farm closest at 5km from the coastline. Clusters of existing and consented wind farms to the south and also to the north of the RSU are theoretically visible, with those to the south more dominant in views due to their closer distance. The addition of the EOWDC will add to combined visibility within the offshore extents of the RSU and only very small areas on land. Figure 16 shows that the combined visibility of the in-planning turbines with the EOWDC is very limited within this RSU both offshore and onshore. This is due to the nearest in-planning turbines (Woodlands Farm) being located at over 20km from northern extents of the RSU.

It is judged that the magnitude of cumulative effect on the Stonehaven to Girdle Ness regional seascape unit is Low given that the majority of the area has potentially existing views of wind farms and the presence of the EOWDC will only marginally increase the areas visible to wind farms and at a considerable distance. As the level of sensitivity to the proposed change is judged to be Medium to Low, the significance of cumulative effect on this RSU is assessed as Moderate-Minor to Minor.

3.1.3. Aberdeen Beach Regional Seascape Unit

This regional seascape unit is approximately 5 km at its nearest point from the closest turbine of the EOWDC. It is short stretch of deposition coastline which is characterised by the influence of Aberdeen city and its harbour. The ZTV illustrates that the majority of this area will have intervisibility with the proposed development. Only localised areas such as behind the Beach Boulevard and areas behind settlements and beach development will have limited views.

This seascape unit is typically dominated by the wide variety of seafront development, including the harbour and sea defences and the movement of sea traffic to and from the harbour. Often large numbers of ships sit for several days or weeks within the Maritime and Coastguard Agency (MCA) designated anchorage area which lies within the inshore waters. These factors all combine to make it a dynamic and slightly chaotic seascape which will assist in reducing the visual influence of the proposed development.

It is therefore judged that the magnitude of impact on the character of the Aberdeen Beach RSU is High to Medium. As the level of sensitivity to the proposed change is judged to be Medium, the significance of effect on the visual aspects of this RSU is assessed as Major-Moderate to Moderate, with no direct effect on the attributes of this seascape unit.

Cumulative Impacts

There are no wind farms within this seascape unit, however there is an existing baseline of distant views of existing and consented wind farms from the offshore part of the unit. The cumulative ZTV (Figure 17) shows that between 1 and 6 km offshore, there is the potential for combined visibility of up to six other existing and consented wind farms with EOWDC, the closest at Tillymaud and Hill of Fiddes, approximately 15km from the coastline within the RSU. The number of wind farms visible increases gradually the further offshore so that at the sea limits of the unit (24 km offshore, GSA, 2001), the ZTV shows that there is potential to see up to 30 existing or consented wind farm sites.

A similar pattern applies to the in-planning wind farms (Figure 18) where combined visibility with EOWDC starts approximately 6km from the coastline and gradually increases to over 12 sites at the offshore extents of the RSU. The closest in-planning turbines at Woodlands Farm are also approximately 15km from the coastline.

All of the existing and consented and in-planning wind farms except EOWDC will be at considerable distances from the areas of shown combined visibility and they will not be prominent elements in views from offshore.

The ZTVs show that the majority of the seaward extents of this unit have existing intervisibility with onshore wind farms but at some distance so the addition of EOWDC in close proximity to the unit has individual effects as identified above but it is judged will only have a Low to Negligible magnitude of cumulative effect due to the scale and distance of the existing, consented and in-planning turbines. As the level of sensitivity to the proposed change is judged to be Medium, the significance of cumulative effect on this RSU is assessed as Moderate-Minor to Negligible.

3.1.4. Aberdeen Bay Regional Seascape Unit

The proposed development lies within the southern part of the Aberdeen Bay regional seascape unit. This RSU stretches along the sandy coast from Donmouth to the Ythan estuary. The southern extents of the unit are more influenced by Aberdeen and its suburbs and the seascape becomes more remote towards Forvie Sands.

The ZTVs show that almost all this seascape unit will have intervisibility with the proposed development. However, the undulating sand dunes, which are a key characteristic of the area, will have marginally less intervisibility.

The proposed turbines will be a dominant feature of the seascape unit and will become a new characteristic within the sea aspect, although distant views of existing and consented onshore wind farms are possible from the RSU. The northern section of the seascape unit will remain more remote from the turbines but a visual link will exist. It is therefore considered that the magnitude of impact on the character of the Aberdeen Bay is High. Elements such as the A90, drilling platform, observation tower and views of the city, combined with the active sea traffic will assist in reducing the effect to some degree. As the sensitivity to the proposed change is judged to be Medium in the south and High to Medium in the north, the significance of effect on this RSU is assessed as Major-Moderate in the south, and Major to Major-Moderate in the north.

Cumulative Impacts

The EOWDC will be the only wind farm within the Aberdeen Bay seascape unit and the existing and consented sites ZTV (Figure 17) shows that the majority of the land, coastline and inshore waters of the Aberdeen Bay seascape unit will only have views of the EOWDC. Just beyond 1km offshore the ZTV shows that there is potential for combined views of 1 or more existing and consented wind farms which gradually increase to 28 other wind farms at the sea extents of the unit. The closest existing wind farm is the Hill of Fiddes which lies approximately 7km from the coastline within this RSU.

The in-planning wind farms will increase the number of wind farms visible with the EOWDC by potentially 12 sites at the sea extents of the unit, but does not alter the overall areas of wind farm visibility. Woodlands Farm is the closest in-planning wind farm at over 10km from the coastline.

Within an approximate 30 km radius from this seascape unit there are 24 existing and consented wind farms and 15 in-planning wind farms. The majority of these wind farms are single turbines or three turbine schemes, with the exception of a couple which have five turbines, and Meikle Carewe which will have 12 turbines.

Hill of Fiddes, Ardgrain, Tillymaud, Mains of Bogfechel, and the in-planning Woodlands Farm and Hill of Fechel turbines are the closest wind farms to the seascape unit.. They will have the potential to have the greatest cumulative effects combined with the EOWDC in views from the offshore areas of this seascape unit. Also, the in-planning Peterhead Harbour turbines will be the nearest turbines to the coast and although approximately 22km from this seascape unit, there is potentially a greater link with the EOWDC given the location.

The majority of the wind farms sites identified have a hub height of around approximately 60 m and blade tip of 100 m. As the EOWDC will have a maximum hub height of 120 m, the scale difference may be more apparent in this seascape unit than the other units due to the closer proximity of the sites. Given this size difference, the existing and consented wind farms will be much more recessive in views from the sea element of the unit and focus will be on the EOWDC.

It is judged that as potential views of wind farms from the outer sea element of the seascape unit is already a characteristic of the unit albeit at some distance, the presence of the EOWDC will mostly be confined to individual effects and the magnitude of cumulative effects will be Low to Negligible. As the sensitivity to the proposed change is judged to be Medium in the south and High to Medium in the north, the significance of cumulative effect on this RSU is assessed as Moderate-Minor to Negligible in the south, and Moderate to Moderate-Minor to Negligible in the north.

3.1.5. Collieston to Peterhead Regional Seascape Unit

This regional seascape unit is approximately 15 km north of the proposed development at its closest point and consists of the rocky stretch of coastline extending from the north of Forvie Sands to Peterhead, including Cruden Bay. The ZTVs illustrate that there will be intervisibility with the proposed development across the majority of the seascape unit except for Cruden Bay due to its sheltered nature from the surrounding higher land. To the north of Cruden Bay the inshore coastal waters will be screened from views of the EOWDC due to the orientation of the coastline and intricate cliffs.

This RSU has a large open scale which already includes large vertical features such as the power station stack and onshore turbines, and has an active outer sea element. The EOWDC will therefore not be a fundamental change to the character of the seascape unit and views of the proposed turbines will be accommodated to some degree by the vast scale of the seascape.

It is therefore judged that the magnitude of impact on the character of the RSU is Medium to Low. As the sensitivity to the proposed change is considered Medium, the significance of effect on the Collieston to Peterhead RSU is assessed as Moderate to Moderate-Minor with no direct effects upon the attributes of this seascape unit, and only limited effects upon views towards the south.

Cumulative Impacts

The cumulative ZTVs illustrate that the majority of the Collieston to Peterhead RSU already has potential views of onshore existing and consented wind farms. However, there are no wind farms within the unit itself. The ZTVs also show that only a sliver of coastline and inner coastal waters will have views of EOWDC only.

Figure 12 shows that Ardgrain, West Knock Farm, and Bruxiehill are the closest existing wind farms to the seascape unit, lying approximately 5 to 10 km from the land extents. The in-planning turbines at Peterhead Harbour and single turbine at Middleton of Rora lie close to the northern extents of the seascape unit.

On the land element of the unit where EOWDC is potentially visible, Figure 17 shows that combined views of up to 28 existing and consented wind farms may be possible. This is mainly on small areas of higher open exposed coastal land. In these areas, which lie to the south of the seascape unit, the greatest cumulative effects would be with Ardgrain and Hill of Fiddes as the closest wind farms to the area and EOWDC. The other wind farms further inland such as Skelmonae, Bruxiehill and West Knock Farm may be visible but will be more recessive in views. The in-planning wind farms will also affect a similar land area to the existing and consented turbines with EOWDC with up to 10 wind farms visible on the higher points.

The sea element of the seascape unit is less exposed to existing and consented wind farms in the inner waters but theoretical views of turbines gradually increases up to 28 sites towards the sea extents of the unit. The in-planning wind farms will slightly increase this number in the same areas as shown on Figure 18 with the exception of Peterhead Harbour turbines. These turbines will be visible with the EOWDC in the inner coastal waters (1 to 5km offshore) from the northern extents of the seascape unit.

The EOWDC will be at a similar distance to the seascape unit as the other closest wind farms in the area (except for the in-planning Peterhead Harbour turbines), but will be more visible due to its size and offshore location. Views of wind farms are a characteristic of the seascape unit and the addition of EOWDC will add another wind farm which, at this distance from the unit, will be noticeable in the southern extents but not a dominant feature.

It is therefore judged that the magnitude of cumulative impact on the character of the RSU is Medium to Low. As the sensitivity to the proposed change is considered Medium to Low, the significance of cumulative effect on the Collieston to Peterhead RSU is assessed as Moderate to Moderate-Minor to Minor.

3.1.6. **Peterhead to Fraserburgh Regional Seascape Unit**

This seascape unit lies at the outer extents of the study area, 35 km from the nearest EOWDC turbine, and embraces the north eastern corner deposition coastline of Aberdeenshire between Peterhead and Fraserburgh. The ZTV shows that the regional seascape unit would have no intervisibility with the proposed development except for the outer sea area. It can be considered at the distance from the proposed development that it would appear as a minor element within the expansive views from within the outer sea extents, where views of closer onshore existing and consented wind farms may also be possible.

Therefore it is judged that the magnitude of impact on the character of the Peterhead to Fraserburgh RSU is Negligible. As the sensitivity to the proposed change is considered Low, the significance of effect on this RSU is assessed as Negligible.

Cumulative Impacts

As judged in the above assessment, the extent of theoretical visibility of the EOWDC only affects the offshore regions of the seascape unit. Within this area the cumulative ZTVs show that up to 18 existing and consented and up to 12 in-planning wind farms would be also visible in the offshore waters with the EOWDC. As the EOWDC will be a minor, if discernable, element within this sea area, the cumulative impacts of the EOWDC on the Peterhead to Fraserburgh regional seascape unit, can also be judged as being of Negligible significance.

3.2. Landscape Effects

The following paragraphs discuss the effects of the EOWDC on the landscape character areas within the study area. As outlined in the Baseline Report there were several character areas identified which do not have any intervisibility with the site and these have not been included in the assessment. The EOWDC ZTVs (Figures 7 to 9) and cumulative ZTVs (Figures 13 to 18) have been referred to in the assessment of the effects. Please refer to Figures 5 and 6 for location of the character areas.

South and Central Aberdeenshire LCA

3.2.1. **Agricultural Heartlands: Formartine Lowlands** (LCA No.4, Figure 5)

The Formartine Lowlands landscape character area is the closest of the Agricultural Heartland landscape type to the proposed development, at just over 3 km from the nearest EOWDC turbine, extending inland approximately 20 km. The ZTV shows that the majority of the area up to 15 km inland will have intervisibility with the proposed turbines, becoming patchy at the western extents as the undulating landscape becomes more pronounced.

The EOWDC will be dominant in the characteristic expansive views for much of the eastern side of this character area but overall the generally large open scale of the Formartine Lowlands character area gives an ability to accommodate such views. Aims for increasing woodland cover as suggested in the Aberdeenshire LCA, and existing vertical features such as existing wind farms and pylons will also reduce any effects.

It is therefore judged the magnitude of impact on the Formartine Lowlands is High to Medium. As the sensitivity to the type of development proposed is Medium to Low, the significance of effect on this character area is Major-Moderate to Moderate to Moderate-Minor.

Cumulative Impacts

The cumulative ZTVs illustrate that almost all of the Formartine Lowlands has existing exposure to wind farms. However, the addition of EOWDC will extend the potential visibility of wind farms to the south eastern edge and corner of the character area where no wind farms are currently visible. Within the character area there are four existing and consented small wind farms at Hill of Fiddes, Ardgrain, Tillymaud (single turbine), and Mains of Bogfechel (single turbine) and in-planning single turbine at Mosseye, Hill of Fechel and two turbines at Woodlands Farm. There are also many other small wind farms and single turbines to the north west of this character area which will have a theoretical visual influence on this area.

The ZTV in Figure 17 shows that towards the north west of the Formartine Lowlands, there would be areas of potential combined visibility of EOWDC with up to 30 existing and consented wind farms on the local high points, but the majority of the visibility with EOWDC would be up to 6 wind farms. Figure 18 shows that up to 12 in-planning wind farms may also be visible from the same areas.

The addition of the EOWDC will increase the number of turbines visible from a large part of this character area. The three turbine wind farms at Hill of Fiddes and Ardgrain are quite noticeable existing features and it is these two sites which will potentially have the greatest cumulative effect with EOWDC on the character area due to their proximity to each other.

It is judged that the magnitude of cumulative effect on the Formartine Lowlands character area is Medium due to EOWDC extending the number of turbines visible in an area which already has a large exposure to wind farms. As the sensitivity to the type of development proposed is Medium to Low, the significance of cumulative effect on this character area is Moderate to Moderate-Minor.

3.2.2. **Agricultural Heartlands: Central Wooded Estates** (LCA No.5, Figure 5)

The enclosed nature of this character area is confirmed by the ZTV as there are very limited areas of intervisibility with the EOWDC, the nearest turbine of which lies 7.5 km away. The largest of these areas is on the east facing slopes of Auchronie Hill, north west of Westhill, at approximately 20 km from the EOWDC. Taking into account this is the only considerable area of intervisibility within the wider character area, it is considered on the whole, the magnitude of impact on the Central Wooded Estates is Negligible. As the sensitivity to the proposed change is Low, the significance of effect on this character area is Negligible.

Cumulative Impacts

The cumulative ZTV figures confirm that there is very little existing visibility of wind farms within the Central Wooded Estates in comparison to the wider study area. The few very small areas of intervisibility with the EOWDC also have visibility of up to 20 other existing and consented wind farms and 12 in-planning wind farms. As above, whilst there is potential for cumulative effects within these small areas, the majority of the character area would not have any, and as such the significance of effect on the Central Wooded Estate character area can be judged as Negligible.

3.2.3. **Agricultural Heartlands: Kincardine Plateau** (LCA No.6, Figure 5)

This triangular character area which lies between the upland areas of the Mounth and edge of Aberdeen is approximately 14.5 km from the nearest turbine of the EOWDC at its closest point. The ZTVs illustrate that there will be some intervisibility with the proposed development on the exposed inland north facing slopes around Muirskie and Auchlunies.

The magnitude of impact on the Kincardine Plateau is judged as Low to Negligible as the lack of strong characteristics and influence of the suburbs of Aberdeen reduce the impact of any views of the proposed development. As the sensitivity to the type of development proposed is Low, the significance of effect on this character area is assessed as Minor to Negligible.

Cumulative Impacts

The cumulative ZTVs show that there would be very little cumulative impacts in the Kincardine Plateau character area given the few areas of intervisibility with the EOWDC. There are no existing or consented wind farms within the area but there will be the potential for some combined views of the EOWDC with up to 18 existing and consented and up to 6 in-planning wind farms. As these areas of intervisibility are on mostly north east facing slopes it is judged that the wind farms will be those in the north, the nearest of which are the cluster of turbines around Udny at just over 20 km from the character area. It may also include Meikle Carewe Wind Farm which is the closest to the character area but lies to the south.

The addition of the EOWDC will have limited cumulative effects mostly confined to the elevated north east facing land at the south of the area where the majority of the wind farms will be at a considerable distance that they would be minor elements in the views. Therefore it is judged that the magnitude of cumulative impact on the Kincardine Plateau is Low to Negligible. As the sensitivity to the type of development proposed is Low, the significance of cumulative effect is assessed as Minor to Negligible.

3.2.4. **Agricultural Heartlands: Ythan Strath Farmland** (LCA No.7, Figure 5)

The ZTVs illustrate that the exposed hill tops of the Ythan Strath Farmland, will have intervisibility with the EOWDC which lies approximately 17 km at its closest point to the nearest turbine and 30 km at it's furthest. Views of the EOWDC will be within a wider context at this distance and elevation. The sheltered wooded estates and small scale field patterns with diverse vegetation cover will preclude large areas of this character area from extensive views out towards the EOWDC.

Taking the above into account, and the existing turbines already included in views, reduces the magnitude of impact on the Ythan Strath Farmland to Medium to Low. As the sensitivity to the type of proposed development is Low, the significance of effect on this character area is assessed as Moderate-Minor to Minor.

Cumulative Impacts

Figure 12 shows that Ythan Strath Farmland has a single turbine at Courtstone, four existing turbines at Skelmonae, with a three turbine extension to Skelmonae currently in planning. There are also other existing wind farms that surround the area.

The cumulative ZTVs show that the entire Ythan Strath Farmland already has exposure to existing, consented and in-planning wind farms. The addition of the EOWDC does not expose any new areas to wind farms but will add to the combined views on the exposed hill tops. Figure 17 illustrates that within these areas up to 30 existing and consented and up to 14 in-planning wind farms will potentially be seen with the EOWDC.

As the EOWDC lies between 17km and 30km from this character area and will be potentially seen from only the exposed hill tops where wind farms are very much an existing characteristic and in closer proximity, it is judged that the magnitude of cumulative impact is Low. As the sensitivity to the type of proposed development is Low, the significance of cumulative effect on this character area is assessed as Minor.

3.2.5. **Agricultural Heartlands: Northern Rolling Lowlands** (LCA No.8, Figure 5)

The Northern Rolling Lowlands character area lies approximately 22 km at its closest point to the nearest turbine of the EOWDC. The ZTV illustrates that the characteristic long distant views from the elevated farmland will potentially include the proposed development. Turbines are a feature of this landscape and at this distance it is unlikely the EOWDC turbines would be seen within the sea but as a minor feature in the horizon behind the undulating landforms and within an expansive view.

It is therefore judged the magnitude of impact on the Northern Rolling Lowlands is Low. As the sensitivity to the type of development proposed is Low, the significance of effect on this character area is assessed as Minor.

Cumulative Impacts

The cumulative ZTVs show that similar to the adjacent Ythan Strath Farmland, the whole of this character area has intervisibility with wind farms. Within the Northern Rolling Lowland, there are existing and consented small wind farms or single turbines at Balquhindachy, Haddo, St Johns Well, Denhill, and Hill of Easterton. St Johns Well Extension and Hillhead are the only wind farms in planning within the character area.

The Northern Rolling Lowlands is also surrounded by a large number of wind farms on all sides especially to the north and west. The addition of the EOWDC does not increase the area exposed to wind farms but will add to the combined cumulative views on the small areas of elevated areas. Figures 17 and 18 show that in these limited areas up to 30 existing and consented and up to 20 in-planning wind farms could potentially be seen. All of these wind farms lie closer to the area than the EOWDC and, as concluded above, views of the EOWDC would be limited and at some distance.

Taking into account the above and that a large part of the area will not have any visibility of the EOWDC, it is judged the magnitude of cumulative impact on the Northern Rolling Lowlands is Low to Negligible. As the sensitivity to the type of development proposed is Low, the significance of cumulative effect on this character area is assessed as Minor to Negligible.

3.2.6. **Agricultural Heartlands: Garvock and Glenbervie** (LCA No.9, Figure 5)

This character area lies just south west of Stonehaven, 27 km from the nearest EOWDC turbine at its closest point and extends beyond the 40 km study area. The ZTV illustrates that intervisibility will be limited to a few northern elevated slopes specifically at Bruxie Hill (which has existing transmitters) and also St John's Hill, which will soon support 9 turbines. Overall, the majority of the study area will not have any intervisibility with the EOWDC, and the key characteristics of views towards the Mounth and Howe of Mearns will be unaffected by the proposed development. Therefore, the magnitude of impact on the Garvock and Glenbervie character area is judged as Negligible. As the sensitivity to the type of development proposed is Medium to Low, the significance of effect on this character area is assessed as Negligible.

Cumulative Impacts

The cumulative ZTVs show that where there is limited intervisibility with the EOWDC, there will also be views of up to 14 consented and existing and up to 6 in-planning wind farms. These are limited to the highest points where the closer St Johns Hill, Hillhead of Auquhirie, Clochnahill, Jacksbank, and Droop Hill will be potentially dominant in view and the EOWDC will be recessive in comparison. It is therefore concluded that the significance of cumulative effects of the EOWDC on the Garvock and Glenbervie character area is Negligible.

3.2.7. **Moorland Plateaux: Grampian Outliers** (LCA No.12, Figure 5)

The ZTV illustrates that only the exposed upland areas of the Grampian Outliers will have intervisibility with the proposed development. The majority of the areas are forested which will prevent any views out to the wider area, but the extensive panoramic views from the promontories will have clear views of the proposed development. As these wide ranging views are elevated but at closest approximately 27 km from the nearest turbine of the EOWDC, the turbines will only be a minor element in often 360 degree views and will not be a dominant feature.

Therefore, the magnitude of impact on the Grampian Outliers can be judged as Negligible. As the sensitivity to the type of development proposed is High to Medium, the significance of effect on this character area is assessed as Negligible.

Cumulative Impacts

The cumulative ZTVs illustrate that at the highest points of the Grampian Outliers, over 30 existing and consented and up to 14 in-planning wind farms could potentially be visible. The majority of these wind farms will be closer to the character areas than the EOWDC and potentially be more noticeable in the available views. The addition of EOWDC would be a minor element, if discernable, within panoramic views where large numbers of turbines are already an existing characteristic.

Therefore, it can be judged that there will be Negligible cumulative effects on the Grampian Outliers character area.

3.2.8. **Moorland Plateaux: The Mounth** (LCA No.13, Figure 5)

The Mounth lies approximately 25km at its closest point to the nearest turbine of the EOWDC and extends beyond the study area. As it is a heavily forested area the only areas of intervisibility with the proposed development as illustrated on the ZTVs are the exposed north and north east facing slopes. The EOWDC may be a noticeable element from the nearest of these areas, but from the majority of views it will be minor if discernable at all.

As the majority of the character area will not have any visibility of the EOWDC it is considered that overall the wild and exposed character will not be changed by the proposed development. An existing wind farm at Mid Hill and the consented Meikle Carewe turbines will also be characteristics of this landscape, reducing any impact the EOWDC might have. Therefore, the magnitude of impact on The Mounth is judged as Negligible. As the sensitivity to the type of development proposed is High to Medium, the significance of effect on this character area is assessed as Negligible.

Cumulative Impacts

Figure 17 illustrates that there is potential for combined visibility of the EOWDC and up to 30 existing and consented and up to 14 in-planning wind farms within The Mounth. These are limited to small areas of high open exposed ground, in particular an area north of Mid Hill wind farm, and also the immediate surroundings to Meikle Carewe. The majority of the wind farms visible will be at a considerable distance to the north and it is most likely that the several existing and consented wind farms which lie to the south of The Mounth will be those potentially with the greater cumulative effect. As discussed above, the EOWDC may be a noticeable element from some of these areas, but given the distance and proximity of other wind farms, it will be recessive within any views.

For the same reasons as identified above, the significance of cumulative effect on The Mounth character area is assessed as Negligible.

Banff and Buchan LCA

3.2.9. **Agricultural Heartlands: Agricultural Heartlands (area)** (LCA No.18, Figure 5)

This character area lies approximately 22.5 km at its closest point to the nearest turbine of the EOWDC, extending to beyond 40 km. The ZTVs show that there is a continuous area of intervisibility with the proposed development extending from north of the Ythan river to just south of Cuminestown. The ZTVs also show another area of potential intervisibility to blade tip only which lies between Brucklay Castle, and New Pitsligo. These areas consists of the characteristic large field patterns with frequent farmstead and houses scattered across the elevated south east facing slopes with open views of the surrounding landscape. Any views of the EOWDC will be seen within these expansive views.

The majority of the character area however will not have any intervisibility with the proposed development and combined with the distance from the coast and existing wind farms in the area, the magnitude of impact on the Agricultural Heartland character area is judged as Low to Negligible. As the sensitivity to the type of development proposed is Low, the significance of effect on this character area is assessed as Minor to Negligible.

Cumulative Impacts

The ZTVs illustrate that the majority of the Agricultural Heartlands character area has existing exposure to wind farms. Within the 40 km study area there are existing turbines at Skelmonae, Newstead, Auchtygills Farm, and Clayfords Farm, with a further four sites in planning. Figures 17 and 18 illustrate that up to 30 existing and consented and up to 14 in planning wind farms will be potentially visible with EOWDC from the limited areas identified above.

The addition of the EOWDC gives the potential for combined effects on a small part of the overall character area. As the EOWDC lies beyond 22 km from the character area, it is considered that whilst it may be seen in views from this area, it will be a minor element and any cumulative effect would be minimal.

Therefore, the magnitude of cumulative impact on the Agricultural Heartland character area is judged as Low to Negligible. As the sensitivity to the type of development proposed is Low, the significance of cumulative effect on this character area is assessed as Minor to Negligible.

3.2.10. **Coastal Farmland: Eastern Coastal Agricultural Plain** (LCA No.21, Figure 5)

The Eastern Coastal Agricultural Plain with open views to the surroundings is approximately 17 km at its closest point to the nearest turbine of the EOWDC and extends north to beyond Fraserburgh. This character area overlaps with the land extents of the Collieston to Peterhead seascape unit. The ZTVs show that the southern extent of the Eastern Coastal Agricultural Plain up to Peterhead has a high level of intervisibility with the proposed development except for an area around and west of Cruden Bay. The proposed development will be clear in views to the south from this area albeit at over 17 km away. However, it is only a small area of the overall character area which will have intervisibility with the proposed development.

It is therefore judged that the magnitude of impact on the Eastern Coastal Agricultural Plain is Medium to Negligible. As the sensitivity to the type of development proposed is Medium to Low, the significance of effect on this character area is assessed as Moderate to Moderate-Minor to Negligible.

Cumulative Impacts

The cumulative ZTV illustrates that the Eastern Coastal Agricultural Plain is theoretically exposed to wind farms across the entire area except for around Cruden Bay. The southern end of the Eastern Coastal Plain has sporadic combined theoretical visibility of up to 20 existing and consented and up to 10 in-planning wind farms with the EOWDC. There are no wind farms within the southern extents of the Eastern Coastal Plain but within the 40 km study area, there are three existing and consented and four proposed wind farms.

The addition of EOWDC will expose some new areas to wind farms in the southern part of the character area but these are limited and adjacent to areas where combined views of other wind farms may be possible. As the character area lies near the coast, the views of the EOWDC will most likely take in the sea and potentially the turbines will be viewed as a separate element to the onshore wind farms in this case.

Taking into account the above, the distance between the EOWDC and the character area, and also that the majority of the character area will not have any intervisibility with the EOWDC, it is judged that the magnitude of cumulative impact on the Eastern Coastal Agricultural Plain is Low to Negligible. As the sensitivity to the type of development proposed is Medium to Low, the significance of cumulative effect on this character area is assessed as Moderate-Minor to Minor to Negligible.

Aberdeen LCA

3.2.11. **Major River Valleys: The Upper Don Valley (Aberdeen)** (LCA No.23, Figure 6)

The enclosed wooded valley of the upper Don area is approximately 12 km at its closest point to the nearest turbine of the EOWDC. The ZTVs illustrate that the Upper Don Valley has limited intervisibility with the proposed development and these areas of intervisibility are restricted to blade tip views only on the higher east facing valley sides. As much of the valley is inward looking and elements such as the sand extraction and pylons lines are dominant, it is judged that the key characteristics of this area will not be affected by the limited blade tip views of the EOWDC and the magnitude of impact on the Upper Don Valley is assessed as Negligible. As the sensitivity to the type of development proposed is Low, the significance of effect on this character area is assessed as Negligible.

Cumulative Impacts

The cumulative ZTVs show that except for a tiny sliver of land, there will be no cumulative effects within this character area. It is therefore considered that overall there will be negligible cumulative effects on the Upper Don Valley.

3.2.12. **Major River Valleys: Dyce Plain** (LCA No.24, Figure 6)

The open flat characteristics of the Dyce Plain, which lies approximately 10 km from the nearest turbine of the EOWDC, allow distant views across the landscape. The ZTV shows that the majority of this area will have intervisibility with the EOWDC with some blade tip only visibility adjacent to Dyce. The industrial and commercial activities around Aberdeen Airport will distract and will reduce the prominence of any visibility of the turbines within views to the east.

Therefore, the magnitude of impact on the Dyce Plain character area is judged as Medium. As the sensitivity to the proposed development is Low, the significance of effect on this character area is assessed as Moderate-Minor.

Cumulative Impacts

The cumulative ZTV shows that there are no views of other wind farms except for a small area south of the airport runway where 1 to 2 other consented and existing wind farms and 1 to 2 in-planning wind farms may be seen in combination with the EOWDC. These will most likely be the cluster of turbines in-planning and existing and consented at Udny and the Hill of Fiddes turbines, which lie approximately 10 km to the north.

Given that the majority of the character area will only have visibility of EOWDC the cumulative effects on the character will be limited. It is therefore judged the magnitude of cumulative effect is Low to Negligible. As the sensitivity to the proposed development is Low, the significance of cumulative effect on this character area is assessed as Minor to Negligible.

3.2.13. **Hills: Tyrebagger Hill/Kirkhill** (LCA No.27, Figure 6)

Tyrebagger Hill and Kirkhill lie at their closest point approximately 12.5 km from the nearest turbine of the EOWDC. As much of this landscape character area is covered by woodland it is only the lower open slopes to the east and to the north where the ZTV illustrates that there would be potential intervisibility with EOWDC. The hills lie directly west of the EOWDC and views of the turbines would be seen behind a foreground of the industrial and commercial development around the airport, which would reduce the impact to some degree.

Taking into account the above and that as the woodland is the main characteristic of this area which would remain unaffected by the presence of the EOWDC, it is judged that the magnitude of impact on Tyrebagger and Kirkhill is Low. As the sensitivity to the proposed development is High to Medium, the significance of effect on this character area is assessed as Moderate to Moderate-Minor.

Cumulative Impacts

The cumulative ZTVs show that there is a small area of potential cumulative visibility on the northern open slopes of Kirkhill. Figure 17 shows that up to 14 existing and consented and up to 12 in-planning wind farms are potentially visible from this area. Within this number, the closest turbines, at approximately 8 – 10 km to the north, will be at Mains of Bogfechel, Tillymaud, Hill of Fiddes, and in-planning turbines at Woodlands Farm, Hill of Fechel, and

Mosseye. Views of these wind farms would be to the north of the character area and the EOWDC would lie to the east in a different part of the view.

As this area of potential combined visibility is limited and covers only a small part of the character area, it is judged that the magnitude of cumulative effects is Low. As the sensitivity to the proposed development is High to Medium, the significance of effect on this character area is assessed as Moderate to Moderate-Minor.

3.2.14. **Hills: Brimmond Hill** (LCA No.28, Figure 6)

The ZTV illustrates that the north and eastern slopes of Brimmond Hill, and only the northern slopes of the adjacent Elrick Hill will be exposed to the proposed development. This character area lies approximately 14 km from the nearest EOWDC turbine. Extensive 360 degree panoramic views are experienced from the top of Brimmond Hill and the EOWDC turbines would be discernable and part of the view but would not dominate. The expansive views also include other wind farms in the wider area, and the masts and pylons on Brimmond Hill which are a strong feature. Also, the ZTVs show a large part of the character area will not have any intervisibility with the EOWDC.

It is therefore judged that the overall magnitude of impact on Brimmond Hill character area is Low. As the sensitivity to the proposed development is Medium, the significance of effect on this character area is assessed as Moderate-Minor.

Cumulative Impacts

The cumulative ZTVs show that from the top of Brimmond Hill there is the potential to see over 30 consented or existing wind farms, and potentially up to 16 in-planning wind farms in combination with the EOWDC. On the lower north and east slopes this number gradually reduces to up to 4 sites for both consented and existing and in-planning wind farms.

The addition of EOWDC will not increase the areas on Brimmond Hill exposed to wind farms due to the elevated nature. However, the EOWDC will become visible in part of the 360 view where no other existing, consented or in-planning wind farm will be seen and as the closest, will be the most discernable. The EOWDC will add to the perception of wind farms being a strong characteristic of the surrounding area but will not fundamentally alter the key elements of the Brimmond Hill character area.

Therefore it is judged that the magnitude of cumulative impact on Brimmond Hill character area is Medium to Low. As the sensitivity to the proposed development is Medium, the significance of effect on this character area is assessed as Moderate to Moderate-Minor.

3.2.15. **Hills: Kincorth and Tullos Hills** (LCA No.30, Figure 6)

The Kincorth and Tullos Hills lie approximately 9 km from the nearest turbine of the EOWDC. The open northerly aspects of this area of elevated land to the south of Aberdeen will have intervisibility with the proposed turbines as shown on the ZTV. The characteristic heathland cover of Tullos Hill enables clear views towards the sea, however, Kincorth Hill is more enclosed with young woodland planting and there are only a few open areas where long distant views can be seen. The turbines will be a discernable feature within the view but will not alter the key characteristics of Kincorth and Tullos Hills.

It is therefore judged that the magnitude of impact on the visual aspects of the Kincorth and Tullos Hills character area is Medium. As the sensitivity to the proposed development is Medium, the significance of effect on this character area is assessed as Moderate.

Cumulative Impacts

The cumulative ZTVs show that Kincorth and Tullos Hills may have views of up to 4 existing and consented and up to 2 in-planning wind farms combined with EOWDC. The areas of combined visibility are predominantly on the north facing slopes which indicate that the other wind farms in view are to the north, rather than those to the south of Aberdeen.

Therefore, the closest existing and consented wind farms to the character area Hill of Fiddes, Tillymaud, and Mains of Bogfechel which lie approximately 20 km to the north. The in-planning Woodlands Farm and Hill of Fechel will also be at a similar distance. The relatively small size and scale of these turbines will mean at this distance that they will not be easily perceived in views where the EOWDC in comparison will be a noticeable feature.

It is therefore judged that the magnitude of cumulative impact is Low. As the sensitivity to the proposed development is Medium, the significance of effect on this character area is assessed as Moderate-Minor.

3.2.16. **Open Farmland: Perwinnes** (LCA No.31, Figure 6)

The ZTV illustrates that except for the lower land surrounding Corby Loch, the whole of the Perwinnes open farmland will potentially have intervisibility with the proposed turbines. Long distance views can be afforded to the surrounding landscape and at approximately 7 km from the nearest turbine of the EOWDC, the turbines will be a dominant feature in views towards the east.

The EOWDC will be a noticeable change in views out from the Perwinnes Open Farmland. Other strong visual elements such as sand extraction, and the radar station, will help to some degree in reducing the effects of the EOWDC on the character area.

It is therefore judged that the magnitude of impact on the visual aspects of the Perwinnes character area is High to Medium. As the sensitivity to the proposed development is Medium, the significance of effect on this character area is assessed as Major-Moderate to Moderate.

Cumulative Impacts

The cumulative ZTVs illustrate that there is potential for combined intervisibility with up to 18 existing and consented and up to 4 in-planning wind farms within the Perwinnes Open Farmland. These areas are located on the higher land to the east of the B997, near the radar station, and also south east of Corby Loch. The closest visible wind farms are most likely to include the cluster around Udny and Hill of Fiddes turbines, at approximately 10 km north of the character area and also Meikle Carewe which is 20 km to the south. However, the potential for cumulative effects with Meikle Carewe are limited due to distance and intervening settlements.

The EOWDC will be a relatively dominant feature in views from this character area in comparison to the smaller turbines identified above, which although theoretically visible will not be particularly noticeable features.

It is judged that the overall magnitude of cumulative impact on the visual aspects of the Perwinnes character area is Low. As the sensitivity to the proposed development is Medium, the significance of cumulative effect on this character area is assessed as Moderate-Minor.

3.2.17. **Open Farmland: East Elrick** (LCA No.34, Figure 6)

East Elrick open farmland is defined as a small area on the eastern slopes of Brimmond Hill between Newhills and Craibstone character areas. It lies approximately 13 km from the nearest turbine of the EOWDC. The ZTV shows that there will be visibility of the EOWDC across the whole area except for where a woodland block on higher land precludes views behind. Although the turbines will potentially be noticeable in the view, the foreground elements such as the suburbs of Dyce, Bucksburn and Bridge of Don will be active and distracting elements.

It is therefore judged that the magnitude of impact on the visual aspects of the East Elrick character area is Medium. As the sensitivity to the proposed development is Medium to Low, the significance of effect on the visual characteristics of this area is assessed as Moderate to Moderate-Minor.

Cumulative Impacts

The cumulative ZTVs show that there is potentially some combined visibility with EOWDC and up to 4 existing and consented and up to 4 in-planning wind farms. As the land gently slopes towards the EOWDC, the closest wind farms within the views are most likely to be those in the north at Hill of Fiddes, Tillymaud, Mains of Bogfechel, Hill of Fechel and Woodlands Farm. EOWDC would potentially be seen with these wind farms within a 90 degree view but given their relatively small size and at approximately 15 km away, they would only be minor elements with the view with EOWDC a much more noticeable element.

It is therefore judged that the magnitude of cumulative impact on East Elrick character area is Low. As the sensitivity to the proposed development is Medium to Low, the significance of cumulative effect on the visual characteristics of this area is assessed as Moderate-Minor to Minor.

3.2.18. **Open Farmland: Newhills** (LCA No.35, Figure 6)

The elevation of the Newhills character area allows views towards the coast. It lies approximately 10 km from the nearest turbine of the EOWDC. The ZTV illustrates that the majority of this area will be exposed to views of the EOWDC with some areas sheltered by development at Bucksburn and Northfield. The Bucksburn valley is also sheltered from views. The surrounding landscape and urban and industrial influences are a characteristic of the views from this area and the EOWDC turbines will a noticeable feature behind.

However, it will not fundamentally change the overall character of the area, and it is therefore judged that the magnitude of impact on Newhills is Medium to Low. As the sensitivity to the proposed development is Low, the significance of effect on this character area is assessed as Moderate-Minor to Minor.

Cumulative Impacts

As this area is relatively open and elevated with views predominantly towards the east and north, the ZTV shows that there is potential for combined visibility of up to four other wind farms and the EOWDC. Assessing the ZTV, the closest wind farms to the north and east are Hill of Fiddes, Mains of Bogfechel, Ardgrain and Courtstone turbines, at approximately 15 km, 15 km, 22 km and 22 km respectively from the character area.

At these distances and due to the size and number of turbines they will not be a strong feature within the view in comparison to the EOWDC, and it is judged that the magnitude of cumulative impact would be Low. As the sensitivity to the proposed development is Low, the significance of cumulative effect on the Newhills character areas is assessed as Minor.

3.2.19. **Open Farmland: Maidencraig** (LCA No.36, Figure 6)

The Maidencraig open farmland lies approximately 12.5 km at its closest point to the nearest turbine of the EOWDC. The ZTV illustrates that the western and southern extent of the Maidencraig character area will not have any views of the development. The higher open land to the east of Kingswells will be more exposed and therefore views of the turbines will be available. They will be noticeable features, but seen behind the active foreground of the city. Views may include the Woodend Hospital tower and the turbines but they will not be in the same portion of view.

It is therefore judged that the magnitude of impact on the Maidencraig character area is Medium to Low. As the sensitivity to the proposed development is Low, the significance of effect on this character area is assessed as Moderate-Minor to Minor.

Cumulative Impacts

The cumulative ZTV shows that there is potential for combined visibility of up to 11 existing and consented and up to 2 in-planning wind farms on a small area of high ground east of Kingswells within this character area. The closest wind farms to this area are approximately 20 km away to the north and south and given the small turbine height of the majority of the wind farms in the area, it is unlikely that any of these would be major elements in the view.

Taking the above into account and the small part of the character area which is potentially exposed to combined views, the magnitude of cumulative impact is judged as Low. As the sensitivity to the proposed development is Low, the significance of effect on this character area is assessed as Minor.

3.2.20. **Open Farmland: Kingshill/Bogskeathy** (LCA No.37, Figure 6)

The Kingshill/Bogskeathy character area has north/north east facing slopes which opens the area up to views towards the proposed development. It lies approximately 14 km from the nearest turbine of the EOWDC. The ZTV shows that the turbines will be visible for the majority of this area where woodland does not preclude views. These views are wide ranging and will encompass a variety of elements of which the EOWDC turbines will be one part.

It is therefore judged that the magnitude of impact on the Kingshill/Bogskeathy character area is Low. As the sensitivity to the proposed development is Medium to Low the significance of effect on this character area is assessed as Moderate-Minor to Minor.

Cumulative Impacts

The cumulative ZTVs illustrate that there will be only a small part of this character area exposed to combined views of EOWDC with up to 2 consented and existing wind farms and 2 in-planning wind farms. As with the character areas above, the cumulative wind farms lie beyond 12 km from the area, and given the height and number of turbines, they will be small elements within the view if discernable at all.

Therefore, the overall magnitude of cumulative impact on the Kingshill/Bogskeathy character area is judged as Negligible. As the sensitivity to the proposed development is Medium to Low the significance of cumulative effect on this character area is assessed as Negligible.

3.2.21. **Open Farmland: Den of Leggart** (LCA No.38, Figure 6)

The Den of Leggart character area lies approximately 12.5 km south of the nearest turbine of the EOWDC. The ZTV illustrates that views from this narrow character area will be sporadic due to the roads and developments which enclose this area to some degree. The area is most exposed at is northern extents as the landform descends to the River Dee and also at a high point at the southern end at the A90/A956 junction. The turbines may be a noticeable feature but will not dominate views from this area.

It is therefore judged that the magnitude of impact on the Den of Leggart character area is Low. As the sensitivity to the proposed development is Low the significance of effect on this character area is assessed as Minor.

Cumulative Impacts

The cumulative ZTV shows that the elevated southern section of the Den of Leggart character area will have potential combined views of EOWDC with up to 4 existing and consented wind farms and up to 4 in-planning wind farms. The closest wind farms lie at Hill of Fiddes, approximately 20 km to the north and Meikle Carewe approximately 10 km to the south. Hill of Fiddes and nearby other wind farms will be minor elements in the view at their scale and distance from the character area. Views of Meikle Carewe will be in the opposite direction to the EOWDC, and given both their distances from the character area, the cumulative effect would not compromise the character of the area.

It is therefore judged that the overall magnitude of cumulative impact on the Den of Leggart character area is Negligible. As the sensitivity to the proposed development is Low the significance of effect on this character area is assessed as Negligible.

3.2.22. **Open Farmland: Loirston** (LCA No.39, Figure 6)

The Loirston study area is enclosed by Kincorth Hill residential development and the A90 on its west, north and east sides. It lies approximately 12 km to the south of the nearest turbine of the EOWDC. The ZTV shows that there is potentially some intervisibility with EOWDC but this is mostly limited to the high land adjacent to the A90 where views across the city will be seen and the turbines will be a noticeable but not dominant part of this view.

It is therefore judged that the magnitude of impact on the Loirston character area is Low. As the sensitivity to the proposed development is Low the significance of effect on this character area is assessed as Minor.

Cumulative Impacts

The Loirston Open Farmland has potential combined visibility with up to 20 existing and consented and up to 2 in-planning wind farms. These are limited to the raised area south of Loirston Loch. As with the Den of Leggart character area, the closest wind farms lie at Hill of Fiddes to the north and Meikle Carewe to the south, and similarly the cumulative effects are limited to a small area where any views of wind farms will be at some distance and will not detract from the character of the area.

It is therefore judged that the magnitude of cumulative impact on the Loirston character area is Negligible. As the sensitivity to the proposed development is Low the significance of cumulative effect on this character area is assessed as Negligible.

3.2.23. **Wooded Farmland: Braes of Don** (LCA No.42, Figure 6)

The Braes of Don area lies approximately 7 km at from the nearest turbine of the EOWDC. The ZTV illustrates that, due to its wooded nature and lower valley, the Braes of Don has only a limited area to the south from where there would be potential intervisibility with the proposed development. As views out to the wider landscape are not a key characteristic, the limited available views of turbines would not fundamentally affect the wooded character.

It is therefore judged that there would be Low to Negligible magnitude of impact. As the sensitivity to the type of development proposed is Low, the significance of effect on the Braes of Don will be Minor to Negligible.

Cumulative Impacts

The cumulative ZTV shows that the majority of the area has no intervisibility with other wind farms and EOWDC. However there is a strip of land near Whitestripes where Figures 17 and 18 show that there could be combined visibility of up to 12 existing and consented wind farms and up to 4 in-planning wind farms with EOWDC.

Given the small size of area potentially affected and the closest wind farm to the character area is approximately 15 km away, it is judged that the magnitude of cumulative impact is Negligible. As the sensitivity to the type of development proposed is Low, the significance of cumulative effect on the Braes of Don will be Negligible.

3.2.24. **Wooded Farmland: Craibstone** (LCA No.43, Figure 6)

Craibstone wooded farmland lies approximately 11 km from the nearest turbine of the EOWDC. Intervisibility with the proposed development as demonstrated by the ZTV is sporadic given the generally wooded nature of the character area. On the more open northern side of this character area there will be views of the EOWDC which will also include the Aberdeen Airport, Dyce and Perwinnes radar station in the foreground. The turbines will be a noticeable feature in these views but will not fundamentally change the characteristics of the area.

It is therefore judged that the magnitude of impact on the Craibstone character area is Medium to Low. As the sensitivity to the proposed development is Medium the significance of effect on this character area is assessed as Moderate to Moderate-Minor.

Cumulative Impacts

The cumulative ZTVs illustrate some very small areas of combined views of up to 2 other existing and consented wind farms with the EOWDC in the Craibstone character area. There are no in-planning wind farms visible. Similar to the adjacent areas where combined visibility is possible, it is most likely to be views of Hill of Fiddes and Mains of Bogfechel turbines, which lie approximately 13 km to the north of the area.

As these areas of combined visibility are very limited and the turbines lie at a considerable distance away where they will not be clearly discernable given the foreground elements, the magnitude of cumulative impact is judged as Negligible. As the sensitivity to the proposed development is Medium the significance of effect on this character area is assessed as Negligible.

3.2.25. **Wooded Farmland: Kingswells** (LCA No.44, Figure 6)

The Kingswells wooded farmland lies approximately 13.5 km from the nearest turbine of the EOWDC. This character area is shown by the ZTV to have intervisibility with the proposed development on the open northern and eastern areas. The sporadic woodland cover will prevent some views and where the turbines are visible, they will be a noticeable feature but the foreground of the city and its suburbs will reduce their prominence.

It is therefore judged that the magnitude of impact on the Kingswells character area is Medium to Low. As the sensitivity to the proposed development is Low the significance of effect on this character area is assessed as Moderate-Minor to Minor.

Cumulative Impacts

The cumulative ZTVs illustrate that within the Kingswells character area there is a limited area of combined visibility of EOWDC with up to 4 other existing and consented wind farms and up to 6 in-planning wind farms. Analysis of the ZTV shows that the closest wind farms are the cluster around Udny and Hill of Fiddes, and Miekle Carewe to the south all approximately 15 km from the character area. At this distance and given the size and number of turbines they will be difficult to discern in views from this area.

Given the above and as it is only a limited areas of combined visibility it is judged that the magnitude of cumulative impact is Negligible. As the sensitivity to the proposed development is Low the significance of cumulative effect on this character area is assessed as Negligible.

3.2.26. **Wooded Farmland: Hazlehead** (LCA No.45, Figure 6)

The Hazlehead wooded farmland lies approximately 12 km from the nearest turbine of the EOWDC. The ZTV illustrates that this area will have limited intervisibility with the proposed development, restricted to the open recreational fields where woodland doesn't preclude views out. In these views the turbines will be noticeable but not prominent due to the city and surrounding development in the foreground.

It is therefore judged that the magnitude of impact on the Hazlehead character area is Low to Negligible. As the sensitivity to the proposed development is Low the significance of effect on this character area is assessed as Minor to Negligible.

Cumulative Impacts

As the cumulative ZTVs illustrate that there are no views of other wind farms within this area there are no cumulative effects.

3.3. Areas of Landscape Significance

Eight 'Areas of Landscape Significance' within the 40 km study area were identified in the baseline report. The effect of the EOWDC on these areas is discussed below. Please refer to Figure 2 for the location of these areas, and also ZTV Figures 7, 8 and 12 to 18.

3.3.1. **Coastal: Balmedie to Longhaven ALS**

This area lies within the Aberdeen Bay and Collieston to Peterhead seascape units. It is approximately 3.5 km at its closest point to the nearest turbine of the EOWDC and over 25 km away at the northern extents. Views of the sea and coastline are an important characteristic of this ALS. The ZTV illustrates that this coastal ALS will have intervisibility with the proposed development for most of its length, excluding the area around Cruden Bay, where surrounding high land precludes views. There will be also some patchy areas where sand dunes and local high points preclude views. The EOWDC lies to the south of this area, so only those views looking towards the south will include the turbines and this, in most locations will also take into account the backdrop of Aberdeen and its suburbs.

The EOWDC will not directly affect the physical characteristics of the ALS, but will have an impact on the visual characteristics, mainly towards the south of the ALS where the turbines will be more dominant in views. The magnitude of impact will ease with distance from the site and it is therefore considered the magnitude of impact will vary from High to Negligible. As the sensitivity to the proposed development is High, the significance of effect on this ALS is assessed as Major to Negligible.

Cumulative Impacts

The cumulative ZTVs illustrate that the coastal ALS area from Balmedie to the Ythan estuary will only have views of the EOWDC.

North of the Ythan estuary within the Forvie Sands area of the ALS there are potentially combined views of up to 22 existing and consented and up to 10 in-planning wind farms with the EOWDC. Hill of Fiddes and Ardgrain are the closest existing wind farms to this specific part of the ALS, at approximately 7 km and 10 km respectively. Ardgrain and Hill of Fiddes are noticeable elements but will be seen in a different portion of the view to the EOWDC. The large numbers of other wind farms potentially visible (including in-planning) from this part of the ALS lie over 15 km to the north west and therefore not particularly noticeable given also the relatively small size and number of their turbines. The nearest turbine of the EOWDC to the area of high cumulative intervisibility at Forvie Sands is approximately 10 km away.

As there is an existing cumulative baseline, the addition of the EOWDC will not add a new feature, but will potentially extend the area where wind farms are visible so that the perception of wind farms increases from this part of the ALS.

At the northern extents of the ALS there are some limited areas of combined visibility with the EOWDC of up to 6 existing and consented wind farms and up to 6 in-planning wind farms. Within this part of the ALS, the closest wind farms are at Ardgrain, West Knock Farm, Bruxiehill, and in-planning Middleton of Rora and Peterhead Harbour turbines, all approximately 15km away except for Peterhead Harbour which will be 5 km from the ALS. The EOWDC at this point will be approximately 21 km to the south. Given the greater distances to the wind farms, whilst the turbines may be visible, they will be minor elements within the view and the addition of the EOWDC will not significantly increase cumulative effects in this area.

Overall, cumulative effects within the Balmedie to Longhaven ALS are limited to the area around the Ythan estuary and Forvie Sands. The addition of the EOWDC will extend the area currently exposed to wind farms and in combination with Ardgrain and Hill of Fiddes turbines there is the potential for wind farms to become a characteristic of this part of the ALS. However, given the size and location of the existing wind farms, they will not be dominant elements in views from this area.

Therefore, the magnitude of cumulative impact on the ALS as a whole is considered to be Low. As the sensitivity to the proposed development is High, the cumulative significance of effect on this ALS is assessed as Moderate.

3.3.2. Area of Landscape Significance – Coastal: Peterhead to Inverallochy ALS

The ZTV illustrates that there would be no intervisibility with the EOWDC within this ALS and therefore there will be no magnitude of impact and no significant effects.

Cumulative Impacts

As there is no intervisibility with the EOWDC, there will be no cumulative effects on this ALS.

3.3.3. Coastal: Findon to Catterline ALS

This area of landscape significance consists of the coastal strip between the railway line and the cliffs from Findon to Catterline which at its closest will be just over 15 km from the nearest turbine of the EOWDC. It lies within both the Inverbervie to Stonehaven and Stonehaven to Girdle Ness seascape units. The ALS will have sporadic areas of intervisibility with the EOWDC. These areas are the open exposed elevated parts of the coastline within which the turbines will be visible in views to the north seen behind Girdle Ness headland.

Views of the sea and coastline are important to this ALS which is on an elevated rocky coastline but the EOWDC will not be sited within the main field of view i.e. it is not directly located off this part of the coast. Taking this into account and that there are only small areas of intervisibility over 15 km in distance from the EOWDC, it is judged that overall the magnitude of impact on the ALS is Negligible. As the sensitivity to the proposed development is High, the significance of effect on this ALS is assessed as Negligible.

Cumulative Impacts

The cumulative ZTVs show that there are only very limited areas of combined visibility of EOWDC and existing and consented wind farms along this coastal ALS. The majority of these small areas lie to the south of the ALS, beyond 30 km from the EOWDC, and include views of up to 12 existing and consented wind farms but no in-planning wind farms.

As the EOWDC lies at a distance from the southern extents of the ALS where the turbines would only be just discernable, and there are only very limited areas of combined visibility, it is judged the magnitude of cumulative impacts would be Negligible. As the sensitivity to the proposed development is High, the significance of cumulative effect on this ALS is assessed as Negligible.

3.3.4. Inland: River Dee Valley ALS

The ZTV illustrates that there would be no intervisibility with the proposed development within this ALS which follows the sheltered River Dee valley. Therefore it is judged that there will be no magnitude of impact and no significant effects.

Cumulative Impacts

As there is no intervisibility with the EOWDC, there will be no cumulative effects on this ALS.

3.3.5. Inland: River Don Valley ALS

This area of landscape significance lies within the Central Wooded Estates landscape character areas, along the northern side of the River Don valley. Its eastern extents lie approximately 7 km from the nearest turbine and at furthest is approximately 17 km west. The ZTV illustrates that for the majority of the area there will be limited or no visibility with the proposed development. The main area of intervisibility is the eastern extents on the open farmland close to Corby Loch.

As only a small area of this ALS would be exposed to the proposed development and views in and along the valley will remain unchanged, it is judged that overall the magnitude of impact on the ALS would be Negligible. As the sensitivity to the proposed development is High, the significance of effect on the ALS is Negligible.

Cumulative Impacts

The cumulative ZTVs illustrate that there is only a tiny sliver of combined visibility with up to 2 existing and consented wind farms, but the majority of the ALS has no visibility of other wind farms within this ALS, therefore it is judged there will be Negligible cumulative effects on this ALS.

3.3.6. Inland: West of Inverurie ALS

This area consists of mostly high ground within the Grampian Outliers and Central Wooded Valleys landscape character areas. It lies approximately 24 km at its closest point to the nearest turbine of the EOWDC and extends beyond the 40 km study area.

The intervisibility with the EOWDC is limited to the highest open areas and much of the forestry cover on the lower slopes precludes long distant views out to the coast. Where views are available they are expansive and include many natural and manmade features such as wind farms. The EOWDC will be a minor element within the view and will not alter the character of this ALS.

It is therefore judged that the magnitude of impact on this ALS is Negligible. As the sensitivity to the proposed development is High, the significance of effect on this ALS is assessed as Negligible.

Cumulative Impacts

The cumulative ZTVs illustrate that most of the ALS is exposed to views of wind farms and the addition of EOWDC will add to small areas of combined visibility from the high promontories and some open elevated land near Inverurie. There are a large number of existing, consented and in-planning wind farms and single turbines which surround this ALS and the addition of the EOWDC will potentially extend the visibility of wind farms to a portion of views where no other wind farm currently lies.

However, as the EOWDC lies at closest 24km from the ALS, and will be a minor element within overall views which include closer wind farms and a large numbers of turbines, it is judged that the magnitude of cumulative impact is Negligible. As the sensitivity to the proposed development is High, the significance of cumulative effect on this ALS is assessed as Negligible.

3.3.7. Inland: North West of Methlick ALS

This small ALS covers a short stretch of the Ythan river valley and two of its small tributaries north west of Methlick. It lies approximately 30 km north west of the nearest turbine of the EOWDC.

The ZTV shows that this is a wooded valley area and that there is no intervisibility with the EOWDC, except for a small area of blade tip visibility on a valley slope. Taking this into account, distance from the EOWDC, and that views within the valley will remain unchanged, it is judged that the magnitude of impact is Negligible. As the sensitivity to the proposed development is High, the significance of effect on this ALS is assessed as Negligible.

Cumulative Impacts

The cumulative ZTVs show that there will be combined visibility of up to 26 other wind farms in the small area of intervisibility with the EOWDC in this ALS. However, as it is a very limited area and given the river valley character will not be altered, there will be Negligible cumulative effects on this ALS.

3.3.8. Inland: Drumtochty to Torphins and Surrounds ALS

This Area of Landscape Significance lies 36 km from the nearest EOWDC turbine at its closest point and covers much of The Mounth character area, extending beyond the 40 km study area. The ZTV show that intervisibility with the EOWDC is limited to the open highest points of the north east facing slopes, and much of this is blade tip visibility only. It is considered at this distance that if seen, the EOWDC will be a very minor element within extensive views. Therefore, it is judged that the overall magnitude of impact is Negligible. As the sensitivity to the proposed development is High, the significance of effect on this ALS is assessed as Negligible.

Cumulative Impacts

The cumulative ZTVs show that where there is potential intervisibility of the EOWDC, views of over 30 existing and consented and up to 16 in-planning wind farms are theoretically visible. Mid Hill and Meikle Carewe are the closest wind farms at approximately 1km and

10km respectively at their closest point. However, the majority of the wind farms potentially seen in combination with EOWDC will be further than 30 km to the north. Taking these distances into consideration and that EOWDC will only be a minor element if seen at all; it is judged that there will be a Negligible magnitude of cumulative effect. As the sensitivity to the proposed development is High, the significance of cumulative effect on this ALS is assessed as Negligible.

3.4. Summary of Seascape and Landscape Effects

Receptor	Approx. Distance to nearest EOWDC turbine	Sensitivity of Receptor	Magnitude of Impact	Significance of Effect	Magnitude of Cumulative Impact	Significance of Cumulative Effect
Regional Seascape Units						
Inverbervie to Stonehaven	30 km	Medium	Negligible	Negligible	Negligible	Negligible
Stonehaven to Girdle Ness	8 km	Medium to Low	Low	Moderate-Minor to Minor	Low	Moderate-Minor to Minor
Aberdeen Beach	5 km	Medium	High to Medium	Major-Moderate to Moderate	Low to Negligible	Moderate-Minor to Negligible
Aberdeen Bay	0 km	Medium (south) High to Medium (north)	High	Major-Moderate (south) Major to Major-Moderate (north)	Low to Negligible	Moderate-Minor to Negligible (south) Moderate to Moderate-Minor to Negligible (north)
Collieston to Peterhead	15 km	Medium	Medium to Low	Moderate to Moderate-Minor	Medium to Low	Moderate to Moderate-Minor to Minor
Peterhead to Fraserburgh	35 km	Low	Negligible	Negligible	Negligible	Negligible
Aberdeenshire and Banff & Buchan LCA						
Formartine Lowlands	3 km	Medium to Low	High to Medium	Major-Moderate to Moderate to Moderate-Minor	Medium	Moderate to Moderate-Minor

Receptor	Approx. Distance to nearest EOWDC turbine	Sensitivity of Receptor	Magnitude of Impact	Significance of Effect	Magnitude of Cumulative Impact	Significance of Cumulative Effect
Central Wooded Estates	7.5 km	Low	Negligible	Negligible	Negligible	Negligible
Kincardine Plateau	14.5 km	Low	Low to Negligible	Minor to Negligible	Low to Negligible	Minor to Negligible
Ythan Strath Farmland	17 km	Low	Medium to Low	Moderate-Minor to Minor	Low	Minor
Northern Rolling Lowlands	22 km	Low	Low	Minor	Low to Negligible	Minor to Negligible
Garvock and Glenbervie	27 km	Medium to Low	Negligible	Negligible	Negligible	Negligible
Grampian Outliers	27 km	High to Medium	Negligible	Negligible	Negligible	Negligible
The Mounth	25 km	High to Medium	Negligible	Negligible	Negligible	Negligible
Agricultural Heartlands (area)	22.5 km	Low	Low to Negligible	Minor to Negligible	Low to Negligible	Minor to Negligible
Eastern Coastal Agricultural Plain	17 km	Medium to Low	Medium to Negligible	Moderate to Moderate-Minor to Negligible	Low to Negligible	Moderate-Minor to Minor to Negligible
Aberdeen LCA						
Upper Don Valley (Aberdeen)	12 km	Low	Negligible	Negligible	Negligible	Negligible
Dyce Plain	10 km	Low	Medium	Moderate-Minor	Low to Negligible	Minor to Negligible
Tyrebagger Hill/Kirkhill	12.5 km	High to Medium	Low	Moderate to Moderate-Minor	Low	Moderate to Moderate-Minor
Brimmond Hill	14 km	Medium	Low	Moderate-Minor	Medium to Low	Moderate to Moderate-Minor
Kincorth and Tullos Hills	9 km	Medium	Medium	Moderate	Low	Moderate-Minor

Receptor	Approx. Distance to nearest EOWDC turbine	Sensitivity of Receptor	Magnitude of Impact	Significance of Effect	Magnitude of Cumulative Impact	Significance of Cumulative Effect
Perwinnes	7 km	Medium	High to Medium	Major-Moderate to Moderate	Low	Moderate-Minor
East Elrick	13 km	Medium to Low	Medium	Moderate to Moderate-Minor	Low	Moderate-Minor to Minor
Newhills	10 km	Low	Medium to Low	Moderate-Minor to Minor	Low	Minor
Maidencraig	12.5 km	Low	Medium to Low	Moderate-Minor to Minor	Low	Minor
Kingshill/Bogskeathy	14 km	Medium to Low	Low	Moderate-Minor to Minor	Negligible	Negligible
Den of Leggart	12.5 km	Low	Low	Minor	Negligible	Negligible
Loirston	12 km	Low	Low	Minor	Negligible	Negligible
Braes of Don	7 km	Low	Low to Negligible	Minor to Negligible	Negligible	Negligible
Craibstone	11 km	Medium	Medium to Low	Moderate to Moderate-Minor	Negligible	Negligible
Kingswells	13.5 km	Low	Medium to Low	Moderate-Minor to Minor	Negligible	Negligible
Hazlehead	12 km	Low	Low to Negligible	Minor to Negligible	None	None
Areas of Landscape Significance						

Receptor	Approx. Distance to nearest EOWDC turbine	Sensitivity of Receptor	Magnitude of Impact	Significance of Effect	Magnitude of Cumulative Impact	Significance of Cumulative Effect
Balmedie to Longhaven	3.5 km	High	High to Negligible	Major to Negligible	Low	Moderate
Peterhead to Inverallochy	33 km	High	None	None	None	None
Findon to Catterline	15 km	High	Negligible	Negligible	Negligible	Negligible
River Dee Valley	13 km	High	None	None	None	None
River Don Valley	7 km	High	Negligible	Negligible	Negligible	Negligible
West of Inverurie	24 km	High	Negligible	Negligible	Negligible	Negligible
North West of Methlick	30 km	High	Negligible	Negligible	Negligible	Negligible
Drumtochty to Torphins and surrounds	36 km	High	Negligible	Negligible	Negligible	Negligible

4.0 Visual Effects

The approach to undertaking the visual assessment is to first establish the extent of the ZTV for the development and then to determine how visible the proposals would be from a range of representative viewpoints and visual receptor groups and the extent of effects upon general visual amenity within the visual envelope. The methodology for this is detailed within Appendices 2 and 4 of the Baseline Report. The ZTVs illustrated in Figures 7 ,8 and 9 indicate the theoretical worst case scenario in terms of the extent of visual exposure. Figure 7 shows the ZTV produced with a bare ground model whilst the ZTVs in Figure 8 and 9 have modelled in settlement and woodlands to give a more realistic scenario. However, in reality, the extent of visual effects arising from the proposed development over land will be greatly reduced due to the subtleties of intervening landform (including, for example, the sand dunes), built form (e.g. all settlements) and localised vegetation (including hedgerows and other blocks of woodland) which are not picked up on the data sets used for ZTV construction. A built model of Aberdeen city and its suburbs has been included within the ZTVs (Figures 8 and 9) which provides a more detailed picture of the visual effects across the city but, as above, the visual effects from the proposed development will still be reduced to some extent by localised details. Prevailing weather conditions will also further influence the actual extent of visibility (please see section 4.0 of the Baseline Report for further information on the average visibility distances).

4.1.1. Overview of Visual Effects on the 40km Study Area

The areas of greatest theoretical visual effect arising from the proposed EOWDC will be along the stretch of coastline and sea adjacent to the turbines within a 5 km radius. Within a 10 km radius the ZTVs show that the majority of the landscape and seascape will have theoretical visibility of the EOWDC. Visibility on land becomes patchier between 10 and 15 km. In the north west, where the land becomes more undulating, there is a linear stretch along the A947 where there is no visibility of the EOWDC at all. The 15km radius includes the whole of Aberdeen and the ZTV shown in Figure 9 gives a greater understanding of the theoretical effects on the city and is discussed later.

Beyond the 15 km radius, theoretical visibility on land is much more intermittent between the south and west and is limited to the local high areas and parts of the more elevated Mounth. To the north and north east there are larger swathes of theoretical visibility which stop at approximately 27 km from the EOWDC. In the north west, the main areas of theoretical visibility extend to just within the 40 km radius study area on the elevated farmland areas. Directly to the east, the visibility is more intermittent and mainly centred on the areas of high ground of the Grampian Outliers.

Beyond the 40 km radius study area, theoretical visibility is very limited and is mostly on small areas of exposed high ground.

The larger scale ZTV in Figure 9 shows that the city centre and harbour area are shown to have very limited theoretical visibility of the EOWDC due to the dense built up nature of the city.

The northern suburbs of Denmore, Middleton Park and Bridge of Don are closest to the EOWDC and most of the open areas and houses with aspects to the coast will have theoretical visibility of the EOWDC. The residential areas of Hilton, Kittybrewster, Rosehill, Middlefield, Cummings Park, Northfield, and Heathryfold which lie on the elevated land on the northern side of Aberdeen which slopes towards the EOWDC will also have theoretical visibility of the turbines.

The coastal edge of Seaton, and obviously the tower blocks, will have views out towards the proposed turbines, but there will be more restricted views within Old Aberdeen and Tillydrone.

The southern elevated side of Aberdeen including Seafield, Garthdee, Kaimhill, Ferryhill, Kincorth and Torry also are shown by the ZTV to have theoretical visibility of the EOWDC.

In reality, due to the densely built up nature of cities there will be few places within Aberdeen, except the coast and views from tower blocks, where clear views of the turbines will be seen. Visibility will be generally limited to glimpsed views between buildings and where roads are aligned with the EOWDC and to those areas where there are no added screening effects from roadside trees and other existing vegetation.

4.1.2. Overview of Cumulative Visual Effects on the 60km Study Area

The cumulative effects for a 60 km study area have been illustrated by the ZTVs in Figures 13 to 18. Figure 12 shows the locations of the 72 wind farms/single turbines within the study area at the time of writing. There are no wind farms within 10 km of the EOWDC and within 20 km there are only four existing and consented and two in-planning sites, none of which are over 3 turbines in size and are not higher than 62 m to hub and 102 m to blade tip. Between 20 and 30 km the number of turbines increases in the north, and there is one wind farm in the south at Meikle Carewe which is the largest in turbine number at this distance with 12 turbines, but is only 70 m high to blade tip. There are a broad cluster of wind farms in the south between 30 and 45km from the EOWDC which include the 25 turbines at Mid Hill and 7 and 9 turbine farms at Tullo and St John's Hill respectively. To the north west of the EOWDC between 20 and 60 km there is an even spread of wind farms, mostly single turbines or small wind farms up to 5 turbines. The exceptions to this are the larger wind farms at Glens of Foudland (20 turbines), Mains of Dummuie (7 turbines), Clashindarroch (18 turbines) and Kildrummy (8 turbines) which all lie in the more remote areas of Aberdeenshire, beyond 40 km from the EOWDC. The vast majority of all the wind farms in the study area, existing, consented, or in-planning, have a maximum hub height of approximately 80 m and maximum blade tip height of approximately 100 m.

Figure 13 shows the combined effects of EOWDC with the existing and consented wind farms and the in-planning wind farms. Figure 14 shows this at a larger scale for an approximate 20 km radius study area. These ZTVs indicate that the majority of the study area has theoretical visibility of one or more wind farms, however only a relatively small area has visibility of the EOWDC on its own (see the blue areas on the ZTVs). This is confined to the immediate coastal areas within 10 km and some patchier areas west of Aberdeen and north east of Ellon. Figure 13 also shows that the west and south west parts of the study area are exposed mainly to existing or consented wind farms with limited areas of combined visibility with the EOWDC. The north east corner of Aberdeenshire is illustrated as having almost complete coverage of theoretical visibility of both existing, consented and in-planning wind farms which the EOWDC will add to, but not significantly increase the area.

Figures 15 and 16 have been produced to show the number of existing, consented or in-planning turbines theoretically visible from any one point where the EOWDC is also theoretically visible. This varies between one turbine to over 125 turbines for existing and consented sites and between 1 turbine and over 50 turbines for in-planning sites. Figures 17 and 18 illustrate the number of wind farm sites visible with the EOWDC, which varies between 1 and over 30 existing and consented sites and between 1 and 26 in-planning sites. All four figures show clearly where the highest areas of theoretical combined visibility are possible. On land, these areas are typically located on higher ground, where slopes are facing towards the site. These areas include the coastal farmland south of Cruden Bay, the elevated land either side of the River Ythan, a ridgeline south east of Old Meldrum, and sporadic areas on promontories within the wider extents of the study area.

The ZTVs illustrate that a large proportion of the greatest combined visibility is located offshore, where visibility theoretically increases to a point where almost all sites could be visible approximately 30km from the coast, directly east of the EOWDC. It is however considered very unlikely that the majority of the turbines would be seen at this distance given that in reality their average size will reduce their prominence and intervening vegetation or buildings which are not modelled into the ZTVs will preclude some views.

4.2. Viewpoints

The following analysis refers to the 20 agreed representative viewpoints referred to in the baseline conditions. Reference should be made to the existing panoramas and wireframes (Figures WF1-10) and to the photomontages (Figures PM1-20) which illustrate the existing and proposed view for each viewpoint.

Cumulative impacts are discussed for each viewpoint (see also Figures 12-18) and cumulative wireframes were created for viewpoints 13, 15, 16, 18 and 19 (CW Figures). As there are many wind farms shown within some of these wireframes to avoid text obscuring the visuals only some of the wind farms have been identified by name to aid orientation. Please also refer to Figure 12 which shows the wind farm locations.

Please note that the timing of the on-site survey work driven by project programme and inclement weather meant that the photographs for viewpoints were taken on two separate occasions in November and January. Unfortunately light levels are limited at this time of year and the location of EOWDC in relation to viewpoints has meant that photographs of those viewpoints in the north and north west were unavoidably taken into low sun.

4.2.1. **Viewpoint 1: Balmedie Beach** (WF-01 and PM-01)

The wireframe and photomontage illustrate that the 11 turbines will be clearly visible from this viewpoint and will occupy 51 of the illustrated 200 and 135 degree views to the south. The closest turbine will be 3.51 km from the viewpoint. The turbines will have a fairly regular arrangement across the horizon but there is an overlap of two turbines in the centre of the group, and the northern turbine appears slightly separate from the other turbines.

The turbines will be dominant in views to the south towards Aberdeen and Girdle Ness. They will be seen on the horizon with open sea behind, approximately 20 degrees to the left of Girdle Ness. On a clear day the proposed development could give an impression of enclosing Aberdeen Bay as there is a relatively small gap of open horizon between the southern turbine and Girdle Ness headland. When visibility is not good enough to see Girdle Ness or Aberdeen Beach, Balmedie Beach becomes more remote in nature and the turbines may appear more dominant. However, the constant movement of ships to and from the harbour and within the designated anchorage area does distract the eye and give scale to the seascape. Walking along the beach from Balmedie towards Forvie Sands, the turbines will not be visible and the view of the more remote sands and coastline will remain intact.

The magnitude of visual impact arising from the proposed development is assessed as High. When combined with the High sensitivity to the change proposed of the key receptor group of walkers on the coastal trail and beach users, the significance of effect is assessed to be Major.

Cumulative Impacts

There will be no other wind farms visible from this location and therefore no cumulative effects.

4.2.2. **Viewpoint 2: A90 -Harehill turn off** (WF-02 and PM-02)

The wireframe and photomontage show that the turbines will occupy 30 degrees of the illustrated 135 and 90 degree views and be a prominent element within the view. The nearest turbine will be 4.44 km from the viewpoint. The turbines will have a regular composition with no overlapping or large spaces between them. The photomontage shows that the three northern turbines will have their bases obscured by the landfill area. Farmsteads and shelterbelts also break up a clear view of the turbines.

At the relatively close distance the turbines lie from the viewpoint they will be a prominent feature of the view and although there are some intervening elements, at this close distance the magnitude of visual impact arising from the proposed development is judged as High. When combined with a Medium to Low sensitivity to the change proposed on the key receptor group of travellers on the A90, the significance of effect is assessed to be Major-Moderate to Moderate.

It should be noted that if the proposed AWPR is constructed, it will be a dominant feature in the foreground of this view. The road position won't obscure views of the turbines, but it will be a significantly distracting element.

Cumulative Impacts

There are no other wind farms visible from this viewpoint and therefore no cumulative effects.

4.2.3. **Viewpoint 3: Jesmond Drive, Middleton** (WF-03)

The wireframe shows that the turbines occupy 18 degrees of the illustrated 135 degree view shown and the bases would be partially obscured by landform. The nearest turbine would be 7.14 km from the viewpoint. The turbines would appear in two groups with a regular arrangement and no overlapping. However, the photograph shows that the turbines are not likely to be visible above the trees with only potential for the very tips of the blades to be seen during the winter months. For this reason, a photomontage was not constructed for this viewpoint.

As the turbines will be screened from view the magnitude of visual impact arising from the proposed development is assessed as Negligible. As the key receptor group of local residents have a High sensitivity to the proposed change, the significance of effect is assessed to be Negligible.

As the ZTV (Figure 9) illustrates, the Middleton area has a high theoretical visibility with the EOWDC and although at this specific viewpoint there would be Negligible effects, it is acknowledged that the turbines may be clearer in views nearby.

Cumulative Impacts

There are no other wind farms visible from this viewpoint and therefore no cumulative effects, however, it is noted that in nearby locations up to 4 existing and consented and up to 2 in-planning wind farms may theoretically be visible. This is likely to include the closest existing and consented wind farms at Hill of Fiddes, Tillymaud, and Mains of Bogfechel and in-planning wind farms at Woodlands Farm and Hill of Fechel. They all lie between 13-15 km away from the viewpoint, and given the built up nature and existing mature trees which surround the area, it is unlikely that they will be noticeable elements.

4.2.4. **Viewpoint 4: B999 Whitecairns** (WF-04 and PM-04)

The wireframe illustrates that the turbines will sit just below the horizon and partially behind the raised landform that lies between the viewpoint and the site. The turbines will occupy 26 degrees of the illustrated 135 and 90 degree views and appear in six groups consisting of 1, 2, 2, 3, 2, and 1 turbine, left to right. The turbines in the middle four groups will be overlapping. The closest turbine is 8.1 km from the viewpoint.

The photomontage shows that the existing shelterbelts and other vegetation will obscure most of the column length of the turbines but the hub and blades will be a noticeable element in the view. The hillside to the left of the turbines, and the coniferous trees to the right, frame the view of the turbines to some extent, potentially slightly increasing their prominence. However, existing features such as the quarried hillside, and closer vertical elements such as pylons and telegraph poles distract the viewer to some degree.

It is therefore judged that the magnitude of visual impact arising from the proposed development is assessed as Medium. As the key receptor groups of travellers on the B999 sensitivity to the proposed change is Medium to Low, and the residents have a High sensitivity, the significance of effect is assessed to be Moderate to Moderate-Minor for road users, and Major-Moderate for local residents.

Cumulative Impacts

There are no other wind farms visible from this viewpoint and therefore no cumulative effects. However it is noted that Hill of Fiddes and Tillmaud Wind Farms lie within 10 km of the viewpoint and may be seen from nearby locations in succession with the EOWDC as they lie in opposite directions.

4.2.5. **Viewpoint 5: Aberdeen Beach** (WF-05 and PM-05)

The wireframe and photomontage show that the turbines will occupy approximately 12.5 degrees of the illustrated 200 and 135 degree views and will be arranged in a relatively tight group with some overlapping and the outer turbines slightly separated from the main group. The closest turbine is 7.52 km from the viewpoint.

The turbines will appear in the open sea with the distant coastline to Peterhead just left of the wind farm. They will be a prominent feature on the horizon and like the many ships which sit or travel through the bay they will give a sense of scale and feeling of slight enclosure to the bay area. The presence of the turbines will not alter the immediate view of the beach and views of Balmedie beach and more distant coastline can be experienced without the turbines in the frame. Although prominent, the turbines will not feel incongruous within this active coastal view.

It is therefore assessed that the magnitude of visual impact arising from the proposed development is High to Medium. As the key receptor group of visitors to the beach have a High sensitivity to the proposed change, the significance of effect is assessed to be Major to Major-Moderate.

Cumulative Impacts

There are no other wind farms visible from this viewpoint and therefore no cumulative effects.

4.2.6. **Viewpoint 6: A90 -West Pitmillan turn off** (WF-06 and PM-06)

The turbines are illustrated in the wireframe as occupying 17 degrees of the illustrated 135 and 90 degree views. They appear in distinct groupings of 2, 3, 3 and 3 turbines with only the last group showing some overlapping of blades. The closest turbine is 9.31 km from the viewpoint.

The photomontage shows that the three turbines to the right of view will be almost completely obscured by the gently rising landform and also the adjacent three turbines will be partially obscured so that only the hubs and blades are visible. The bases of the other turbines will be screened but top of the column and blade tips will be visible appearing over the open fields and sporadic trees. The visible turbines will be a discernable moving element within the large scale, relatively uniform view. However, the view is not devoid of existing movement with the traffic on the A90 and also the three Hill of Fiddes turbines nearby.

It is therefore judged that as the view will remain largely unchanged, the magnitude of visual impact arising from the proposed development is Medium to Low. As the sensitivity of travellers on the A90 to the proposed change is Medium to Low, the significance of effect is assessed to be Moderate to Moderate-Minor to Minor.

Cumulative Impacts

The cumulative ZTVs illustrate that there is up to 4 existing and consented wind farms visible from the viewpoint location. The existing three Hill of Fiddes turbines lie approximately 3 km to the west of this viewpoint and the three Ardgrain turbines lie approximately 9 km to the north. The consented Tillymaud single turbine will be 9 km to the west. From site visits there are no wind farms visible with EOWDC in the angle of view shown, but the Hill of Fiddes turbines are evident appearing behind the viewpoint and Ardgrain are potentially visible to the north.

The addition of the EOWDC to the 360 view available from this viewpoint will extend the presence of turbines to a new part of the view. The four wind farms will only be visible in succession and not in the same portion of view. As the Hill of Fiddes Wind Farm is much closer to this viewpoint and a prominent element, the more distant and obscured EOWDC and Ardgrain turbines will be less conspicuous.

The magnitude of cumulative visual impact is therefore judged as Low. As the sensitivity of travellers on the A90 to the proposed change is Medium to Low, the significance of cumulative effect is assessed to be Moderate-Minor to Minor.

4.2.7. **Viewpoint 7: Torry Battery** (WF-07 and PM-07)

The wireframe and photomontage show that the turbines will appear in five groups spread evenly across the horizon occupying 12 degrees of the illustrated 200 and 135 degree views. The closest turbine is 7.89 km from the viewpoint. The viewpoint is almost directly in line with the rows of the turbines so that the central group's three turbines overlap very closely. The turbine groups on either side gradually fan out, and the western turbine will be seen on its own.

The proposed development lies within a sea space framed by the harbour entrance walls. The turbines could therefore be perceived as having more of a visual relationship with the harbour and shipping activity than the coastline beyond. The turbines are prominent in the view but not considered out of place with the active seascape. They cover a small section of the expansive view and views of the sandy coastline to the west and also the more open remote sea to the east can be experienced without the turbines in the focal point.

Therefore, the magnitude of visual impact arising from the proposed development is assessed as High to Medium. As the key receptor group of visitors and coastal walker's sensitivity is High to Medium, the significance of effect is assessed to be Major to Major-Moderate to Moderate.

Cumulative Impacts

The cumulative ZTVs show that up to 6 existing and consented wind farms may theoretically be visible from this viewpoint at Torry Battery. The closest wind farms to the viewpoint are at Hill of Fiddes, Tillymaud, Mains of Bogfechel, Ardgrain and Meikle Carewe. There is unlikely to be views of Meikle Carewe given the orientation of the viewpoint and intervening landform. The three turbines of Hill of Fiddes are closest at 20 km, which given the relatively small size of turbine and as shown by the lack of visibility in the photograph, would be minor elements within the view. It is therefore judged that the magnitude of cumulative effect would be Negligible. As the key receptor group of visitors and coastal walker's sensitivity is High to Medium, the significance of effect is assessed to be Negligible.

4.2.8. **Viewpoint 8: South College Street, Aberdeen** (WF-08)

The wireframe shows that the turbines are evenly arranged in seven groups with overlapping turbines and single turbines occupying 10.5 degrees of the illustrated 135 degree view. The closest turbine is 9.19 km from the viewpoint. The wireframe also shows that half of the turbines will be partially obscured by landform. In reality the photograph shows that the buildings and structures in the city centre will obscure views of all the turbines, and for this reason a photomontage has not been constructed. It may however, be possible to see blade tips from the higher floors of the adjacent flats and offices.

Therefore, the magnitude of visual impact arising from the proposed development is assessed as Negligible. As the key receptor group of workers, travellers and shoppers has a Low sensitivity to the proposed change, the significance of effect is assessed to be Negligible.

Cumulative Impacts

There are no other wind farms visible from this viewpoint and therefore no cumulative effects.

4.2.9. **Viewpoint 9: Forvie Nature Reserve** (WF-092 and PM-09)

The wireframe illustrates that the turbines will occupy 11.5 degrees of the illustrated 200 and 135 degree views and the bases of nine of the turbines will be obscured by the landform. The closest turbine will be 10.27 km from the viewpoint. The wind farm will be arranged in three groups of 2, 3, and 6 turbines. The two turbines at the left of view will appear separate from the other two groups and will be fully visible on the horizon.

The photomontage shows that all but two of the turbines will be clearly seen above the sand dunes. The remaining 9 turbines will have just the hub and blades visible. Those turbines that are visible will be a prominent vertical feature appearing above the simple dune landscape and will be a noticeable change. The turbines will appear in the same general portion of view as the Seaton tower blocks and coastal development at Aberdeen (when seen on a clear day) so the EOWDC will not extend the influence of manmade elements to other more remote parts of Forvie Sands within this view. It should also be noted that the ever evolving nature of sand dunes will mean that over time the turbines may become more visible or more hidden from this viewpoint.

Taking into account the above it is judged that the visible turbines are a noticeable feature but the view will largely remain unchanged, therefore the magnitude of visual impact arising from the proposed development is Medium. As the key receptor group of visitors and walkers have a High sensitivity to the type of change proposed, the significance of effect is assessed to be Major-Moderate.

Cumulative Impacts

At this specific viewpoint within Forvie Sands there are no other existing and consented or in-planning wind farms visible. However, within nearby areas of the sand dunes there is potential for views up to 18 existing and consented wind farms and up to 4 in-planning sites. The closest of these are at Hill of Fiddes and Ardgrain, with a larger number beyond 10 km to the north and east of Forvie Sands. The wind farms will be seen in a different portion of view to the EOWDC turbines, so that any cumulative effects would be in succession. As discussed above, the EOWDC will be a noticeable feature and whilst there would be no cumulative effects from the viewpoint itself, the addition of EOWDC in views from the Forvie Sands will potentially increase the perception of wind farms as a feature of the surrounding landscape.

4.2.10. **Viewpoint 10: Midstocket Road/North Anderson Drive** (WF-10 and PM-10)

The wireframe shows that the turbines appear in three distinct groups evenly arranged across 9 degrees of the illustrated 135 and 90 degree views. The closest turbine is 10.47 km from the viewpoint.

The photomontage shows that the group of three turbines to the right will be clearly visible above the hospital buildings in the gaps between the foreground housing and trees. The other turbines will potentially be seen interspersed between chimneys and trees and as a result will be less noticeable. Overall, the turbines will be discernable but will be a minor element within a busy and fragmented view and the view will remain largely unchanged.

It is therefore assessed that the magnitude of visual impact is Low. As the key receptor groups of local residents and travellers on the A90 have a High and Medium to Low sensitivity, respectively, to the proposed change, the significance of effect is assessed to be Moderate for residents and Moderate-Minor to Minor for travellers.

Cumulative Impacts

There are no other wind farms visible from this viewpoint and therefore no cumulative effects.

4.2.11. **Viewpoint 11: Leslie Road (A978), Aberdeen** (WF-11 and PM-11)

Leslie Road is aligned with the turbine site and the wireframe shows the wind farm as three groups occupying 11 degrees of the illustrated 95 and 90 degree views. The closest turbine will be 8.07 km from the viewpoint.

The photomontage shows that the buildings at the end of the street will obscure all but the blade tips of the turbines. The gap created by the hipped roofs of the buildings in the background will potentially allow more of the blades to be seen and the movement will be discernable.

Given that only the tips of the blades will be seen but movement may be a distracting visual element, it is assessed that the magnitude of visual impact is Low. As the key receptor group of local residents and travellers have a High and Medium sensitivity to the proposed change respectively, the significance of effect is assessed to be Moderate for residents, and Moderate-Minor for travellers along Leslie Road.

Cumulative Impacts

There are no other wind farms visible from this viewpoint and therefore no cumulative effects.

4.2.12. **Viewpoint 12: Kincorth Hill** (WF-12 and PM-12)

The wireframe illustrates that the eleven turbines will appear as almost one group across 8.5 degrees of the illustrated 135 and 90 degree views, with the three turbines to the west slightly apart from the rest. There will be some overlapping of blades and the turbine bases will be below the horizon. The closest turbine will be 11.56 km from the viewpoint.

The turbines lie beyond the end of the distant coastline and into the open sea and will be a noticeable element within the busy active view. The landform and vegetation to the left and right of the view frames Aberdeen Bay so that the turbines are a central focus thus increasing their prominence to some degree. However, there are also many distracting elements in views of the city and the consistent shipping activity to and from the harbour.

As the turbines will be a noticeable feature which will cause a partial alteration to the view the magnitude of visual impact is judged as Medium. As the key receptor group of walkers and visitors have a High to Medium sensitivity to the proposed change, the significance of effect is assessed to be Major-Moderate to Moderate.

Cumulative Impacts

There are no other wind farms clearly visible from this specific point on Kincorth Hill, however the cumulative ZTVs illustrate it should be possible to see up to 4 existing and consented and up to 2 in-planning wind farms. The closest wind farm will be the consented Meikle Carewe which lies approximately 15 km to the south of the viewpoint. However, the surrounding vegetation and landform at the viewpoint doesn't allow views to the south. The closest wind farms to the north are beyond 20 km away and given the relatively small scale of turbines, they will be difficult to discern.

It is therefore judged that the magnitude of cumulative visual impact at this viewpoint is Negligible. As the key receptor group of walkers and visitors have a High to Medium sensitivity to the proposed change, the significance of effect is assessed to be Negligible.

4.2.13. **Viewpoint 13: Udny Station** (WF-13 and PM-13)

The wireframe illustrates that the turbines will occupy 17 degrees of the illustrated 200 and 135 degree views and will be in a generally regular arrangement with the northern three turbines slightly further apart. The closest turbine will be 12.63 km from the viewpoint.

The photomontage shows that only the hub and blades of three of the turbines and blades from five of the turbines will be visible above the rolling agricultural landscape. The other three turbines will be screened completely by existing vegetation. The visible turbines will be a minor element within the expansive view but at this relatively close distance the movement of the blades will be detectable and potentially draw the eye towards them. However, overall it will be a minor alteration to the view which already has views of the closer turbines at Hill of Fiddes.

It is therefore assessed that the magnitude of visual impact is Medium to Low. As the key receptor group of local residents have a High sensitivity to the proposed change, the significance of effect is assessed as Major-Moderate to Moderate.

Cumulative Impacts (Cw-13)

The wireframe in Figure CW13 shows the exiting situation of Hill of Fiddes turbines and the EOWDC, with no other turbines visible in the view. The existing three turbines at Hill of Fiddes lie just over 1 km from the viewpoint, two of which can be seen emerging from a coniferous shelterbelt to the left of the view. The cumulative ZTVs shows that from very close to the viewpoint up to 12 existing and consented and up to 6 in-planning wind farms may theoretically be visible. These will include the single turbines at Mains of Bogfechel and Tillymaud, and in-planning turbines at Woodlands Farm and Hill of Fechel, which lie to the west, between approximately 4 km and 8 km away from the viewpoint. The other wind farms potentially seen from this area lie beyond 10 km away to the north and west. In reality local vegetation around the viewpoint will obscure clear views of many of these turbines given their relatively small size.

Therefore the main potential for cumulative effect from this viewpoint lies with the addition of the EOWDC with the existing Hill of Fiddes turbines. Whilst not visible at the exact viewpoint, there is also potential for the Tillymaud turbine as the next closest turbine to be a noticeable feature within the immediate area. The EOWDC will increase the perception of wind farms being part of the landscape and within a new section of view that does not already have views of turbines. However, as the wireframe shows, the EOWDC turbines will be partially obscured which will reduce cumulative visual effects.

Therefore, the magnitude of cumulative visual impact is judged as Low. As the key receptor group of local residents have a High sensitivity to the proposed change, the significance of effect is assessed as Moderate.

4.2.14. **Viewpoint 14: A96/Kirkhill Forest** (WF-14 and PM-14)

The wireframe illustrates that the turbines will occupy 12 degrees of the illustrated 135 and 90 degree views and will be in a regular arrangement. They will sit slightly below the horizon with the blades protruding above. The closest turbine will be 14.13 km from the viewpoint.

The landform naturally opens up to show the sea from this area, but at this specific point, the photomontage shows that the forestry will obscure views of the northern six turbines. The remaining visible turbines will be seen with two partially obscured by vegetation. The turbines will appear as if they were on land at this point with views of the sea behind. They appear in a separate section of the view to the city which, with prominent tower blocks, is potentially more of a focus in the view than the turbines.

It is considered that the views of the turbines from the adjacent A96 would be more obscured at this point and due to the direction of the road will be more focused on Aberdeen but further south clearer views could be possible.

As the turbines will be noticeable, albeit half of them and the view will remain largely unchanged, it is assessed that the magnitude of visual impact is Low. As the travellers have a Medium to Low sensitivity to the proposed change, the significance of effect is considered Moderate-Minor to Minor.

Cumulative Impacts

The cumulative ZTVs show that there are no other wind farms visible from this viewpoint and therefore there will be no cumulative effects.

4.2.15. **Viewpoint 15: Brimmond Hill** (WF-15 and PM-15)

The wireframe shows that the turbines will appear below the horizon across 10 degrees of the illustrated 200 and 135 degree views. They will be regularly spaced with the three southern turbines slightly further apart from the others. The closest turbine will be 14.41 km from the viewpoint.

The photomontage shows that the turbines will be clearly visible within the inshore waters and will lie between Aberdeen city and Perwinnes radar station, a small but prominent point in the view. The turbines will appear beyond the open rolling farmland between the visible settlements at Aberdeen and Dyce.

There are many elements in this part of the view which includes the frequent movement of helicopters and planes to and from Dyce. The turbines will add to this dynamic landscape as a noticeable feature in the sea. Overall, as this viewpoint encompasses a 360 degree view, the majority of the view will remain unchanged, and elements such as the masts on top of Brimmond Hill will still be a dominant feature.

It is therefore judged that the magnitude of visual impact of the proposed development is no more than Medium. As the key receptors of walkers have a High to Medium sensitivity to the proposed change, the significance of effect is judged as Major-Moderate to Moderate.

Cumulative Impacts (CW-15)

The cumulative ZTVs show that from this viewpoint there is the potential to see over 30 consented or existing wind farms, and potentially up to 16 in-planning wind farms in combination with the EOWDC. The cumulative wireframe (Figure CW15) illustrates the existing, consented and in-planning wind farms which are dotted across the landscape in views to the north. Please note that only a selection of the wind farms in the wireframe have been named to aid orientation. Views to the south are obscured to some degree by intervening forestry.

In the views to the west, north and north east from this elevated position the wireframe shows that theoretically the large majority of the in-planning and existing and consented wind farms are visible. However, most of these will not be discernable with the naked eye and lie below the horizon where existing vegetation and settlement will obscure views.

The most noticeable turbines, albeit only just visible in the photograph and in site visits are the existing Hill of Easterton three turbines which are on a similar elevation to Brimmond Hill and are just clear in the skyline, above Kirkhill Forest, at 24 km to the north west. The Hill of Fiddes turbines lie closest to the viewpoint at 17.5 km and the hub and blades can be just made out appearing behind the undulating landform to the left of one of the Brimmond Hill masts. The wireframe and photograph shows that although there are many existing wind farms in the landscape, there is limited visibility with the majority of them. Given this limited intervisibility of the existing wind farms, the in-planning wind farms most likely to be visible at this point would be the single turbines at Mosseye, Hill of Fechel, Mains of Balquhain and the two turbines at Woodlands Farm.

The extensive views from Brimmond Hill encompass a wide variety of land use and the existing turbines visible are not prominent features. Although a large number of turbines are theoretically visible, the relatively small height, small turbine numbers and distance from the viewpoint reduce cumulative visual effects. The addition of the EOWDC will be seen in a separate part of the view to any other wind farms and as the turbines will be viewed entirely in the sea, this further disconnects it to any other views of turbines. Taking this into account and the larger scale of turbines, the magnitude of cumulative impact of EOWDC within existing and consented and in-planning wind farms at this viewpoint is judged as Low. As the key receptors of walkers have a High to Medium sensitivity to the proposed change, the significance of cumulative effect is judged as Moderate to Moderate-Minor.

4.2.16. **Viewpoint 16: Formartine and Buchan Way, nr Quilquox** (WF-16)

The wireframe shows that the turbines will occupy 7.5 degrees of the illustrated 200 degree view. They will appear at similar heights and an arrangement of groupings of 2, 3, 3 and 3 will be discernable elements in the view. The closest turbine will be 25.98 km from the viewpoint.

The photograph illustrates that intervening landform is likely to obscure the bottom of the turbine columns but they will be a noticeable element in the horizon but within a small part of an expansive panoramic view. The wireframe illustrates that the turbines would be seen with a backdrop of the sea, but due to the visibility on the day the photograph was taken, the sea and coastal landform is not discernable in the photograph and the turbines appear as if on land. Wind farms at Ardgrain and Hill of Fiddes are prominent in the view and lie either side of the EOWDC. The EOWDC turbines, if visible, will appear at a similar height to the Hill of Fiddes at this distance.

The magnitude of visual impact of the proposed development is therefore assessed as Low. As the key receptors of local residents and cyclists have a High and a Medium sensitivity respectively to the proposed change, the significance of effect is judged as Moderate for local residents and Moderate-Minor for cyclists.

Cumulative Impacts

Figure CW16 presents a cumulative wireframe which illustrates the many wind farms theoretically and actually visible from this viewpoint. The cumulative ZTVs illustrate that up to 18 existing and consented and up to 4 in-planning wind farms may theoretically be visible from this viewpoint.

As shown in the photograph and wireframe, the existing wind farms at Ardgrain and Hill of Fiddes are the most visible of existing wind farms in the area and sit either side of the EOWDC turbines. The wireframe also indicates that Tillymaud, Mains of Bogfechel, and the in-planning turbines at Woodlands Farm, Mains of Balquhain and Hill of Fechel will be seen to the right of the view. Mid Hill and even Meikle Carewe Wind Farms are shown to be theoretically visible, but at over 50 km away it is very unlikely. The four turbines at Skelmonae although not shown in the wireframe, lie at close proximity to the north west of the viewpoint. There are also other wind farms such as St John's Well and Hill of Easterton which are visible nearby

Within this area of Aberdeenshire wind farms have now become a characteristic feature of the landscape as demonstrated by the wireframe and photograph. The addition of the EOWDC at this viewpoint which will be at a similar scale in the view to the existing turbines will contribute to this character and sit comfortably within the view. Therefore it is judged that the magnitude of cumulative impact is Low. As the key receptors of local residents and cyclists have a High and a Medium sensitivity respectively to the proposed change, the significance of cumulative effect is judged as Moderate for local residents and Moderate-Minor for cyclists.

4.2.17. **Viewpoint 17: Minor road near Netherley and Durris Forest** (WF-17 and PM-17)

The wireframe illustrates that the turbines will occupy 4 degrees of the illustrated 135 and 90 degree views and appear in an evenly spaced line of turbines on the horizon. The closest turbine will be 24.99km from the viewpoint.

The photomontage shows that at this distance from the proposed development, the turbines will be noticeable but not dominant within the wider panoramic view. The landform obscures most of the columns of the turbines and the power lines in the foreground lie across some of the turbines at this point. The tower blocks seen on the horizon are more prominent than the turbines due to their mass, but will be slightly smaller in height that the turbines.

Taking into account the above, and as the turbines will be a relatively minor element within an expansive and fragmented view, it is judged that the magnitude of visual impact is Low to Negligible. As the key receptor group of local residents have a High sensitivity to the proposed change, the significance of effect is assessed to be Moderate to Negligible.

Cumulative Impacts

The cumulative ZTV illustrates that there are up to 2 existing and consented and up to 2 in-planning wind farms theoretically visible from this viewpoint. This will most likely include the consented Meikle Carewe Wind Farm which lies 3 km to the south of this viewpoint. Although the turbine size is not particularly large (70 m blade tip), at 3 km away, the Meikle Carewe Wind Farm will be a dominant feature. The addition of the EOWDC which as discussed above will be noticeable, but not in the same portion of view, and therefore cumulative effects with Meikle Carewe would be limited to successional views only.

The nearest in-planning wind farm is Woodlands Farm at just under 30 km to the north, and it is unlikely given the scale of turbines that they would be a discernable element.

It is therefore considered that overall the magnitude of cumulative visual impact on this viewpoint is Low to Negligible. As the key receptor group of local residents have a High sensitivity to the proposed change, the significance of effect is assessed to be Moderate to Negligible.

4.2.18. **Viewpoint 18: A975 near Slains Castle** (WF-18 and PM-18)

The wireframe illustrates that the turbines will occupy 5 degrees of the illustrated 135 and 90 degree views. They will appear in front of the headland in five separate groups with overlapping turbines. The closest turbine will be 22.23 km from the viewpoint.

The photomontage shows that the turbines will be a noticeable feature within the view appearing above the distant headland but not taller than the intervening landform to the right of view. This landform will partially obscure the columns of the three turbines to the right of view. The turbines will be a similar height to the ruins of Slains Castle but will be recessive in comparison to the bulk of the ruins.

The generally simplistic nature of the view with large open fields and strong features such as Slains castle and the cliff coastline, increases the prominence of the EOWDC turbines within a small section of the overall view, but the majority of the view will remain unchanged.

Therefore the magnitude of visual impact is considered overall to be Low. As the key receptor group of visitors to Slains Castle and the coastline have a High sensitivity to the proposed change, the significance of effect is assessed to be Moderate.

Cumulative Impacts

The cumulative ZTVs illustrate that up to 4 existing or consented and up to 2 in-planning wind farms may be theoretically visible from this viewpoint. The wireframe in Figure CW18 identifies that Ardgrain Wind Farm is the closest existing turbines within this portion of the view at just over 12 km away, but as shown on the photograph they are not easily discernable. The wind farms shown behind the EOWDC are all beyond 50 km from the viewpoint and in reality would not be seen due to distance and intervening vegetation and built form.

The other wind farms in close proximity to the viewpoint but which lie behind the viewpoint (not shown on wireframe) are the three turbines at West Knock Farm 14 km to the north west, and the single turbine at Bruxiehill, 14 km to the north of the viewpoint. The in-planning Peterhead Harbour and Middleton of Rora turbines lie beyond 10 km to the north.

The existing, consented, and in-planning wind farms lie at considerable distances from this viewpoint and due to their relatively small scale they are not easily visible. The EOWDC will not be seen in combination with the other wind farms, and even in succession other wind farms will not be a noticeable feature of the view.

The addition of the EOWDC will increase the number of wind farms theoretically visible but given the separation and distance to each wind farm at this viewpoint, the magnitude of cumulative impact is judged to be Low to Negligible. As the key receptor group of visitors to Slains Castle and the coastline have a High sensitivity to the proposed change, the significance of cumulative effect is assessed to be Moderate to Negligible.

4.2.19. **Viewpoint 19: Mither Tap, Bennachie** (WF-19)

Due to the time of year the assessment was undertaken, photographs were not able to be taken from this viewpoint, so only a wireframe was constructed.

The wireframe shows that the turbines would appear spread in six groups across 7 degrees of the illustrated 200 degree view. The closest turbine will be 32.02km from the viewpoint. Only the very tips of the blades will be visible above the horizon, with the majority of the turbines seen with the backdrop of the sea.

Site visits have shown that the surrounding landuse and development will most likely obscure much of the turbines in views on a clear day when the coast is visible. They will also be a very minor element within the expansive 360 degree views possible from this high viewpoint, where existing turbines are a common feature.

It is therefore judged that the magnitude of visual impact will be Low to Negligible. As the key receptor group of walkers have a High to Medium sensitivity to the proposed change, the significance of effect is assessed to be Moderate to Moderate-Minor to Negligible.

Cumulative Impacts

The wireframe (Figure CW19) clearly shows the number of wind farms within the distant landscape that are theoretically visible from this viewpoint. The cumulative ZTVs also show that over 30 existing and consented and up to 18 in-planning wind farms theoretically could be visible from this promontory.

However, site visits have shown that it is only the closest of these turbines which are discernable with many of the single turbines and small wind farms recessive within the undulating farmland landscape. The vast majority of the wind farms lie to the west, north and north east of the viewpoint, the closest of which are approximately 11 km away. Those to the south lie closest at 30 km to the viewpoint.

The EOWDC will lie beyond an area of landscape (Central Wooded Estates character area) to the east of the viewpoint which does not have any wind farms, existing or proposed. If seen, the EOWDC can be perceived as having a stronger relationship with the northern wind farms and that it is quite separated from the southern wind farms, closest of which is Meikle Carewe (approximately 35 km away), which will also be difficult to discern at this distance.

As is has been assessed that the EOWDC will be a minor element within the overall view when visible, the addition of the EOWDC with the existing, consented and in-planning turbines will not significantly alter the expansive views available at Bennachie, so that the magnitude of cumulative impact is judged to be Negligible. As the key receptor group of walkers have a High to Medium sensitivity to the proposed change, the significance of cumulative effect is assessed to be Negligible.

4.2.20. **Viewpoint 20: A95 near Uras** (WF-20 and PM-20)

The wireframe illustrates that the turbines will appear just above the headland, with blade tips only visible, and will occupy 3.5 degrees of the illustrated 135 and 90 degree views. The closest turbine will be 33.58 km from the viewpoint.

The photomontage shows that it is very difficult to see the turbine blades above the headland and perhaps only on days when the sun is shining on the blades will they be discernable, and then they will be a very minor element within the open landscape.

The large scale landscape with relatively simple components will remain unchanged by the presence of the turbines and therefore the magnitude of visual impact is assessed as Negligible. As the key receptor group of travellers on the A92 have a Medium sensitivity to the proposed change, the significance of effect is considered Negligible.

Cumulative Impacts

The cumulative ZTVs illustrate that there will be no other wind farms visible from this view point and as such, there will be no cumulative effects.

4.3. Effects upon Visual Receptor Groups

The Baseline Report provides an outline of the range of visual receptor groups who can reasonably anticipated to be affected by the proposed EOWDC development. The effects upon these receptors are discussed below.

4.3.1. Local Residents

The closest residents to the proposed EOWDC site are those living in Blackdog and Balmedie. There are also individual properties at Tarbothill Farm, Wester Hatton and Hatton which lie along the section of coast between the A90 and the turbines. The turbines will lie at just over 3 km from all of these settlements. The EOWDC turbines will be a prominent feature for residents when travelling to and from their homes. Only those houses with outlooks towards the sea are likely to see the turbines consistently. Many of the houses in these areas are orientated to shelter from the cold east coastal winds and therefore will be less affected by views of the turbines.

However, at this close distance, the turbines will fundamentally alter any available views of those residents whose properties are orientated towards the sea and the magnitude of visual impact on these residents is judged to be High. As they have a High sensitivity to the proposed change, the significance of effects is assessed as Major.

Cumulative Effects

There are no existing, consented or in-planning wind farms which lie in close proximity to the settlements identified above and therefore there would be no significant cumulative effects of the EOWDC with another wind farm on the local residents.

4.3.2. Travelling Public - Rail

Passengers on trains arriving at Aberdeen will potentially have intermittent views of the EOWDC where it is visible above and in-between the city's buildings, as illustrated by the ZTVs. Cuttings and embankments are not modelled into the ZTV so although theoretically there may be visibility around Tullos Hill, this is most likely curtailed by the cuttings. Rail passengers are also restricted to some degree in their angle of view and it is only where the rail line curves around the coastline before Aberdeen that the side of the train would face the direction of the EOWDC.

It is therefore judged that there will be an overall Negligible magnitude of impact on rail passengers. As their sensitivity to the type of development proposed is Medium to Low, the significance of effect is assessed as Negligible.

Cumulative Effects

Where it has been identified above that there is potential visibility of the EOWDC, there will be no combined views of other wind farms. Whilst there is potential for the rail passengers to view wind farms along the stretches of rail line south of Aberdeen, the potentially short intermittent views of the EOWDC will not significantly add to any sequential cumulative effects and it is therefore considered that the magnitude of cumulative impact would be Negligible. As their sensitivity to the type of development proposed is Medium to Low, the significance of cumulative effect is assessed as Negligible.

4.3.3. Public Paths

The Aberdeenshire Coastal Path will be exposed to the EOWDC for much of its length between Girdle Ness and Peterhead. The turbines will become a consistent feature when travelling along the route, as the path generally keeps close to the coastline. Local topography and coastal features may interrupt views to some extent but overall the magnitude of visual effect on the walkers on the coastal path will be High within the areas around Aberdeen Beach and Aberdeen Bay, but will reduce to Low and Negligible with distance. As they have a High to Medium sensitivity to the proposed change, the significance of effect will be Major to Major-Moderate reducing to Moderate-Minor to Negligible with distance from the EOWDC.

Cumulative Effects

It can be expected that the main focus of the users of the coastal path will be the sea and coastline, with any long views inland a secondary aspect to the experience of the route. Within the areas identified above where the EOWDC will potentially have a High magnitude of effect there will be no other wind farms visible in the coastal views. There is potential for the inland existing, consented and in-planning wind farms to be seen but these will not be dominant in views from the coast as most lie beyond 7km from the coast. It is only the north east corner between Peterhead and Fraserburgh where existing, consented and in-planning turbines lie closer to the coast and the flatter coastal plain allows clearer views. However, in these areas, views of the EOWDC are limited if visible at all.

It is therefore judged that the magnitude of cumulative effect on the walkers on the coastal path will be Negligible. As they have a High to Medium sensitivity to the proposed change, the significance of cumulative effect will be Negligible.

4.3.4. Travelling Public - Sea Routes

The Orkney/Shetland passenger ferries leave Aberdeen on a regular basis. The route will pass in close proximity to the turbines and the EOWDC will be a prominent feature at the start or end of the passage. The overall magnitude of impact is judged as Low as it will be a temporary visual impact, and for a small proportion of the ferry's overall route. As the passengers on the Ferry will have a Medium to Low sensitivity to the proposed change, the overall significance of effect is considered Moderate-Minor to Minor although it is accepted that, on passing the EOWDC the magnitude of effect will be temporarily High, and therefore the significance of effect would temporarily be Major-Moderate to Moderate.

There are many fishing, commercial, and industrial ships which use Aberdeen Harbour and these will have views of the turbines when leaving or arriving. Many of the ships sit out for lengths of time in MCA designated anchorage area in the vicinity of the proposed EOWDC site, so they will be potentially the closest visual receptors to the proposed development. Smaller fishing vessels from the local village harbours may be more affected as they do not travel as far offshore as the larger ships and may have visibility of the EOWDC for the duration of their fishing trips. However, as they will be focussed on their line of work and due to their generally transient nature, effects would be reduced. It is judged that the magnitude of effect is overall Medium. As the workers on the ships would have a generally Low sensitivity to the type of change proposed, the significance of effect is assessed as Moderate-Minor.

Recreational sailing and yachting are not common in the immediate waters around the EOWDC, mainly due to the amount and size of harbour traffic in the area. Those sailors using the cruising routes in the wider area may have some visibility of the turbines. They would have a Medium sensitivity to the type of development proposed as they although they may have an interest in their surroundings, which already include a relatively high level of marine activity; they also will be concentrating on the sailing or racing. The magnitude of effect is overall judged as Medium, but it is accepted that there may be a temporarily High magnitude of effect when the vessels pass in close proximity to the EOWDC. The significance of effect is therefore overall Moderate, and temporarily Major-Moderate when in close proximity to the EOWDC.

Cumulative Effects

The EOWDC will be the only wind farm within the North Sea in the study area. Existing and consented onshore turbines are already potentially seen at a distance from offshore but are not prominent or easily discernable features. The proposed in-planning wind farms slightly increase the number of wind farms potentially visible but apart from the turbines at Peterhead Harbour and those in-planning between Peterhead and Fraserburgh, they are not any closer to the coast than existing wind farms. The combined effects of EOWDC and the existing, consented and in-planning wind farms is therefore limited by this distance and the smaller scale of the onshore wind farms. It is judged that the cumulative effects of EOWDC on offshore receptors will be Negligible. Taking into account the various sensitivities of the offshore receptors, the magnitude of cumulative effect will still be Negligible.

4.3.5. Visitors to the Area

Apart from those using the coastal path (as discussed above), visitors to the area with greatest potential to be affected by the EOWDC would be those visiting Aberdeen Beach, Balmedie Beach, and Forvie Sands. The effects on receptors at these locations are discussed in the viewpoint assessment.

4.4. Sequential Visual Effects on Main Roads

The theoretical sequential cumulative visual impact on a selection of main roads, as agreed with the consultees, has also been assessed using data obtained from the ZTV and transferred to graphs. These illustrate the number of wind farm sites that may theoretically be visible at mile intervals along the routes and indicate the distances from these locations to the various identified wind farms. These graphs are shown in Appendix 2 and should be read in conjunction with Figure 19 which identifies the agreed routes.

Each graph is necessarily at a different scale that relates to the distance to the various wind farms within the vicinity of each particular route. Miles are indicated along the horizontal axis on the graphs, rather than kilometres, as the majority of people more readily relate to these when travelling. However, kilometre distances have also been shown for ease of reference.

It should be noted that the graphs only illustrate point data at discrete mile intervals. They do not record continuous visibility along the routes and as such there remains the possibility that further views of the EOWDC and other wind farms may also, although not necessarily, be available between these mile intervals. In these instances where the graph does not show a wind farm as visible, there is most likely no visibility, or the visibility could be intermittent, or, if continuous, it will be for less than a mile. Where visibility is shown, the graphs present a worst case scenario of theoretical visibility as represented by the ZTVs. In reality this visibility will be limited due to distance, intervening local vegetation, road cuttings and embankments which would not have been modelled in the ZTV, and the orientation of the particular wind farm in relation to the direction of travel.

4.4.1. A90

The A90 is the main road from the south to Aberdeen, and to Peterhead and Fraserburgh in the north. The ZTV shows that within the study area to the south of Aberdeen, visibility of the EOWDC is limited until the junction with the A956 where the road occupies a high point and views of Aberdeen city are very clear. Visibility will be intermittent as the A90 goes through Aberdeen with only glimpse views of EOWDC available from a few high points (such as where the A90 runs to the west of Kincorth and the Anderson Drive section of the A90 between Mastrick and Middlefield). As the A90 reaches the northern side of Aberdeen (at Bridge of Don) clear views of the EOWDC will be seen. This visibility when travelling north extends to just beyond Balmedie.

Travelling south from Peterhead, the first stretches of potential visibility will occur at Longhaven to just east of Auchiries, approximately 25 km from the EOWDC. Visibility is then limited until Toll of Burness where views of EOWDC will potentially be clear until a lower stretch of road east of Ellon where the topography limits any views. As the road rises again just after the roundabout with the B9005, views of the EOWDC are again potentially possible and, apart from a few dips in the road precluding views, the visibility of the EOWDC continues all the way to Balmedie.

In reality, site assessment has shown that localised cuttings and roadside vegetation will reduce visibility of the EOWDC from a number of areas where the ZTV suggests potential visibility. Both distance to the proposed development and the orientation of the view will also play a part in reducing any visual effects. It is therefore judged that overall the magnitude of impact on the users of the A90 is High for the section of road in the immediate vicinity of the proposed development (approximately <5 km) reducing to Medium around Ellon in the north and Aberdeen in the south, and Low to Negligible elsewhere. As the sensitivity of road users to the type of development is Medium to Low, the significance of effect is Major-Moderate to Moderate within approximately 5 km, Moderate to Moderate-Minor around Ellon and Aberdeen, and Minor to Negligible elsewhere.

Cumulative Impacts

Reference should be made to graphs 01 to 06, and Figure 19 which illustrate the sequential cumulative effects on the A90 of the proposed development with other wind farms within a 60 km radius. For the purposes of clearly showing the effects, the A90 has been split into three sections; South, Aberdeen Trunk Road, and North. There are also separate graphs for existing, consented and in-planning wind farms.

A90 South (Graphs 01 and 02)

As described above, the south section of the A90 will have limited, if any, views of EOWDC and the graph illustrates that there will be no other wind farms visible at two points where the EOWDC is theoretically visible. The graph suggests however that, travelling on the A90 from the limits of the 60 km radius study area which starts at Stracathro Services, there will be potentially views of 11 existing or consented wind farms and 1 in-planning wind farm at various points along the road and therefore there is the potential for EOWDC adding to the sequential cumulative effects that already arise from the existing wind farms. The in-planning wind farm is the extension to Skelmonae which is potentially only visible at one point, approximately 38 km north of the A90 and at this distance will be most unlikely to be seen from the road.

The existing or consented wind farm graph suggests that around Laurencekirk to Stonehaven there may be potential combined and sequential visibility of up to eight sites for most of this stretch between distances of 1 and 15 km from the road. Beyond 2 miles north of Stonehaven the graph shows that views of wind farms decreases and it is only Meikle Carewe that is potentially visible within 15 km of the A90 between Stonehaven and the A93 Junction before Aberdeen.

A90 Aberdeen (Graphs 03 and 04)

The 3 mile section of the A90 which routes through Aberdeen is shown by the graphs to have theoretically combined views of Mid Hill, Hillhead of Auquhirie (and extension), Clochnahill, Meikle Carewe wind farms, and EOWDC. Clochnahill, Mid Hill and Hillhead of Auquhirie (and extension) will lie beyond 25 km from the road and will be seen in the opposite direction to the EOWDC. Meikle Carewe will also be seen in the opposite direction to the EOWDC, but will be between 15 and 20 km from the road.

However, the experience on site indicates that at present there is no obvious visibility of the more distant existing wind farms and views towards EOWDC will be intermittent and limited.

A90 North (Graphs 05 and 06)

On the northern stretch of the A90, the graphs suggest that there could be up to 20 existing and consented wind farms and up to 9 in-planning wind farms not including the EOWDC theoretically visible along the length, although eight existing and consented, and one in-planning wind farms will be beyond 40 km from this stretch of the A90 and can therefore safely be presumed to be unlikely to be detected by those travelling the route. The graphs also suggest that, from Peterhead to Bridge of Don, there will theoretically almost be a continuous view of wind farms. Those most likely to be seen along the road in conjunction with the EOWDC include Ardgrain, Hill of Easterton, Hill of Fiddes, Tillymaud, and Mains of Bogfechel. The in-planning Peterhead Harbour, Woodlands Farm, Mosseye and Hill of Fechel turbines will also be theoretically visible from a large stretch of the A90 and will also contribute to the overall sequential effects.

A90 Overview

The graphs and ZTVs show that whilst there is little combined visibility of the EOWDC with other wind farms for the majority of the A90 the EOWDC will extend the potential sequential visibility of wind farms to stretches of the road which currently do not have views of wind farms. This is more pronounced in the northern section of the A90, compared to the southern section where the EOWDC has limited intervisibility with the road.

Overall, the graphs indicate that there theoretically will be views of wind farms for the majority of the A90 route identified in the graphs. However, the majority of the onshore turbines are not higher than 60 m hub/100 m blade tip and site assessment has found that in reality the existing wind farms do not have a large visual envelope or presence when travelling the route. Whilst the graphs are helpful in understanding the theoretical scenario they do show the worst case scenario. Site investigation along the routes indicated that, when travelling at the appropriate road speed, it is only those turbines within a reasonably close distance of the route that will really be perceived.

It is therefore judged that the overall magnitude of sequential cumulative impact of the EOWDC on the A90 is Medium. As the sensitivity of travellers on the A90 to the type of development proposed is Medium to Low, the significance of sequential cumulative effect is assessed as Moderate to Moderate-Minor.

4.4.2. **A920**

The A920 has been assessed as one continuous road, 39 miles long, from Cairnborrow to Ellon. The graphs and ZTVs show that visibility of EOWDC is not theoretically possible until 2 miles east of Old Meldrum, at which point it will be 20 km away and along the course of the road to the east it will not be closer than 15 km. The ZTV shows there will be intermittent visibility and at some points this will be limited to blade tip only. Site assessment also confirmed that much of this road is enclosed by roadside vegetation and in reality views of EOWDC would be much more restricted than is shown by the ZTV.

It is therefore judged that the magnitude of sequential impact on the travellers using the A920 is Low to Negligible. As the sensitivity of the travellers to the type of development proposed is Medium to Low, the significance of sequential cumulative effect is assessed as Moderate-Minor to Minor to Negligible.

Cumulative Impacts (Graphs 07 and 08)

The graphs show that there are 30 existing and consented wind farms potentially visible along this stretch of road, and a further 15 in-planning wind farms, not including the EOWDC. In the eastern stretch where the EOWDC is potentially visible, the graph shows that there could be combined views of Hill of Fiddes, Ardgrain, Hill of Easterton, Tillymaud, and Skelmonae. These wind farms would lie considerably closer to the A920 than the EOWDC, at distances of between 3 and 15km. The in-planning wind farms which would be seen in combination with the EOWDC include Hill of Fechel, Mosseye, Woodlands Farm, Skelmonae Extension, and Hillhead, Oldmeldrum turbines. Again, these would all lie noticeably closer to the route than the EOWDC.

The A920 is potentially exposed to wind farms along its entire length with very few gaps. The addition of EOWDC will not extend the sequential views but will potentially give combined cumulative effects. As judged above, however, views of EOWDC are limited and therefore combined cumulative effects would also be limited.

It is therefore judged that the magnitude of cumulative impact on the travellers on the A920 is Low to Negligible. As the sensitivity of the travellers to the type of development proposed is Medium to Low, the significance of cumulative effect is assessed as Moderate-Minor to Minor to Negligible.

4.4.3. **A93**

The A93 is a main road which follows the River Dee for much of its length towards Ballater. The ZTV shows that due to its sheltered valley enclosure there is no intervisibility of the EOWDC along any of the A93 within the study area and therefore no visual effects.

Cumulative Impacts

As there are no visual effects arising from EOWDC along this road there will be no cumulative effects. Although not included in the appendix, graphs were produced and they confirmed that only Mid Hill and Meikle Carewe would be seen along the A93with no visibility of EOWDC.

4.4.4. **A947**

The A947 is the main road that links Banff and Aberdeen via the towns of Turriff and Oldmeldrum. The ZTVs suggest that there are only a few locations along this road which will have potential intervisibility with the EOWDC. These are located at a couple of local high points just north of Oldmeldrum and some high land between Oldmeldrum and Newmachar. There is also potential visibility at Dyce, although local residential and industrial development will obscure some views.

As the visibility of the EOWDC is from very limited areas and for short stretches of the route, the magnitude of impact on travellers along the A947 is considered Low to Negligible. As the sensitivity of travellers to the proposed type of change is Medium to Low, the significance of effect is assessed as Moderate-Minor to Minor to Negligible.

Cumulative Impacts (Graphs 09 and 10)

The graphs illustrate that there are potentially 36 existing and consented wind farms, and 18 in-planning wind farms theoretically visible along the A947, not including the EOWDC. Ardgrain, Hill of Fiddes, Mains of Bogfechel, Skelmonae, and Tillymaud will potentially be seen in combined views with the EOWDC. The in-planning Hill of Fechel, Skelmonae Extension, Bogenjohn Farm, St Fergus Moss and Woodlands Farm turbines are also shown on the graphs to be visible with the EOWDC.

The majority of the A947 is shown by the graphs to have visibility of wind farms, especially the stretch between Fyvie and Oldmeldrum which has the potential to see up to 21 wind farms at once. However, site assessment has shown that while there are views of some of these wind farms, roadside vegetation and development obscures clear views from long stretches of the road.

The sequential cumulative effect along the A947 can already be judged to be high without the EOWDC turbines. The addition of EOWDC will potentially extend the sequential effects for a short length of the eastern section of the road. This short stretch of visibility is considered to be insignificant enough that the sequential cumulative effect arising from the inclusion of EOWDC is not overall increased. Therefore it can be concluded that the magnitude of cumulative impact of the EOWDC is Negligible. As the sensitivity of the traveller on the A947 to the proposed change is Medium to Low, the significance of cumulative effect is assessed as Negligible.

4.4.5. **A948**

The A948 connects New Deer with Ellon and is 14 miles long. The ZTV and graphs show that the EOWDC will be visible for the southern 3 miles before it joins the A90 at Ellon. The proposed turbines will be approximately 15 km at their closest to the road. There will be no intervisibility with the site along the rest of the route.

As the EOWDC will be clearly visible in views along only the southern extents of the road, where roadside vegetation and development permits, the magnitude of effect on travellers on the A948 is considered Medium for this stretch and Negligible elsewhere. As the sensitivity of travellers to the proposed change is Medium to Low, the significance of effect is assessed as Moderate to Moderate-Minor to Negligible.

Cumulative Impacts (Graphs 11 and 12)

The graphs suggest that the A948 is theoretically exposed to 26 existing and consented wind farms and 13 in-planning sites, not including the EOWDC. The majority of these sites are potentially visible between Auchnagatt and Ellon, with up to 20 wind farms theoretically visible at once within a short stretch, 4 miles north of Ellon.

EOWDC is first visible at 11 miles from New Deer, and the graphs suggest that there would also be combined visibility of Mains of Bogfechel, Hill of Fiddes, Ardgrain, Tillymaud, and Haddo Wind Farms. Hill of Fechel, Mosseye, Skelmonae Extension, and Woodlands Farm would be the only in-planning wind farms seen in combination with the EOWDC. These would all, except Haddo and Hill of Easterton, lie closer to the road than the EOWDC.

The addition of the EOWDC does not expose new stretches of the A948 to visibility of wind farms. There will be combined visibility of EOWDC at the southern end of this road which will add to the number of wind farms sequentially viewed. It is therefore judged that the magnitude of cumulative effects on travellers is Low. As the sensitivity of travellers to the proposed change is Medium to Low, the significance of cumulative effect is assessed as Moderate-Minor to Minor.

4.4.6. **A96**

The A96 is the main road linking Inverness and Aberdeen via Inverurie and Huntly. The ZTV shows that the EOWDC will only be visible at the southern extents of this road from Dyce to the edge of Aberdeen city centre. Apart from potential blade tip visibility within an area around Kintore, there will be no visibility of the EOWDC from the A96.

Given this, it is judged that the magnitude of visual impact upon travellers along the A96 will be Medium from the identified southern extents only but Negligible from all other sections of the route. As the sensitivity of travellers to the proposed change is Medium to Low, the significance of visual effect is assessed as Moderate to Moderate-Minor to Negligible.

Cumulative Impacts (Graphs 13 and 14)

The graphs suggest that views are theoretically available of up to 17 existing and consented wind farms and 8 in-planning sites, not including the EOWDC at various points along the A96's length. The graphs also suggest that the EOWDC will be potentially visible in the southern section of the road where no other wind farms will be visible except for a short section where combined views may be possible with the single turbine at Mains of Bogfechel.

Starting at Huntly, the existing large wind farms at Glens of Foudland and Mains of Dummuie are very visible as well as the smaller Hill of Tillymorgan Wind Farm. Beyond these wind farms the in-planning graph shows that Newton of Fortrie, Hospital Wood, Auchinderran, Backhill of Yonderton and Hillhead (Bonnykelly) wind farms will be visible within a 2 miles stretch.

Travelling south east, between Kirkton of Culsalmond and Inverurie the smaller wind farms at Hill of Easterton, Gordonstown Hill and single turbines at Hill of Burns and Cowhill become visible within 20km from the road. In addition, the in-planning Hillhead (Old Meldrum) and Mains of Balquhain will be visible within 20km of the road.

From Inverurie the existing, consented and in-planning turbines gradually diminish and it is only the existing Mains of Bogfechel which is potentially seen within 15 km of the road before the EOWDC starts to become visible.

The addition of the EOWDC will thus result in limited combined cumulative effects on the A96 but, as it will be visible along a stretch of the A96 where no existing, consented or in-planning wind farms will be visible, it can be considered that it will extend the existing sequential cumulative effects for the length of the road within the study area. However, the visibility of wind farms between Kirkton of Culsalmond and Dyce is limited as the smaller wind farm sites gradually lie beyond 10 km from the road and site assessment confirmed that roadside vegetation and development will prevent extensive continuous views across the surrounding landscape.

It is therefore judged that the magnitude of sequential cumulative impact on the travellers on the A96 is Medium. As the sensitivity of travellers to the proposed change is Medium to Low, the significance of effect is assessed as Moderate to Moderate-Minor.

4.5. Visual Effects at Night

The turbines at EOWDC will be marked to be visible by day and by night, with prevailing visibility conditions, and will be lit in accordance with the International Association of Lighthouse Authorities (IALA) standards and as specified by Trinity House. For aviation purposes it is proposed that turbines will be lit in accordance with the Civil Aviation Authority (CAA) requirements.

The turbine lighting has a visible range of 5 nautical miles (NM) (approximately 9 km). As a result the coastal areas from Newburgh to Girdle Ness will potentially have additional visual glare or night glow where views of the EOWDC are available. However, views out to sea will be compromised to a degree, within most of this area, by the light spillage from existing lighting associated with the urban areas, road lighting, harbour, and lighthouses and especially the ships in the designated anchorage area. At the time of the assessment site visit, it was noted that there were over 20 large ships in the designated anchorage area and at night their lighting was very prominent where views of the bay are possible. The lighting of the turbines would therefore not be isolation and would only extend the existing presence of lights in the sea.

The significance of visual effects of the EOWDC at night is therefore considered not to exceed what has already been assessed for the daytime.

4.6. Summary Table of Visual Effects

Receptor	Approx. Distance to nearest EOWDC turbine	Sensitivity of Receptor	Magnitude of Impact	Significance of Effect	Magnitude of Cumulative Impact	Significance of Cumulative Effect
Vpt 1 Balmedie Beach	3.51 km	High	High	Major	None	None
Vpt 2 A90 (Harehill)	4.44 km	Medium to Low	High	Major-Moderate to Moderate	None	None
Vpt 3 Jesmond Drive, Middleton	7.14 km	High	Negligible	Negligible	None	None
Vpt 4 B999 Whitecairns	8.1 km	High (residents) Medium to Low (travellers)	Medium	Major-Moderate (residents) Moderate to Moderate-Minor (travellers)	None	None
Vpt 5 Aberdeen Beach	7.52 km	High	High to Medium	Major to Major-Moderate	None	None
Vpt 6 A90 (West Pitmillan)	9.31 km	Medium to Low	Medium to Low	Moderate to Moderate-Minor to Minor	Low	Moderate-Minor to Minor
Vpt 7 Torry Battery	7.89km	High to Medium	High to Medium	Major to Major-Moderate to Moderate	Negligible	Negligible
Vpt 8 South College Street, Aberdeen	9.19 km	Low	Negligible	Negligible	None	None
Vpt 9 Forvie Nature Reserve	10.27 km	High	Medium	Major-Moderate	None	None
Vpt 10 Midstocket Road/North Anderson Drive	10.47 km	High (residents) Medium to Low	Low	Moderate (residents) Moderate-Minor to	None	None

LDĀDESIGN

Receptor	Approx. Distance to nearest EOWDC turbine	Sensitivity of Receptor	Magnitude of Impact	Significance of Effect	Magnitude of Cumulative Impact	Significance of Cumulative Effect
		(travellers)		Minor (travellers)		
Vpt 11 Leslie Road (A978) Aberdeen	8.07 km	High (residents) Medium (travellers)	Low	Moderate (residents) Moderate-Minor (travellers)	None	None

A96	11 km	Medium to Low	Medium to Negligible	Moderate to Moderate-Minor to Negligible	Medium	Moderate to Moderate-Minor

5.0 Other Assessment Considerations

5.1. Varying Turbine Heights

As the nature of the deployment centre is that it will be used to test emerging wind turbine technologies the turbines erected may be of varying heights. At this stage, two potential indicative scenarios of heights have been identified; Turbines 1 to 6 could have a hub height of 100 m and blade tip height of 160 m above LAT, Turbines 7 to 11 could have a hub height of 120 m and blade tip height of 195 m above LAT (as per the worst case scenario). This would give a hub height difference of 20 m and blade tip difference of 35 m. To understand the visual impacts of these height variations, wireframes were also created for Viewpoints 1, 2, 5, 7, 12 and 15. Please see Figures TH1-3.

The wireframes illustrate that the height difference will be difficult to discern at even the closest distance and that the identified variations in turbine height will not significantly alter the view. As is shown in Viewpoint 7 and 12 which show the eastern five turbines being larger, it is mostly in views from the south or north where the turbines height difference will be seen. Elsewhere, the distance between the turbines will offset the turbine height difference and, due to the influences of perspective, it will not be a noticeable difference. It is therefore concluded that the potential height variations would not increase the significance of impacts already identified in the assessment of the worst case scenario.

5.2. Potential Ocean Laboratory

The potential Ocean Laboratory would be subject to a separate planning application but has been included in this section as there may be cumulative impacts. The potential Ocean Laboratory could consist of a 120 m high mast and platform unit (20 x 20 x 4 m) and which could lie in the water south of the EOWDC turbines. Whilst the exact potential Ocean Laboratory details had yet to be confirmed at the time of this assessment, the dimensions given above were used to model the structure into wireframes for viewpoints 1, 2, 5, 7, 12 and 15 (Figures OL1-3) as locations where it could potentially be seen in full at relatively close distances. Please note that in reality the mast element of the Ocean Lab structure would be less dominant than shown on the wireframes.

The following paragraphs discuss the visual impacts of the Ocean Laboratory in combination with the EOWDC turbines at the aforementioned viewpoints.

5.2.1. **Viewpoint 1** (OL-01 top)

The top wireframe in Figure OL-01 illustrates the location and approximate structure of the potential Ocean Laboratory in views from Balmedie Beach, viewpoint 1. It slightly extends the extent of the EOWDC development across the view but, due to distance it will appear as the smallest element. The base platform has the potential to draw the eye to a lower section of the view than the adjacent turbine blades. As a static structure in comparison to the movement of the turbines, it will appear as a separate but not incongruous element to the view.

5.2.2. **Viewpoint 2** (OL-01 bottom)

The bottom wireframe in Figure OL-01 illustrates the proposed location and approximate structure of the potential Ocean Laboratory from the A90 – Harehill turn off, viewpoint 2. The platform will be the main focus of the laboratory and as the wireframe shows it will be seen below the horizon line with a backdrop of sea. The structure will extend the extent of the EOWDC across the view consistent with the spacing of the turbines. By its nature, the potential Ocean Laboratory will be seen as a separate element to the turbines, but at this viewpoint the distance to it and spacing with the turbines allow it to sit comfortably within the view.

5.2.3. **Viewpoint 5** (OL-02 top)

The top wireframe in Figure OL-2 illustrates the location and approximate structure of the potential Ocean Laboratory from Aberdeen Beach, viewpoint 5. The wireframe illustrates that the potential Ocean Laboratory will be nearer the viewpoint than the turbines and lie in front of the centre of the turbine group. It will therefore not extend the visible development across the view but will interrupt the rhythm of turbines and blades as the platform structure is a strong element below the adjacent turbine blades.

5.2.4. **Viewpoint 7** (OL-02 bottom)

The bottom wireframe in Figure OL-2 illustrates the location and approximate structure of the potential Ocean Laboratory from Torry Battery, viewpoint 7. The wireframe illustrates that the potential Ocean Laboratory will lie within a gap of the evenly spaced turbine group. The platform will be seen with a backdrop of land, just above the sea level. As in Viewpoint 5, the Ocean Laboratory will interrupt the rhythm of the turbine spacing and the platform will potentially be a noticeable feature in contrast to the turbines.

5.2.5. **Viewpoint 12** (OL-03 top)

The top wireframe in Figure OL-3 illustrates the location and approximate structure of the potential Ocean Laboratory from Kincorth Hill, viewpoint 12. The wireframe illustrates that from this viewpoint the potential Ocean Laboratory will sit between two turbines in the centre of the group. The platform will be seen with a backdrop of sea and due to the spacing of the turbines seen from this viewpoint; the structure will be less noticeable than if it were separate from the group.

5.2.6. **Viewpoint 15** (OL-03 bottom)

The bottom wireframe in Figure OL-3 illustrates the location and approximate structure of the potential Ocean Laboratory from Brimmond Hill, viewpoint 15. The wireframe illustrates that the potential Ocean Laboratory will lie at the southern end of the turbines and will be seen with a backdrop of the sea, with no protrusion into the skyline. At this viewpoint which is looking down on to the proposed development, the platform of the potential Ocean Laboratory will blend into the seascape, reducing its visual impact.

5.3. Menie Estate

Although a private estate, due to the high profile of the proposed developments at the Menie Estate the impacts of the EOWDC on the estate have been discussed by EOWDC with Trump Estates in October and November 2010 with further discussion in March 2011. A brief summary of the potential visual and landscape effects are set out below. These have been informed by both desk based study and the proximity of the Balmedie viewpoint (viewpoint 1).

The Menie Estate lies to the north west of the turbines, approximately 4 km at its southern extents from the nearest turbine of the EOWDC. Views from the estate to the south east will include views of the turbines, which will be similar to those illustrated for Viewpoint 1 – Balmedie Beach. However, whilst at 4km the turbines will be a feature in views from within the estate, the turbines are not anticipated to result in any unacceptable effects upon residential amenity or the immediate setting of the Estate.

In terms of any perceived potential effects upon residential amenity within the Estate, findings at recent Public Inquiries indicate that any potentially significant (i.e. oppressive or overbearing views) are only likely to exist within 1 km of a proposed development.

6.0 Construction, Decommissioning, and Mitigation

6.1. Construction Phase

During the construction phase the effect of increased activity of construction vessels travelling to the site, the presence of jack-up barges and the progressive construction of the wind turbines will constitute the main effect, albeit temporary. During this phase there will be some minor effects on the surrounding seascape. There will also be minor effects on the associated visual receptors and general visual amenity, during construction operations, which although temporary may be more significant than during the operational stages due to the increase in activity and vessel movements.

The additional effects arising from marine vessel activity associated with the cable installation, cargo barges or transportation of materials, including land based or harbour construction activity, are also considered to be relatively insignificant as there is an existing baseline of marine activity in the area.

6.2. Decommissioning Phase

During the decommissioning phase, there will also be visual effects associated with the decommissioning activity. This will be similar to that of the construction phase and relatively insignificant due to the existing baseline of marine activity in the area. As the anticipated length of decommissioning will be slightly less than for the construction phase, these impacts will be more temporary than for the construction period. Following the decommissioning stage there would be no residual effects on the seascape, landscape or visual receptors.

6.3. Mitigation

The inherent characteristics of the proposed development suggest that there are very limited opportunities for incorporating mitigation measures for seascape, landscape and visual effects. However, beneficial mitigation is included in the layout of the turbines and the size of the proposed development. The scheme incorporates integral mitigation measures to minimise the risk of aesthetically visually uncomfortable turbine arrangements.

Also, careful consideration is given to the colour of the turbines in order to ensure that they remain moderately recessive visually, albeit within the parameters of ensuring sufficient visibility for vessels out at sea. There is a need to balance the objective of reducing their visibility with the existing standard requirements for ensuring visibility of structures out at sea. Thus, the need to paint the lower sections of the turbine columns yellow, in accordance with Trinity House Lighthouse Service requirements, is unavoidable.

7.0 Summary

7.1. Seascape Effects Summary

The scale and extent of the proposed EOWDC, located just over 2 km east off the coast, will inevitably affect the surrounding seascape and landscape environments. The primary source point of the effects will be the eleven turbines.

The turbine columns are necessarily large structures which will be introduced into the existing seascape character of the area which currently does not include any offshore wind structures.

Being sited out at sea, the turbines are to be placed within an immediate receiving environment that has both the scale and simplicity of form to, not only accommodate the development, but also to provide it with an appropriate contextual setting. Thus, although the turbines are in themselves of a substantial scale, visual aesthetics and the nature of the receiving environment, that includes an expansive horizon line, big skies, simple composition and linear form of views, and the general scale of the seascape, indicates that they are not inappropriate to offshore locations.

Whilst any direct physical effects arising from the principal offshore components will be limited for the majority of the seascape and landscape resource, there will be a range of indirect visual effects upon the various identified regional seascape units, landscape character areas, and designated coastal landscapes within the study area.

The proposed EOWDC site will be located within the Aberdeen Bay regional seascape unit which will thus, carry the greatest effect arising from the EOWDC development. The EOWDC will be a prominent feature within the seascape unit and will become a defining characteristic. However, the scale of the seascape unit and the presence of existing marine activity and prominent man made elements along the coast will assist with reducing the overall extent of the effect locally to Major to Major-Moderate in the north and Major-Moderate in the south of the seascape unit.

Given the distance between the proposed site and the coastline, the wind turbines will also be theoretically visible from the five other regional seascape units and will thus have a degree of indirect effect upon the visual attributes of their character. A combination of distance; the nature and scale of these units; and, the fact that effects are confined to visual influence only; will, however, assist with reducing the overall extent of effect to Major-Moderate to Moderate at Aberdeen Beach, no more than Moderate between Stonehaven to Girdle Ness and Collieston to Peterhead, with Negligible effects beyond.

The landscape character areas defined for the study area will also experience a range of effects on their visual characteristics. The most significant effects of Major-Moderate to Moderate will be upon the Perwinnes Open Farmland and Major-Moderate to Moderate to Moderate-Minor on the Formartine Lowlands which both lie adjacent to the coastline, and due west of the EOWDC, where views across the sea are a key characteristic. The more elevated inland character areas encompass far ranging and expansive views within which the EOWDC will be a noticeable element, but not dominant, and therefore will not result in any significant effects.

The EOWDC will have a Major to Negligible effect on the locally designated Area of Landscape Significance which lies along the coast from Balmedie to Longhaven, extending to, at its closest, 3 km from the nearest turbine. However, significant effects will reduce to Negligible the further north within this ALS and it is noted that there will be no effects on the ALS at Cruden Bay due to the surrounding topography.

7.2. Visual Effects Summary

The proposed eleven turbines have a maximum nacelle height of 120 m above LAT, with a maximum height to blade tip of 195 m. They will thus be seen, both individually and collectively, as large visual elements set within a simple open setting, comprised predominantly of sea, coastal edge and sky. As they are close to land, in the wider study area, where visible, they will be seen with or without the sea context rising above the predominantly undulating landscape. The turbines will also be seen; admittedly by a far fewer number of visual receptor groups, in views from the sea where they will be seen against a backdrop of either the Aberdeenshire deposition coastline with farmland behind or against the complex and dynamic coastline extending from Aberdeen city and Girdle Ness headland.

Inland, theoretical visibility is highest primarily to the north and north west of the site from within the more open undulating landscape. The city and its suburbs, combined with the more pronounced landform to the south and west, substantially limit views of the EOWDC from within these areas of Aberdeenshire. The visual effects arising from the offshore turbines will be greatest when seen in exposed views within an approximate 15 km radius of the site and extending north along the coast from those locations where there are clear views of the EOWDC. This is demonstrated by the assessment of Major and Major-Moderate effects upon many of the receptors at the representative viewpoints within this distance. However, as the viewpoint assessment also illustrates, there are not necessarily significant effects at close distances as views of the turbines can be easily obscured by local topography, vegetation, and buildings.

The visual effects will ease considerably with distance from the site. However, given the size of the turbines, they will still be a noticeable feature from the northern coastline at distances of up to 20kmas demonstrated by Viewpoint 18. At similar distances inland from the EOWDC the landform and components of the landscape will obscure or reduce the prominence of the turbines so that they will only be a minor element in the view. The significant number and diversity of built elements sited intermittently along the coastline near the EOWDC site will also help to absorb the visual profile of the proposed turbines within distant views.

The magnitude and extent of visual effects is also reduced as the proposed development will be seen to shift from being the main focus of view (such as at Viewpoint 1 at Balmedie Beach) to occupying a more peripheral or oblique position within the field of view from other viewpoints.

The visual impact on Aberdeen is limited by the densely built up nature of a city and only in the more open elevated areas are the turbines likely to be visible, but then with a busy and complex foreground which will help to moderate any significant effects.

Any visual effects on receptors within the sea will be temporary due to the generally transient nature of views available from marine vessels making passage. There will, however, be temporary Moderate effects on those receptors out at sea, such as recreational sailors, who have an interest and enjoyment in the surrounding seascape.

Upon evaluation, the visual effects arising from the proposed EOWDC development have not been found to be inappropriate. Although the presence of the turbines will fundamentally change the views from the nearby coastline, and where visibility permits, they will be a noticeable but minor feature in views for distances of up to approximately 20 km on land, the extent of visibility of the EOWDC is relatively constrained as evidenced by the ZTV plans Offshore, the EOWDC will be a noticeable feature for a considerable distance across the expansive open sea and will thus provide an identifiable focal point and visual reference within the maritime setting.

Upon consideration the overall visual effect is therefore considered to be Moderate with only localised and isolated areas of more significant effect.

Due to the individual turbine spacing, the potential height differences of the turbines as proposed will not be significantly noticeable even at the closest viewpoints.

7.3. Cumulative Effects Summary

The assessment of cumulative effects found that, due to the offshore location of the EOWDC, and that the majority of the many wind farms within Aberdeenshire are located beyond 20 km from the site, the combined and successional cumulative effects were mostly Minor or Negligible and no more than Moderate in significance for visual, seascape and landscape cumulative effects.

As a consequence of being the closest (11-19 km) to the EOWDC, the existing and consented Hill of Fiddes, Ardgrain, Tillymaud, Mains of Bogfechel turbines and the in-planning Woodlands Farm and Hill of Fechel are the most frequent existing or consented wind farms to be seen in theoretical views with the EOWDC. However, these wind farms, at approximately half the height of EOWDC and with only between 1 and 3 turbines, have a relatively confined visual envelope which reduces the cumulative effect.

Although there are no significant combined cumulative effects, the sequential cumulative effects of EOWDC are potentially greater given the large number of wind farms in the study area.

The sequential assessment of visibility from the main roads within the study area showed that the EOWDC would potentially extend the visibility of turbines further than currently exists along the A90 and A96 thus creating Moderate to Moderate-Minor sequential effects along these roads. Along the other key routes studied, the EOWDC will become part of an existing sequential effect and not significantly add to it.

The proposed Ocean Laboratory will potentially bring about greater cumulative effects with the EOWDC turbines than any of the other wind farms within the study area. Due to the depth of the platform structure, it will be a noticeable, but not incongruous, element in views from the coastline, and from elevated positions where the base of the turbines can be seen. As illustrated by the viewpoints beyond 10 km, the platform will become less of a discernable feature at further distances. Please note that the potential Ocean Laboratory will be subject to a separate planning application.

European Offshore Wind Deployment Centre

Environmental Statement

Appendix 20.1: Cultural Heritage Baseline Technical Report

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

1 CULTURAL HERITAGE ASSESSMENT

1.1 Information for the Non-Technical Summary

1 The cultural heritage baseline study initially gathered data regarding nationally important cultural heritage assets within 10 km of the European Offshore Wind Deployment Centre (EOWDC) and selected assets beyond this distance, by means of desk-based research and site visits. This data in conjunction with Zones of Theoretical Visibility (ZTVs) produced for the Seascape and Landscape Visual Impact Assessment (SLVIA) have been used to identify those assets that may be subject to setting impacts.

2 A wide range of cultural heritage assets is present in the study area, with asset types as diverse as prehistoric burial cairns, a medieval cathedral, 19^{th} century mills and 20^{th} century halls of residence present. This diversity reflects the long history of Aberdeen as a settlement and the intensive history of settlement in the fertile coastal strip of Aberdeenshire. Of the assets considered 14 have been identified as being potentially subject to setting impacts, all of these lie outside Aberdeen City. Assets within Aberdeen itself have been found to have no intervisibility with the EOWDC that could potentially result in setting impacts.

1.2 Introduction

3 The Cultural Heritage Setting Assessment considers the potential effect of the EOWDC upon the setting of onshore cultural heritage assets of national importance. This report details the results of the baseline study undertaken in order to identify onshore cultural heritage assets that may be subject to setting impacts.

4 The baseline report details the approach to data gathering and the results of consultation. It summarises relevant legislation, planning policy and guidance and identifies nationally important assets in the study areas. It then goes on to identify those assets where there is potential for impacts upon setting and their cultural significance. Detailed descriptions of setting and intervisibility are presented as part of the Cultural Heritage Environmental Impact Assessment (EIA) Technical Report.

1.2.1 Methodology Consultation

5 The following consultation was undertaken

- Aberdeen City Council

Aberdeen City Council was approached in order to establish whether they had specific concerns or requirements for data to be provided, in particular visualisations. Comments were also invited upon the proposed scope of the assessment.

Robert Forbes, The Planning Officer, indicated that he did have some concern regarding potential impacts upon the setting of Girdle Ness Lighthouse, and requested that visualisations from elevated points to the south and south-west of the lighthouse were provided in order to help assess the potential impact upon views of the lighthouse.

The potential impact upon the setting of the lighthouse has been assessed using wireframes and a site visit. The wireframes are presented within this report along with photographs illustrating various views of the lighthouse. However, photomontages (visualisations) have not been prepared. The wireframes give an adequate demonstration of the scale of the turbines in relation to the lighthouse in views from the south, whilst the photomontages for the Torry Battery and Kincorth Hill viewpoints (SLVIA Viewpoints 07 & 12 respectively) provide an indication of the EOWDC's appearance from the vicinity of the lighthouse and from high ground to its southwest. The inclusion of photomontages for Nigg Bay would not afford any substantive information that is not available from that presented here.

The Archaeology Unit indicated that all consultation was to be undertaken through the Planning Officer.

- Aberdeenshire Council Archaeology Service

Aberdeenshire Council Archaeology Service was approached in order to establish whether they had specific concerns or requirements for data to be provided, in particular visualisations. Comments were also invited upon the proposed scope of the assessment.

The Archaeology Service indicated that it had no concerns regarding potential setting impacts.

- Historic Scotland

Historic Scotland was approached in order to establish whether they had specific concerns or requirements for data to be provided, in particular visualisations. Comments were also invited upon the proposed scope of the assessment.

No specific concerns were noted. However, it was suggested that the assessment be accompanied by visualisations to illustrate the potential impact upon the setting of Straloch Garden and Designed Landscape (GDL), Hare Cairn and Forvie Chruch and deserted village, as well as those proposed for the Seascape, Landscape and Visual Impact Assessment (SLVIA) for south of Dunnottar Castle (A92 near Uras) and Torry Battery. It was suggested that assets in the vicinity of Straloch GDL, such as Tillygreig hut-circles (SM12450) be considered.

Visualisations have been included for Torry Battery (Viewpoint 07 of SLVIA) and from near Forvie Church (Viewpoint 09 of SLVIA). No visualisations have been presented for Straloch GDL or Dunnottar Castle, as there is no intervisibility, or Hare Cairn or Tillygrieg hut-circles, as there is no potential for a significant impact upon its setting from the EOWDC.

- Scottish Natural Heritage (SNH)

SNH was approached in order to establish whether they had specific concerns or requirements for data to be provided, in particular visualisations.

Comments were also invited upon the proposed scope of the assessment (e-mail dated 1st March 2011). SNH had indicated early in the project's lifespan that impacts upon the setting of cultural heritage assets should be considered by the Environmental Statement (ES).

SNH indicated that the proposed scope of the study was acceptable (e-mail dated 25th March 2011) and did not require any further visualisations.

1.2.2 Key Guidance Documents

6 The following guidance documents have been referred to:

- COWRIE (2007a) *Historic Environment Guidance for the Offshore Renewable Energy Sector*
- COWRIE (2007b) *Guidance for Assessment of Cumulative Impacts on the Historic Environment from Offshore Renewable Energy*
- Historic Scotland (2008) *Scottish Historic Environment Policy (SHEP)*
- Historic Scotland (2009) *Assessment of Impact upon the setting of the Historic Environment Resource*
- Historic Scotland (2010) *Managing Change in the Historic Environment: Setting*

1.2.3 Data Information and Sources

7 Two concentric study areas have been used to gather and present the baseline data:

- Inner study area (Environmental Statement (ES) Figures 20.1, 20.2 and 20.3): This extends 10 km from the outermost proposed turbines. Within it data has been gathered for all designated nationally important assets (scheduled monuments , Category A-listed buildings and Inventory Gardens and Designed Landscapes (GDL)) and conservation areas; and
- Outer study area: this extends 40 km from the proposed turbines to take in the area for which the Zone of Theoretical Visibility (ZTV) has been prepared for the SLVIA. Within it assets specifically identified by consultees as being of concern have been considered.

8 There is no guidance regarding appropriate study areas for cultural heritage setting impact assessments. The study area has been defined in order to take in those assets that are most likely to be affected by the proposed development. Assets further inshore are less likely to be affected as their setting is less likely to relate to the sea.

9 Data were gathered from the following data sources:

- Databases of designated assets held by Historic Scotland;
- National Monuments Record of Scotland (NMRS);
- Aberdeen City Council Sites and Monuments Record (SMR); and
- Aberdeenshire Council Historic Environment Record (HER)

10 Assets are referred to by the reference number associated by their designation. Scheduled monument numbers (officially 'Ancient Monument

Index Numbers') are prefixed 'SM' and numbers referring to listed buildings (officially 'Historic Building Numbers') are prefixed 'LB'. Where an asset is both scheduled and listed it is referred to by its scheduled monument number.

11 The results of the desk-based study were augmented by site visits undertaken on 8th and 9th March 2011.

1.3 Baseline Description

1.3.1 Scheduled Monuments in the Inner Study Area

12 There are 18 scheduled monuments in the inner study area. These are predominantly prehistoric in date, with cairns, settlement remains and standing stones present. However, amongst the schedulings are later assets, including medieval chapels, St Machar's cathedral and Torry Battery. These are summarised in Table 1 and their locations shown on ES Figure 20.1.

TABLE 1 Scheduled Monuments in the Inner Study Area

SM No	NAME
1907	Mote Hill, palisaded settlement and cairn
3275	The Temple Stones, stone circle NE of Potterton House
3277	Hare Cairn, cairn 600m W of Keir
3282	Bishops' Manor, manor house and chapel
3283	Dubford, standing stone 400m N of
4055	Tullos Cairn, cairn
4060	Crab's Cairn, cairn
4263	Lang Stane, standing stone, Hilton Drive
7124	Old Aberdeen Market Cross
7644	Forvie Church and deserted village (site of)
9215	Torry Battery, battery 130m ESE of Old South Breakwater
10400	St Fittick's Church, Aberdeen
10403	Balnagask motte, Baxter Place, Aberdeen
10424	Aberdeenshire Canal, remains of, Station Road, Woodside, Aberdeen
12433	Home Farm Cottage, cairn 325m N of
12452	Foucausie, hut circle 250m SSE of
12541	Sands of Forvie, hut circles and ring cairn 1020m E of East Cottage
90001	St Machar's Cathedral and graveyard

13 The schedulings are scattered throughout the inner study area, though most are located in Aberdeen or nearby (ES Figure 20.1). Six are within Aberdeen itself (SM 1907, 4263, 7124, 10403, 10424 & 90001), whilst four lie in open ground to the south-east (SM 4055, 4060, 9215 & 10400).

1.3.2 Category A-Listed Buildings in the Inner Study Area

14 There are 86 Category A-listed buildings within the inner study area, though there are only 62 individual listings, as several listings take in more than one building (Table 2, ES Figures 20.2 and 20.3). Of these 83 are within Aberdeen or its suburbs. Consequently, the buildings present are predominantly churches and eighteenth and nineteenth century townhouses and similar urban building types. However, also present are buildings that reflect Aberdeen's maritime and industrial heritage, with buildings such as the

Custom House (LB19982) and the Grandholm Works (LB18985) present. Also later dwellings have been listed, such as Rosemount Square (LB 20471), a block of local authority flats completed in 1948, and Crombie Halls, student accommodation completed in 1960.

15 Outside Aberdeen, there are three Category A-listed buildings. These are Girdle Ness Lighthouse (LB 20078), Orrok House (LB 2778) and the Turing Slab (LB 9166), a medieval stone in Foveran Parish Church.

TABLE 2 Listed Buildings in the Inner Study Area

Listed Building Number	Name
LB 2778	Orrok House
LB 9166	Foveran Parish Church Turing Slab
LB 18985	Grandholm Works, Old Spinning Mill, Wing Mill, Engine and Turbine Houses
LB 19937	Belmont Street, former St Nicholas Congregational Church
LB 19940	Schoolhill and Belmont Street, former Triple Kirks Churches, including Steeple and former East Free Church
LB 19941	Broad Street and Queen Street, Greyfriars John Knox Church
LB 19943	Kings College Chapel, College Bounds
LB 19946	33 King Street, Aberdeen Arts Centre
LB 19953	King Street, St Andrew's Cathedral (Episcopal)
LB 19957	St. Machar's Cathedral, Chanonry
LB 19961	Spital, St Margaret of Scotland Chapel and former Convent including 17 Spital
LB 19964	Carden Place at Albert Terrace, St Mary's Church (Episcopal), including gatepiers and boundary walls
LB 19966	Union Street, Back Wynd, Schoolhill and Correction Wynd, The Kirk of St Nicholas Uniting (Church of Scotland and United Reformed)
LB 19967	Union Street, 9 Back Wynd, Schoolhill and Correction Wynd, St Nicholas Churchyard, including boundary walls and gatepiers
LB 19977	Concert Hall, Advocates' Hall
LB 19978	Schoolhill and Blackfriars Street, Art Gallery including War Memorial and Cowdray Hall, Robert Gordon's College Archway and former Gray's School of Art
LB 19982	35 Regent Quay, Custom House
LB 19983	27,29,31 King Street, including Railings
LB 19990	Castle Street and 2 Broad Street, Town House, including Municipal Offices, Court Houses and Tolbooth
LB 19991	Union Street, South Silver Street and Golden Square, Music Hall
LB 19992	Old Aberdeen Town House, High Street, Old Aberdeen.
LB 19995	Aberdeen Royal Infirmary Woolmanhill
LB 19999	Castlegate, Mercat Cross
LB 20005	Elphinstone, Bishop, Memorial, King's College Grounds, College Bounds, Old Aberdeen.
LB 20065	Westburn Road and Argyll Place, Victoria Park, Fountain
LB 20067	Brig O' Balgownie over River Don
LB 20073	Wellington Suspension Bridge over River Dee, at Craiglug
LB 20078	Girdle Ness Lighthouse
LB 20082	Little Belmont Street, former Old Town's School
LB 20088	Schoolhill, Robert Gordon's College including North gates and

Listed Building Number	Name
	boundary walls
LB 20096	Broad Street, Marischal College
LB 20098	12 and 14 Devanha Gardens, Devanha House, including Piers and boundary walls
LB 20108	Westburn Road and Cornhill Road, Westburn Park, Westburn House, including Railings
LB 20156	Broad Street, Provost Skene's House, including Archway and South Building
LB 20162	5 Castle Street (former Clydesdale Bank)
LB 20174	53 Castle Street, Sheriff Court Annex and High Court of Justiciary (Formerly Bank of Scotland)
LB 20186	Chanonry, 9 (West Side) Mitchell Hospital Old Aberdeen
LB 20186	Chanonry, 9 (West Side) Mitchell Hospital Old Aberdeen
LB 20288	Don Street, 20, 22 (East Side) Bede House, Old Aberdeen.
LB 20299	Don Street, (N.W. Side) "The Chapter House" "Cruickshanks Lodgings"
LB 20331	1 Great Northern Road, The Northern Hotel
LB 20333	Guild Street and 1 Trinity Street, Tivoli Theatre
LB 20334	62, 62a and 62b Hamilton Place at Whitehall Road, including gatepiers and boundary walls
LB 20335	64, 64a, 66, 66a and 66b Hamilton Place, including gatepiers and boundary walls
LB 20336	68, 68a and 70 Hamilton Place, including gatepiers and boundary walls
LB 20337	72 Hamilton Place, including gatepiers, boundary walls and Provosts Lamps
LB 20338	74 and 76 Hamilton Place, including gatepiers and boundary walls
LB 20339	78 and 80 Hamilton Place, including gatepiers and boundary walls
LB 20340	82, 82a and 84 Hamilton Place, including gatepiers and boundary walls
LB 20341	86, 86a, 88 and 88a Hamilton Place, including gatepiers and boundary walls
LB 20342	90 and 92 Hamilton Place, including gatepiers and boundary walls
LB 20343	94, 94a and 96 Hamilton Place, including gatepiers and boundary walls
LB 20360	High Street, 81 (West Side) Old Aberdeen.
LB 20374	High Street, 96 (East Side) Old Aberdeen
LB 20471	1-13 (Inclusive Numbers) Rosemount Square, at Leadside Road, South Mount Street, Richmond Street and Kintore Place
LB 20484	48 and 50 Shiprow (including former House of Provost Ross)
LB 20573	Union Terrace, 1, 2, 3 and 146 Union Street
LB 20605	Rosemount Viaduct, His Majesty's Theatre
LB 20628	79 Hamilton Place at Blenheim Place, including gates, gatepiers and boundary walls
LB 20629	98 Hamilton Place at Fountainhall Road, including gatepiers and boundary walls
LB 20673	Guild Street Aberdeen Railway Station and road over bridge
LB 43908	Maberly Street, Broadford Works With Returns To Ann Street and Hutcheon Street
LB 50016	Crombie Halls of Residence, Meston Walk

1.3.3 Gardens and Designed Landscapes in the Inner Study Area

16 There are no gardens or designed landscapes appearing in the Inventory in the inner study area (ES Figure 20.4).

1.3.4 Conservation Areas in the Inner Study Area

17 There are ten conservation areas in the inner study area. All but one of these is located within Aberdeen (ES Figure 20.4). They vary greatly in character, including areas as diverse as Old Aberdeen, Union Street and Fortdee. The exception is Kingseat Hospital, this was built in 1904 and was the first village hospital in Britain, taking in 'pauper lunatics' from Aberdeen. The following conservation areas lie within the inner study area:

- Kingseat Hospital
- Albyn Place/Rubislaw
- Bon-Accord Crescent/Crown St.
- Ferryhill
- Footdee
- Great Western Road
- Marine Terrace
- Old Aberdeen / Balgownie
- Union Street
- Rosemount/Westburn

1.3.5 Assets Considered in the Outer Study Area

18 Six assets in the outer study area have been considered; Straloch GDL (ES Figure 20.4), a 19th century park appearing in the Inventory of Gardens and Designed Landscapes, Tillygreig hut-circles (ES Figure 20.1, SM 12450) Dunnottar Castle (ES Figure 20.1, SM 986), which is scheduled and Category A-listed and three scheduled cairns to the south of Aberdeen (ES Figure 20.1, SM 4125, SM 4126 & SM 12342). The first three have been included as they were raised in Historic Scotland's response to the Request for Scoping Opinion, whilst the last have been included because of their location near the summit of a hill immediately outside the inner study area.

19 Other designated parks and gardens in the outer study area have been considered but the ZTV indicates that these will have no substantive intervisibility with the EOWDC and hence are not considered further.

1.3.6 Assets that May be Subject to Setting Impacts

20 Assets that may be subject to setting impacts have been identified by way of desk-based research and site visits. Given the distance of the proposed EOWDC from the shore, approximately 2 km, potential setting impacts are restricted to those that may result from visual change. Therefore the Zone of Theoretical Visibility (ZTV) generated for the SLVIA has been used in order to help identify assets where the wind turbines will be visible or, where relevant, views of assets that will be affected, within a distance of 40 km from the proposed turbines. A version of the ZTV, based on a Digital Surface Model (DSM), has been used, which takes into account obstructions such as buildings. The assets that may potentially be affected by the proposed

EOWDC are detailed below. The assets are considered from north to south in the following order: scheduled monuments, listed buildings, conservation areas and GDLs.

21 Forvie Church and deserted village (ES Figure 20.1, SM7644) comprise the remains of a medieval church and village buried by sand dunes. The church and adjacent huts were excavated and left exposed by archaeologists in the 1950s, but most of the village remains covered by sand dunes. The buried remains have exceptional potential in terms of their value as a source of data regarding medieval society, economy and material culture as they have been unaffected by later development or farming. The cultural significance of the site resides in its potential as a data source. The asset is surrounded by the Sands of Forvie, an extensive sand dune system, and lies some 300 m from the shoreline. The proposed EOWDC turbines will be visible from the church at a distance of 10 km.

22 To the west of Forvie Church, lie a scheduled ring cairn and hut-circles (ES Figure 20.1, SM12541), some 800 m from the shoreline. Only two of the 19 hut-circles recorded in 1950 are now visible, the remainder having been covered by sand-dunes. As with the medieval site, there is potential for exceptional preservation and the site therefore has great potential as a data source and its cultural significance resides in this potential. The proposed EOWDC will be visible to the south, at a distance of 9.8 km.

23 Tillygrieg hut-circles (ES Figure 20.1, SM12450) comprise the scheduled upstanding remains of two Late Bronze Age or Iron Age date. They are located near the top of a gentle east-facing slope and are surrounded by farmland. They are unusually well-preserved for this part of Aberdeenshire and have potential to yield information regarding settlement history and economy. The upstanding remains are slight and no more than 0.3 m in height, as such they are not visible in the wider landscape. The proposed EOWDC turbines will be partially visible to the south-east of the hut-circles, at a distance of 13.9 km.

24 Hare Cairn (ES Figure 20.1, SM3277) is a Bronze Age burial cairn located on the top of a small hillock. The surrounding field is given over to pasture. It has been partially excavated, but survives as an appreciable mound with exposed kerb. Despite the disturbance it has potential to yield data regarding Bronze Age burial practices. The cairn's cultural significance resides in its value as a potential data source and in its potential to provide a tangible link to the past. The proposed EOWDC turbines will be fully visible to the south-east of the cairn, at a distance of 4.8 km.

25 The Temple Stones (ES Figure 20.1, SM3275) comprises the remains of a recumbent stone circle. It is located on the shoulder of a hill, overlooking the Milden Burn to the south. Many of the stones have been removed and only the recumbent stone remains in situ, the pillar stones are present but have fallen over. Of the rest of the stone circle only one stone remains. The recumbent stone lies at the south-west of the monument. Stones cleared from the surrounding field have been dumped behind the recumbent stone. Despite its fragmentary survival there is potential for subsurface features to yield information regarding the construction and history of use of the stone circle and, by extension, contemporary ritual practices and its cultural significance resides in this potential. The proposed EOWDC turbines will be visible to the east at a distance of 4.3 km.

26 Dubford Stone (ES Figure 20.1, SM3283) is a single standing stone, which is thought to be the final remnant of a recumbent stone circle. The stone is located in an improved pasture field on a natural shelf. Despite its fragmentary survival there is potential for subsurface features to yield information regarding the construction and history of use of the stone circle and, by extension, contemporary ritual practices and its cultural significance resides primarily in this potential. The proposed EOWDC will be fully visible to the east at a distance of 5.5 km.

27 Torry Battery (ES Figure 20.1, SM9215) comprises the remains of a coastal battery built in the mid-19th century to protect the entrance to Aberdeen Harbour and control Aberdeen Bay. It was manned during both World Wars and also saw use as temporary housing for civilians in the 1930s, who had become homeless as a result of the economic crisis. The battery's cultural significance resides in importance as tangible link to the past, providing visible evidence of Britain's response to external threat, Aberdeen's importance as a port and of historic military tactical thinking. Its role as civilian housing adds further to this, as the battery provides a link to the results of the economic crisis of the 1930s. The proposed EOWDC will be fully visible to the north-east of the Battery at a distance of 7.9 km

28 To the south of Aberdeen is a ridge. Located on the higher parts of this are five scheduled Bronze Age burial cairns (ES Figure 20.1). Two of these, Tullos cairn (SM4055) and Crab's cairn (SM4060) lie within the inner study area. Immediately outside the study area lies Baron's cairn (SM4126), while further southwest are Cat Cairn (SM4125) and Loirston cairn (SM12342). These survive as substantial mounds and are surrounded by unimproved grassland and gorse. The cairns' cultural significance relates to their potential as sources of data regarding contemporary burial practice and their potential as a tangible link to the past, as the visitor will appreciate to some degree the relationship of the cairns to the landscape that they overlook and the inter-relationship between the various cairns, which is indicative of the surrounding area having been intensively occupied in the Bronze Age. The proposed EOWDC turbines will be fully visible to the north of the cairns at a distance of at least 9.6 km.

29 Orrok House (LB2778) is a country house built between 1770 and 1782. The house is surrounded by its wooded policies, which have been laid out in order to retain an open aspect to the south, and is approached by way of a short driveway from the north. The house is located on a gentle south-facing slope and its policies are surrounded by arable fields. The house's cultural significance relates to its architectural quality and its completeness as a late 18th century house with policies. The proposed turbines will be fully visible from the area of the house at a distance of 5.6 km. They will be located to the south-east of the house.

30 Girdle Ness Lighthouse (LB20078) was designed by Robert Stevenson and built in1833. It was fitted with a new double light system and in 1860 was described by the Astronomer Royal as 'the best lighthouse that I have seen'. The lighthouse stands at the eastern end of Girdle Ness, between Greyhope Bay and Nigg Bay. The lighthouse's cultural significance rests in its technological importance, its direct relationship with the Stevenson family and hence the development of Scottish lighthouses. However, it also has aesthetic value as a prominent landmark, isolated on the headland. The

proposed turbines will be fully visible to the north-east of the lighthouse at a distance of 7.9 km.

1.3.7 Assets with No Potential for Setting Impacts

31 Following desk-based study and site visits, it is considered that there is no potential for impacts upon the setting of the assets detailed below. Reference to the ZTV and site visits has established that the proposed EOWDC will not be visible from the assets listed in Table 3, below nor will views from a third location relevant to the setting of these assets be affected.

1.4 Summary

The baseline study has sought to identify nationally important onshore cultural heritage assets that may be subject to setting impacts resulting from the proposed EOWDC. The study utilised desk-based research and site visits to establish baseline conditions and identify those assets from which the proposed EOWDC will be visible or where the proposed EOWDC would be visible in views relevant to the appreciation of the asset’s setting. Fourteen such assets were identified and have been carried through to impact assessment. These comprise a diverse range of scheduled monuments and listed buildings, including prehistoric burial cairns and standing stones, a late 18th century house and a coastal battery and lighthouse dating to the 19th century.

1.5 GAZETTEER OF SCHEDULED MONUMENTS & LISTED BUILDINGS

Ref. No.	Name	Description	Status	NGR
SM 1907	Mote Hill, palisaded settlement and cairn	Conical mound located in Seaton Park in Aberdeen. Excavation has revealed this not to be a motte but remains of an Iron Age enclosed settlement	Scheduled Monument	393664, 808866
SM 3275	The Temple Stones, stone circle NE of Potterton House	Recumbent stone circle - though the flankers to the recumbent stone have fallen. Several of the stones bear cup-marks	Scheduled Monument	395290, 816360
SM 3277	Hare Cairn, cairn 600m W of Keir	Flat topped cairn which has seen some past disturbance enclosed by a modern dyke	Scheduled Monument	395523, 817652
SM 3282	Bishops' Manor, manor house and chapel	Remains of a manor complex which survive as the turf covered wall footings of at least 3 buildings	Scheduled Monument	391168, 814284
SM 3283	Dubford, standing stone 400m N of	Standing stone c 1.85m high, located in field. The stone fell in 1993 and was re-erected in May 1993	Scheduled Monument	394005, 813098
SM 4055	Tullos Cairn, cairn	Remains of a massive burial cairn 20m in diam and stands 2m high (another 3 cairns are located in the close vicinity indicating it may be part of a relict prehistoric funerary landscape)	Scheduled Monument	395902, 804103
SM 4060	Crab's Cairn, cairn	Circular burial cairn, 14m in diam. Damaged by wartime installations. A short cist containing an urn was found in the cairn in the late 18th century (another 3 cairns are located in the close vicinity indicating it may be part of a relict prehistoric funer	Scheduled Monument	396325, 803750
SM 4263	Lang Stane, standing stone, Hilton Drive	Substantial standing stone c3m high, prob Neolithic or BA date (major local landmark)	Scheduled Monument	392236, 808358
SM 7124	Old Aberdeen Market Cross	Market cross of Old Aberdeen - formerly stood in front of the Town House at the north end of High Street - moved but now returned to its original position. The only original part of this cross is the Knop with four coats of arms of Bishop Gavin Dunbar surmounted by (the remains of) crouching beasts which dates to the 16th century the rest of the cross	Scheduled Monument	393914, 808469

Ref. No.	Name	Description	Status	NGR
SM 7644	Forvie Church and deserted village (site of)	The remains of a 12th century church which became ruinous by the 15th century and a nearby medieval settlement of square huts. This site was partially excavated in 1953	Scheduled Monument	402033, 826594
SM 9215	Torry Battery, battery 130m ESE of Old South Breakwater	Remains of a military battery built between 1857-61. It later served as a training ground and staffed throughout WWI & WWII. The extant remains include the perimeter wall, the gateway and the guardhouse	Scheduled Monument	396543, 805631
SM 10400	St Fittick's Church, Aberdeen	Former parish church and its graveyard founded between 1189 and 1199. The building was reconstructed and enlarged in the 18th century before being abandoned in 1829	Scheduled Monument	396274, 804964
SM 10403	Balnagask motte, Baxter Place, Aberdeen	Medieval motte visible as a substantial grass covered mound, located in a modern housing estate. This motte would have originally held a prominent position overlooking the Dee Estuary and Nigg Bay but now enclosed by the SE outskirts of Aberdeen	Scheduled Monument	395743, 805110
SM 10424	Aberdeenshire Canal, remains of, Station Road, Woodside, Aberdeen	Remains of a section the Aberdeenshire Canal and a bridge, visible as an earthwork and an upstanding structure respectively. Well preserved - drained section of drained canal located within a grass covered playing field	Scheduled Monument	392249, 809025
SM 12433	Home Farm Cottage, cairn 325m N of	A stoney mound built on top of a natural knoll this is the remains of a probable neolithic or Bronze Age cairn. It has been slightly clipped by the modern road to its east	Scheduled Monument	394703, 816514
SM 12450	4 Tillygreig Cottages, hut circles 540m and 570m W of	The remains of two hut circles of late Bronze-Age or Iron-Age date. They are visible as two low, grass-covered penannular stony banks lying on a gentle east facing slope, at 170 m above sea level	Scheduled Monument	388100, 822500
SM 12452	Foucausie, hut circle 250m SSE of	Hut circle visible as a low scrub and tree covered pennanular stoney bank	Scheduled Monument	390778, 811903
SM 12541	Sands of Forvie, hut circles and ring cairn 1020m E of East Cottage	A complex of prehistoric remains including 2 Late bronze Age or Iron Age hut circles and a Bronze Age ring cairn	Scheduled Monument	401061, 826334

Ref. No.	Name	Description	Status	NGR
SM 90001	St Machar's Cathedral and graveyard	The parts of this cathedral that are not in ecclesiastical use as the parish church are scheduled. This includes the ground underlying the whole of the Cathedral and the surrounding graveyard. The first cathedral on this site was begun c1130-1165	Scheduled Monument	393915, 808761
LB 2778	Orrok (Or Orrock) House	1781-2 3 storey gabled main block with single storey roofed wings of same depth	Category A Listed Building	396401, 819560
LB 9166	Foveran Parish Church Turing Slab	Medieval stone bearing two incised armoured figures (cf Kinkell, qv) beneath a canopy. Located within Foveran Parish Church	Category A Listed Building	398494, 824141
LB 18985	Grandholm Works, Old Spinning Mill, Wing Mill, Engine And Turbine Houses	1793-4 Flax spinning mill, adjoining wing mill, engine and wheel house with associated water systems, turbines and pumps	Category A Listed Building	392570, 809602
LB 19937	Belmont Street, Former St Nicholas Congregation al Church	1865 2 storey, 5 bay Italian Romanesque former chapel	Category A Listed Building	393945, 806236
LB 19940	Schoolhill And Belmont Street, Former Triple Kirks Churches, Including Steeple And Former East Free Church	1844, Partially ruinous remains of formerly three adjoining Gothic post-disruption churches	Category A Listed Building	393883, 806293
LB 19941	Broad Street And Queen Street, Greyfriars John Knox Church	1903 Perpendicular Gothic Church	Category A Listed Building	394290, 806424
LB 19943	Kings College Chapel, College Bounds	16th century Aisleless, ashlar (freestone) built, 122' 6" x 28', 6 bays and 3-sided apse with stout buttresses large traceried windows N-side and apse, small windows high up on S Squat S.W. tower with crown top, 99' high	Category A Listed Building	393956, 808149

Ref. No.	Name	Description	Status	NGR
LB 19946	33 King Street, Aberdeen Arts Centre	1829-30 landmark Greek Revival symmetrical, rectangular plan former church with dominant advanced giant Ionic tetra style portico to N (entrance elevation), surmounted by square-plan clock tower with circular top stage, based on Lysicrates Monument	Category A Listed Building	394409, 806519
LB 19953	King Street, St Andrew's Cathedral (Episcopal)	1816-17 with later additions and alterations Perpendicular Gothic Cathedral	Category A Listed Building	394473, 806471
LB 19957	St. Machar's Cathedral, Chanonry	Nave and ruins of transepts and crossing	Category A Listed Building	393920, 808785
LB 19961	Spital, St Margaret Of Scotland Chapel And Former Convent Including 17 Spital	1892 restored 20th century. Convent complex incorporating small Gothic chapel, a convent wing, pair of later 19th century classically detailed houses linked to earlier convent by internal corridor	Category A Listed Building	394056, 807407
LB 19964	Carden Place at Albert Terrace, St Mary's Church (Episcopal), Including Gatepiers And Boundary Walls	1862-4 with 20th century additions and restoration. Simple medieval plan gothic church	Category A Listed Building	392866, 805949
LB 19966	Union Street, Back Wynd, Schoolhill And Correction Wynd, The Kirk Of St Nicholas Uniting (Church Of Scotland And United Reformed)	1755, 1835-7, 1875-7. Early burgh church in city centre location incorporating some 12th and 15th century fragments	Category A Listed Building	394073, 806302

Ref. No.	Name	Description	Status	NGR
LB 19967	Union Street, 9 Back Wynd, Schoolhill And Correction Wynd, St Nicholas Churchyard, Including Boundary Walls And Gatepiers	Dating from 16th century city centre graveyard surrounding Kirk of St Nicholas	Category A Listed Building	394086, 806184
LB 19977	Concert Hall, Advocates' Hall	1869 2 storey and basement, 5 bay classical Advocates Hall	Category A Listed Building	394343, 806375
LB 19978	Schoolhill And Blackfriars Street, Art Gallery Including War Memorial And Cowdray Hall, Robert Gordon's College Archway And Former Gray's School Of Art	1885 Art Gallery with 1905 sculpture court. Renaissance-style buildings	Category A Listed Building	393884, 806372
LB 19982	35 Regent Quay, Custom House	1771 Custom House, 3 storey and basement 5-bay townhouse	Category A Listed Building	394588, 806185
LB 19983	27,29,31 King Street, Including Railings	1818-1840 2 storey and basement, 12 bay Classical building comprising former Medico-Chirurgical Hall, County Records Office and Private House. Constructed as three separate buildings but appear to form one unit	Category A Listed Building	394422, 806436
LB 19990	Castle Street And 2 Broad Street, Town House, Including Municipal Offices, Court Houses And Tolbooth	1615-29 & 1868-74 House, Court House & Tolbooth. Flemish medieval turreted Town House incorporating remaining part of 17th century Tolbooth	Category A Listed Building	394370, 806358

Ref. No.	Name	Description	Status	NGR
LB 19991	Union Street, South Silver Street And Golden Square, Music Hall	1820 with 19th and 20th century additions and restoration. Monumental tall single storey 5 bay neo-Greek Aberdeen civic building	Category A Listed Building	393745, 806064
LB 19992	Old Aberdeen Town House, High Street, Old Aberdeen.	1788 3 Storey House, 1721 coat of arms from previous building	Category A Listed Building	393915, 808479
LB 19995	Aberdeen Royal Infirmary Woolmanhill	Hospital complex centred on neo-classical main block of 1833-40	Category A Listed Building	393710, 806470
LB 19999	Castlegate, Mercat Cross	1686, repaired 1821-2 Mercat Cross situated in centre of Castlegate	Category A Listed Building	394496, 806380
LB 20005	Elphinstone, Bishop, Memorial, King's College Grounds, College Bounds, Old Aberdeen.	1926 Tomb chest with recumbent bronze, subsidiary figure groups	Category A Listed Building	393943, 808152
LB 20065	Westburn Road And Argyll Place, Victoria Park, Fountain	1878 octagonal fountain in centre of large circular pool	Category A Listed Building	392703, 806789
LB 20067	Brig O' Balgownie Over River Don	Dated 1314-18, repaired circa 1444, largely rebuilt early 17th century with further repairs in 19th and 20th centuries Road bridge over the River Don	Category A Listed Building	394129, 809606
LB 20073	Wellington Suspension Bridge Over River Dee, At Craiglug	1829-31 with later alterations Depressed arch suspension bridge over the River Dee	Category A Listed Building	394316, 804968
LB 20078	Girdleness Lighthouse, Greyhope Road, Including Fog Signal At South Side At NJ 9724 0530	1833 Robert Stevenson Circular tapered with corbelled gallery 3rd. floor and top; iron cupola. Main light altered 1847 and 1890.Approach flanked by flat roofed single storey lodges with archway between	Category A Listed Building	397159, 805348

Ref. No.	Name	Description	Status	NGR
LB 20082	Little Belmont Street, Former Old Town's School	1840-41 Monumental single storey former school building in the late Greek Revival Style	Category A Listed Building	393985, 806250
LB 20088	Schoolhill, Robert Gordon's College Including North Gates And Boundary Walls	1731-1732 Classical hospital building set in extensive grounds with 1830-32 alterations and additional wings	Category A Listed Building	393880, 806496
LB 20096	Broad Street, Marischal College	19th century Tudor-Gothic collegiate complex based around a central quadrangle and courtyard	Category A Listed Building	394240, 806535
LB 20098	12 And 14 Devanha Gardens, Devanha House, Including Piers And Boundary Walls	1813 2 Storey and basement, 5-bay Regency House	Category A Listed Building	393910, 805030
LB 20108	Westburn Road And Cornhill Road, Westburn Park, Westburn House, Including Railings	1839 with later 19th century addition, Single storey 3 bay House	Category A Listed Building	392676, 807055
LB 20156	Broad Street, Provost Skene's House, Including Archway And South Building	16th-17th 4 storey U-plan town house	Category A Listed Building	394198, 806385
LB 20162	5 Castle Street (Former Clydesdale Bank)	1839-42, 3 storey 6 and 2 bay classical former bank building with impressive Corinthian columned quadrant corner entrance portico	Category A Listed Building	394422, 806361

Ref. No.	Name	Description	Status	NGR
LB 20174	53 Castle Street, Sheriff Court Annex And High Court Of Justiciary (Formerly Bank Of Scotland)	1801 additions 1859 5x5 bay Classical former bank on prominent sloping corner site	Category A Listed Building	394436, 806307
LB 20186	Chanonry, 9 (West Side) Mitchell Hospital Old Aberdeen	Dated 1801,Single Storey H-plan	Category A Listed Building	393826, 808671
LB 20288	Don Street, 20, 22 (East Side) Bede House, Old Aberdeen.	1676 3 storey house	Category A Listed Building	393953, 808529
LB 20299	Don Street, (N.W. SIDE) Chr(39)The Chapter House chr(39) Chr(39)CRUICKSHANKS Lodgingschr(39)	1653-5 2 storey L plan House	Category A Listed Building	394021, 809633
LB 20331	1 Great Northern Road, The Northern Hotel	1938 purpose built 47 bedroom hotel on corner site with art deco detail	Category A Listed Building	393042, 807944
LB 20333	Guild Street And 1 Trinity Street, Tivoli Theatre	1872 -1909 3 storey, 7 bay theatre with striking Venetian Gothic polychromatic round arched entrance	Category A Listed Building	394189, 806033
LB 20334	62, 62a And 62b Hamilton Place At Whitehall Road, Including Gatepiers And Boundary Walls	1885 1887 2 bay villa with Egypto-Greek detailing	Category A Listed Building	392440, 806338

Ref. No.	Name	Description	Status	NGR

Appendix 20.2: Cultural Heritage EIA Technical Report

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

1 CULTURAL HERITAGE

1.1 Information for the Non-Technical Summary

1 The potential impact of the EOWDC has been considered in relation to the setting of all nationally important designated cultural heritage assets within 10 km of the turbines and selected assets beyond this limit.

2 Potential impacts of greater than negligible significance have been identified in five cases: Hare Cairn, the Peterseat cairns, Torry Battery, Orrok House and Girdle Ness Lighthouse. The first three are Scheduled Monuments, whilst the latter two are Grade A-listed buildings.

3 The impacts upon Hare Cairn, the Peaterseat cairns, Torry Battery and Orrok House have been assessed as being of minor significance and those upon Girdle Ness Lighthouse as being of minor to moderate significance. No mitigation is proposed in relation to these impacts and they will persist throughout the lifetime of the EOWDC and cease upon decommissioning.

1.2 Introduction

4 The Cultural Heritage Setting Impact Assessment considers the potential impact of the EOWDC upon the setting of onshore cultural heritage assets. Such impacts may result from the proposed EOWDC appearing in views related to the setting of cultural heritage assets, and only those assets where this may occur have been carried through to the impact assessment.

5 Impacts have been assessed with reference to current guidance and are considered in terms of the asset's cultural significance.

1.2.1 Methodology Consultation

6 The following consultation was undertaken

- Aberdeen City Council

Aberdeen City Council was approached in order to establish whether they had specific concerns or requirements for data to be provided, in particular visualisations. Comments were also invited upon the proposed scope of the assessment.

Robert Forbes, The Planning Officer, indicated that he did have some concern regarding potential impacts upon the setting of Girdle Ness Lighthouse, and requested that visualisations from elevated points to the south and south-west of the lighthouse to be provided in order to help assess the potential impact upon views of the lighthouse.

The potential impact upon the setting of the lighthouse has been assessed using wireframes and a site visit. The wireframes are presented within this report along with photographs illustrating various views of the lighthouse. However, photomontages (visualisations) have not been prepared. The wireframes give an adequate demonstration of the scale of the turbines in relation to the lighthouse in views from the south, whilst the photomontages for the Torry Battery and Kincorth Hill viewpoints (SLVIA Viewpoints 07 & 12 respectively) provide an indication of the EOWDC's appearance from the vicinity of the lighthouse and from high ground to its southwest. The inclusion of photomontages for Nigg Bay would not afford any substantive information that is not available from that presented here.

The Archaeology Unit indicated that all consultation was to be undertaken through the Planning Officer.

- Aberdeenshire Council Archaeology Service

Aberdeenshire Council Archaeology Service was approached in order to establish whether they had specific concerns or requirements for data to be provided, in particular visualisations. Comments were also invited upon the proposed scope of the assessment.

The Archaeology Service indicated that it had no concerns regarding potential setting impacts.

- Historic Scotland

Historic Scotland was approached in order to establish whether they had specific concerns or requirements for data to be provided, in particular visualisations. Comments were also invited upon the proposed scope of the assessment.

No specific concerns were noted. However, it was suggested that the assessment be accompanied by visualisations to illustrate the potential impact upon the setting of Straloch Garden and Designed Landscape (GDL), Hare Cairn and Forvie Chruch and deserted village, as well as those proposed for the Seascape, Landscape and Visual Impact Assessment (SLVIA) for south of Dunnottar Castle (A92 near Uras) and Torry Battery. It was suggested that assets in the vicinity of Straloch GDL, such as Tillygreig hut-circles (SM12450) be considered.

Visualisations have been included for Torry Battery (Viewpoint 07 of SLVIA) and from near Forvie Church (Viewpoint 09 of SLVIA). No visualisations have been presented for Straloch GDL or Dunnottar Castle, as there is no intervisibility, or Hare Cairn or Tillygrieg hut-circles, as there is no potential for a significant impact upon its setting from the EOWDC.

- Scottish Natural Heritage (SNH)

SNH was approached in order to establish whether they had specific concerns or requirements for data to be provided, in particular visualisations. Comments were also invited upon the proposed scope of the assessment (e-mail dated 1st March 2011). SNH had indicated early in the project's lifespan that impacts upon the setting of cultural heritage assets should be considered by the Environmental Statement (ES).

SNH indicated that the proposed scope of the study was acceptable (e-mail dated 25th March 2011) and did not require any further visualisations..

1.2.2 Key Guidance Documents

7 The following guidance documents have been referred to:

- COWRIE (2007a) *Historic Environment Guidance for the Offshore Renewable Energy Sector*
- COWRIE (2007b) *Guidance for Assessment of Cumulative Impacts on the Historic Environment from Offshore Renewable Energy*
- Historic Scotland (2008) *Scottish Historic Environment Policy (SHEP)*
- Historic Scotland (2009) *Assessment of Impact upon the setting of the Historic Environment Resource*
- Historic Scotland (2010) *Managing Change in the Historic Environment: Setting*

1.2.3 Data Information and Sources

8 Two concentric study areas have been used to gather and present the baseline data:

- Inner study area (Environmental Statement Figure 20.1, 20.2, 20.3): This extends 10 km from the outermost proposed turbines. Within it data has been gathered for all designated nationally important assets (scheduled monuments, Category A listed buildings and Inventory Gardens and Designed Landscapes (GDL)) and conservation areas; and
- Outer study area: this extends 40 km from the proposed turbines to take in the area for which the Zone of Theoretical Visibility (ZTV) has been prepared for the SLVIA. Within it assets specifically identified by consultees as being of concern have been considered.

9 There is no guidance regarding appropriate study areas for cultural heritage setting impact assessments. The study area has been defined in order to take in those assets that are most likely to be affected by the proposed development; assets further inshore are less likely to be affected as their setting is less likely to relate to the sea.

10 Data were gathered from the following data sources:

- Databases of designated assets held by Historic Scotland;
- National Monuments Record of Scotland (NMRS);
- Aberdeen City Council Sites and Monuments Record (SMR); and
- Aberdeenshire Council Historic Environment Record (HER)

11 Assets are referred to by the reference number associated by their designation. Scheduled monument numbers (officially ‘Ancient Monument Index Numbers’) are prefixed ‘SM’ and numbers referring to listed buildings (officially ‘Historic Building Numbers’) are prefixed ‘LB’. Where an asset is both scheduled and listed it is referred to by its scheduled monument number.

12 The results of the desk-based study were augmented by site visits undertaken on 8^{th} and 9^{th} March 2011.

1.2.4 Impact Methodology

1.2.4.1 Significance Criteria

13 During the construction, operation and decommissioning phases of developments, the setting of cultural heritage assets may be affected. There is considerable debate over definitions of setting and approaches to the assessment of setting impacts (Lambrick, 2008), with no standardised industry-wide approach. Historic Scotland has produced a guidance note on setting as part of its 'Managing Change in the Historic Environment' series of documents. This states that

Setting should be thought of as the way in which the surroundings of a historic asset or place contribute to how it is experienced, understood and appreciated.

14 Hence setting is not simply the visual envelope of the asset in question. Rather, it is those parts of the asset's surroundings that are relevant to the cultural significance of the asset. In general, there will be an appreciable historical relationship between the asset and its setting, either in terms of a physical relationship, such as between a castle and the natural rise that it occupies, or a more distant visual relationship, such as a designed vista or the view from, for example, one Roman signal station to another. Some assets' cultural significance will relate to an aesthetic relationship with their surroundings which may result from design or be fortuitous. In such instances the relevant landscape elements will be considered to form part of the asset's setting. The cultural significance of assets has been considered in terms of the values described in Scottish Historic Environment Policy (SHEP HS 2008, 58):

- Intrinsic - those relating to the fabric of the asset;
- Contextual – those relating to the monument's place in the landscape or in the body of existing knowledge; and
- Associative – more subjective assessments of the associations of the monument, including with current or past aesthetic preferences.

15 Most setting impacts will relate to contextual and associative values.

16 The sensitivity of a cultural heritage asset to changes in its setting can be evaluated in the first instance by reference to any relevant designation, whereby assets designated as nationally important will generally be considered the most sensitive. Consequently, the assessment has focussed on nationally important cultural heritage assets in the study areas which are considered in relation to impacts upon setting, with other assets being considered where, in the assessor's professional opinion, there is potential for significant impacts or where they have been raised by consultees. Following reference to the designation of the asset, sensitivity can be more finely assessed by reference to the importance of the asset's surroundings, to its character and value as a cultural heritage asset and the appreciation of its value. Also taken into account is the extent to which an asset is visible on the ground. Some assets may have a well-defined and appreciable setting but the asset itself is barely perceptible; such assets will generally be less sensitive than those that are readily appreciable.

17 Table 1 is a general guide to the attributes of cultural heritage assets of high, medium, low or negligible sensitivity to setting impacts. It should be noted

that not all the qualities listed need be present in every case and professional judgement is used in balancing the different criteria.

Table 1 Guideline Criteria for Assessment of Sensitivity of a Cultural Heritage Asset to Effects on its Setting

Sensitivity	Guideline Criteria
High	The asset has a clearly defined setting that is readily appreciable on the ground and is vital to its significance or the appreciation thereof. The asset will generally be readily appreciable on the ground.
Medium	The asset's significance and the appreciation thereof relate to some extent to its setting. The asset will generally be appreciable on the ground.
Low	The asset's surroundings have little relevance to its significance or the appreciation thereof. The asset is difficult to identify on the ground or its setting is difficult to appreciate on the ground.
Negligible	The asset is imperceptible in the landscape and its significance or the appreciation thereof does not relate to its surroundings.

18 The magnitude of an impact reflects the extent to which relevant elements of the setting of the cultural heritage asset are changed by the development and the effect that this has upon the significance of the asset and the appreciation thereof. Guideline criteria for assessing magnitude are described in Table 2. As with other criteria presented, this is intended as a general guide and it is not anticipated that all the criteria listed will be present in every case.

19 The following are guides to the assessment of magnitude of impact based on those provided by Historic Scotland (2009):

- *Obstruction of or distraction from key views.* Some assets have been sited or designed with specific views in mind, such as the view from a Roman signal station to an associated fort or a country house with designed vistas. The obstruction or cluttering of such views would reduce the extent to which the asset could be understood and appreciated by the visitor. Developments outside a key view may also distract from them and make them difficult to appreciate if they are particularly prominent. In such instances the magnitude is likely to be greatest where views have a particular focus or a strong aesthetic character.

- *Changes in prominence.* Some assets are deliberately placed in prominent locations in order to stand out from the surrounding landscape, for example prehistoric cairns are often placed to be silhouetted against the sky and churches in some areas are deliberately placed on ridges in order to be highly visible. Developments can reduce such prominence and therefore reduce the extent to which such assets can be appreciated.

- *Changes in landscape character.* A particular land use regime may be essential to the appreciation of an asset's function, for instance the fields surrounding an Improvement period farmstead are inextricably linked to its appreciation. Hence, changes in land use can leave the asset isolated and reduce its value. In some instances, assets will have aesthetic value or a sense of place that is tied to the surrounding landscape character.

- *Duration and reversibility of impact.* Effects that are short term or readily reversible are generally of lesser magnitude than those that are long term or permanent.

- *Effects upon a defined setting.* These will be of greater magnitude than those that affect unrelated elements of the asset's surroundings or incidental views to or from an asset that are unrelated to the appreciation of its value.

20 It should be noted that the assessment of magnitude will be based on the interplay of these factors. No single factor will be taken to over-ride other factors, for instance an adverse impact that would be of high magnitude will not generally be reduced to low magnitude, simply on the grounds that it is reversible. It should also be noted that whilst the development may be present within the visual envelope of an asset this does not automatically mean there is an impact on the setting of the asset. Where this is the case, the reasoning behind this will be given.

Table 2: Criteria for Assessment of Magnitude of an Effect on the Setting of a Cultural Heritage Asset

Magnitude	Guideline Criteria
High beneficial	The contribution of setting to the cultural heritage asset's significance is considerably enhanced as a result of the development; a lost relationship between the asset and its setting is restored, or the legibility of the relationship is greatly enhanced. Elements of the surroundings that detract from the asset's cultural heritage significance or the appreciation of that significance are removed.
Medium beneficial	The contribution of setting to the cultural heritage asset's significance is enhanced to a clearly appreciable extent as a result of the development; as a result the relationship between the asset and its setting is rendered more readily apparent. The negative impact of elements of the surroundings that detract from the asset's cultural heritage significance or the appreciation of that significance is appreciably reduced.
Low beneficial	The setting of the cultural heritage asset is slightly improved as a result of the development, slightly improving the degree to which the setting's relationship with the asset can be appreciated.
Negligible	The contribution of the asset's surroundings to its cultural significance is changed, but in such a way that the change is barely perceptible.
Low adverse	The contribution of the setting of the cultural heritage asset to its significance is slightly degraded as a result of the development, but without adversely affecting the interpretability of the asset and its setting; characteristics of historic value can still be appreciated, the changes do not strongly conflict with the character of the asset, and could be easily reversed to approximate the pre-development conditions.
Medium adverse	The contribution of the setting of the cultural heritage asset to its significance is reduced appreciably as a result of the development and cannot easily be reversed to approximate pre-development conditions. Relevant setting characteristics can still be appreciated but less readily.
High adverse	The contribution of the setting of the cultural heritage asset to its significance is effectively lost or substantially reduced as a result of the development, the relationship between the asset and its setting is no longer readily appreciable.

1.2.4.2 Significance

21 The significance of an impact on a cultural heritage asset is assessed by combining the magnitude of the impact and the sensitivity of the cultural heritage asset. The matrix in Table 3 provides a guide to decision-making but is not a substitute for professional judgement and interpretation, particularly

where the sensitivity or impact magnitude levels are not clear or are borderline between categories. Predicted impacts of major or moderate significance equate to potentially significant impacts in terms of the EIA Regulations.

Table 3: Guideline Criteria for Assessing the Significance of Effects on Cultural Heritage Assets

Magnitude	**Sensitivity**			
	Negligible	**Low**	**Medium**	**High**
High	Negligible	Moderate	Major	Major
Medium	Negligible	Minor	Moderate	Major
Low	Negligible	Negligible	Minor	Moderate
Negligible	Negligible	Negligible	Negligible	Minor

1.2.5 Implications of Significance

22 Where the significance is classified as moderate or major this is considered to be a potentially significant effect. It should be noted that significant effects need not be unacceptable or reversible.

1.2.6 Cumulative Impact Assessment Methodology

23 For the purposes of the cumulative impact assessment the potential effect of adding the Ocean Laboratory to the EOWDC has been considered. The potential cumulative impacts of the EOWDC with other wind farms (consented/operational and proposed) have also been considered. In keeping with the approach used in the SLVIA wind farms up to a distance of 60 km from the EOWDC have been considered.

24 Aggregate extraction, existing and planned subsea cables and pipelines and established fishing activities have not been considered as these activities will not result in any visual change that might result in an impact upon setting.

25 Navigation and shipping have not been considered further as these are considered to be a neutral part of the baseline conditions.

26 Offshore oil and gas installations have not been considered further as all such installations are over 40 km from the shore and hence have no impact upon the setting of cultural heritage assets.

1.2.7 Worst Realistic Case

27 The impact assessment has been undertaken with reference to the largest turbines within the Rochdale Envelope; eleven 10 MW turbines with a hub height of 120 m and blade tip height of 195 m above LAT. The variations in height that will occur as different turbines are deployed will have no substantive effect on the assessment, as the potential impacts upon setting relate to the visibility of turbines rather than their aesthetic appearance.

1.3 Impact Assessment

28 No differentiation has been drawn between setting impacts during the construction, operation and decommissioning phases as the magnitude of impact and hence significance will be the same for all phases. Clearly, there will be increased shipping traffic during the construction and decommissioning phases and the vessels present will be of a different type to those currently operating. However, the ships will be operating in a body of water in which a substantial number of large vessels operate and, as such, it is considered that this will not constitute an impact upon setting.

29 The potential for impacts to occur has been considered for all assets identified by the baseline study as having potential intervisibility with the EOWDC; fourteen such assets have been identified.

1.3.1 Potential Impacts

1.3.1.1 Forvie Church and Deserted Village (SM7644, near to Viewpoint 09 SLVIA))

30 Forvie Church and deserted village (SM7644) comprise the remains of a medieval church and village buried by sand dunes. The church and adjacent huts were excavated and left exposed by archaeologists in the 1950s, but most of the village remains covered by sand dunes. The exposed remains are not visible in the wider landscape. The associated buried remains have exceptional potential in terms of their value as a source of data regarding medieval society, economy and material culture as they have been unaffected by later development or farming. The asset is surrounded by the Sands of Forvie, an extensive sand dune system, and lies some 300 m from the shoreline. The surrounding dunes restrict views out from the church, though the sea can be glimpsed to the south.

31 The surroundings of the asset make very little contribution to the experience and understanding of the asset, as the dunes make it impossible to understand how the settlement related to its surroundings, but it is part of a heritage trail and is therefore visited by the public. The site’s significance relates almost entirely to its intrinsic value as a data source, though the adjacent sand dunes are relevant to an appreciation of how the church has survived undisturbed. The setting of the church is therefore defined as the dunes surrounding it and it is considered that the church is of low to medium sensitivity to impacts upon setting.

32 The proposed EOWDC turbines will be visible from the vicinity of the church at a distance of approximately 10 km. The degree of visibility will vary greatly depending upon the viewer’s location and in much of the area around the church the proposed turbines will be at least partially screened from view. Viewpoint 09 of the SLVIA is nearby and gives an indication of the degree of visual change.

33 The turbines will lie outside the church’s setting and will in no way affect the extent to which it can be experienced or understood. It is considered therefore that there will be a degree of visual change, but that this will constitute an impact of at most negligible magnitude upon the setting of the church.

34 The church is considered to be of at most medium sensitivity to impacts upon setting and the impact is considered to be of negligible magnitude, the church's cultural significance and the potential for that significance to be appreciated will remain unchanged. The impact upon its setting is therefore considered to be of **negligible** significance. The impact will finish upon decommissioning.

1.3.1.2 Forvie Ring Cairn and Hut-circles (SM12541)

35 Forvie ring cairn and hut-circles (SM12541) lie among the Sands of Forvie, some 800 m from the shoreline. Only two of the 19 hut-circles recorded in 1950 are now visible, the remainder having been covered by sand-dunes. As with Forvie Church, there is potential for exceptional preservation and the site has great potential as a data source. The exposed structures cannot be seen from more than a few metres away. The surrounding dunes restrict views in most directions, with open views only being available inland.

36 The surrounding dunes completely mask any relationship that the asset may have had with its surroundings. Again the surrounding dunes are relevant to an understanding of the site formation processes at work and consequently the dunes are considered to form the asset's setting and it is concluded that the ring cairn and hut-circles are of low sensitivity to setting impacts.

37 The EOWDC will be partially visible to the south, at a distance of 9.8 km. The proposed turbines will lie outside the setting of the asset and will not affect the appreciation of the asset.

38 The cultural significance of the cairn and hut-circles will be undiminished by the presence of the turbines. It is concluded that there will be an impact of negligible magnitude upon their setting and with a low sensitivity that this will constitute an impact of **negligible** significance. The impact will finish upon decommissioning.

1.3.1.3 Tillygrieg hut-circles (SM12450)

39 Tillygrieg hut-circles (SM12450) comprise the scheduled upstanding remains of two Late Bronze Age or Iron Age date. They are located near the top of a gentle east facing slope and are surrounded by farmland. They are unusually well-preserved for this part of Aberdeenshire and have potential to yield information regarding settlement history and economy. The upstanding remains are slight and no more than 0.3 m in height; as such they are not visible in the wider landscape.

40 The hut-circles were built by farmers who worked the surrounding land. The broader landscape does not contribute to their cultural significance or their appreciation thereof. The adjacent farmland constitutes their setting and they are considered to be of low sensitivity to setting impacts.

41 The proposed EOWDC turbines will be partially visible to the south-east of the hut-circles, at a distance of 13.9 km. They will be seen beyond a line of pylons that occupies the foreground of views east form the hut-circles.

42 The cultural significance of the hut-circles will be undiminished by the presence of the turbines. It is concluded that there will be an impact of

negligible magnitude upon their setting and with a low sensitivity this will constitute an impact of **negligible** significance. The impact will finish upon decommissioning.

1.3.1.4 *Hare Cairn (SM3277)*

43 Hare Cairn (SM3277) is a Bronze Age burial cairn located on the top of a small hillock. The surrounding field is given over to pasture. It has been partially excavated, but survives as an appreciable mound with exposed kerb. Despite the disturbance it has potential to yield data regarding Bronze Age burial practices. The cairn's cultural significance resides in its value as a potential data source and in its potential to provide a tangible link to the past. The latter is considered further below.

44 The cairn's elevated location makes it a prominent feature in the surrounding landscape. Similarly, extensive views are available form the cairn over the surrounding farmland. It is evident that the cairn has been placed in order to be prominent in the farming landscape. The setting of the cairn is therefore defined as the knoll upon which it is located and the surrounding farmland. The views to and from the cairn are important to an understanding of the cairn's function and its designed relationship with its surroundings and it is considered to be of high sensitivity to impacts upon setting.

45 The proposed turbines will be fully visible to the south-east of the cairn, at a distance of 4.8 km. The cairn lies over 2 km from the coast and the proposed turbines will be seen beyond the coastal fringe in which the town of Balmedie is visible, as is the A90.

46 The presence of the proposed turbines in views eastwards from the cairn will not affect the contribution of the cairn's surroundings to its experience, appreciation or understanding. The cairn's prominence will not be changed – the proposed turbines will not be visible in combination with the cairn from land to the west – nor will they affect the degree to which the cairn's relationship with the farmland to its west can be appreciated. It is concluded that the proposed turbines will lie outside the setting of the cairn.

47 The cultural significance of the cairn will be undiminished by the presence of the turbines. It is concluded that there will be an impact of negligible magnitude upon its setting and with a high sensitivity that this will constitute an impact of **minor** significance. The impact will finish upon decommissioning..

Mitigation

48 No mitigation is proposed in relation to the impact upon the setting of the Hare Cairn.

Residual Impacts

49 No mitigation is proposed in relation to impacts upon the setting of Hare Cairn and the predicted impacts will remain adverse and of minor significance. The impact will finish upon decommissioning.

Cumulative Impacts

50 The potential for cumulative impacts to result from the EOWDC and the potential Ocean Laboratory has been considered. The Ocean Laboratory could comprise a 120 m mast with a platform 20 m above LAT. It could be

located to the south of the proposed EOWDC turbines. It has been concluded that there will be no cumulative impact. The predicted impact relates to the proposed turbines appearing as large structures in views from the cairn. The Ocean Laboratory would be seen amongst the turbines and would not alter the effect.

51 The potential for cumulative impacts to arise from the EOWDC and onshore wind farms has been considered. The cumulative ZTV (SLVIA Figure 15) indicates that up to two other consented wind farms will theoretically be visible from the cairns. The closest will be approximately 7.5 km to the north. The indicative ZTV for proposed wind farms (SLVIA Figure 16) indicates that up to two proposed wind farms will be visible from the cairns, the closest of which will lie some 15 km away. Given the distance and that both the EOWDC and the other wind farms lie outside the setting of the cairn, it is concluded that there is no potential for cumulative impacts.

1.3.1.5 The Temple Stones (SM3275)

52 The Temple Stones (SM3275) comprise the remains of a recumbent stone circle. It is located on the shoulder of a hill, overlooking the Milden Burn to the south. Many of the stones have been removed and only the recumbent stone remains *in situ*, the pillar stones are present but have fallen over. Of the rest of the stone circle only one stone remains. The recumbent stone lies at the southwest of the monument. Stones cleared from the surrounding field have been dumped behind the recumbent stone. Despite its fragmentary survival there is potential for subsurface features to yield information regarding the construction and history of use of the stone circle and, by extension, contemporary ritual practices and its cultural significance resides in this potential.

53 Located on top of a ridge, the Temple Stones command wide views over the rolling agricultural land to the north and west, over the golf course to the east to the coastal lowlands and the North Sea. As with the current example, recumbent stone circles are generally orientated towards the south or south-west in order that the recumbent stone and pillars would frame the “moon and in some cases they may also have faced the winter sun” (Bradley 2005, p111). In some instances topographic features are also framed. The setting of the stones is defined as the ridge upon which they are located. There is no clear relationship with land beyond this, though it must be assumed that the view to the south-west was important. Because of its mutilated condition, it is difficult to understand the relationship of this asset with the wider landscape but its relationship with the ridge is still clear and the key alignment is still apparent. It is concluded that it is of medium sensitivity to setting impacts

54 The EOWDC will be visible to the east at a distance of 4.3 km. The proposed turbines will not affect the contribution of the surroundings to the Temple Stones cultural significance. They lie outside its setting and well away from the key south-westerly alignment of the stones.

55 The cultural significance of the stones will be undiminished by the presence of the turbines. It is concluded that there will be an impact of negligible magnitude upon its setting and with a medium sensitivity this will constitute an impact of **negligible** significance. The impact will finish upon decommissioning.

1.3.1.6 Dubford Stone (SM3283)

56 Dubford Stone (SM3283) is a single standing stone, which is thought to be the final remnant of a recumbent stone circle. The stone is located in an improved pasture field on a natural terrace. Despite its fragmentary survival there is potential for subsurface features to yield information regarding the construction and history of use of the stone circle and, by extension, contemporary ritual practices and its cultural significance resides primarily in this potential. The stone's location commands extensive views over the surrounding farmland to the south and the sea is visible to the east. A number of modern features are prominent in the surrounding landscape, in particular the city of Aberdeen is visible to the south.

57 The stone's surroundings make little contribution to its cultural significance and there are no clear relationships with land beyond the terrace upon which it is located. If the identification of the site as a recumbent stone circle is correct, it may be assumed that the key alignment was to the south or south-west. However, this is no longer appreciable on the ground. The setting of the stone is therefore defined as the field in which it is located. The stone's relationship with the terrace upon which it is located is clear, but there are no demonstrable relationships with land beyond the terrace; the very incomplete survival of the asset making it impossible to discern key alignments. Consequently, it is concluded that the stone is of low sensitivity to impacts upon setting.

58 The proposed EOWDC will be fully visible to the east at a distance of 5.5 km. The turbines will lie outside the setting of the stone and well away from the probable southward alignment of the asset in its original form.

59 The visibility of the proposed turbines from the standing stone will not affect the extent to which it can be understood or appreciated or the contribution of its surroundings to its cultural significance. It is concluded that there will be an impact of negligible magnitude upon its setting and with a low sensitivity this will constitute an impact of **negligible** significance. The impact will finish upon decommissioning..

1.3.1.7 Peterseat Cairns (SM4055, SM4060, SM4125, SM4126 & SM12342)

60 The cairns to the south of Aberdeen around Peterseat are considered as a group, as the setting and sensitivity of the individual cairns and the magnitude of impact is essentially the same in all cases.

61 Tullos cairn (SM4055), Crab's cairn (SM4060) and Baron's cairn (SM4126) lie at the northern end of a gorse-covered ridge, which overlooks Aberdeen and Aberdeen Bay to the north. Cat Cairn and Loirston cairn (SM4126 and SM12342 respectively) lie further along the ridge to the southwest. The southern part of the ridge is occupied by light industrial units. The cairns survive as substantial mounds and are located on natural eminences upon the ridge. They command extensive views across Aberdeen to the north. It must be assumed that the cairns were placed in order to be prominent in views from the wider landscape, most probably settlement and farmed land in the area of the River Dee; an area that is now covered by housing. In such views they were probably sky-lined, though this is no longer the case, owing to the cairns' degraded state and the gorse.

62 The cairns' cultural significance relates primarily to their potential as sources of data regarding contemporary burial practice and their potential as a tangible link to the past, as the visitor will appreciate to some degree the relationship of the cairns to the landscape that they overlook and the inter-relationship between the various cairns. The latter will help the visitor appreciate the long history of human activity in the Aberdeen area. The setting of the cairns is therefore defined as the ridge that they occupy and to a lesser degree the lower land to the north, which they were intended to overlook. Views of the cairns in the wider landscape are not possible but views from the cairns are relevant to their appreciation as they allow the visitor to understand how the cairns might have fitted into the wider prehistoric landscape. The cairns are considered to be of high sensitivity to impacts upon setting as the intended visual relationship with the land that they overlook is appreciable to a substantial degree and the spatial relationship between the cairns suggests that they form a relict Bronze Age funerary landscape, resulting in additional group value.

63 The proposed turbines will be fully visible to the north of the cairns with the nearest at a distance of at least 9.6 km. They will be seen beyond the coastal fringe, which is largely occupied by modern housing and other buildings, including blocks of flats and other large structures.

64 The proposed turbines will lie outside the setting of the cairns and will not affect the appreciation of their relationship with their surroundings or their contribution to its cultural significance. It is considered that there will be an impact of negligible magnitude upon their setting and with a high sensitivity this will constitute an impact of **minor** significance. The impact will finish upon decommissioning.

Mitigation

65 No mitigation is proposed in relation to the impact upon the setting of the Peterseat cairns.

Residual Impacts

66 No mitigation is proposed in relation to impacts upon the setting of the Peterseat cairns and the predicted impacts will remain adverse and of minor significance. The impact will finish upon decommissioning.

Cumulative Impacts

67 The potential for cumulative impacts to result from the EOWDC and the potential Ocean Laboratory has been considered. The Ocean Laboratory could comprise a 120 m mast with a platform 20 m above LAT. It could be located to the south of the proposed EOWDC turbines. It has been concluded that there will be no cumulative impact. The predicted impact relates to the proposed turbines appearing as large structures in views from the cairns. The Ocean Laboratory would be seen amongst the turbines and would not alter the effect.

68 The potential for cumulative impacts to arise from the EOWDC and onshore wind farms has been considered. The cumulative ZTV (SLVIA Figure 15) indicates that up to two other consented wind farms will theoretically be visible from the cairns. The closest will be over 20 km away. The indicative ZTV for proposed wind farms (SLVIA Figure 16) indicates that up to two proposed wind farms will be visible from the cairns, the closest of which will lie some 15 km away. Given the distance and that both the EOWDC and the

other wind farms lie outside the setting of the cairns, it is concluded that there is no potential for cumulative impacts.

1.3.1.8 *Torry Battery (SM9215, Viewpoint 07 SLVIA)*

69 Torry Battery (SM9215) comprises the remains of a coastal battery built in the mid-19th century to protect the entrance to Aberdeen harbour and Aberdeen Bay. It was manned during both World Wars and also saw use as temporary housing for civilians in the 1930s, who had become homeless as a result of the economic crisis. It is located on the headland of Girdle Ness and overlooks the entrance to the harbour, which lies immediately to the north (Plate 1). To the northwest, Aberdeen can be seen stretching up the coast, while to the east Girdle Ness Lighthouse is prominent. Most of the view northwards is occupied by the sea.

70 The Battery's cultural significance resides in its importance as a tangible link to the past, providing visible evidence of Britain's response to external threat, Aberdeen's importance as a port and, given its long history of use, of the development of military tactics and technology. Its role as civilian housing adds further to this, as the battery provides a link to the results of the economic crisis of the 1930s.

71 Much of this significance is intrinsic to the fabric of the Battery but contextual values are also very important and the relationship between the battery and its surroundings contributes to these values. Its position overlooking the entrance to Aberdeen's Harbour and the bay beyond is significant in the understanding of its operation and function. The Battery also has associative value and its rather isolated and exposed location adds to an appreciation of the plight of families housed here during the 1930s. The setting of the battery is therefore defined as the headland upon which it is located, the entrance to Aberdeen Harbour, which it has been placed to overlook and defend, and Aberdeen Bay, which its guns covered.

72 The EOWDC will be fully visible to the north-east of the Battery at a distance of 7.9 km (see photomontage SLVIA Viewpoint 07). The proposed turbines will be seen in a body of water that sees substantial numbers of shipping movements, with the sea providing a backdrop. SLVIA Viewpoint 07 is located at the gate to the carpark adjacent to the Battery. This location is slightly lower than the Battery itself. The photomontage shows that the wind turbines will be seen as a well-balanced arrangement with proposed turbines occurring in five groupings.

73 The Battery is of high sensitivity to setting impacts as it is a readily appreciable asset that has a clear relationship with its surroundings that adds greatly to the visitor's understanding and appreciation of the asset's history and function. This contributes to the Battery's contextual value. The location also adds to its associative value as it contributes to the visitor's appreciation of life for the Battery's inhabitants, in particular during its time as temporary housing.

74 The presence of the EOWDC will introduce large modern structures into the setting of the Battery. While this will constitute a visual impact that is of High to Moderate magnitude (see SLVIA of the EOWDC), the magnitude of impact upon setting will be substantially less. The proposed turbines will not be seen in a context entirely free of other large modern features, rather they will be

seen with a substantial number of other modern features – rig support vessels, flats in Aberdeen, the harbour infrastructure and large retail units to the north of Footdee. The nearest proposed turbine will be 7.9 km from the Battery and will not affect the Battery's dominance of the harbour entrance. The proposed turbines will break up the view across the bay, but given that they will occupy some 12 degrees of the 200 degree view, their distance from the Battery and that the horizon will be clearly visible between the five groupings, the relationship between the Battery and the bay will remain readily appreciable; it will still be possible to experience the views across the bay and hence understand that the Battery's guns covered the whole bay. The EOWDC will not affect views of the Battery from the wider landscape, nor will it affect the relationship between the Battery and the headland element of its setting or the entrance to the harbour. It is therefore considered that the impact upon the setting of Torry Battery will be of negligible magnitude and adverse.

75 It is concluded that the impact of the EOWDC on the setting of the Torry Battery which is of high sensitivity and of negligible magnitude, will be potentially adverse and of **minor** significance as the setting will be altered by the development but this will not reduce the extent to which it contributes to the cultural significance of the Torry Battery. The impact will finish upon decommissioning.

Mitigation

76 No mitigation is proposed in relation to the impact upon the setting of Torry Battery.

Residual Impacts

77 No mitigation is proposed in relation to impacts upon the setting of Torry battery and the predicted impacts will remain adverse and of minor significance. The impact will finish upon decommissioning.

Cumulative Impacts

78 The potential for cumulative impacts to result from the EOWDC and the potential Ocean Laboratory has been considered. The Ocean Laboratory could comprise a 120 m mast with a platform 20 m above LAT. It could be located to the south of the proposed EOWDC turbines. It has been concluded that there will be no cumulative impact. The predicted impact relates to the proposed turbines appearing as large structures in views from the Torry Battery. The Ocean Laboratory would be seen amongst the turbines and would not alter the effect.

79 The potential for cumulative impacts to arise from the EOWDC and onshore wind farms has been considered. The cumulative ZTV (SLVIA Figure 15) indicates that up to two other consented wind farms will theoretically be visible from Torry Battery. The closest will be over 20 km away. Given the distance and that the other wind farms lie outside the setting of the Battery, it is concluded that there is no potential for cumulative impacts. The indicative ZTV for proposed wind farms (SLVIA Figure 16) indicates that no proposed wind farms will be visible.

1.3.1.9 Orrok House (LB2778)

80 Orrok House (LB2778) is a country house built between 1770 and 1782. The house is surrounded by its wooded policies, which have been laid out in order

to retain an open aspect to the south, and is approached by way of a short driveway from the north. The house is located on a gentle south-facing slope and its policies are surrounded by arable fields (Plate 2).

81 The house's cultural significance relates to its architectural quality and its completeness as a late 18th century house with policies. It therefore combines intrinsic, contextual and associative values. The house's surrounding contribute to all of these values. The policies contribute to the intrinsic and value, as the house presents a good example of a late 18th century country house complete with original planting. The surrounding rich agricultural land and farm-buildings are relevant to an appreciation of the wealth of the area. The house and policies is prominent in views from land to the south and the house is clearly intended to look out over these. The setting of the house is therefore defined at the small hill upon which it stands and the fields that it overlooks to the south. Views relevant to the appreciation of the relationship with its setting are those to the south from the house and those of the house from the south. There are no natural or artificial focal points in the views from the house.

82 The proposed turbines will be fully visible from the south of the house at a distance of 5.6 km. They will be located to the south-east of the house. They will be seen as a group. The foreground of the views will be composed of rolling farmland with the wooded hills to the north of Balmedie visible in the middle distance. The proposed turbines will appear in the background of these views.

83 The house is a readily appreciable asset and its relationship with its surroundings is likewise readily appreciable. It is considered to be of high sensitivity to impacts upon setting.

84 The proposed EOWDC will introduce large modern features into the view from the house; the proposed turbines will lie outside the setting of the house but within a view that is relevant to it. The view is currently dominated by agricultural land. However, they will appear in the background beyond the agricultural land and there is no evidence that the view has in anyway been composed in terms of framing or focal points etc. Rather the house appears to have been placed in order to command panoramic views. The turbines will therefore not disrupt these views, but will simply add another element to them.

85 It is concluded that the impact of the EOWDC upon the setting of Orrok House, which is of high sensitivity and will be of negligible magnitude, will be of **minor** significance and will cease upon decommissioning. The impact will finish upon decommissioning.

Mitigation

86 No mitigation is proposed in relation to the impact upon the setting of Orrok House.

Residual Impacts

87 No mitigation is proposed in relation to impacts upon the setting of Orrok House and the predicted impacts will remain adverse and of minor significance. The impact will finish upon decommissioning.

Cumulative Impacts

88 The potential for cumulative impacts to result from the EOWDC and the potential Ocean Laboratory has been considered. The Ocean Laboratory could comprise a 120 m mast with a platform 20 m above LAT. It could be located to the south of the proposed EOWDC turbines and therefore will be at the rear of the array when viewed from Orrok House. It has been concluded that there will be no cumulative impact. The predicted impact relates to the proposed turbines appearing as large structures in views from Orrok House. The presence of the Ocean Laboratory would be seen amongst the turbines and would not alter the effect.

89 The potential for cumulative impacts to arise from the EOWDC and onshore wind farms has been considered. The cumulative ZTVs for consented and proposed wind farms (SLVIA Figures 15 & 16 respectively) indicate that no other wind farms will be visible from Orrok House. It is concluded that there is no potential for cumulative impacts upon the setting of Orrok House.

1.3.1.10 <u>*Girdle Ness Lighthouse (LB20078)*</u>

90 Girdle Ness Lighthouse (LB20078) was designed by Robert Stevenson and built in1833. It was fitted with a new double light system and in 1860 was described by the Astronomer Royal as ‘the best lighthouse that I have seen’. The lighthouse stands at the eastern end of Girdle Ness, between Greyhope Bay and Nigg Bay. Aberdeen Bay and the North Sea occupy views to the north and east (Plates 3 & 4). Immediately adjacent are lattice work towers (Plate 5) In views to the west the foreground is occupied by the bleak headland, beyond which Aberdeen is visible. The lighthouse is a prominent landmark being highly visible from the south, across Nigg Bay, and from points to the west, including Torry Battery. In these views the pristine white vertical form of the lighthouse is seen in contrast to the low rugged form of the headland, with the sky providing a backdrop (Plate 6).

91 The lighthouse’s cultural significance comprises intrinsic, contextual and associative elements. Its intrinsic value relates to its technological importance, while its contextual and associative values relate to its direct relationship with the Stevenson family and, hence, the development of Scottish lighthouses, its relationship with the entrance to the harbour and its prominence in the surrounding landscape and importance as a landmark. Consequently, the setting of the lighthouse comprises:

- The headland upon which it is located, as this is relevant to both the contextual and associative values as its flat form contributes to the prominence of the lighthouse and hence its functional and aesthetic characteristics;
- The harbour entrance which is visible to the west as this relates the lighthouse to the other elements of Aberdeen’s maritime heritage;
- The sea to the north, east and south as the lighthouse is clearly inextricably linked to the sea.

92 The proposed turbines will be fully visible to the northeast of the lighthouse at a distance of 7.9 km. Their appearance will vary depending on the location of the viewer, but from the lighthouse and land to its south, the locations that are of greatest relevance to the impact assessment, the proposed turbines will be

seen as five groupings. From some locations to the south the proposed turbines will lie directly behind the lighthouse, but from most of the coastal road they will be seen to the left. The wireframes demonstrate that the lighthouse will appear substantially larger than the turbines in views from its south. From the lighthouse itself and from elevated locations to its south the the proposed turbines will be seen with the many large ships that currently operate from Aberdeen Harbour and frequently anchor in the area to the east of the mouth of the River Don, Aberdeen Harbour Board figures indicate that it handles almost 9000 vessels use the harbour annually. The photomontage presented for the viewpoint at Torry Battery (Viewpoint 07 SLVIA) shows how this may appear.

93 The lighthouse is of high sensitivity to impacts upon setting. It is a prominent feature and its surroundings contribute to many aspects of its significance.

94 The proposed turbines will be located in Aberdeen Bay and hence within the setting of the lighthouse. Although this will affect views from the lighthouse, this will not constitute an impact upon setting as the relationship of the lighthouse with its surroundings or the degree to which this relationship can be understood and appreciated will be unchanged. However, views of the lighthouse from the south will be affected in ways that will constitute an impact upon setting. The proposed turbines will be seen in combination with the lighthouse in these views. From a very limited area they will be seen directly behind the lighthouse. This will only occur in a small part of Greg Ness. The appearance of the turbines in combination with the lighthouse will reduce to some extent the dominance of the lighthouse as the proposed turbines will also be white vertical features. However, the turbines will be located 7.9 km from the lighthouse, hence in views across Nigg Bay they will be over 9 km from the viewer, while the lighthouse will be 1.2 km or more away. The lighthouse will appear taller than the turbines in such views. The lighthouse's relationship with its surroundings will remain readily appreciable, however, its dominance of certain views will be reduced by the presence of the turbines and hence the aesthetic element of its associative value may be considered to be reduced, though this will depend on the preferences of the viewer. Given the turbines' distance from the lighthouse, the lighthouse will remain the dominant feature on the headland and in views from the south and the vertical form of the turbines will match that of the lighthouse.

95 The potential impact of the EOWDC upon the setting of the lighthouse, which is of high sensitivity, has been assessed as of low magnitude. Following the application of professional judgement, it is concluded that the impact will be of **minor** to potentially **moderate** significance. This conclusion has been reached because the impact relates to the aesthetics of views of the lighthouse from a limited area to the south and that for the majority of views there will be little or negligible impact. However, it is also recognised that the magnitude of the aesthetic impact will depend largely on the viewer's predisposition towards wind turbines, rather than, for example, the creation of visual discordance or a reduction in the lighthouse's contribution to a valued view. The extent to which the lighthouse's functional relationship with its surroundings will remain unchanged. The impact will finish upon decommissioning.

Mitigation

96 No mitigation is proposed in relation to the impact upon the setting of Girdle Ness lighthouse.

Residual Impacts

97 No mitigation is proposed in relation to impacts upon the setting of Girdle Ness lighthouse and the predicted impacts will be of minor to moderate significance. The potential impact will finish upon decommissioning.

Cumulative Impacts

98 The potential for cumulative impacts to result from the EOWDC and the potential Ocean Laboratory has been considered. The Ocean Laboratory could comprise a 120 m mast with a platform 20 m above LAT. It could be located to the south of the proposed EOWDC turbines. It has been concluded that there will be no cumulative impact. The predicted impact relates to the proposed turbines appearing as large structures in views of the lighthouse. The Ocean Laboratory would be seen amongst the turbines and would not alter the effect.

99 The potential for cumulative impacts to arise from the EOWDC and onshore wind farms has been considered. The cumulative ZTV (SLVIA Figure 15) indicates that up to two other consented wind farms will theoretically be visible from the area of the lighthouse. The closest will be over 20 km away. Given the distance, it is concluded that there is no potential for cumulative impacts. The indicative ZTV for proposed wind farms (SLVIA Figure 16) indicates that no proposed wind farms will be visible.

Monitoring

100 No monitoring is proposed.

1.3.2 Summary of Impact Assessment

58 The results of the impact assessment are summarised in Table 4.

TABLE 4
Impact Assessment

Potential Impact / Activity	**Sensitivity of Receptor**	**Magnitude of Effect**	**Significance**	**Mitigation**	**Significance after Mitigation**	**Monitoring**	**Cumulative / In-combination**
Impact upon setting of Torry Battery	High	Negligible	Minor	None proposed	Minor	None proposed	None
Impact upon setting of Orrok House	High	Negligible	Minor	None proposed	Minor	None proposed	None
Impact upon setting of Girdle Ness Lighthouse	High	Low	Minor to moderate	None proposed	Minor to moderate	None proposed	None
Impact upon setting of Peterseat cairns	High	Negligible	Minor	None proposed	Minor	None proposed	None
Impact upon setting of Hare Cairn	High	Negligible	Minor	None proposed	Minor	None proposed	None
Impact upon setting of other assets	Low - Medium	Negligible	Negligible	None Proposed	Negligible	None proposed	None

1.4 Summary

101 The potential impact of the EOWDC has been considered in relation to all nationally important designated cultural heritage assets within 10 km of the proposed turbines and selected assets beyond this.

102 Potential impacts of greater than negligible significance have been identified in five cases: Hare Cairn, the Peterseat cairns, Torry Battery, Orrok House and Girdle Ness Lighthouse. The first three are Scheduled Monuments, whilst the latter two are Grade A-listed buildings.

103 The impacts upon Hare Cairn, the Peaterseat cairns, Torry Battery and Orrok House have been assessed as being of minor significance and those upon Girdle Ness Lighthouse as being of minor to moderate significance. No mitigation is proposed in relation to these impacts and they will persist throughout the lifetime of the EOWDC and cease upon decommissioning.

List of Tables

1.0 Introduction

Given below is the description of the commercial fishing baseline for the proposed European Offshore Wind Deployment Centre (EOWDC) development, taking into account FEPA, CPA, Defra and CEFAS requirements as specified in the 2004 Guidelines (Cefas, 2004) and BWEA 2004 Recommendations (BWEA, 2004).

In the case of the wild salmon and sea trout fisheries, the combination of the regional socio-economic importance of these activities and the potential significance of the impacts from the proposed development are such that they have been separately assessed.

As there is no single data source or recognised model for establishing commercial fisheries baselines within small, discrete sea areas such as wind farm sites the following description of the baseline has, therefore, been derived using data and information from a number of sources.

2.0 Summary

To date, there have been very low levels of fishing activity within the proposed EOWDC site, largely as a result of the poor productivity of the area. Four local vessels have been identified as operating within the general area of the site, all of which are inshore demersal trawlers. These vessels range between 8 and 11 m in length, three of which register their home ports as Aberdeen. The fishing grounds of these vessels were stated to be between Aberdeen Harbour Fairway Buoy and the buoys off the Black Dog Firing Range, with the main target species being plaice. In addition to trawling, these three vessels have the capacity to deploy creel (potting) gears. The fourth vessel fishing the area, whose home port is Peterhead, fishes on a part time basis and only occasionally visits the site to trawl for plaice. From the consultation undertaken and the evidence obtained, it is apparent that the area of the proposed EOWDC site constitutes only a small proportion of the fishing grounds of these vessels.

Analysis of Vessel Monitoring System (VMS) plot data from over 15m vessels suggests that vessels with plots recorded within the site are steaming through it to more productive fishing grounds further afield. The nearest scallop dredging areas are on the Bennachie ground, which lies in the deeper offshore waters beyond Aberdeen Bay. The nearest nephrops grounds are identified well to the south of the site, off the coast of Montrose. Potting, largely by virtue of the habitat requirements of the main target species, is concentrated in areas to the south and north of the site.

3.0 Study Area(s)

The study area for the assessment of commercial fishing intensity and values is shown in Figure 3-1 below. The approach has been to follow a focus from a larger regional area down to the local area and the specific area of the site.

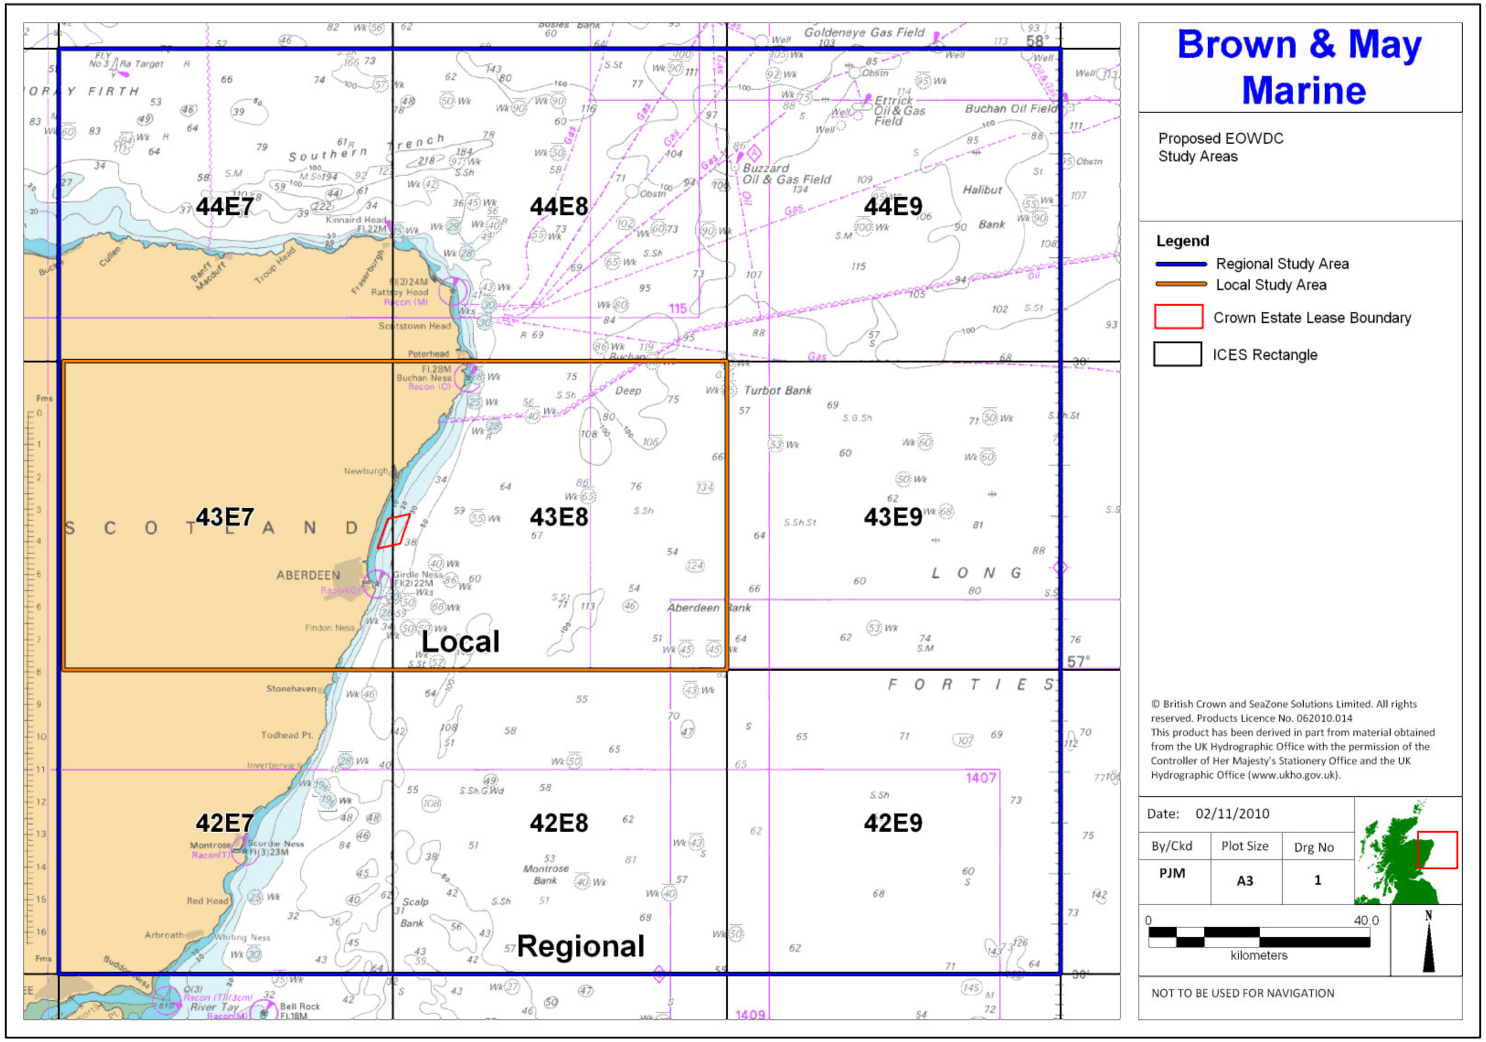

Figure 3-1 Proposed EOWDC Study Areas

4.0 Methodology

4.1 Consultation

Consultation with the relevant local fishermen was principally undertaken by the Scottish Fishermen's Federation (SFF) between 2008 and 2010. The SFF represents approximately 90% of Scottish fishermen.

Four vessels were identified as fishing in the development area and direct consultation was undertaken with the skippers of these vessels, who along with the District Fisheries Officer provided valuable contributions to this report.

The information gathered through consultation has been verified by:

- Michael Sutherland, John Watt and John Ewan; of the Scottish Fishermen's Federation (SFF)
- Ian Balgowan; President Scottish Inshore Whitefish Producers

4.2 Key Guidance Documents

The following documents have been referenced for both the Baseline and Impact Assessments:

- Offshore Wind Farms, Guidance Note for Environmental Impact Assessment in Respect of FEPA and CPA Requirements - Version 2; Cefas, MCEU, Defra, DTI, June 2004
- Strategic Environmental Assessment(SEA) of Draft Plan for Offshore Wind Energy in Scottish Territorial Waters: Volume 1: Environmental Report; Marine Scotland 2010
- UK Offshore Energy – Strategic Environmental Assessment; DECC, January 2009
- Recommendations for Fisheries Liaison; FLOW, May 2008
- Fisheries Liaison Guidelines – Issue 5; UK Oil & Gas, 2008
- Guidelines to Improve Relations between Oil & Gas Industries and Near-shore Fishermen, UKOOA (renamed UK Oil & Gas), August 2006
- Fishing & submarine Cables – Working Together, International Cable Protection Committee (CPC), February 2009
- Options and Opportunities for Marine Fisheries Mitigation Associated with Wind farms, COWRIE 2010.
- Scoping Response -Marine Scotland (15.12.10)

4.3 Data Sources, Sensitivities and Qualifications

The principal sources of data and information used were:

- International Council for the Exploration of the Sea (ICES)
- Marine Management Organisation (MMO)
- Marine Scotland, Marine Scotland Science (MS)
- Scottish Fisheries Protection Agency (SFPA)
- European Fisheries Commission (Europa)

Analysis of the data and information sources used for the commercial fishing assessment are subject to the following qualifications, limitations, sensitivities and gaps:

4.3.1 International Council for the Exploration of the Sea (ICES) Statistical Rectangles

ICES statistical rectangles are the smallest spatial unit used for the collation of fisheries statistics used by the EC and member states. The boundaries of ICES rectangles align to 1˚ of longitude and 30' of latitude. As is apparent from Figure 3-1 above, however, the areas of ICES rectangles are large relative to the area of the proposed EOWDC site, which is situated on the border of ICES rectangles 43E7 and 43E8. Evaluation of fisheries statistics by ICES rectangle should therefore recognise the small proportion of the statistical rectangles that the proposed EOWDC site covers.

4.3.2 MMO Fisheries Statistics

The MMO collects and collates fisheries data by ICES rectangle. The principal source of data comes from the European Commission (EC) daily log sheets that all vessels over 10m are required to complete and submit.

Vessels of under 10 m in length are currently not obliged to submit daily log sheets, although voluntary submissions can be made. In addition, local fisheries officers undertake dockside checks on vessels under 10 m. The "Registration of Buyers and Sellers of First Sale Fish and Designation Auction Site Scheme" introduced in 2005 and the reporting requirements of the "Shellfish Entitlement Scheme" introduced in 2004, have further contributed to the validity of fisheries data for the under 10 m fleet. The MMO fisheries statistics for this category, especially in years prior to the introduction of the Scheme, in some cases underestimate the true levels of fishing in areas where a large percentage of the activity is by vessels within this category.

It should be noted that vessels referred to as "foreign" in the MMO fisheries data only include foreign vessels landing into UK ports. Foreign vessels fishing in the area but landing into non-UK ports are not recorded. The values given for foreign vessels should therefore not be taken as an indication of the total foreign activity.

4.3.3 MMO Surveillance Sightings

Surveillance sightings in UK waters are recorded by fishery protection aircraft and surface craft as a means of policing fisheries legislation. These data provide a good indication of the relative distribution of fishing activity by method and nationality but should not be taken as a quantitative assessment of fishing activity, given the low frequency of the flights over an area, which are generally once a week and only during daylight hours.

4.3.4 MMO UK Satellite Tracking (VMS) Data

All EU registered fishing vessels of more than 15 m in overall length are monitored by satellite tracking. The positions of the vessels are transmitted approximately every 2 hours via satellite link to the MMO and other national EU control centres. The MMO receives information on all UK vessels irrespective of location, and of foreign vessels within UK waters. The MMO cannot however disclose data on foreign vessels without prior permission from the regulating body of the applicable member state and disclosure of UK vessels' identities is restricted under the Data Protection Act (1998).

There has also been a change in MMO policy with regards to the release of individual vessel coordinates data even if the vessel's identities are withheld. Instead the number of plots by vessel type in a grid of rectangles of approximately 70 $n.m^2$ is provided. The 2009 data have therefore been presented separately from the 2005-2008 datasets given the differences in format.

5.0 Fisheries Controls and Legislation

Whilst the international aspect of European fisheries negotiation, such as the setting of quotas, remains a reserved power, the implementation of fisheries regulations is devolved to the Scottish Parliament, and administered by Marine Scotland.

5.1 Fishing Vessel Licenses

All vessels engaged in commercial fishing must hold a valid licence. The system is designed to prevent increases in both fleet numbers and catching capacities through a system of vessel capacity units (VCUs). In addition to limiting any further increases in fishing vessel numbers, decommissioning schemes have, over the past 20 years, resulted in significant reductions in the numbers of UK and certain other member states' fleets.

5.2 Territorial Limits

Member States' territorial fishing limits extend out to 12 nm. With some exceptions, access within 6n.m of the coast is restricted to the vessels of that Member State. The only vessels from other member states allowed access within the UK's 6-12nm limit are those with historic rights.

Figure 5-1 below shows there are no historic rights for other Member State's vessels within Scotland's 12 nm limit off the east coast and hence within the area of the proposed EOWDC site.

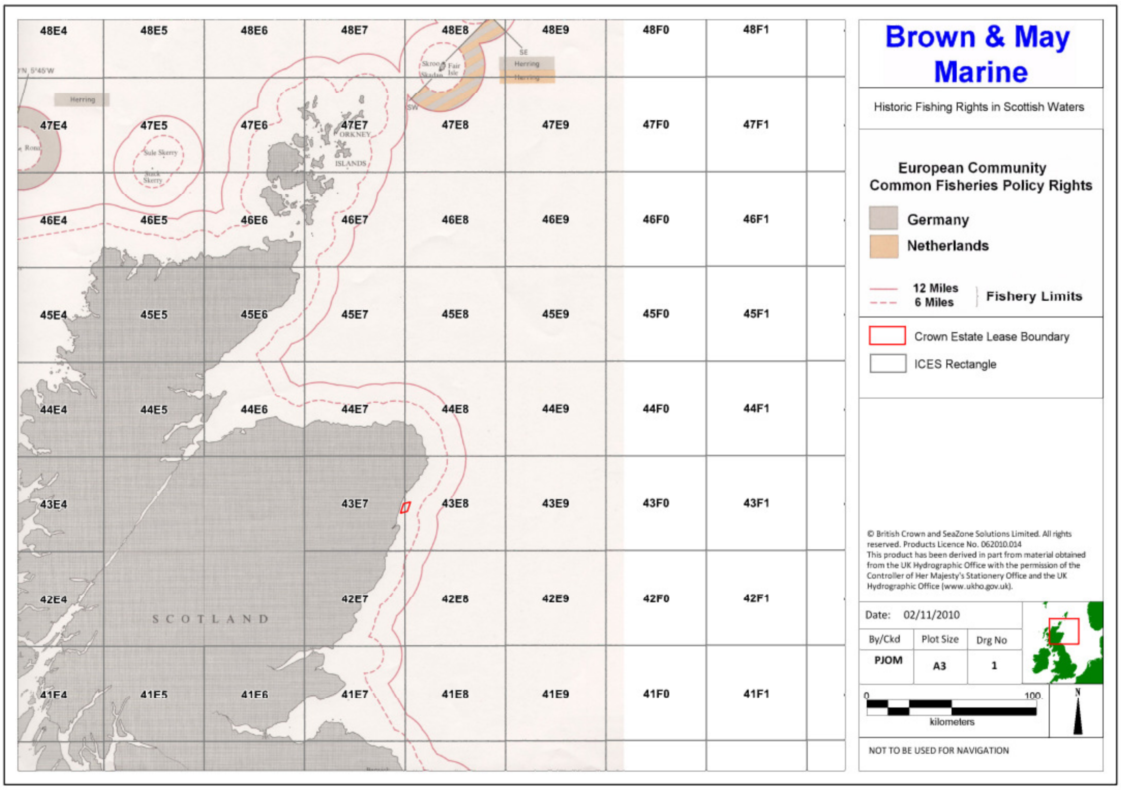

Figure 5-1 Historic Fishing Rights in Scottish Waters (Source: Admiralty Chart Q6385)

There is however, a number of UK flagged and licensed fishing vessels under foreign ownership, which could in theory have rights to fish within the UK 12 n.m limit.

5.3 Quota Restrictions

The Scottish Executive manages quotas for fish stocks and controls the activities of fishing vessels and fishing effort (days at sea) in the Scottish waters of the North Sea, West of Scotland and Faroese waters, plus all inshore fisheries within the 12 nm territorial limit (Scottish Government, 2010b). Such controls and regulations have had, and will continue to have, direct and indirect impacts on existing and future commercial fisheries baselines.

The principal remit of the EC Common Fisheries Policy (CFP), ratified in the early 1980's, is the long-term conservation of fish stocks in EU waters. A central element of the CFP is the system of quotas by ICES area and sub-area. Species identified as requiring management are defined as pressure stocks. Annual Total Allowable Catches (TACs) are allocated for each pressure stock by area or sub-area.

National, regional and individual quotas for the over 10 m fleet are assigned on the basis of historical rights and track records. Vessel quotas are in effect tangible assets which can and are sold or leased, and national quotas can, and have been, exchanged or swapped between member states.

The system of quotas has however been criticized as a conservation measure despite being in place for more than 20 years as the primary stock conservation measure of the CFP. It is recognised that regulation by quotas encourages the discarding of either undersized or over quota fish at sea. In recognition of such failings, the CFP is currently under review, which could result in significant changes to future fisheries management policies and legislation.

Figure 5-2 and Figure 5-3 overleaf illustrate patterns of progressively reducing TACs and UK quotas in ICES Area IV (North Sea) for the principal pressure stock species since 2006. Blue whiting are the species caught in greatest numbers in the North Sea.

	2006	2007	2008	2009	2010
Horse Mackerel	42,727	42,727	39,309	39,309	207,335

5.4 Effort (Days at Sea) Restrictions

Over 10 m vessels are also subject to days at sea (effort) limitations as part of the EC's policy of reducing fishing effort in EU waters. The regulation (Annex V, Council Regulation (EC) No 2287/2003) is somewhat complex and relates to gear type, mesh size and elected management periods. In essence, vessels using demersal whitefish gears are restricted to the equivalent of 14-15 days a month at sea.

5.5 Shellfish Entitlements

Since 2004 vessels must also be specifically licensed to catch crabs and lobsters. Under these arrangements, shellfish entitlements allowing unrestricted amounts of crabs and lobsters to continue to be caught were issued to owners of licensed vessels that had a track record of landing over a particular weight of these species per year. It is a condition of vessels of 10 m and under with shellfish entitlement that they submit weekly log sheets for crab and lobster landings.

5.6 Under 10 metre Fleet

The under 10 m fishing fleet has not, as yet, been subject to the same levels of restrictions upon their activities as the over 10 m sector. They are now however also subject to sea area and quota restrictions for certain species mainly as part of the 'Cod Recovery Programme'. Table 5-1 below shows the under 10 m quota allocations for 2010, 2009, 2008 and 2007.

Table 5-1 Under 10m Final Quota Allocations (Source: MMO)

Species	2010 Quota (Tonnes)	2009 Quota (Tonnes)	2008 Quota (Tonnes)	2007 Quota (Tonnes)
North Sea Cod	588.0	561.3	403.1	281.0
North Sea Haddock	127.9	80.5	131.6	175.2

North Sea Turbot/ Brill	10.6	15.0	17.9	22.7
North Sea Dab/ Flounder	19.4	18.9	18.7	17.6

5.7 Regional and Local Fishing Restrictions

Restrictions upon fishing activities in addition to those transposed from EU and UK law are known as Scottish Statutory Instruments (SI), a form of secondary legislation in Scotland, created by the Scotland Act 1998, and used to exercise devolved powers.

There are no local fishing restrictions within the 3 nm limit specific to the Aberdeen Bay area (Figure 5-4). Fishing activity is instead constrained by other factors, such as species abundance and the avoidance of traffic entering and leaving the harbour.

In a wider regional context, the following fishing restrictions are imposed in the areas defined in Figure 5-4:

- Aberdeen to Mons Craig – Use of mobile or active gear is prohibited between 1st October and 31st March each year
- Mons Craig to Doolie Ness –Use of mobile or active gear prohibited all year
- Doolie Ness to Lang Craig – Use of mobile or active gear is prohibited between 1st October and 31st March each year within one mile and between 1st April and 30th September each year within one half mile
- Lang Craig to Arbroath - Use of mobile or active gear prohibited all year

In addition restrictions are placed on scallop dredging activity in terms of the number of dredges a vessel can operate. This activity is stated as predominantly taking place in areas to the south and east of the proposed EOWDC site (SFPA, 2007).

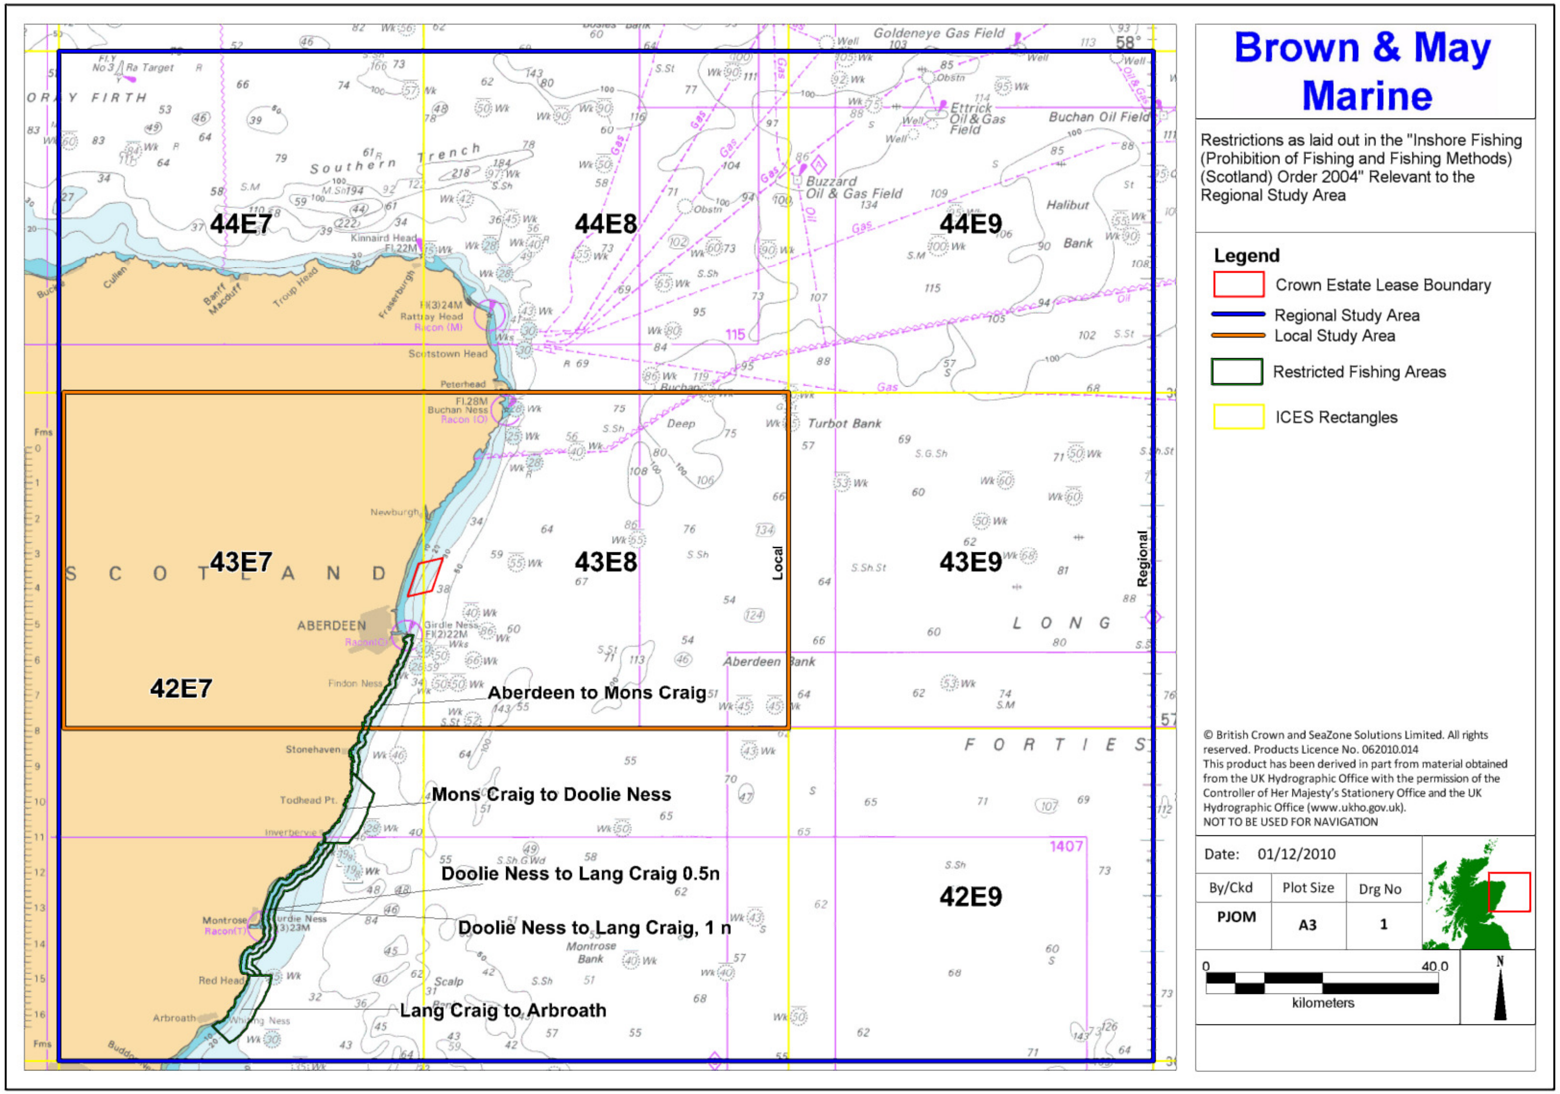

Figure 5-4 Restrictions as laid out in the "Inshore Fishing (Prohibition of Fishing and Fishing Methods) (Scotland) Order 2004" relevant to the Regional Study Area

6.0 Commercial Fishing in Scotland and Aberdeen

6.1 National Context

The following information has been taken from the Scottish Sea Fisheries Statistics (SSFS) 2009 and Marine Scotland publicly available information sources.

Since 1983 the structure and capacity of the UK and Scottish fishing fleets have been primarily dictated by the EU Common Fisheries Policy (CFP). Between 1997 and 2002 the Multi Annual Guidance Programme (MAGP) within the CFP was devised to manage fleet structures. In effect, fishing by method was restricted by capacity limits and effort reduction targets. When this programme ended it was replaced by member state level controls which impose effort level ceilings through a system of exit/entry restrictions. In essence, fleet capacity cannot be increased, allowing vessels only to enter the fleet when an equivalent or larger capacity has exited the fleet.

One of the most significant impacts upon the Scottish fleet in recent years has been the two successive decommissioning schemes in 2001-2002 and 2003-2004, under which 165 vessels were removed from the national demersal fleet.

In 2010 the Scottish Government introduced Licence Parking as a measure to help the fleet adjust to current, restrictive conditions. The principle is to enable multiple existing fishing licenses to be combined and placed upon a single fishing vessel – thus sharing it – in order to reduce fixed and variable costs over both the short and long term. Alternatively, those wishing to leave the industry may be bought out and their effort concentrated on remaining vessels (under previous licensing rules this was not possible). The process of ‘parking’ is however reversible; a parked license can be ‘unparked’. Over 40 vessels have applied for this scheme to date. In consultation with industry stakeholders and the Scottish Fisheries Council, Ministers have now also introduced a publicly funded (co-funded by the European Fisheries Fund) fleet resilience grant scheme aimed at disposing of those vessels made dormant through license parking.

6.1.1 Scottish Landings Values

Table 6-1 lists the ports included within the three port districts, Fraserburgh, Peterhead and Aberdeen, in the region of the proposed development.

Table 6-1 Ports within the East Coast Port Districts of Fraserburgh, Peterhead and Aberdeen (Scottish Government, 2010a)

Fraserburgh	Peterhead	Aberdeen
Fraserburgh	Boddam	Aberdeen
Gardenstown	Peterhead	Arbroath
Macduff	Port Errol	Catterline
Pennan		Gourdon
Portsoy		Johnshaven
Rosehearty		Montrose
Sandhaven & Pitullie		Stonehaven
Whitehills		

Figure 6-1 below gives the 2009 total landings values for all vessels into Scottish ports by district and species group.

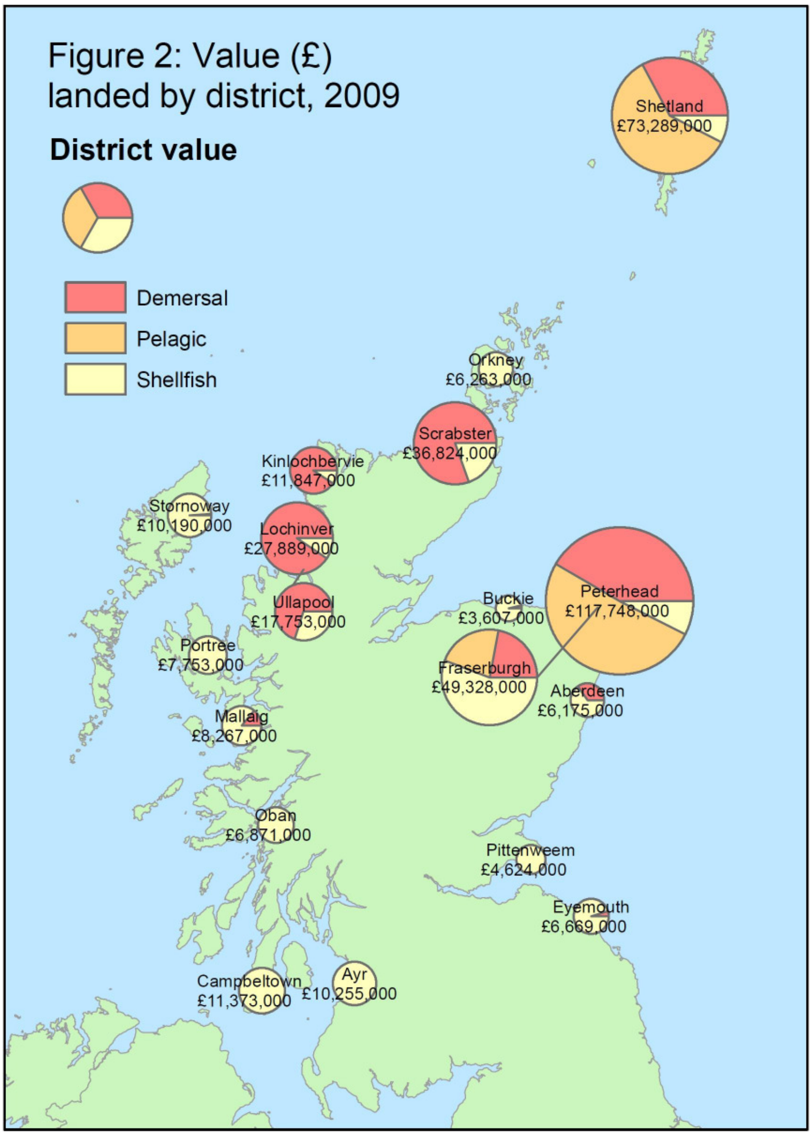

Figure 6-1 Total Landings Values (£) into Scottish ports by Port District, 2009 (Extracted from: Scottish Government, 2010a) ("Figure 2" in the picture refers to the report from which it was taken)

The 2009 total landings values show Peterhead (£117,748,000) to be the most important port district in Scotland and indeed within the UK, followed by Fraserburgh (£49,328,000) and Scrabster (£36,824,000) respectively. Aberdeen port district is fifteenth, with a 2009 total landings value of £6,175,000.

6.1.2 District Fleet Sizes

Table 6-2 shows that at the end of 2009 2,174 active fishing vessels were recorded as based in Scotland, a reduction of 31 (-1.4%) from 2008, which is the smallest fleet recorded for Scotland since the Second World War. Reductions occurred in 11 of the 18 districts, with losses mainly in the North West, including the Isles. Five districts saw an increase in vessel numbers, Oban (+6), Eyemouth (+5), Aberdeen (+3), Orkney (+2) and Kinlochbervie (+1).

Table 6-3 below gives fleet numbers by length for the three port districts in the region of the proposed EOWDC site. The majority of vessels based in Aberdeen are under 10 m, whereas fleets in Peterhead and Fraserburgh consist mainly of over 10 m vessels.

Table 6-2 Vessel Numbers by District (2005-2009) (Scottish Government, 2007; 2008; 2009; 2010a)

	Number of active vessels					
District	2005	2006	2007	2008	2009	Change between 2005-2009

6.2 Aberdeen

6.2.1 Historic Context

The fishing industry was the mainstay of Aberdeenshire's economy for much of the 1800 and 1900's. By 1892 it was Scotland's leading whitefish port (Aberdeen Maritime Museum, 2007). Trawling employed over 1,000 people (on boats as well as dockside) in 1900, a number that had doubled to more than 2,000 by 1910. Haddock was the most important species landed, followed by cod.

Aberdeen's importance as Scotland's premier fishing port remained high throughout the early and mid 1900's. In 1956 Aberdeen continued to land over 75% of Scotland's total whitefish catch and was known as a 'distant water port', with vessels fishing grounds as far afield as Faroese and Icelandic waters.

In the years spanning from the 1950's to the 1970's, a series of disputes and confrontations arose amongst fishing interests active in the grounds around Iceland. In 1958, Iceland, concerned about the over exploitation of declining fish stocks, increased its fishing limits from 4 to 12 nm. Among the foremost affected were UK registered vessels. In 1972 a second dispute ensued following Iceland extending its territorial fishing limits to 50 nm. An agreement, lasting for 2 years was reached the following year limiting UK vessel access through the implementation of certain restrictions. However, when this agreement ended in 1975 the third and most confrontational 'Cod War' commenced. This culminated in Iceland threatening NATO with the closure of a base at Keflavik. A six month agreement was reached to restrict British vessels, after which time they were excluded from Iceland's 200 nm. limit, an outcome that heralded the demise of the UK's distant water fleet based at Aberdeen and other ports.

Aberdeen's fishing industry suffered a further setback in the mid to late 70's when many fishing vessel owners, suffering from a general downturn in the industry, transferred their vessels from Aberdeen to Fraserburgh or Peterhead. This was primarily due to Aberdeen's status as a 'dock labour' port, whereby all vessels landing into the port had to use the unionised dock labour for discharging their catch. By relocating to other ports vessels were able to make significant cost savings through the crews landing their own catches.

After the decline of the distant water fleet, the relative importance of the home fleet increased, and until around 15 years ago there were approximately 40 active full-time fishing vessels operating out of Aberdeen (Sutherland, 2007). Measures were however implemented by the EU in response to declining fish stocks that required a reduction in fishing effort. As a further response to the EU requirement of a reduction in fishing effort, the UK introduced decommissioning policies in Scotland in 2001 and 2002 (Section 6.1). This had a negative effect on the structure of the Aberdeen fishing fleet. There were no restrictions upon the age of vessels being decommissioned and frequently relatively new vessels were withdrawn, leaving an ageing industry in decline (Sutherland, 2007).

6.2.2 Aberdeen Port Today

The rapid expansion of oil and gas interests in the North Sea in the 1970's saw Aberdeen become the principal service port for the UK's offshore oil and gas industries. Where before the majority of the docks were given over to fishing vessels, there now remains only one fish quay – Commercial Quay. Although the market now handles significantly reduced quantities of fish, some vessels registered to other ports still land into Aberdeen. The port also has an important general maritime trade (in timber and grain, for example) as well as some naval activity.

There remain a number of fish processing plants in Aberdeen, with fish brought in by road transport from other ports in the north and west.

Interests within the fishing industry, notably the Scottish Fishermen's Federation (SFF), have derived benefits from the offshore oil and gas industries, which over the last 30 years have pursued a policy of deploying fishing vessels for oil-based work. The success of this diversification has contributed to the SFF establishing a Services Company which sources crew and vessels for work such as guard vessel duties and Marine Mammal Observation (MMO) duties.

7.0 MMO Fisheries Statistics

7.1 Landings Values by ICES Rectangle

7.1.1 Regional Study Area

Figure 7-1 and Figure 7-2 below illustrate the relative values of UK commercial fishing by method and species in comparison the ICES rectangles covering the regional area.

It can be seen that ICES rectangle 43E7, within which the inshore part of the proposed EWODC site is located has significantly lower landings values than other ICES rectangles in the region, largely due to its very small sea area. Rectangles to the north of the site contain the highest average landings values within the regional area. Bottom otter trawling for nephrops and whitefish is the principal fishing method undertaken in the regional study area, concentrated mainly in the northern rectangles, followed by scallop dredging by boat dredge mainly in the southern rectangles. Potting is generally deployed in inshore areas.

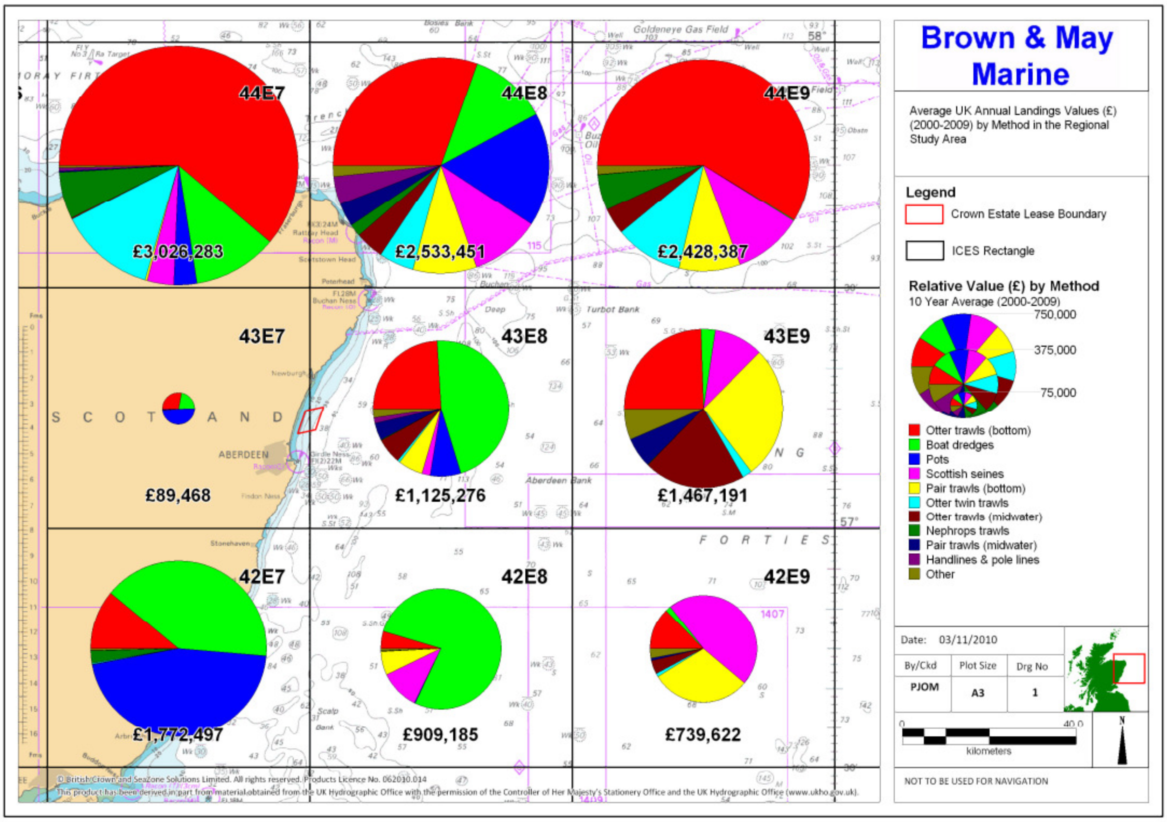

Figure 7-1 Averaged UK Annual Landings Values (2000-2009) by Method in the Regional Study Area

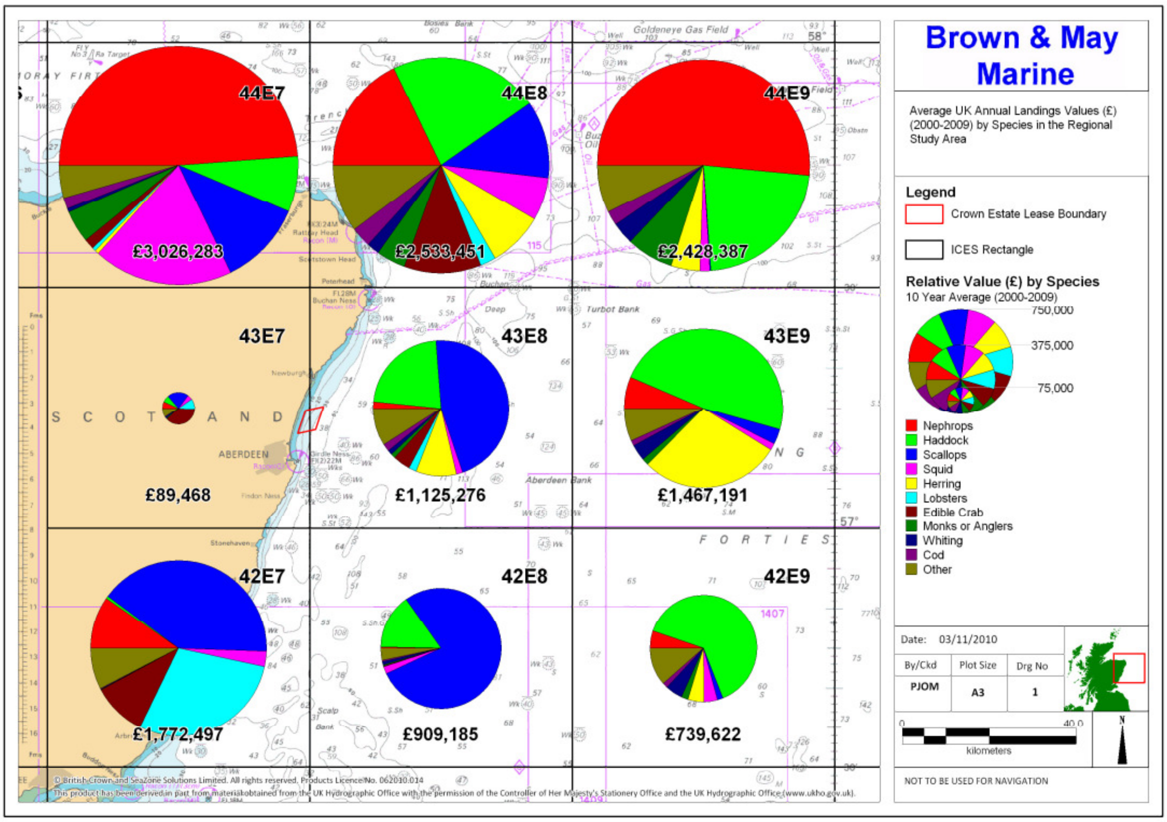

Figure 7-2 Averaged UK Annual Landings Values (2000-2009) by Species in the Regional Study Area

7.1.2 Local Study Area

ICES Rectangle 43E7

Figure 7-3 and Figure 7-4 below give the 10 year averaged annual values of landings by method and species for 43E7, the rectangle in which the inshore part of the proposed EOWDC site is located. These indicate that the majority of the value of fishing in the area of the proposed EOWDC site in 43E7 is from: potting for crab and lobsters; bottom otter trawling for whitefish and nephrops; and dredging for scallops, respectively. Other methods such as hand lines and pole lines, gillnets and Scottish seines recorded only low values.

Whereas the value of potting is largely derived from 10-15 m vessels, a greater percentage of the value of bottom otter trawling is from the 15 m and over fleet. Nearly all the value from boat dredging is derived from 15 m and over vessels.

There has been no foreign vessel activity recorded within ICES rectangle 43E7.

Figure 7-5 and Figure 7-6 give the annual landings values by method and species from ICES rectangle 43E7. Potting values have increased significantly since 2004, being consistently the highest value method since 2005, however this may be due to the introduction of shellfish entitlements in 2004 and the requirement for weekly catch returns. Bottom otter trawling, which had the highest average landings between 2000 and 2003 had seen a marked decline in the years following. There are significant fluctuations in the annual landings values for a number of principal species between 2000 and 2009. Edible crab, not generating particularly high landings values between 2000 and 2003 overall, had a significant increase in the following years, peaking in 2007 at £67,030. This in turn, coincided with a peak in potting, and the highest recorded value for one species in the 10 year period. Similarly, scallops, targeted by boat dredges, which previously had low landings values levels, experienced a sharp peak in 2004 with relatively high values subsequently.

	Pots	Otter trawls - bottom	Boat dredges	Handlines and pole-lines	Gillnets	Scottish seines	Otter twin trawls	Other trawls (not specified)	Nephrops trawls

Figure 7-6 Total Annual Landing Values by Species for 43E7, 2000-2009 Not Including Foreign Vessels (Source: MMO)

ICES Rectangle 43E8

Figure 7-7 and Figure 7-8 give the 10 year averaged annual values of landings by method and species for 43E8, within which the eastern section of the proposed EOWDC site is partially located.

It can be seen from Figure 7-7 and Figure 7-8 that the large majority of mechanical dredging and bottom otter trawling is by the 15m and over fleet. As is reflected in Figure 7-8, vessels employing these methods target scallops and whitefish respectively. There are low levels of pelagic activity by foreign vessels. Creel fishing (potting), shown in Figure 7-7 is undertaken almost exclusively by the under 10 m fleet.

Figure 7-9 and Figure 7-10 below give the annual landings values by species from ICES rectangle 43E8. Boat dredging for scallops and bottom trawling for whitefish have the overall highest landings values for the 10 year period between 2000 and 2009, with the former having significantly higher landings values than any other method since 2005. However, since a peak of annual landings of haddock by bottom trawling in 2004 of £752,470, landings values for the following years have dropped significantly.

7.2 Fishing Values by Landing Port

Table 7-1 below gives the average value for rectangles 43E7 and 43E8 by port, relative to the total landings into each port. It can be seen that, with the exception of Boddam and Port Erroll (see Figure 10-1), both rectangles constitute only a small proportion of each port's total landings. In addition, as a result of the very small area of rectangle encompassed by the proposed EOWDC site, it is considered that the majority of fishing activity within rectangles 43E7 and 43E8 is undertaken in areas outside this site.

7.3 Fishing Effort by Port

Table 7-2 and Table 7-3 show the annual fishing effort (days fished/year) by port and vessel size category, for ICES rectangles 43E7 and 43E8 respectively. As is stated above, it is considered that the majority of activity will be undertaken in areas of the rectangles outside of proposed EOWDC site.

7.4 Fisheries Seasonality

Figure 7-11 – Figure 7-14 give the averaged (2000-2009) monthly landings values by method and by species for rectangles 43E7 and 43E8, not including foreign vessels.

ICES Rectangle 43E7

Figure 7-11 and Figure 7-12 show that values of creel fishing (potting), targeting crab and lobster, is higher in the second half of the year. Bottom otter trawl landings, targeting haddock and plaice, are highest between June and November, with a peak in July. Dredging for scallops is highest in May, with very low levels in the final months of the year. There is a seasonal summer otter trawl fishery for squid between July and October.

ICES Rectangle 43E8

The seasonality patterns described for ICES rectangle 43E7 above, are broadly repeated in rectangle 43E8 (Figure 7-13 and Figure 7-14), although this rectangle records far higher monthly landings values. The scallop fishery appears less erratic than in 43E7, with a gradual increase in landings from the beginning of the year to a peak in June, tailing off again in the latter months. Bottom otter trawling is highest in the summer months and the latter half of the year, with very low recorded activity in April. Creel fishing (potting) activity, in comparison both to the other methods employed in the rectangle and to the amount of activity in 43E7, is low. There is a short, seasonal fishery for herring in August and September.

8.0 Satellite Tracking

Since January 2005, all European Community vessels over 15 m in length have been fitted with satellite tracking equipment which transmits the vessels' position a minimum of every 2 hours to the relevant Member States' fisheries authorities. Each Member States' Fisheries Monitoring Centre (FMC) monitors the activities of their fishing vessels to ensure compliance with fisheries legislation.

All UK satellite data is still collected in one dataset by the MMO. The data was obtained from the MMO in CSV format.

It is recognised that satellite data is only indicative of the activity of certain types of fishing vessels, i.e. those over 15 m in length. Furthermore, the data do not specify whether a vessel is fishing or steaming. Position plots of vessels that are stationary in port have not been included.

Figure 8-1 overleaf provides an overview of the relative density of activity by UK over 15 m fishing vessels. It can be seen that the proposed EOWDC site is situated in an area of low recorded density, with higher levels of activity in the north and south. Table 8-1 provides the numbers of vessels, and the 2 hourly position plots of those vessels, tracked within the proposed EOWDC site for the same period.

Table 8-2 gives a breakdown of the individual vessels recorded by satellite tracking inside the proposed EOWDC site in 2008. As can be seen, the numbers of plots is very low, indicating that vessels are steaming through the proposed EOWC site to and from more distant fishing grounds.

Figure 8-2 and Figure 8-3 show the tracks of the vessel identified by the MMO as GBR66, in 2008, the vessel obtaining the highest plot count within the proposed EOWDC site. Figure 8-2 shows the vessel tracks in the regional area and Figure 8-3 shows the vessel tracks within the proposed EOWDC site, respectively. Whilst it is possible, given the pattern of sightings (Figure 8-3), that this vessel may have undertaken some occasional trawling to the north of the proposed EOWDC site, it would appear that the immediate site vicinity sustains, at most, only a very small proportion of total activity of this vessel.

Figure 8-4 shows the range of activity of the vessel identified as GBR842 between 2005 and 2006, demonstrating that the vessel's fishing grounds are in areas considerably further offshore than the area of the proposed EOWDC site. Figure 8-5 suggests that the tracks recorded through the proposed EOWDC site can be attributed to the vessel steaming.

As a result of the different data set provided for satellite tracked vessels in 2009 (previously discussed), Figure 8-6 to Figure 8-8 separately show activity for this period. Figure 8-6 provides the density of over 15 m vessels for all methods. Figure 8-7 and Figure 8-8 show the density by scallop dredging and demersal trawling for whitefish, respectively – the principal fishing methods undertaken in the area by the over 15 m fleet. As with previous years, these figures show higher levels of activity located in grounds further offshore. Again it is likely that the majority of sightings that occurred within the rectangle that encompasses the proposed EOWDC site are a result of vessels steaming to grounds to the north and east of the site, as consultation with local fishermen and the SFF confirms that no scalloping dredging or trawling by over 15 m vessels occurs within the site.

9.0 Fisheries Surveillance

Figure 9-1 gives the positions of vessels identified by Fisheries Protection surveillance by nationality. As shown, in this ten year period only 1 vessel was recorded within the proposed EOWDC site. No foreign vessels were observed in proximity to the proposed EOWDC site.

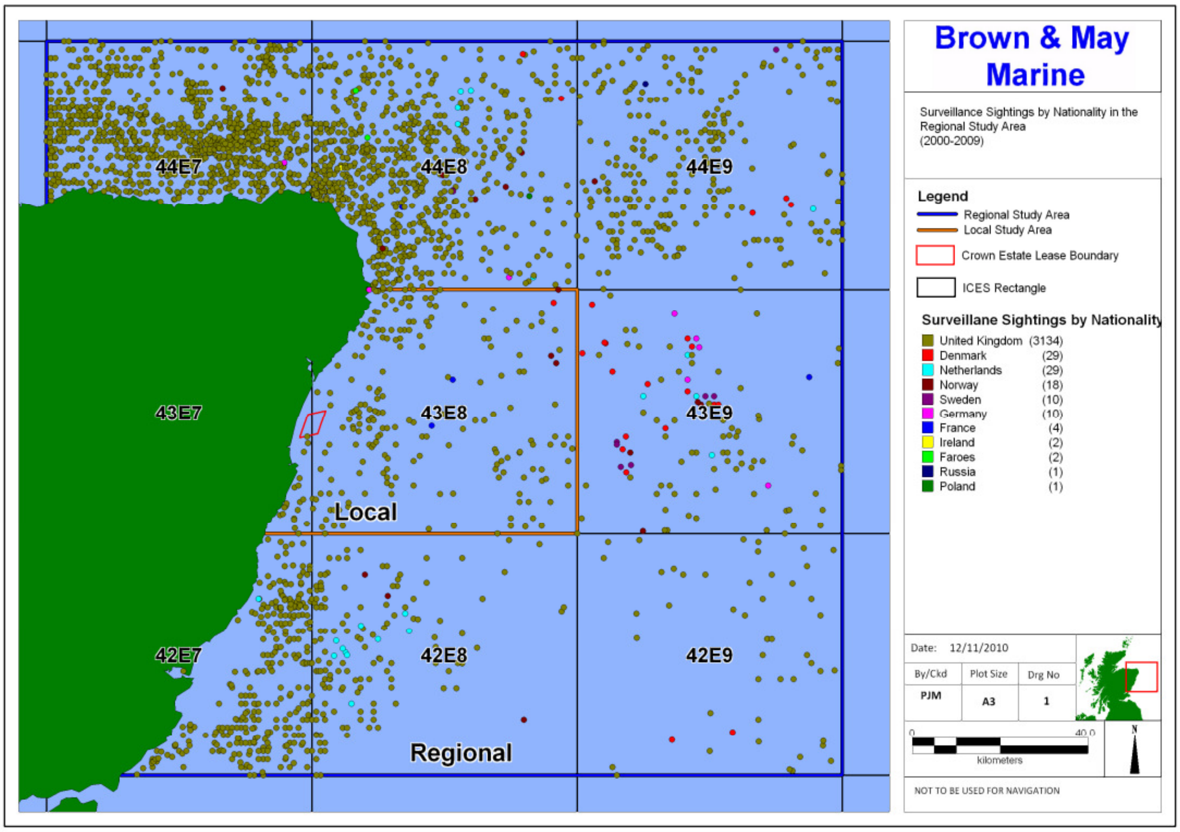

Figure 9-1 Surveillance Sightings by Nationality in the Regional Study Area (2000-2009) (Source: MMO)

Figure 9-2 shows the surveillance sightings by method. The majority of vessel categories observed in the vicinity of the proposed EOWDC site are demersal trawlers, scallop dredgers and potters/whelkers. Those labelled “Null” are vessels where the fishing method was unidentified.

The sightings plotted in Figure 9-1 and Figure 9-2 should however be taken in the context of the frequency of the surveillance patrols. Patrols over a particular area are generally at no more than weekly intervals and undertaken during daylight hours. These figures can therefore only be taken as a general indicator of the relative spatial distribution of different types of activity.

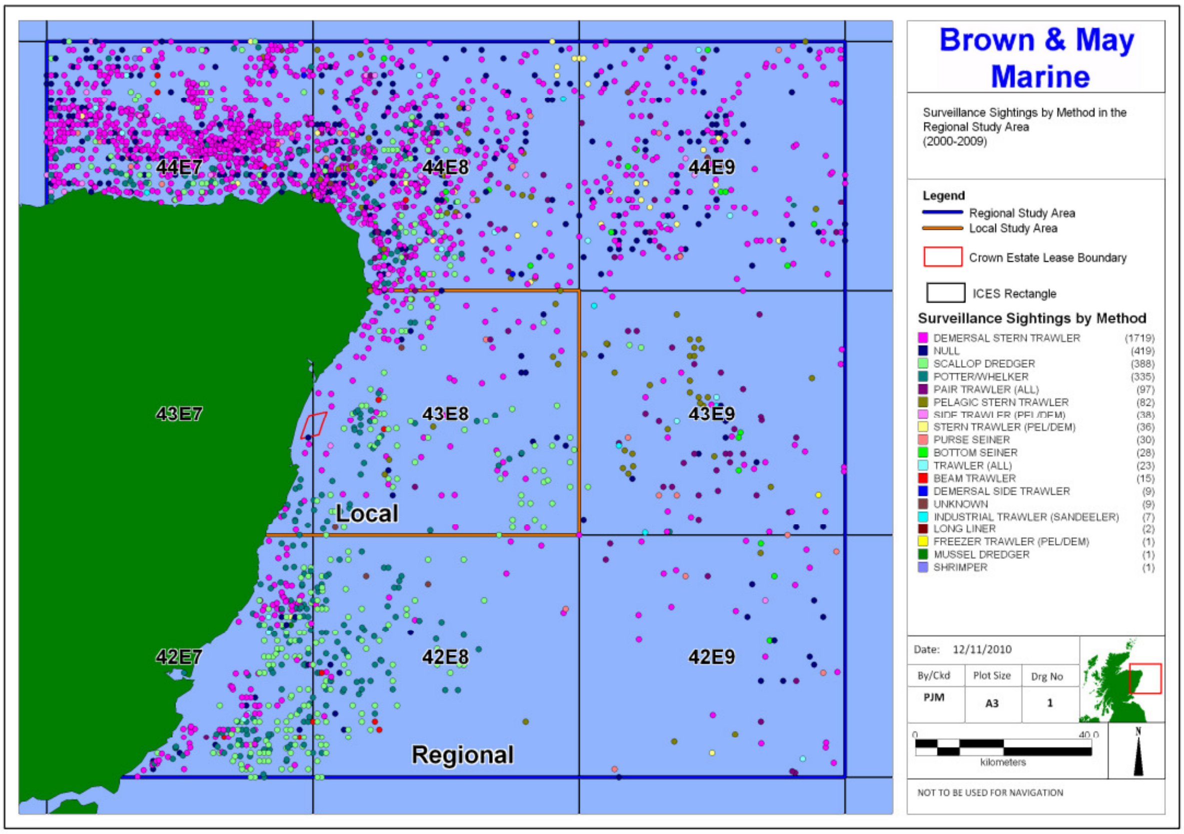

Figure 9-2 Surveillance Sightings by Method in the Regional Study Area (2000-2009) (Source: MMO)

10.0 Fishing Vessels, Methods, Operating Patterns and Practices

The information given in this section was gathered by the Scottish Fishermen's Federation (SFF) on the behalf of Brown and May Marine Ltd. A series of fieldwork trips and consultation with local fishermen was undertaken to ascertain the types, levels and locations of fishing activity in the regional area encompassing the proposed EOWDC site. The information was primarily gathered between 2008 and 2010.

10.1 Vessels by Port

Fishing vessels based at ports which could potentially be affected by the proposed EOWDC development extend from Port Erroll (Cruden Bay) in the North to Gourdon Bay in the south (Figure 10-1 below). Within this area Aberdeen is the largest harbour. A number of the small ports and harbours are used only during the spring, summer and autumn months by both full and part-time vessels as well as a number of small vessels, undertaking jigging, or rod fishing, or laying a few pots.

A common feature of these smaller harbours is their exposure to the easterly gales which are a feature of a north-east Scottish winter. The photographs given in Figure 10-2 to Figure 10-8 below show ports and vessels in the area of the proposed EOWDC.

10.2 Fishing Methods

Figure 10-9 shows the fishing areas as identified through consultation with fishing interests in the area of the proposed EOWDC site.

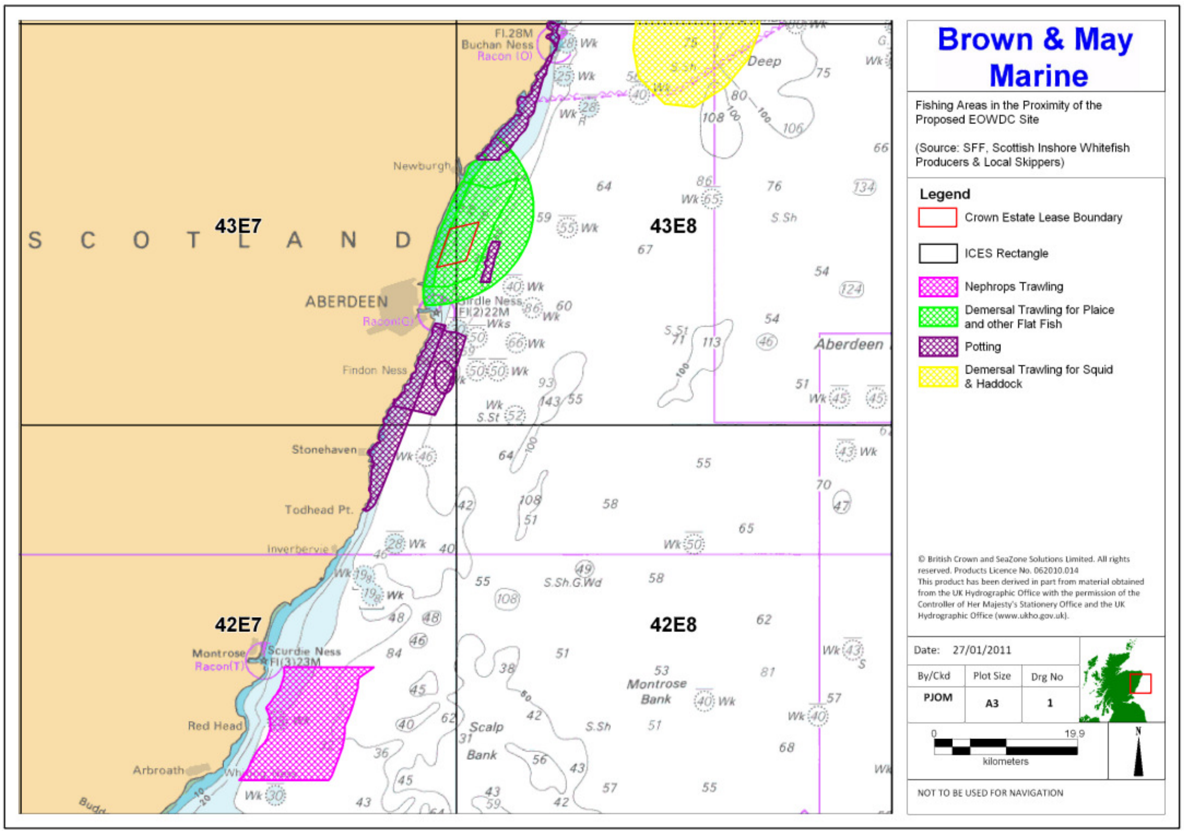

Figure 10-9 Fishing Areas in the proximity of the Proposed EOWDC Site

10.2.1 Demersal (bottom) Trawling

Demersal trawling is the most common fishing method in Scottish waters in terms of vessel numbers. Basic operating principles are the same throughout, with vessels towing one or more trawl nets, the lateral openings of which are affected by the trawl doors. The ratio of towing warp paid out to water depth is generally 3:1. Tow duration may vary from a single pass over a fish mark to tows of up to 5 hours. Towing speeds vary between 2 knots and 4 knots.

There is demersal trawling for whitefish in the general area around the proposed EOWDC site. In the past vessels from ports north of Aberdeen trawled the bay between Girdle Ness and Cruden Skares, just off the coast of Whinnyfold (Figure 10-1), for flat and roundfish, however, these vessels now target the more lucrative and reliable nephrops fisheries further offshore. Bottom trawling for flatfish, specifically for plaice, is the only trawling activity undertaken within the boundaries of the proposed EOWDC site, largely as a result of seabed substrate, which is sandy, homogenous ground largely devoid of features. This activity is restricted to a maximum of three to four inshore vessels during the summer. Figure 10-9 shows the principle demersal trawling grounds in and adjacent to the proposed EOWDC site. A few of the Aberdeen skippers also charter their vessels for rod and line fishing on wrecks to supplement their commercial fishing income.

10.2.2 Potting

Pots, or creels, are essentially traps baited to catch shellfish such as lobster, crab or nephrops. They are generally deployed in inshore waters, although some larger vessels will fish offshore areas. The priority of this fishery is the delivery of live catch. The scale of this activity can range from a 'hobbyist' fisherman setting 20 pots, to the long range vivier crabber which may set several hundred creels and keep crabs alive in purpose-built onboard vivier tanks.

Although it has been possible in the past to target brown crab in the Aberdeen Bay area, this activity has declined considerably as the port's uses have changed. It was stated by the Aberdeen District Fisheries Officer in 2010 that no part of the proposed EOWDC site is used by creel boats (Fraser, 2010). This is principally due to the risks associated with the large volume of marine traffic transiting, anchoring or sheltering in the bay. Potting activity for crab and lobster is generally concentrated approximately 5 nm to the north and south of the proposed EOWDC site.

The low levels of potting activity in the proposed EOWDC site are also attributed to the low productivity of the area. Higher concentrations of potting however occur in the coastal zones to the north and south of the site (Figure 10-9).

Due to the majority of vessels being smaller, local craft which are susceptible to weather limitations, activity normally takes place in the spring and summer, although some fish all year round.

10.2.3 Scallop Dredging

Vessels generally tow between one and two beams onto which a number of dredges are attached, depending on vessel size, engine power and winch capacity. The principal type of dredge used is the English 'Springer' type whereby the scallops are 'raked' from the seabed by steel teeth that are attached along the leading edge of the dredges which penetrate the seabed to a depth of approximately 20cms.

By virtue of their activity, scallop vessels are extremely migratory, fishing one location before moving to another and finally returning when the ground is thought to have recovered. In this way most of the suitable grounds around Scotland are fished. The Bennachie ground, which lies in the deeper offshore waters beyond Aberdeen Bay, is, at times, also fished for scallops. There is currently no evidence of scallop dredging occurring in the proposed EOWDC site.

10.2.4 Jigging and Hand Lining

As the name suggests, hand lining is fishing by hand using a multi-hooked line. Jigging is much the same except a mechanical, and generally computerised, jigger is used. The hooks are rigged with feathers or fish-like lures and 'jigged' up and down a few inches to attract the target species, which are pelagic fish or squid. This method is predominantly undertaken inshore, but larger craft may target shoaling fish further offshore. A further variation on hand-lining, known as 'ripper' is used to target cod and pollack on wrecks and pinnacles.

This method, as with potting, is for the most part undertaken in summer months and is carried out by a variety of small craft, both by professional and part-time fishermen. It was stated that there is very little jigging for mackerel within the boundaries of the proposed EOWDC site (pers comm, Ian Balgowan, 4th April 2008).

10.3 Vessels Active within the Proposed EOWDC Site

It was stated by the Aberdeen District Fisheries Officer that four vessels have been identified operating on occasions within and around the proposed EOWDC site (Fraser, 2010). Figure 10-10, Figure 10-12, Figure 10-13 and Figure 10-14 provide photographs of these vessels, with accompanying basic vessel specifications. All of these vessels are configured to undertake demersal trawling. In addition several of the vessels operate pots. Two of the vessels stated their activities were concentrated between the Aberdeen Harbour Fairway Buoy and the buoys off the Black Dog Firing Range, in the summer months between May and October. These vessels operate out of Aberdeen port. The two remaining vessel operate out of Peterhead and visit the area only occasionally, and also in the summer months.

SKUA II

Figure 10-10 Inshore Demersal Otter Trawler and Potter, Skua II

Registration	A17
Home Port	Aberdeen
Length	8.27m
Engine	130HP
Trawl Footrope	14m grass rope
Trawl Doors	Bison V, 760mm
Towing Depth	5.5 – 55m
Trawling Season	May to August

Figure 10-11 illustrates the trawl tows of Skua II, one of the four trawlers stated as operating in the proposed Eowdc site site. It can be seen that the majority of the vessel's fishing grounds lie inshore of the western boundary of the proposed EOWDC site.

Length	9.7m
Engine	119HP
Trawling Season	May to August (Flatfish); September to April (Squid & Haddock)

11.0 Future Fisheries

At present no new fisheries are foreseen in the area surrounding Aberdeen Bay, and in all probability there is unlikely to be an increase in either fishing effort or vessel numbers. It is also possible that increasing conservation concerns will lead to the implementation of designated protected marine conservation areas which will conceivably have the effect of enforcing further restrictions upon certain commercial fishing activities.

There exists the possibility that fishing practices within the proposed EOWDC site could change during its operational life. An example is the appearance of large shoals of squid inshore during the summer in the Moray Firth, providing a valuable fishery which previously did not exist. Furthermore, squid has been recorded at low levels in inshore areas in the proximity of the proposed EOWDC site. It is however considered that this species favours rockier grounds and that the substrate in Aberdeen Bay is not suitable.

Finally, future environmental and/or economic constraints may force fishermen to alter or amend current fishing practices. It is possible that vessels may be reconfigured with alternative gear, either to target the same species, or a different fishery.

Commercial Fisheries

Information for the Non-Technical Summary

Commercial fishing activities in the region within which the proposed EOWDC site is situated are considered to be at relatively low levels. Potting for crab and lobsters; demersal otter trawling for whitefish and nephrops; and dredging for scallops, account for the majority of the activity within the regional area.

With regards to the local area, from consultation with the Scottish Fishermen's Federation (SFF), local fishermen and the District Fishery Officer, it is understood that only four, 11-metre and under demersal trawlers actively fish in the area of the site, targeting mainly flatfish. Two of the vessels operate out of Aberdeen and two from Peterhead (Section 10.3 Baseline Assessment).

Whilst larger trawlers operating out of Aberdeen may transit through the site, in view of the operating costs of these larger vessels, the area of the site is not sufficiently productive to justify such vessels actually fishing within it.

The principal fishing grounds for potting are located further south and to the north of the site (Section 10.2 Baseline Assessment). During consultation with local potting skippers, it was stated that the proposed EOWDC site is not recognised as a productive potting ground.

In view of the limited number of turbines proposed, the small area of the site and the low level of fishing activity within it, the overall impacts on commercial fishing are expected to be negligible, although for a small number of local vessels, the potential impacts may be of minor significance.

Introduction

In the absence of published guidelines from Marine Scotland regarding the impacts that could potentially be sustained by commercial fishing via the introduction of offshore renewable developments in Scottish waters, the impacts requiring assessment for the proposed EOWDC development are as specified in the Cefas/MCEU (2004) Guidelines, which are as follows;

- Adverse impacts on commercially exploited species
- Complete loss of or restricted access to traditional fishing grounds
- Safety issues for fishing vessels
- Interference with fisheries activities
- Increased steaming times to fishing grounds
- Presence of seabed obstacles and obstruction
- Any other concerns raised by local fishermen and fishing organisations

The assessments of the above impacts are addressed separately for the construction/decommissioning phases and operational phase in terms of site specific and cumulative effects.
It is considered that the potential impacts associated with the decommissioning phase will be of no greater significance than those of the construction phase, and in view of the absence of piling will, in reality, be less.

Methodology Consultation

Consultation with local fishermen and other stakeholders was principally undertaken by the Scottish Fishermen's Federation (SFF) between 2008 and 2010. The SFF represent approximately 90% of Scottish fishermen.

In addition, direct consultation was undertaken with the skippers and owners of the vessels who were identified as fishing in the area of the development, and the District Fisheries Officer, between October 2010 and January 2011.

The individuals and organisations consulted were:

- Aberdeen District Fisheries Office (281010);
- Fisheries Research Services (211107);
- Scottish Fishermen's Federation (211107);
- Sydney McLean – Boy Paul – Peterhead (170111);
- Ricky Greenhowe – Skua II- Aberdeen (170111);
- John Anderson – Tern – Aberdeen (170111);
- Stuart Willox – Maddie Marie – Peterhead (170111); and
- Scottish Inshore Fish Producers Association (December 2007 &150211).

Key Guidance Documents

For both the baseline and impact assessments account has been taken of the following;

- Offshore Wind Farms, Guidance Note for Environmental Impact Assessment in Respect of FEPA and CPA Requirements - Version 2; Cefas, MCUE, Defra, DTI, June 2004
- Strategic Environmental Assessment (SEA) of Draft Plan for Offshore Wind Energy in Scottish Territorial Waters: Volume 1: Environmental Report; Marine Scotland 2010
- UK Offshore Energy – Strategic Environmental Assessment; DECC, January 2009
- Recommendations for Fisheries Liaison; FLOW, May 2008
- Fisheries Liaison Guidelines – Issue 5; UK Oil & Gas, 2008
- Guidelines to Improve Relations between Oil & Gas Industries and Near-shore Fishermen, UKOOA (renamed UK Oil & Gas), August 2006
- Fishing & Submarine Cables – Working Together, International Cable Protection Committee (CPC), February 2009
- Options and Opportunities for Marine Fisheries Mitigation Associated with Wind Farms, COWRIE 2010.
- Scoping Response -Marine Scotland (15.12.10)

Data Information and Sources

The principal data and information sources used were:

- International Council for the Exploration of the Sea (ICES)
- Marine Management Organisation (MMO)
- Marine Scotland, Marine Science (MS)
- Scottish Fisheries Protection Agency (SFPA)
- European Fisheries Commission (Europa)
- Brown & May Marine in-house databases

Impact Assessment Methodology

The assessment aims to describe the magnitude of effect for each potential impact (i.e. the change created by an activity in terms of its spatial extent, duration and scale) and the sensitivity of each receptor (i.e. the environmental resources that would be affected) based on its importance and recoverability. The effect and sensitivity of the receptor are then used to derive the significance of each potential impact. The criteria used in the assessment are given below:

Spatial Extent of Effect

- A national/international effect
- A regional effect
- A local, site specific effect including within 5km of the site

Duration of Effect

- A long term/permanent effect (more than 10 years)
- A medium effect (existing for 5 to 10 years)
- A short term effect (existing for 1 to 5 years)
- A temporary effect (existing for less than 1 year)

Scale of Effect

- Above accepted standards/guidelines
- Within accepted standards/guidelines
- Where there are no standards/guidelines available, the impact relative to background conditions

Recoverability of the Receptor

- High
- Medium
- Low or None

Importance of the receptor (taking into account international, national and regional legislation, and function within the ecosystem)

- High

- Medium
- Low or None

The impact significance is then given as ***MAJOR, MODERATE, MINOR*** or ***NEGLIGIBLE*** guided by the matrix given in Table 1.

Table 1 Matrix Used to Guide Significance Ratings of Impacts

		Sensitivity of Receptor			
		VERY HIGH	**HIGH**	**MEDIUM**	**LOW**
Magnitude of Effect (based on spatial, duration and scale)	**VERY HIGH**	Major	Major	Major	Moderate
	HIGH	Major	Major	Moderate	Minor
	MEDIUM	Major	Moderate	Moderate	Minor
	LOW	Moderate	Minor	Minor	Negligible
	NEGLIGIBLE	Minor	Negligible	Negligible	Negligible

Certain elements of the following assessments are based upon incomplete knowledge and data gaps. In such instances, the assessment may be based upon a number of assumptions and, therefore, a degree of uncertainty will exist.

Implications of Significance

Where the significance for a potential impact is classified as ***MODERATE*** *to* ***MAJOR*** or ***MAJOR****,* it is considered to be a potentially significant effect. It should be noted however that significant effects may not be unacceptable as their effect may be reversible. A ***NEGLIGIBLE*** significance is assigned to a potential impact if it produces no discernible effect on the environment resource in question.

Cumulative and In-combination Impact Assessment Methodology

The cumulative impact assessments have applied the same methodology and potential impacts outlined above.

In view of the limited number of vessels and their operational ranges in relation to the locations of designated Special Areas of Conservation (SAC) and Special Protected Areas (SPA) it is considered that there will be no in-combinations effects as defined under the Habitats Regulations Appraisal (HRA). Any impacts relating to salmon are dealt with in the EOWDC Salmon and Seat Trout Impact Assessment.

Cumulative impact assessments have been undertaken on all existing and any reasonably foreseeable project/development activities. The following elements that are considered to have the potential to contribute to cumulative impacts are;

- **Other Offshore Wind Farms**

The closest wind farm developments to the EOWDC site are the proposed Firth of Forth developments 58 km to the south and the Moray Firth developments 117 km to the north.

- **Shipping and Navigation**

The potential cumulative impacts associated with commercial shipping and navigation are discussed in Section 15 (Shipping and Navigation).

- **Offshore Oil Developments**

Currently available information suggests that within the foreseeable future, there will be no oil and gas exploration or production activities within the general area of the proposed EOWDC site which would contribute to cumulative effects. This activity has therefore been scoped out of the cumulative assessment process.

- **Introduction of Marine Protected Areas (MPAs)**

The Marine (Scotland) Act has established powers for the development of Marine Protected Areas (MPAs) in the seas around Scotland. These areas have yet to be defined so at present it is unclear as to the potential location of any future MPAs. It is however likely, given the nature of the seabed in the general area of EOWDC site, that no MPAs will be designated and as such will not contribute to a cumulative effect.

In terms of other spatial restrictions, as mentioned in the Baseline Assessment, there are no local fishing restrictions within 3 nm limit specific to the Aberdeen Bay area; however the use of mobile or active gear is prohibited during certain times of the year in four areas to the south of the site. These have therefore been scoped out of the cumulative assessment process.

- **Aggregate Dredging**

The Middle Bank licensed dredging area in the Firth of Forth, approximately 150 km from the EOWDC site is the closest licensed dredging area. It should also be noted however that at present it is not active. This activity has therefore been scoped out of the cumulative assessment process.

- **Other Offshore Works**

Due to erosion in Aberdeen Bay, the foreshore required beach replenishment works, with 70,000 cubic tonnes of material dredged from local offshore areas between July and August 2006. It is expected that such works will be required every five to seven years (pers. comm. FRS, 2007). It is therefore possible that beach replenishment works may occur within the general area of the EOWDC site during its lifespan.

- **Ocean Laboratory**

It is proposed that an Ocean Laboratory may be installed within the site and will be subject and separate application and EIA. As such, at this stage it will only be assessed in terms of its cumulative effect.

Assessment of Impacts against a Changing Baseline

A number of factors unrelated to the proposed EOWDC development may cause changes to the commercial fishing baseline over the life of the project. For instance, the trend in UK commercial fishing over the last 30 years has been one of decline. This trend, with specific reference to Aberdeen, is detailed further in the Baseline Assessment (Section 6.0).

Worst Realistic Case

As mentioned above, current trends in fishing indicate that levels of activity are unlikely to increase over the lifetime of the project. The impact assessment therefore assumes the current baseline as the worst realistic case in terms of the levels and types of fishing activity.

For the majority of impacts, the realistic worst case site layout is assumed to be the highest density of wind turbines within the site, i.e. 11 wind turbines, giving a minimum distance between turbine towers of 790 m. In terms of the smallest navigable distance between structures, the worst case would be jacket foundations which, with the implementation of 100 m safety zones, would leave spacing between turbines of 550 m. At present 50m safety zones around turbines are planned, which is in-line with other UK offshore wind farm sites. It is possible, however, that this zone could be up to 100 m and therefore 100 m should be assumed as worst case. A 200 m anchor exclusion is also planned around cables.

Impact Assessment

Adverse Impacts on Commercially Exploited Species

Construction & Decommissioning Phase

Potential Impacts

As discussed in Section 9 (Marine Ecology), the principal impacts which could adversely affect commercially exploited species, which are confined to the construction and decommissioning phases, are noise and vibration and habitat loss. Potting for crabs and lobsters, demersal otter trawling for whitefish and nephrops, and dredging for scallops accounted for the majority of the commercial fishing activity in the regional study area by recorded landings values.

Available research into the effects of noise and vibration suggests that the impacts on the main target species in the area of the development are not considered to be on the same scale as for hearing specialists such as clupeids (Nedwell & Howell, 2004). It is however accepted that fish and mobile shellfish species, such as crabs and lobsters, may temporarily vacate the site or a part of it as a result of noise or vibration disturbance.

The potential impacts on salmonids are discussed separately within the salmon and sea trout assessment for the proposed EOWDC.

As only 11 turbines are to be installed, the number of piling events will be small. Under normal conditions, based on data from wind farms constructed to date, the duration of piling individual foundations typically varies between 20 minutes and thirteen hours. For the purposes of assuming a worst case scenario, five days is taken as the theoretical maximum duration for the installation of a single foundation, with the worst case actual piling time being 24 hours continuous (further details in Chapter 3, Description of the Proposed Development).

Research at the Horns Rev Offshore Wind Farm also suggests that it is unlikely that there would be any significant long-term detrimental effect on the relevant commercial fish and shellfish stocks (Hydit *et al*., 2006). To date, within UK waters, there is no available research data regarding the recovery time of localised shellfish stocks following piling. Observations of potters in, for example, the operational Barrow Offshore Wind Farm, however, suggest that within a matter of months, crabs and lobsters return to an operational site in sufficient quantities to support resumption of commercial potting activities, indicating no longer term adverse impacts. Figure 1 shows a 10 metre potter which recommenced working in the operational Barrow wind farm site within a matter of months following completion of construction works.

Figure 1 10 metre Fishing in the Barrow Wind Farm

The installation of turbines and the laying and burial of the intra-field and export cables, is, as stated in Section 9, not expected to increase suspended sediment concentrations to levels which would have any significant adverse impact on commercially exploited species.

It is predicted that potential impact of the proposed EOWDC on commercially exploited species will be of *MEDIUM* sensitivity, *LOW* magnitude and therefore of *MINOR* significance.

Mitigation

In order to minimise, as far as is practically possible, any potential impacts from piling noise, in line with standard practice, soft start piling will be employed.

Residual Impacts

In view of the above, it is predicted that the potential site specific impact will be localised, temporary and at worst of *MINOR* significance and confined to the local area.

It is likely that the decommissioning phase would be over a shorter time frame than construction and would not involve piling. The impacts are therefore expected to be of lower significance than during the construction phase.

Cumulative Impacts

Other Offshore Wind Farms

The potential cumulative impact of noise and vibration and increased sediment concentrations, as a result of piling and cable burial activities from other offshore wind farm developments, is discussed in Section 9 (Marine Ecology). The closest wind farm developments to the EOWDC site are the proposed Firth of Forth developments 58 km to the south and the Moray Firth developments 117 km to the north. It is unlikely all three developments would be under construction or decommissioning at the same time. The potential cumulative impact has therefore been assessed to be of *NEGLIGIBLE* magnitude, *LOW* sensitivity and therefore of *NEGLIGIBLE* significance.

Shipping & Navigation

The principal impact which could adversely affect commercially exploited species during the construction or decommissioning phase is noise. This is discussed in Section 9 (Marine Ecology), which predicts the contribution to cumulative effects to be of *LOW* sensitivity, *LOW* magnitude and, as such, of *NEGLIGIBLE* significance.

Other Offshore Works

It is unlikely that beach replenishment works in Aberdeen Bay would coincide with the construction or decommissioning phase of the EOWDC. Should this occur however, the comparative sediment levels from the foundation piling and cable installations would be low, localised and over a short duration so that the contribution to cumulative effects would be of *LOW* magnitude with *LOW* sensitivity and therefore of *NEGLIGIBLE* significance.

Ocean Laboratory

In view of the limited number of wind turbines, the contribution of an additional piling event for the construction of the offshore Ocean Laboratory to cumulative effects is expected to be of *LOW* magnitude, *LOW* sensitivity and therefore of *NEGLIGIBLE* significance.

Operational Phase

Potential Impacts

As discussed in Section 9 (Marine Ecology), there is little evidence to suggest that the principal commercially targeted species, i.e. flatfish, in the proposed EOWDC site would be adversely affected by the electro-magnetic effects of inter-array and export cables.

It is therefore predicted that the potential impact will be of *LOW* magnitude, *LOW* sensitivity and therefore of *NEGLIGIBLE* significance.

Mitigation

The presence of foundation structures will provide refuge for mobile species and increase the surface area for colonisation of prey species and/or for the settlement of juvenile shellfish. The addition of scour protection, if used, would provide additional habitat and shelter for commercially important fish and shellfish species, thus resulting in a *BENEFICIAL* impact.

A study (Linley *et al*., 2007) undertaken on behalf of BERR on the reef effects of offshore wind farms supported this and provided the following findings:

- The structures may result in new habitat opportunities, extending the distributions of some mobile species such as crabs, lobsters and finfish, thereby enhancing the productivity of these populations and subsequently commercial fishing in the area;

- There is evidence to indicate that juveniles of some species such as whiting, crabs and lobsters preferentially use rocky reefs as a habitat which suggests that the scour protection on turbines may offer direct benefits to these species;

- The high niche diversity (including interstitial spaces between rocks) is likely to promote recovery from storm events, reduce predation and support a more bio-diverse community than could be expected from unprotected turbines.

Sampling programmes undertaken at the Horns Rev and Nysted Offshore Wind Farms concluded that the hard substrate around turbine bases was beneficial to the reproduction and growth of native mobile species such as crabs, providing shelter and nursery grounds (presented by S. Leonhardt at the Danish Monitoring Programme Conference, November 2006).

Residual Impacts

The residual impact of the proposed EOWDC on commercially exploited species during its operational phase is likely to be *NEGLIGIBLE* significance and in some cases potentially *BENEFICIAL* which in turn could have a *BENEFICIAL* effect for certain fishing methods such as potting.

Cumulative Impacts

As the operational EOWDC is expected to have no significant adverse impacts on commercially exploited species, it will therefore not make any contribution to cumulative effects.

Complete Loss of or Restricted Access to Traditional Fishing Grounds

Construction & Decommissioning Phase

Potential Impacts

The complete loss of, or restricted access to, traditional fishing grounds was the primary concern raised by local fishermen actively fishing in the area of the proposed EOWDC site. A significant adverse impact would only occur if there were no alternative local fishing areas of similar productivity. As shown by the Baseline Assessment, the levels of activity within the site are low and confined to very few local vessels. In addition, the overall area of the site is small and the construction phase over a relatively short period. As such, the potential impact has been assessed to be of *LOW* magnitude, *MEDIUM* sensitivity and therefore of *MINOR* significance for those local vessels known to fish the area.

Mitigation

Whilst construction safety procedures and schedules have yet to be finalised, it is envisaged that an exclusion zone will be in operation during the construction of the EOWDC. As a worst case approach, this would include a 500 m zone around all inter array cable, foundation and turbine installation works. In practice, it may be that smaller sections of the site would be subject to the exclusion zone at any one time. Similarly, during the export cable burial works, vessels not associated with the EOWDC would be expected to keep 500 m away from all cable installation works. Export cable burial is expected to take approximately 52 hours in total at 500 m/hour for a maximum length of 26 km.

On-going liaison will be maintained to ensure fishermen are informed of construction/decommissioning vessels schedules and routes.

Residual Impacts

In the national and regional contexts, the impact of loss of fishing area will be of *NEGLIGIBLE* significance. In the case of the four local vessels identified as fishing the area of the EOWDC site and export cable route the temporary residual impact is expected to be of *MINOR* significance.

Cumulative Impacts

Other Offshore Wind Farms

In view of the limited number of vessels actively fishing in the area, their operational ranges, and that the closest wind farm developments are 58 km and 117 km from the proposed EOWDC site, it is considered that the potential cumulative impact will be of *NEGLIGIBLE* magnitude, *LOW* sensitivity and subsequently of *NEGLIGIBLE* significance.

Shipping & Navigation

The potential cumulative effect with shipping and navigation is discussed in Section 15 (Shipping and Navigation) however, overall, it is considered to be *NEGLIGIBLE* magnitude, *LOW* sensitivity and therefore of *NEGLIGIBLE* significance.

Other Offshore Works

If beach replenishment works in Aberdeen Bay were to occur during the construction or decommissioning phase of the project, in view of the number of vessels involved, the potential impact would be of short duration and localised and as such considered to be of *NEGLIGIBLE* significance.

Ocean Laboratory

The cumulative effect of an additional piling event for the construction of the offshore Ocean Laboratory is expected to be of *LOW* magnitude, *LOW* sensitivity and therefore of *NEGLIGIBLE* significance.

Operational Phase

Potential Impacts

An adverse impact will only occur if fishing vessels which previously fished the site could not return to it once construction activities had been completed. As previously stated, only four demersal trawlers, who fish the area for only part of the year, have the potential to be impacted. The evidence given in the Baseline Assessment also suggests that the majority of these vessels fishing areas are inshore of the site.

As such in the national and regional contexts, the potential impact for larger vessels has been assessed to be of *LOW* magnitude, *LOW* sensitivity and subsequently of *NEGLIGIBLE* significance. In the case however, of the four local vessels identified as fishing the area of the EOWDC site, the impact is expected to be of *MEDIUM* magnitude, *MEDIUM* sensitivity and consequently of *MODERATE* significance.

Mitigation

Evidence from UK wind farms has shown that demersal trawling and certain other fishing methods can resume within operational wind farms. A minimum blade clearance height of 22 m is in excess of the air height of the largest UK fishing vessels. Figure 2 shows a 10 metre demersal trawler fishing inside the Kentish Flats Offshore Wind Farm and Figure 3 is a photograph taken onboard a 24 metre demersal trawler hauling its net inside the Barrow Offshore Wind Farm.

Figure 2 10 metre Vessel Fishing in the Kentish Flats Offshore Wind Farm

Figure 3 24 metre Vessel Fishing in Barrow Offshore Wind Farm

Residual Impacts

Whilst fishing may resume within the operational site once the construction exclusion zones have been removed, with some modifications to towing patterns and gears, there will be a small loss of fishing area resulting from the safety zones around the turbines which could result in an adverse impact of *MINOR* significance on the four local vessels known to fish the area.

This may however be compensated by increased concentrations of fish attracted into the site as a consequence of the addition of underwater structures, which has been shown to be the case in the Kentish Flats Offshore Wind Farm (pers. comm. Whitstable skippers 2011) The residual loss of fishing area is therefore considered to be of *NEGLIGIBLE* significance and there may in fact be potentially *BENEFICIAL* effect for certain methods.

Cumulative Impacts

Other Offshore Wind Farms

In view of the limited number of vessels actively fishing in the area, their operational ranges, and that the closest wind farm developments are 58 km and 117 km from the proposed EOWDC site, it is considered that potential cumulative impacts will be of *NEGLIGIBLE* magnitude*, LOW* sensitivity and subsequently of *NEGLIGIBLE* significance.

Shipping & Navigation

The potential cumulative impacts with commercial shipping and navigation are discussed in Section 15 (Shipping and Navigation) and are assessed to be of *NEGLIGIBLE* magnitude*, LOW* sensitivity and therefore of *NEGLIGIBLE* significance*.*

Other Offshore Works

If beach replenishment works in Aberdeen Bay were to occur, it could result in some temporary loss of close inshore fishing areas. As such the cumulative impact has been assessed to be of *LOW* magnitude*, LOW* sensitivity and therefore of *NEGLIGIBLE* significance.

Ocean Laboratory

The cumulative effect of an offshore Ocean Laboratory is expected to be of *NEGLIGIBLE* magnitude, *LOW* sensitivity and therefore of *NEGLIGIBLE* significance.

Safety Issues for Fishing Vessels

Construction & Decommissioning Phase

Potential Impacts

In line with standard practice, construction exclusion zones will be in place around all offshore construction activities from which all vessels other than construction vessels will be excluded. Risks to fishing vessels safety would therefore only occur if infringements of these safety zones occurred. It should also be recognised that in line with standard maritime practice, the ultimate responsibility in regards to safety lies with the master of a vessel. With compliance with the imposed safety zones, the safety risks to fishing vessels should be within acceptable limits. This issue is considered further within the Navigational Risk Assessment (appendix 15.1).

Mitigation

Obligatory formal notices (Notice to Mariners), fisheries liaison and distribution channels will be established to ensure that construction and safety information is efficiently and effectively disseminated to the relevant skippers and vessel owners.

It is also envisaged that the Scottish Fishermen's Federation (SFF), who have over 30 years experience in dealing directly with oil interests in the North Sea, will play an important role in fisheries liaison and information distribution.

The Navigation Risk Assessment (Section 15) considers that, providing skippers of fishing vessels are aware of, and respect, safety exclusion zones, the safety risks during construction would be within acceptable limits.

Operational Phase

The safety issues associated with the operational phase are discussed in Section 15 which considers that with appropriate mitigation in place any potential impacts are deemed to be of low significance.

Providing standard offshore safety procedures are implemented and skippers of fishing vessels adhere to them, the safety risks would be considered to be within acceptable limits.

Interference to Fishing Activities

Construction & Decommissioning Phase

Potential Impacts

All of the potential impacts included in this assessment could be considered to cause interference to fishing activities. The only other impact yet to be considered is the potential navigational conflicts which may arise between construction/decommissioning/survey vessels and fishing vessels such as the fouling of static gear marker buoys and dhans or causing trawlers to change their towing directions. Due to the low number of fishing vessels in the proposed EOWDC area the potential impact has been assessed to be of *LOW* magnitude, *MEDIUM* sensitivity and therefore of *MINOR* significance.

Mitigation

Where possible, construction and decommissioning vessels will adhere to established transit routes. On-going liaison will also be maintained to ensure fishermen are informed of construction vessels schedules and routes.

Contractors laying and trenching the export cable will also be obliged to adhere to standard fisheries notification and liaison procedures as specified by the International Cable Protection Committee (ICPC).

Liaison will also be undertaken to identify the locations of static gears to provide contractors with the required information in order to enable them to avoid conflicts with static gears.

Residual Impacts

With the procedures described above, residual impact is expected to be of *NEGLIGIBLE* significance.

Cumulative Impacts

Taking into consideration the limited number of vessels actively fishing in the area, the distance from other developments and activities, and with adherence to standard procedures and on-going liaison, the potential of cumulative interference effects are predicted to be of *NEGLIGIBLE* significance.

Operational Phase

Residual Impacts

It is predicted that, with adherence by maintenance vessels to the same procedures as described above for construction vessels, the impact will be of *NEGLIGIBLE* significance.

Cumulative Impacts

Similarly, as with the construction and decommissioning phases, there is not expected to be any significant cumulative effects.

Increased Steaming Times to Fishing Grounds

Construction & Decommissioning Phase

Potential Impacts

The implementation of safety exclusion zones, described above, could in theory, result in short-term increases in steaming distances and times, and therefore higher operational costs. In the worst case, the entire site would be closed to all vessels, including fishing vessels for the duration of construction and decommissioning activities. The experience of the construction of wind farms in the UK to-date however indicates that this is unlikely to be the case with exclusion zones being temporary and transitory around specific construction activities.

Figures 8.1 to Figures 8.8 in the Baseline Assessment give examples of 15 metre and over UK fishing vessels entering and exiting Aberdeen harbour through the area of the proposed EOWDC site in transit to fishing grounds further afield. It can be seen that these vessels steam to fishing grounds often in excess of 200 nm from Aberdeen Harbour and any increase in overall steaming distances and times due to deviations around the site would be considered to be minimal. As such the potential impact has been assessed to be of *LOW* magnitude, *LOW* sensitivity and subsequently of *NEGLIGIBLE* significance.

In the case of the smaller local vessels, a significant proportion of their traditional fishing grounds are located inshore of the EOWDC site, as indicated by the example of plotter tracks shown in the Baseline Assessment (Figure 10.11). It is however accepted that during the construction and decommissioning phases, there may be occasions when the presence of safety exclusion zones may temporarily increase the steaming times of local vessels with a history of fishing in and around the EOWDC site area. As a result, the potential impact is considered to be of *LOW* magnitude, *MEDIUM* sensitivity and subsequently of *MINOR* significance.

Mitigation

During the construction and decommissioning phases, the appropriate notifications will be provided, and on-going liaison will be maintained, to keep skippers of fishing vessels informed of the schedule of the imposition of exclusion zones around construction and decommissioning activities.

Residual Impacts

In the case of the larger class of vessels, whose fishing grounds are considerable distances from the site, it is predicted that the impact on steaming times will be of *NEGLIGIBLE* significance. For the smaller local vessels the temporary impact will be of *MINOR* significance.

Cumulative Impacts

Other Offshore Wind Farms

The potential cumulative impacts are considered to be of *NEGLIGIBLE* significance, with a *NEGLIGIBLE* magnitude and *LOW* sensitivity, as the closest wind farm developments are 58 km and 117 km from the proposed EOWDC site.

Shipping & Navigation

The potential cumulative impacts with commercial shipping and navigation are discussed in Section 15 (Shipping and Navigation) and expected to be of *NEGLIGIBLE* magnitude, *LOW* sensitivity and therefore of *NEGLIGIBLE* significance.

Other Offshore Works

If beach replenishment works in Aberdeen Bay were to occur at the same times as construction and decommissioning activities, it could result in some temporary increases to steaming times. As such the potential cumulative impacts has been assessed to be of *LOW* magnitude*, LOW* sensitivity and therefore of *NEGLIGIBLE* significance.

Ocean Laboratory

The cumulative effect of an offshore Ocean Laboratory is expected to be of *NEGLIGIBLE* magnitude, *LOW* sensitivity and therefore of *NEGLIGIBLE* significance.

Operational Phase

Potential Impacts

An adverse impact on steaming times would only occur if fishing vessels were prohibited or were unable to safely steam through the operational EOWDC site. Consultation undertaken by the SFF with fishermen and their representatives has identified concerns regarding the safety of steaming through operational wind farms.

The worst case scenario of 11 turbines with jacket foundations would result in a minimum navigable distance between turbine centres of 550 m, this allows for a 100 m exclusion zone and turbine base. This distance is substantially greater than many commercial harbour approach channels and entrances, including Aberdeen Harbour.

As a result the potential impact is predicted to be of *LOW* magnitude*, LOW* sensitivity and therefore of *NEGLIGIBLE* significance.

Mitigation

As stated above, there is evidence to show that fishing vessels fish within operational wind farms where the distance between turbine rows range from 500 m to 700 m, e.g. Kentish Flats Offshore Wind Farm and Barrow Offshore Wind Farm. It is therefore reasonable to assume that in the appropriate conditions it should be possible for fishing vessels to steam through the EOWDC site.

Residual Impacts

As fishing and other vessels should be able to steam through the operational site, the impact on steaming times and distances during the operational phase is predicted to be of *NEGLIGIBLE* significance.

Cumulative Impacts

As the potential impact of the operational site on steaming times and distances has been assessed to be of *NEGLIGIBLE* significance, there is no potential for cumulative impacts.

Presence of Seabed Obstacles and Obstructions

Construction & Decommissioning Phase

Potential Impacts

Waste or debris left on the seabed by construction or decommissioning vessels could result in damage or loss of fishing gears, as well as representing a safety hazard. Offshore works such as cable trenching, construction vessel anchoring or jack up legs can produce seabed obstructions which have caused fastenings and damage to fishing gears.

As such, the potential impact is considered to be of *HIGH* sensitivity, *LOW* to *HIGH* magnitude and therefore of *MINOR to MAJOR* significance.

Mitigation

Contractors engaged will be contractually obliged and monitored to ensure compliance and adherence to company and standard offshore policies prohibiting the discarding of objects or waste at sea. They will also be required to report and recover any accidentally dropped objects. Furthermore seabed obstructions and spoils identified during post-construction monitoring, which might represent a hazard to fishing, will be rectified.

Residual Impacts

With compliance to obligatory standards by contractors and, if necessary, the implementation of rectification measures, the residual impacts are expected to be within acceptable limits and as such to be of *NEGLIGIBLE* significance.

Cumulative Impacts

As the impacts associated with construction and decommissioning phases of the EOWDC site are considered to be of *NEGLIGIBLE* significance, there is no potential for cumulative effects.

Operational Phase

As maintenance contractors will be under the same contractual obligations as construction and decommissioning contractors, the cumulative impacts of seabed obstacles will be the same as for the construction and decommissioning phases, i.e. of *NEGLIGIBLE* significance.

EOWDC Future Research and Monitoring Opportunities

The proposed EOWDC is designated as a development site in close proximity to a major fishing port; as such Marine Scotland's research facility offers opportunities for projects to be undertaken to research practical measures for enhancing the co-existence between operational wind farms and commercial fishing. Such projects could include:

- Trials using local fishing vessels to demonstrate the most appropriate and effective operating practices within operational wind farms for a variety of fishing methods.

- Sampling surveys using local fishing vessels to monitor potential reef effects during the operational phase.

- Trials into the practical and commercial viability of other fishing methods not currently used in the area by local vessels but which could be feasibly and productively deployed within operational wind farms.

Summary of Impact Assessment

A summary of the various impacts assessed above is given in Table 2. As is apparent, the overall impact of the proposed EOWDC on commercial fishing is expected to be very small, being for the most part *NEGLIGIBLE* and in the few cases where discernable impacts might occur, they will be of no more than of *MINOR* significance.

In the national and regional contexts, in view of the limited number of turbines and the comparatively small area of the site, and relatively low levels of fishing activity, it is to be expected that the overall impact on commercial fishing will be so low as to be of *NEGLIGIBLE* significance.

With regards to the local context, the Baseline Assessment has determined that only four local vessels fish the site area and export cable route to any significant extent, and the fishing effort that does occur is at relatively low levels and seasonal. Whilst there could be some temporary impacts of *MINOR* significance associated with loss of fishing area during the construction and decommissioning phases, every endeavour will be made to liaise with skippers to mitigate these as far as is practically possible.

Once operational, it is expected that fishing will be able to resume within the site, however, changes in operating patterns maybe required, such as changing established towing patterns and some gear modifications e.g. shortening the fleet lengths of potting gear and fixed nets. It is possible, that as found in the operational Kentish Flats and Barrow Offshore Wind Farms, there may be a beneficial reef effect whereby fishermen can exploit concentrations of fish and shellfish attracted into the site.

As stated above, the EOWDC is to be an experimental site and should practical trials into the coexistence between commercial fishing and the operational site be undertaken, local vessels, provided they are suitably certified, could be used for the undertaking of such trials.

As discussed in chapter 9 (marine ecology) the principal impacts which could adversely affect commercially exploited species during the construction and decommissioning phases are noise, vibration and habitat loss and suspended sediment. After mitigation these impacts are deemed, at worst, to be of *MINOR* significance and confined to the local area. There is little evidence to suggest that the principal commercially targeted species, i.e. flatfish, in the proposed EOWDC site would be adversely affected by the electro-magnetic effects of inter-array and export cables during the operational phase, the potential impact is therefore deemed to be of *NEGLIGIBLE* significance.

Cumulative impacts are, for the most part, expected to be of *NEGLIGIBLE* significance. This is a consequence of the little offshore development, either existing or planned, in the vicinity of the site. Furthermore, as the EOWDC development is expected to result in very few impacts above *MINOR* significance, and those which do occur would be temporary and localised, the contribution of the development to cumulative impacts is expected to be minimal.

Table 2 Environmental Impact Assessment Summary Matrix

Potential Impact/ Activity	Receptor	Spatial extent	Duration	Magnitude	Probability of effect occurring	Sensitivity	Significance level	Mitigation measures and rationale	Significance level after mitigation
CONSTRUCTION AND DECOMMISSIONING									
Adverse impacts on commercially exploited species	All vessels	Local	Temporary	Low	Uncertain	Medium	Minor	Use of appropriate engineering techniques, e.g. soft start piling. Low sensitivity of principal target species.	Minor
Complete loss of, or restricted access to traditional fishing grounds	Larger vessels Local vessels	Local	Temporary	Low	Certain	Low Medium	Negligible Minor	Effective, on-going liaison	Negligible for larger vessels Possibly minor for local vessels
Safety issues for fishing vessels	All vessels	Local	Temporary	Low to High	Unlikely	High	Minor to major if collision occurred	Implementation and adherence to standard offshore safety procedures. Involvement of the SFF for liaison and information distribution.	Within acceptable limits
Interference to fishing activities	All vessels	Local	Temporary	Low	Unlikely	Medium	Minor	Construction vessels using existing shipping routes. On-going liaison informing skippers of construction vessels schedules and routes.	Negligible
Increased steaming times to fishing grounds	Larger vessels Local vessels	Local	Temporary	Low	Unlikely Likely	Low Medium	Negligible Minor	Transitory, short term exclusion areas around construction activities within the site. Limited numbers of potentially impacted vessels. Low probability of a significant number of steaming routes likely to be affected.	Negligible for larger vessels Possibly minor for local vessels

Potential Impact/ Activity	Receptor	Spatial extent	Duration	Magnitude	Probability of effect occurring	Sensitivity	Significance level	Mitigation measures and rationale	Significance level after mitigation
Presence of seabed obstacles and obstructions	All vessels	Site-specific	Temporary	Low to High	Uncertain	High	Minor to major if fastening occurred	Contractors are required to report and recover any accidentally dropped objects. Seabed obstructions and spoils identified during post-construction monitoring, which might represent a hazard to fishing, will be rectified.	Within acceptable limits
Restriction of access during laying of export cables	All vessels	Local	Temporary	Low	Certain	Low to medium	Negligible, possible minor for some local vessels	Short duration and small transitory area of exclusion. Limited numbers of potentially affected vessels.	Negligible, possibly minor for some local vessels
OPERATIONAL									
Adverse impacts on commercially exploited species	All vessels	Local	Temporary	Low	Unlikely	Low	Negligible	The presence of underwater structures will provide refuge for mobile species and increased surface area for colonisation of prey species and/or the settlement of juvenile shellfish. Scour protection, if used, will likely offer additional habitat for species by providing shelter and nursery grounds.	Negligible to beneficial
Complete loss of, or restricted access to traditional fishing grounds	Larger vessels Local vessels	Local	Permanent	Low Medium	Unlikely Likely	Low Medium	Negligible Moderate	Certain fishing practices may resume within the operational site with some modification to operating practices.	Negligible to beneficial Minor

Potential Impact/ Activity	Receptor	Spatial extent	Duration	Magnitude	Probability of effect occurring	Sensitivity	Significance level	Mitigation measures and rationale	Significance level after mitigation
Safety issues for fishing vessels	All vessels	Site-specific	Permanent	Low to High	Unlikely	High	Minor to Major if collision occurred	Implementation and adherence to standard offshore safety procedures.	Within acceptable limits
Interference to fishing activities	All vessels	Local	Permanent	Low	Unlikely	Medium	Minor	Maintenance vessels using existing shipping routes. On-going liaison informing skippers of maintenance vessels schedules and routes.	Negligible
Increased steaming times to fishing grounds	All vessels	Local	Permanent	Low	Unlikely	Low	Negligible	Potential for fishing vessels to steam through the site in favourable conditions. Limited numbers of potentially impacted vessels. Low probability of a significant number of steaming routes likely to be affected.	Negligible
Presence of seabed obstacles and obstructions	All vessels	Site-specific	Temporary	Low to High	Uncertain	High	Minor to Major if fastening occurred	Contractor obligations and standard offshore practices should have removed obstructions and obstacles. Any scour protection rock placement would be adjacent to wind turbine bases.	Within acceptable limits
Damage to fishing gear/vessels from exposed cables	All vessels	Site-specific	Temporary	Low to High	Unlikely	High	Minor to Major	Cable burial to at least 0.6 m depth. Implementation and adherence to standard offshore safety procedures. Cable route surveys. Temporary exclusion zones until issues are rectified.	Negligible to Minor

1.0 Introduction

The following document describes the current salmon and sea trout ecology and fisheries baseline assessment for the proposed European Offshore Wind Deployment Centre (EOWDC).

Scottish salmon populations are recognised as being of national and international importance (Malcolm *et al.*, 2010). In addition to their ecological value, salmon and sea trout are species of importance from a socioeconomic perspective on a local, regional and national level in Scotland.

2.0 Summary

2.1 Ecology

Salmon and sea trout smolts migrate seawards in the spring, generally from April to June. The seaward migration in both species is thought to be an active process with fish swimming close to the surface and it does not appear to be a period of acclimation when moving from fresh to salt water.

Salmon post-smolts make limited use of the estuarine environment moving quickly to the open sea towards their feeding grounds. Limited research carried out to date suggests post-smolts may travel relatively close to the coast in the initial phases of their migration.

Salmon originating in rivers from Aberdeenshire southwards are thought to migrate back from their feeding grounds through the North Sea, approaching the coast as far south as Northumberland and then start a northerly coastal migration towards their home rivers. Grilse (one sea winter salmon) enter the rivers from early summer until shortly before spawning in autumn, whilst multi sea winter salmon enter the rivers over a greater period of time.

Unlike salmon, sea trout post-smolts are not believed to travel to distant waters to feed; instead they generally remain in coastal waters. In the North East region sea trout generally enter the rivers from June to September with peak runs varying between rivers.

2.2 Fisheries

The right to fish for salmon in Scotland is a heritable right, whether in inland waters or at sea. The fisheries are managed by their owner or leaseholder under a framework of regulations laid down by central government. Under Scottish legislation the term salmon applies to both salmon and sea trout.

In the salmon fishery districts located in close proximity to the proposed EOWDC, the Ythan, Don and Dee, the majority of the total salmon and sea trout catch comes from the rod-and-line fishery. Net fisheries are however of relative importance in other districts within the regional area, such as the Ugie and more significantly the Esk.

The Don is the salmon fishery district located in the immediate vicinity of the proposed EOWDC. The majority of the reported catch in the district is by rod-and-line, a high percentage of which is by catch and release. Reported catches by the net fishery are comparatively low, with no net-and-coble currently taking place in the district and fixed engines recording very low reported catches in recent years.

3.0 Study Area

For the purposes of this assessment the study area has been defined on a local, regional and national scale (Figure 3.1). The local area comprises the zone relevant to the salmon fishery district located in the immediate vicinity of the EOWDC, the Don, whilst the regional area includes all the salmon fishery districts within the North East region; Ugie, Ythan, Don, Dee and Esk. Given the migratory behaviour of salmon and sea trout and the relative importance of the fishery across the country, a national focus has also been briefly described.

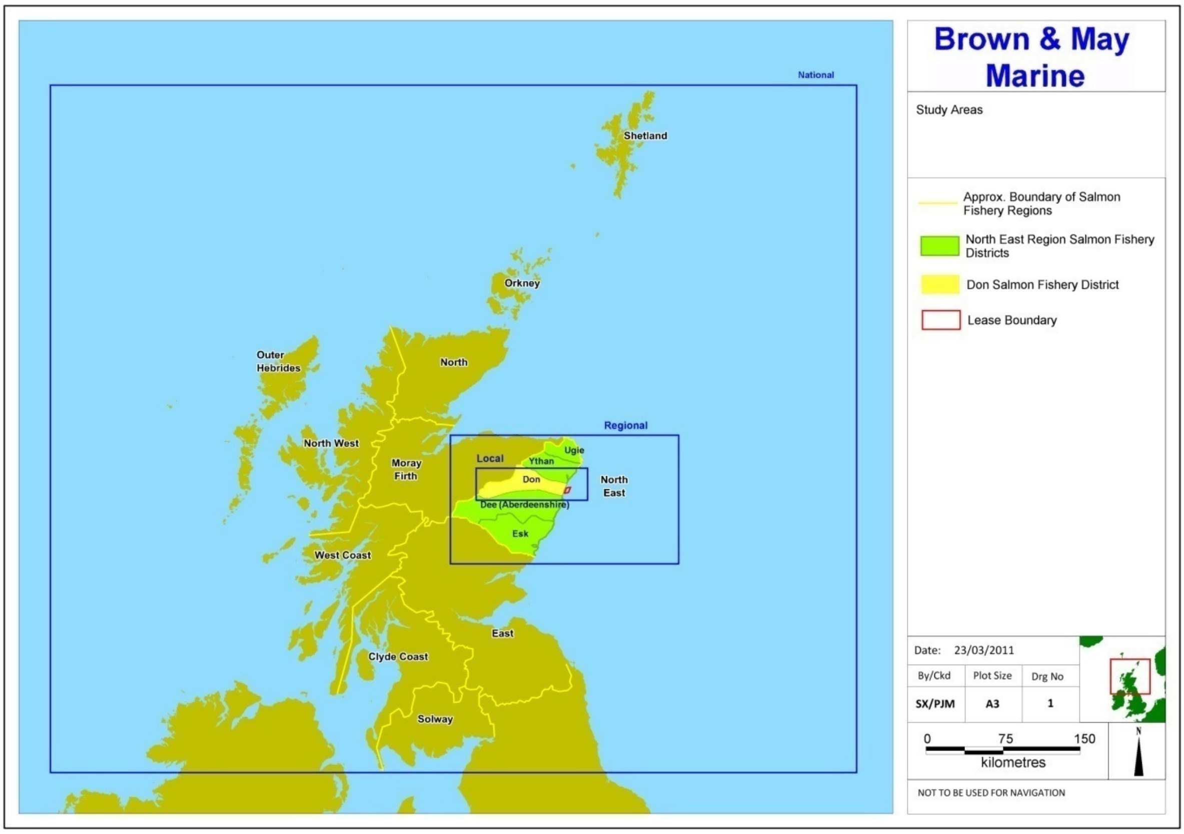

Figure 3.1 Study Areas

4.0 Methodology

4.1 Consultation

Consultation meetings were held with all the District Salmon Fishery Boards located within the North East region and with representatives of the netting fishery in the North East.

These were as follows:

- Ugie District Salmon Fishery Board (26/10/2010)
- Ythan District Salmon Fishery Board (26/10/2010)
- Don District Salmon Fishery Board (27/10/2010)
- Dee District Salmon Fishery Board (17/01/2011)
- Esk District Salmon Fishery Board (27/10/2010)
- Usan Fisheries (Montrose) (17/02/2011)

In addition to the above meetings, questionnaires were circulated to all the salmon district fishery boards in Scotland, through the Association of Salmon Fishery Boards (ASFB), and to netsmen, through the Salmon Net Fishing Association of Scotland. This process was aimed at gathering information at a national level and to note the main concerns of the boards and the netsmen with regards to wind farm developments in Scotland. At the time of writing, a sample of 14 salmon boards, netsmen and other organisations have completed and returned the questionnaires (See Appendix 01).

Consultation with coastal netting individual right holders will be undertaken once the location of the export cable is defined.

4.2 Key Guidance Documents

The following guidance documents have been used for undertaking this baseline assessment:

- Strategic Environmental Assessment (SEA) of Draft Plan for Offshore Wind Energy in Scottish Territorial Waters: Volume 1: Environmental Report; Marine Scotland 2010
- Offshore Wind Farms, Guidance Note for Environmental Impact Assessment in Respect of FEPA and CPA Requirements - Version 2; Cefas, MCUE, DTI, June 2004.
- Marine Scotland Scoping Response (December 2010 and January 2011 update)
- Scottish Natural Heritage Scoping Response (29/09/2010)
- Scottish Environment Protection Agency Scoping Response (24.09.2010)
- UK Offshore Energy – Strategic Environmental Assessment; DECC, January 2009
- Recommendations for Fisheries Liaison; FLOW, May 2008

4.3 Data and Information Sources

There is no standard guidance for the establishment of salmon and sea trout fisheries baseline assessments in relation to offshore wind farm developments. A range of different data and information sources have therefore been used to inform this assessment. These are as follows:

- Marine Scotland Science (MSS)
- Association of Salmon Fishery Boards (ASFB)
- Salmon Net Fishing Association of Scotland
- North East Region District Salmon Fishery Boards and Fisheries Trusts
- Atlantic Salmon Trust
- Scientific papers and other relevant publications

4.4 Data & Information Sensitivities, Limitations and Gaps

4.4.1 MSS Salmon & Sea Trout Fisheries Catch Statistics

MSS catch statistics divide salmon catches into "salmon" and "grilse". In this context, the term salmon refers to multi-sea-winter salmon (MSW) whilst grilse refers to one-sea-winter salmon (1SW).

Each fishery in Scotland is required to provide the number and total weight of salmon and grilse and sea trout caught and retained in each month of the fishing season.

Rod and line fisheries are also required to provide the monthly numbers and total weight of those salmon, grilse and sea trout which were caught and released back into the river, this practice is known as “catch and release”. As a result, MSS catch data for the rod and line fishery is broken down into two categories, “rod and line” and “catch and release”. It should be noted that the total catch by the rod and line fishery is in effect the sum of the catches recorded in both categories. Where appropriate, data from both categories have been combined to give an indication of the total rod and line catch. Similarly, the catch by net and coble and fixed engines (bag and stake nets) has been combined in some instances to provide an indication of the total catch by the net fishery.

The catch data used for the purposes of this assessment are as reported. It is recognised that there may be a degree of error within the catch dataset due to misclassification of fish between the grilse and salmon categories. In addition, further errors as a result of misreporting of catches may also exist. The data used are as provided by Marine Scotland Science on 08/10/2010.

The catch data used in this report are Crown copyright, used with the permission of Marine Scotland Science. Marine Scotland is not responsible for interpretation of these data by third parties.

4.4.2 Salmon Fishery Regions and Districts

Each salmon fishery district applies its own voluntary or statutory conservation code, closure times, policies and regulations and has in place different management and conservation schemes (e.g hatcheries, fish counters, water quality control and monitoring schemes). In addition, different districts include varying numbers of rivers and tributaries within their jurisdictions and have different catchment areas.

The areas and names of some districts have changed over time. In the regional study area, for example, catch statistics are collected for the South Esk, North Esk and Bervie districts separately, however, these districts were superseded by the Esk Salmon Fishery District and abolished in 1988 (S.I, 1998/ 994). For the purposes of this assessment the former, smaller districts will be used as they provide a better spatial resolution for analysis of catch data.

The boundaries of the salmon fishery regions and districts could not be provided by MSS as GIS data layers as a result of third party copyright ownership of these data. The district and region boundaries shown in the charts provided in this report were produced by geo-referencing a raster image. These should therefore be taken as approximate and for illustrative purposes only.

4.4.3 Data Gaps

There is limited information available to date to accurately define the migratory routes and patterns of Scottish salmon and sea trout. Furthermore, the spatial resolution of the available data and information does not allow for the numbers and the origin of the fish potentially migrating through or near the proposed EOWDC to be evaluated.

It is also recognised, that current knowledge on salmon exceeds that of sea trout. As a result some aspects of the ecology assessment given below have been covered in greater detail for salmon than for sea trout.

5.0 Salmon & Sea Trout Ecology Baseline Assessment

5.1 Introduction

Atlantic salmon *(Salmo salar)* and sea trout *(Salmo trutta)* are anadromous migratory species which utilise both freshwater and marine habitats during their life cycles. Both are species of the family *Salmonidae*, being commonly referred to as salmonids.

Atlantic salmon is widely distributed within the EU, from Portugal in the south to Sweden and Finland in the north. The UK salmon population, however, comprises a significant proportion of the total European stock, with Scottish rivers being a European stronghold of the species (JNCC, 2010). The distribution of salmon rivers in Scotland is shown in Figure 5.1 below.

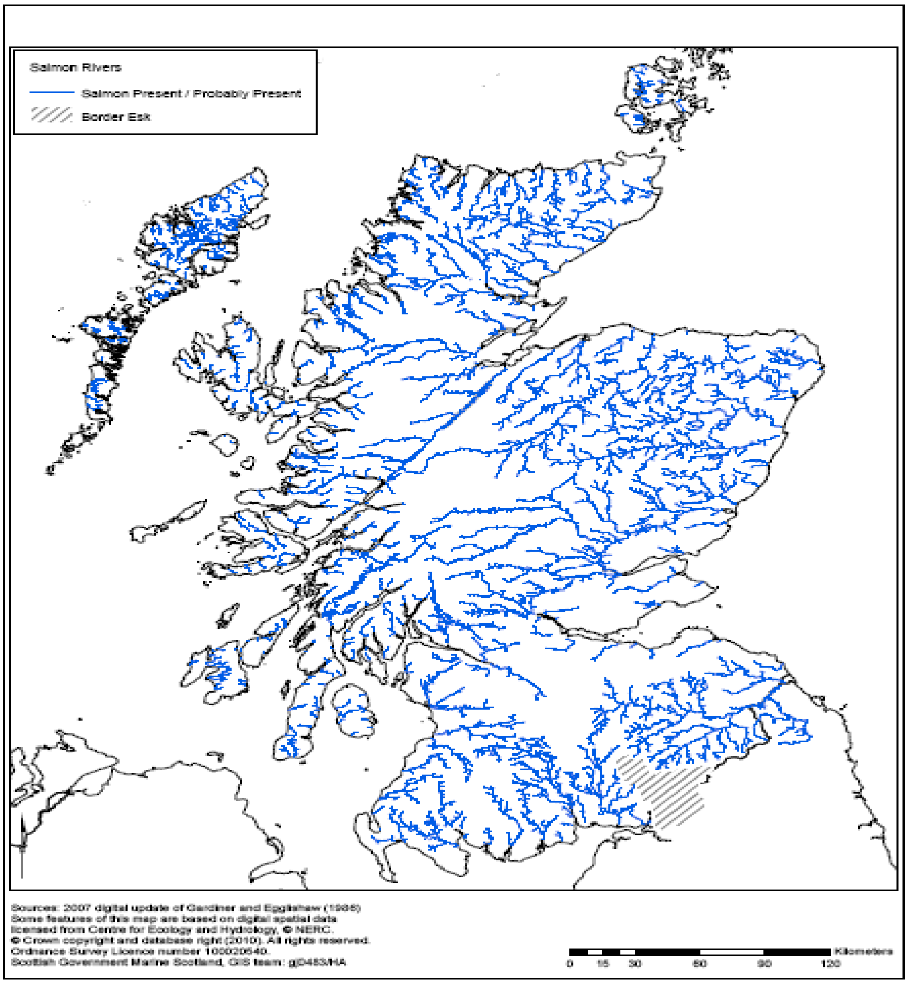

Figure 5.1 Distribution of Salmon Scottish Rivers. Updated from original salmon distribution map of Gardiner and Egglishaw (1985) (Source: Malcolm *et al*., 2010)

Sea trout is the migratory form of the common and widely distributed brown trout. Both forms are recognised as the same species and are present together with Atlantic salmon in many Scottish rivers. The distribution of sea trout in western Europe extends from north Portugal to the White Sea and Cheshkaya Gulf, including Iceland and the Baltic Sea (Elliott, 1994).

5.2 Life cycle

5.2.1 Salmon

The early development of Atlantic salmon takes place in freshwater, where they undergo a number of physiological changes to become 'smolts', the form in which they migrate to sea.

Spawning takes place in late autumn in the rivers. Eggs are deposited in redds (nests excavated by the females in gravelly substrates). The eggs hatch the following early spring.

Newly hatched salmon, known as 'alevins', remain hidden in the riverbed gravels feeding from the attached yolk sac. Once the yolk sac has been depleted the alevins are known as 'fry' and start feeding on small invertebrates. Salmon fry grow quickly during the first year increasing in size to become 'parr'.

Parr remain in the river for one to four or five years, depending on water temperatures and food availability. In Scottish rivers they most commonly stay in the river for two or three years

In spring, once parr have reached a length of 12-14 cm, they undergo a transformation both externally and internally, which allows them to adapt to salt water. They are then known as 'smolts'. Smolts move down rivers in April to June to start their oceanic migration. Once they enter the sea they are known as post-smolts, until the spring of the following year (Malcolm *et al*., 2010)

After one or more years feeding at sea salmon return to their home rivers to spawn, this generally occurs in late autumn or early winter. The amount of time spent at sea prior to the spawning migration varies from one winter for 'grilse' to up to four for 'multi-sea-winter' salmon (MSW).

Once they have spawned salmon are known as "kelt". Whilst the majority of Atlantic salmon (90-95%) die following their first spawning, some individuals survive and may spawn up to seven or more times during their lifetime. The majority of repeat spawners, however, survive to spawn only once or twice in their lifetime (Flemming, 1996). The survivors are predominantly female and return to sea to feed between spawning (Mills *et al*., 2003).

A summary of the basic salmon life-stage terminology is given in Table 5.1 below.

Table 5.1 Basic salmon life-stage terminology (Hendry & Cragg-Hine, 2003)

Development Stage		Description
1	Alevin	From hatching to end of dependence on yolk sac for primary nutrition
2	Fry	From independence of yolk sac to end of first summer
3	Parr	From end of first summer to migration as smolt
4	Smolt	Fully silvered juvenile salmon migrating to sea
5	Post-smolt	From departure from river to end of first winter in the sea
6	Grilse	Adult salmon after first winter in sea
	Multi-sea-winter (MSW)	Adult salmon after more than one winter in sea, commonly referred to as "spring" fish when entering river before June
7	Kelt	Spent or spawned adult

5.2.2 Sea trout

The life cycle of the sea trout is similar to that of Atlantic salmon. Spawning generally occurs between mid October and January. Smolting takes place in spring once a threshold size is reached. Most sea trout populations in the UK become smolts after two or three years in the river (AST, 2010a). Smolts leave the river around the same time as salmon, between April and early June (SNH, 2010). Female individuals are more likely to become smolts and migrate to sea (MSS, 2010a; SNH, 2010).

Most sea trout return to the rivers after twelve or more months at sea. These can be seen in the rivers between May and October (SNH, 2010) and are often found together in the same redds as brown trout as spawning time approaches in late autumn (MSS, 2010a).

Some immature fish return to the rivers after only a few months at sea, often in July and September (SNH, 2010). These are small fish, regionally known as 'finnock', 'herling' or 'whitling' and are found feeding in most Scottish estuaries as they move in and out with the tide (MSS, 2010a). Many gather in larger rivers and lochs, not necessarily in their natal systems, and over-winter in fresh water before returning to the sea in spring.

Unlike salmon, a significant proportion of spent sea trout kelts survive and make their way back to sea to recover and grow (SNH, 2010). Once they start to return they are annual spawners. There is however evidence of alternate year spawning as opposed to annual spawning in some stocks with long distance migrations (Solomon, 2007).

Some individuals return to the sea soon after spawning (mid October-December) whilst others remain in the rivers and estuaries, migrating out in the spring (AST, 2010a).

5.3 Migrations

A summary of the information currently available on salmon and sea trout migrations, primarily based on the review paper "Review of Migratory routes and behaviour of Atlantic salmon, sea trout and European eel in Scotland's coastal environment: implications for the development of marine renewables", recently published by MSS (Malcolm *et al.* 2010), including a number of other relevant research publications, is given below. The migratory patterns and behaviour of salmon and sea trout in the vicinity of the proposed EOWDC has been the primary focus.

5.3.1 Salmon

5.3.1.1 Smolt and Post-Smolt Migration

The beginning of the down river migration of smolts is thought to be related to environmental factors such as temperature and water flow (McCormick *et al.*, 1998). The importance of these factors may however be variable and stimulate migration in different ways (Carlsen *et al*., 2004). Downstream migration within the river is mainly nocturnal and often triggered by increases in flow (Hendry & Cragg-Hine, 2003; Moore *et al.*, 1998a). In addition, social factors, such as the presence of other migrants in the river, may also play a role (Hansen & Jonsson, 1985; Hvidsten *et al*., 1995).

It is believed that salmon smolts use environmental cues in the rivers related to favourable ocean conditions allowing them to arrive at sea at an appropriate time (Hvidsten *et al*., 2009). Smolts from upper tributaries generally start migration earlier than those from lower tributaries, resulting in a synchronised sea entry of smolts from the same watershed (Stewart *et al.* 2006). Timing in the spring migration may therefore play an important role in salmon post-smolt survival at sea (Aas *et al.*, 2011).

Studies of the movement of Atlantic salmon post-smolts indicate active, directed swimming during migration, rather than passive drifting, with fish generally moving close to the surface (Lacroix *et al*., 2005; Lacroix *et al.*, 2004). It is suggested that there is no apparent period of acclimation required when moving from fresh to saltwater (Moore *et al.*, 1998a; Lacroix and McCurdy, 1996). Post-smolts are believed to make limited use of the estuarine habitat, moving rapidly to the open ocean (Marschall *et al*., 1998; Moore *et al*., 1998a, Malcolm *et al*., 2010). Limited existing data suggest that they usually swim close to the surface (1-3m depth) and make irregular dives down to 6.5m depth (Davidsen *et al.* 2008). A preference for warmer water layers, irrespective of salinity concentrations, has also been suggested (Plantalech manel-la *et al*., 2009).

Studies undertaken within fjords in Norway (Thorstad *et al*., 2004) suggest salmon post-smolts do not use the immediate near-shore areas during migration, the mean reported distance to shore being 370m. Similarly, tagging experiments carried out by Finstad *et al*. (2005) in the same area, found salmon used the full width of the fjord and travelled rapidly. Further studies undertaken in Canada, (Lacroix *et al*., 2005) in the Bay of Fundy, showed that fish travelled near the coast at a distance 2.5-5km from shore.

It should be noted that the current knowledge on salmon post-smolt migration and behaviour is principally based on the results of experiments and research carried out in Canada and Norway which have been summarised above. The lack of data specific to salmon post-smolts originating from Scottish rivers makes predictions of their behaviour in coastal waters difficult and speculative. Furthermore, Scottish coastal waters, especially in the case of the east coast rivers where there are no substantial bays or sea lochs (fjords), differ substantially from the locations where studies have been carried out in Canada and Norway.

It is also recognised that the migratory behaviour of post-smolts may vary depending on their river of origin. A recent study undertaken by Plantalech manel-la *et al.* (2011) found differences in early marine migratory behaviour between salmon from two different stocks and it was suggested that the distance that a salmon travels to reach the open coastline may influence its early marine migratory behaviour and performance.

The information given above, despite its limitations, provides an indication of the likely behaviour of salmon post-smolts during migration. As identified in Malcolm *et al*. (2010*)* the common findings across the research carried out to date can be summarised as follows:

- Post-smolts were always observed to migrate rapidly and actively towards open marine areas after leaving their home river
- Post-smolts did not appear to follow nearby shores closely, although this may occur in areas where coastal currents are substantial.
- Limited information on swimming depths suggests post-smolts generally use shallow depths (generally 1-3m, but up to 6m).

Data and information are also lacking to accurately define the routes followed, the areas used and the behaviour of salmon post-smolts in distant waters. The available information on the distribution and abundance of salmon at sea is principally based on records of tagging experiments from the West Greenland and Faroese fisheries (Shelton *et al*., 1997; Malcolm *et al*., 2010). A summary of relevant available information on salmon distribution in the sea and their behaviour is given below.

Post-smolts are thought to move in schools whilst heading off to deep-sea feeding area (Shelton *et al.*, 1997; Mills *et al.*, 2003). The best known feeding locations are in the Norwegian Sea and the waters off southwest Greenland, however, there are believed to be many other sub-arctic feeding areas. MSW salmon undertake longer migrations than grilse, which tend not to travel beyond the Faroe Islands and the southern Norwegian Sea (Mills *et al*., 2003).

The results of tagging experiments of salmon post-smolts suggest they travel rapidly over long distances. Studies in the Faroe-Shetland Channel (Shelton *et al*, 1997) found minimum progression rates of 7-30km/day; similarly, data from the North Sea the Norwegian Sea and the Barents Sea, indicate minimum progression rates of between 6 and 24km/day (Holm *et al*., 2003).

Historic recapture data from smolts tagged in Scottish rivers (Dee, Tay and North Esk), and data from the Girnock Burn (a tributary of the Dee) recorded between 1968 and 1982, suggest that at least some of the Scottish MSW salmon use the north-western Atlantic Area, around West Greenland (Malcolm *et al*., 2010).

Data recorded from the East Greenland and Irminger Sea fisheries, suggest these areas are of less importance to Atlantic salmon in general, and Scottish salmon in particular. This should however be taken in the context of the limited data that are available for these areas (Malcolm *et al*., 2010).

Information derived from smolt and adult salmon tagging studies (Jakupsstovu, 1988; Hansen and Jacobsen, 2003) also suggest Scottish salmon make use of sea areas around the Faroes. Hansen and Jacobsen (2003) found Scottish salmon tend to be more prevalent around the Faroes in the autumn rather than in the winter, including fish from the Spey, Brora, Tay, North Esk and Dee. In addition, whilst the Scottish salmon found in West Greenland, East Greenland and Irminger are thought to mainly be MSW fish, studies carried out around the Faroes suggest that both 1SW (grilse) and MSW salmon occur in the area, depending on the zone fished and the time of the year (Malcolm *et al*., 2010).

5.3.1.2 Pre-spawning Migration

The timing and duration of the pre-spawning migration of Atlantic salmon varies from river to river. It depends on the distance from the sea to the spawning areas and the degree of interaction between hydrologic regimes, the geomorphology of the river network and stream temperatures (Tetzlaff *et al.*, 2008).

Salmon of different sea-ages tend to return at different times of year and often spawn in different parts of a river (Potter and Ó Maoiléidigh, 2006). In most countries salmon runs tend to only take place at specific times of the year, normally during late summer and autumn. In Scotland, however, salmon enter the rivers throughout the year, resulting in the existence of a range of salmon runs. This is of importance to the salmon fisheries as it provides fishing opportunities over extended periods of time (MSS, 2010b).

In Scotland, the majority of grilse (1SW salmon) enter the rivers from early summer until shortly before spawning in autumn and early winter. Many of the MSW salmon also enter rivers over that same period of time, however, for the Scottish MSW salmon class as a whole, river entry occurs over a greater period of time, extending back to the autumn months of the year before spawning (Youngson *et al*., 2002). Based on the time of the year when the fish enter the river, salmon can be broadly classified as winter, spring, summer and autumn salmon.

In addition the quality of salmon varies depending on the run, with large spring-running MSW salmon being particularly highly prized (Potter and Ó Maoiléidigh, 2006). In the past, spring salmon runs made a major contribution to the Scottish fisheries, especially to those of the east coast and its rivers. Concern on the state of this component of the stock has, however, risen in recent years, as it has declined more significantly than other stock components (Potter and Ó Maoiléidigh, 2006; MSS, 2003; Youngson *et al*., 2002; Smith *et al*., 1998).

River entry is thought to be highly dependent on flow conditions. Research undertaken in the late 1980s in the Fowey estuary, and more recently in the Avon, indicated that fish have to wait for suitable river conditions, particularly elevated flows, before they enter freshwater and that, provided there are suitable holding areas, fish may remain in the estuary for long periods (Potter and Dare, 2003; Potter, 1988). Studies carried out in the Dee (Smith & Johnstone, 1996) found that fish enter and ascend the river relatively quickly during elevated river flows and that river entry may be delayed during periods of drought. This scenario was also noted at consultation meetings with the North East Region Salmon Fishery Boards (Consultation meeting, 2010a-d; Consultation meeting, 2011a).

The return migration in adult salmon is, as described for post-smolts, an active process with fish generally being found swimming near the surface (1-5m depth) and occasionally diving to greater depths (Aas *et al*., 2011). There does not appear to be a required period of acclimation during the transition from salt to fresh water (Hogåsen, 1998) and provided that river conditions are favourable, river entry seems to take place quickly (Thorstad *et al.,* 1998).

Studies carried out in Iceland on the migratory pattern of homing Atlantic salmon in coastal waters (Sturlaugsson and Thorisson*,* 1997) found that salmon migrated close to the coast, with some individuals entering into estuaries (most often for brief periods), and even into rivers (for up to more than one day) on their way to their natal streams. The depth records suggested that in general salmon migrated in the uppermost few metres. A diurnal rhythm in vertical movements was also noted, with salmon staying deeper at night and closest to the surface at noon.

The review paper by Malcolm *et al.* (2010), suggests a range of potential migratory routes for salmon in Scottish coastal waters, primarily using the results of adult fish tagging studies and the spatial distribution of tag returns from adult fish tagged as smolts as they left Scottish rivers. In this exercise the assumption that fish would return to their river of origin is needed. A summary of the findings of Malcolm *et al.* (2010) is given below.

The spatial distribution of tag recaptures from fish caught and marked in the Northumberland drift net fishery during 1977 was studied by Potter and Swain (1982). Based on these data, it was found a strong northward migration of salmon from Northumberland as far north as Aberdeenshire, with decreasing recaptures in regions further north. Potter and Swain (1982) concluded that 94% of the fish caught in the North East of England drift net fishery were heading to Scottish rivers.

Similarly, salmon tagging studies carried out near Montrose (Pyefinch and Woodward, 1955; Shearer, 1958) also suggest a predominant northerly movement as far as the south of the Moray Firth.

Whilst the information provided above supports the idea of a general northward migration of salmon in coastal areas around the proposed EOWDC site, given that this information is based on recaptures of tagged adult fish, rather than smolts, it is not possible to be certain of the river of origin of the fish recaptured. The results of smolt tagging studies carried out in the Girnock Burn (1968-81) on the Aberdeenshire Dee, however, also suggest an overall northward direction of travel in coastal waters around the east coast of Scotland for both grilse (1SW salmon) and MSW salmon.

The northward movement based on the results of Potter and Swain (1982) and the tagging studies in the Girnock Burn (1968-81) is illustrated in Figure 5.2 and Figure 5.3 respectively, as presented in Malcolm *et al*. (2010).

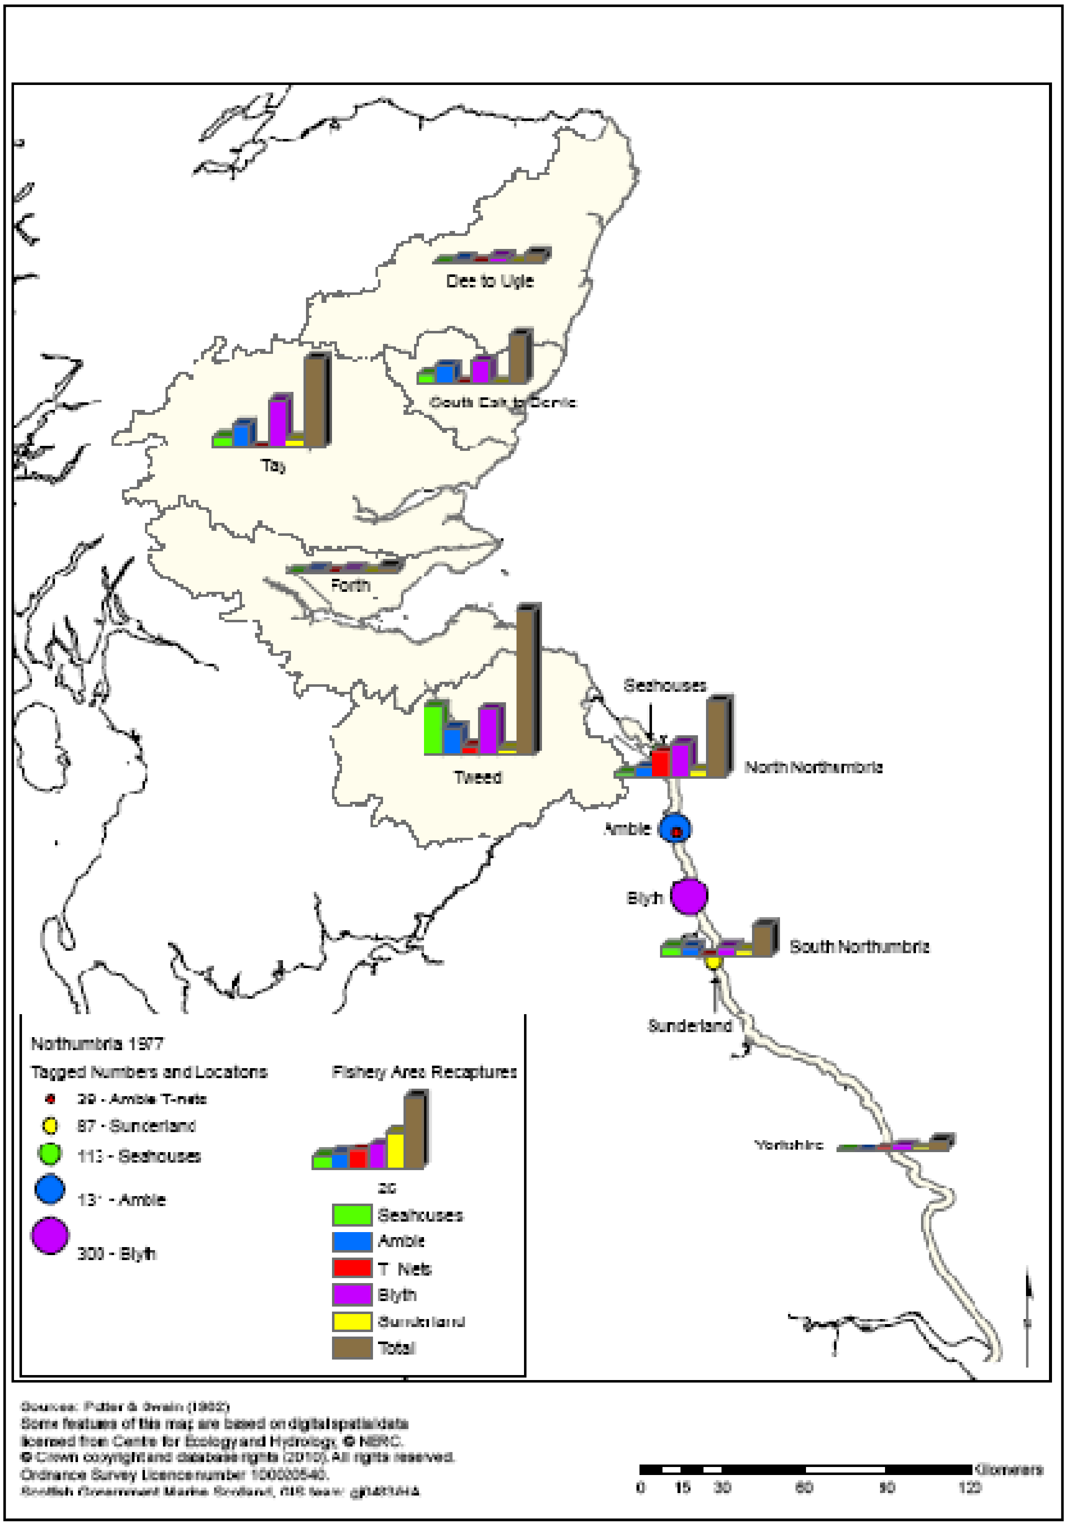

Figure 5.2 Coastal Movement of Salmon caught in the North East England Drift Net Fishery (after Potter and Swain, 1982). Tagging locations are shown as coloured circles; the size of circles is proportional to the number of fish tagged. Bar charts indicate the number of fish recaptured, colour coded by tag location (Source: Malcolm *et al*., 2010)

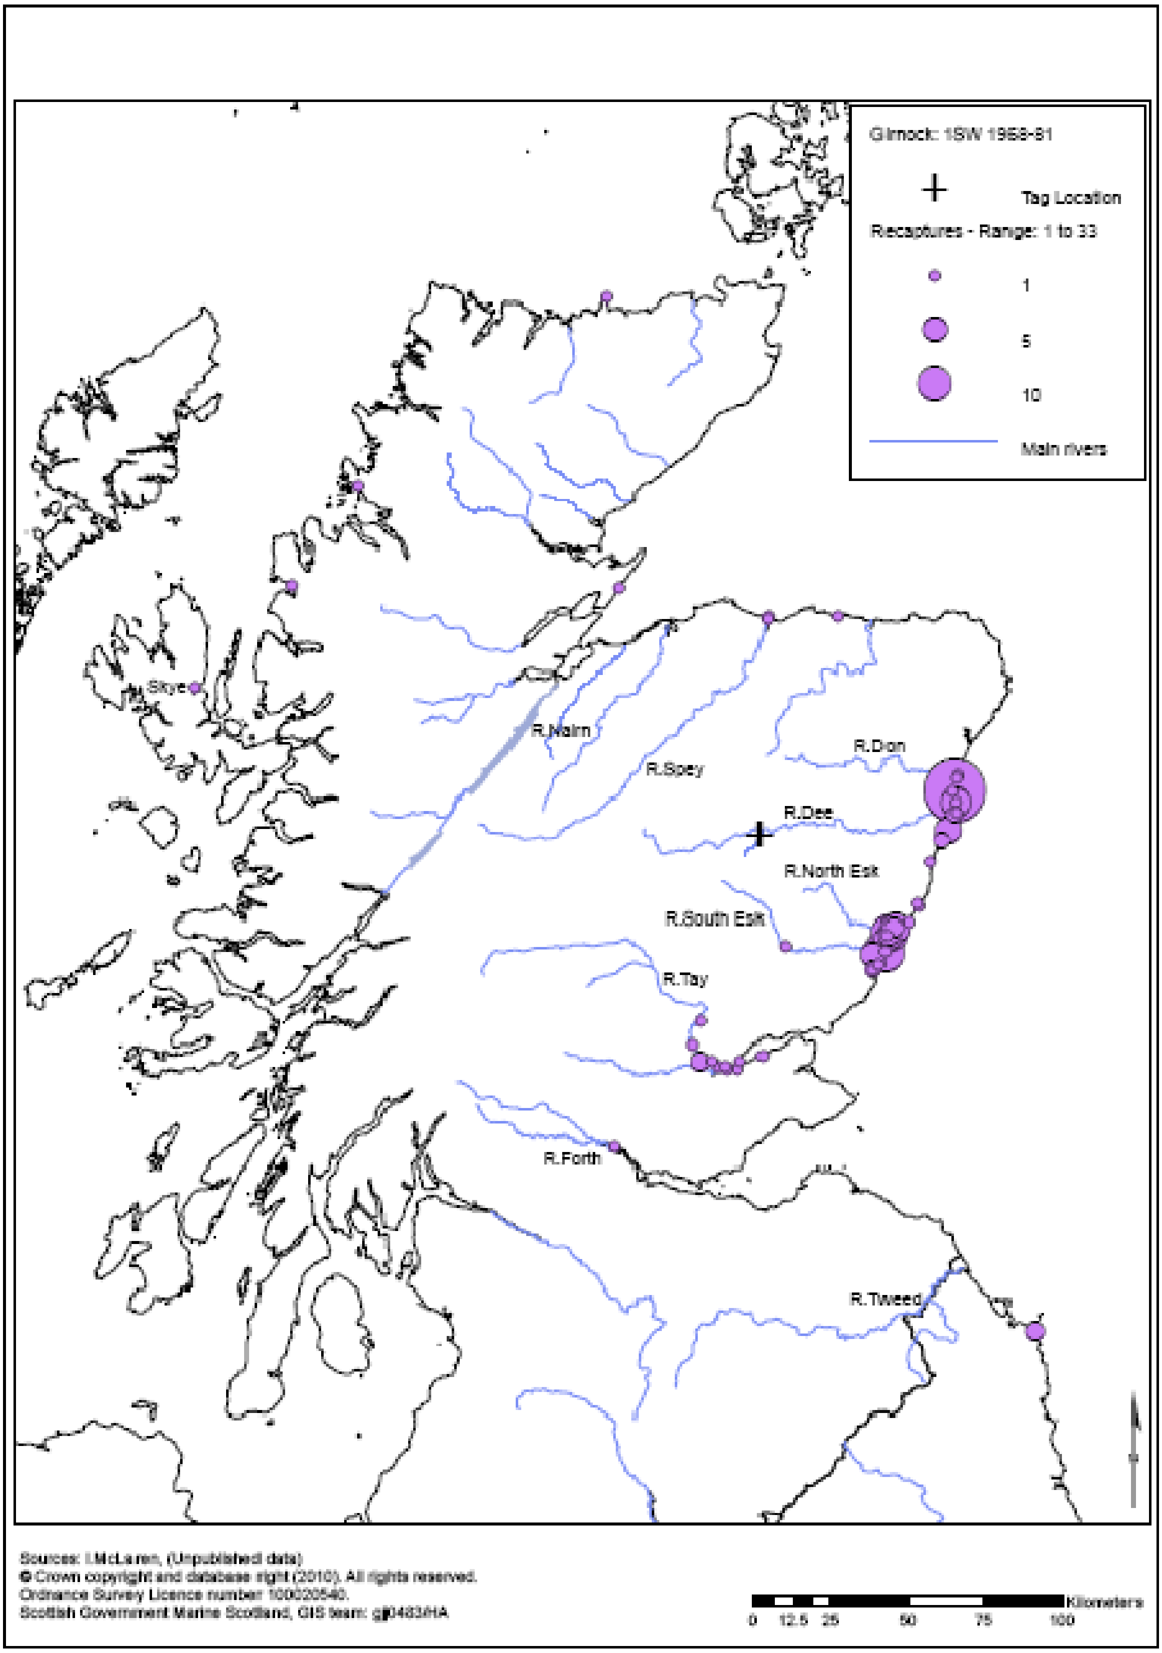

Figure 5.3 Distribution of Recaptures of 1SW (grilse) tagged in the Girnock Burn as Smolts (1986-81). Circle sizes are proportionate to the number of recaptures from a particular location (Source: Malcolm *et al.*, 2010)

Considering the results of the studies mentioned above, it appears reasonable to assume that for salmon originating in the North East coast rivers, the general direction of coastal movement is northerly and coastal migration may start as far south as the north east coast of England. This is in line with the model of adult salmon migration proposed by Shearer (1992) where it was suggested that from Aberdeenshire southwards, fish travel in a northerly direction having migrated south past their home rivers through the North Sea and approach the coast around Northumberland (Malcolm *et al*., 2010).

Whilst it is likely that the majority of salmon migrating in coastal waters around the proposed EOWDC originated in nearby rivers, given the complexity of the movements recorded from studies in other Scottish regions (Malcolm *et al*., 2010), where in some cases salmon were found migrating both northwards and southwards, it is difficult to assess the potential for this coastal area to be used by salmon originating elsewhere in Scotland. An indication of the general patterns of adult salmon movement around the Scottish coast based on the information provided above and further studies carried out in other regions around Scotland, is given in Figure 5.4 below (Source: Malcolm *et al*., 2010).

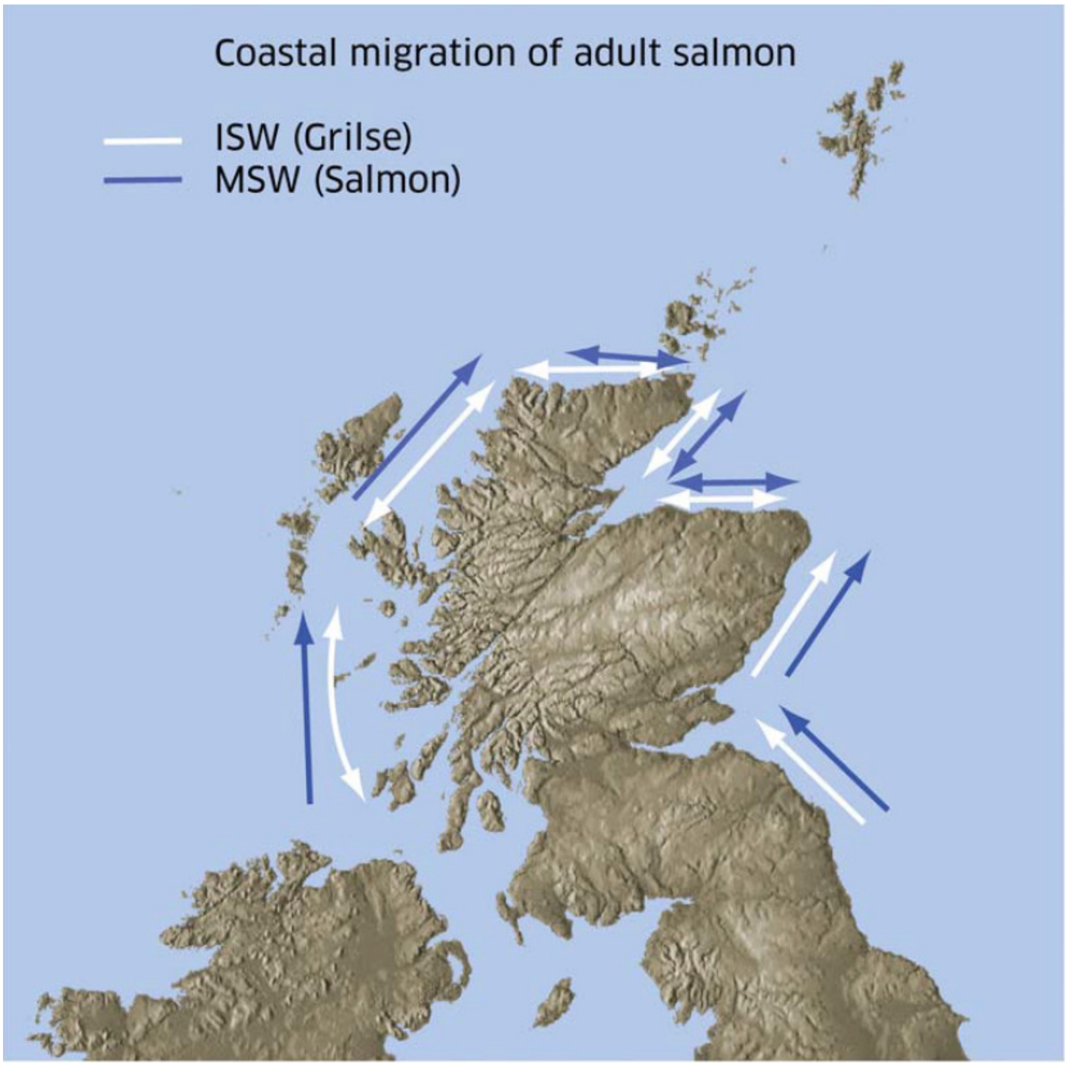

Figure 5.4 Dominant directions of Travel for Atlantic Salmon (1SW and MSW) in Scottish coastal waters based on tagging studies (Source: Malcolm *et al*., 2010)

5.3.2 Sea Trout

5.3.2.1 Smolt and Post-smolt Migration

Seaward migration in sea trout, like in salmon, is thought to be an active process (Thorstad *et al*., 2004; Thorstad *et al*., 2007). Tagging studies carried out in the River Conwy, North Wales (Moore *et al.,* 1998b) found sea trout smolts migrating seawards on ebb tides and swimming close to the surface. In addition, the movements in the lower portion of the estuary were found to be indicative of active directed swimming and it was suggested that there was no apparent period of acclimation when moving from fresh to saltwater.

As mentioned in Section 5.2.2 above, most sea trout smolts are thought to leave the river around April and early June. Information gathered by Pratten and Shearer (1983) in the River North Esk, found the peak of the sea trout smolt migration to occur usually in May or June.

Sea trout differ from Atlantic salmon in that generally they do not venture off to distant feeding grounds in the sea, but instead, remain in coastal areas. A range of migratory strategies have however been observed in sea trout stocks, including estuary residence, local coastal movements and extensive open sea migration (Solomon, 2007).

Detailed tracking studies on the migration of sea trout post-smolts have been carried out in sea lochs, in the west coast of Scotland (Pemberton, 1976a; Middlemas *et al*., 2009) and in Norwegian fjords (Finstand *et al*., 2005; Thorstad *et a*l., 2007). The results of these studies suggest a relatively local movement with sea trout remaining within sea lochs and fjords during the first couple of months at sea (Malcolm *et al*., 2010).

In the east coast of Scotland, data on sea trout post-smolts is scarce, being principally derived from tagging studies carried out in the North Esk. Studies by Pratten and Shearer (1983) found that the majority of reported recaptures were from the Montrose area, although numerous examples of tagged sea trout travelling appreciable distances (>100km) along the coast were also found. In addition, four tagged fish were recaptured in excess of 500km from the North Esk, three off the Scandinavian coast and one in the River Barvas, North West Lewis. Further research by Shearer (1990) in the North Esk, concluded that most sea trout post-smolts were probably staying within a short distance of the Esk rivers, although some recaptures were observed as far north as the river Spey and as far south as the River Tweed (Malcolm *et al*., 2010).

5.3.2.2 Spawning Migration

As previously discussed for salmon, river entry in sea trout is also thought to be related to flow conditions, with fish having to wait for suitable river conditions, particularly elevated flows, before entering the freshwater habitat (Potter and Dare, 2003; Consultation Meeting. 2010a-d; Consultation Meeting, 2011a).

Timing in river entry is also variable in sea trout. Based on information gathered in consultation meetings undertaken with the North East region Salmon Fishery Boards and the analysis of MSS salmon and sea trout catch statistics, it appears that the main sea trout runs in the North East salmon fishery region occur in the summer months from June to September, with peak runs varying between rivers. Similarly, information gathered in the North Esk (Pratten and Shearer, 1983) where the sea trout population was sampled by means of a stationary trap, found that finnock (post-smolts) returning to fresh water in the year of their smolt migration where moving upstream from July onwards, with a peak of movement occurring in the autumn. The same study found the main run of adult sea trout occurred between July and October.

The information available to date, does not allow for common patterns, behaviour or routes, either in general or for particular rivers, to be determined. Whilst tagging studies carried out in the east coast suggest that sea trout generally remain in their local area, it appears clear that sea trout exhibit a wide range of migrations (Malcolm *et al*., 2010). The findings of the principal studies carried out in the regional study area are summarised below.

Nall (1935) analysed the findings of tagging studies carried out between 1914 and 1935 along the east coast of Scotland. In the majority of cases, recaptures were made within the local estuarine, river or firth areas, with very few distant recaptures being observed (within 40 miles). As previously explained (Section 5.3.2.1), studies undertaken by Pratten and Shearer (1983) and Shearer (1990) in the Montrose area, found similar patterns, with the majority of fish being found in adjacent rivers, although longer migrations were also observed.

The distribution of sea trout recaptures from tagging programmes in the rivers North Esk, South Esk and Bervie is illustrated in Figure 5.5, as presented in Malcolm *et al.* (2010).

Little is known about the behaviour during migration around Scottish coastal and distant waters. Research carried out in Norway indicates a preference for swimming at depths below 3m, however, within the same study, records of sea trout at depths up to 28m were also observed (Rikardsen, 2007).

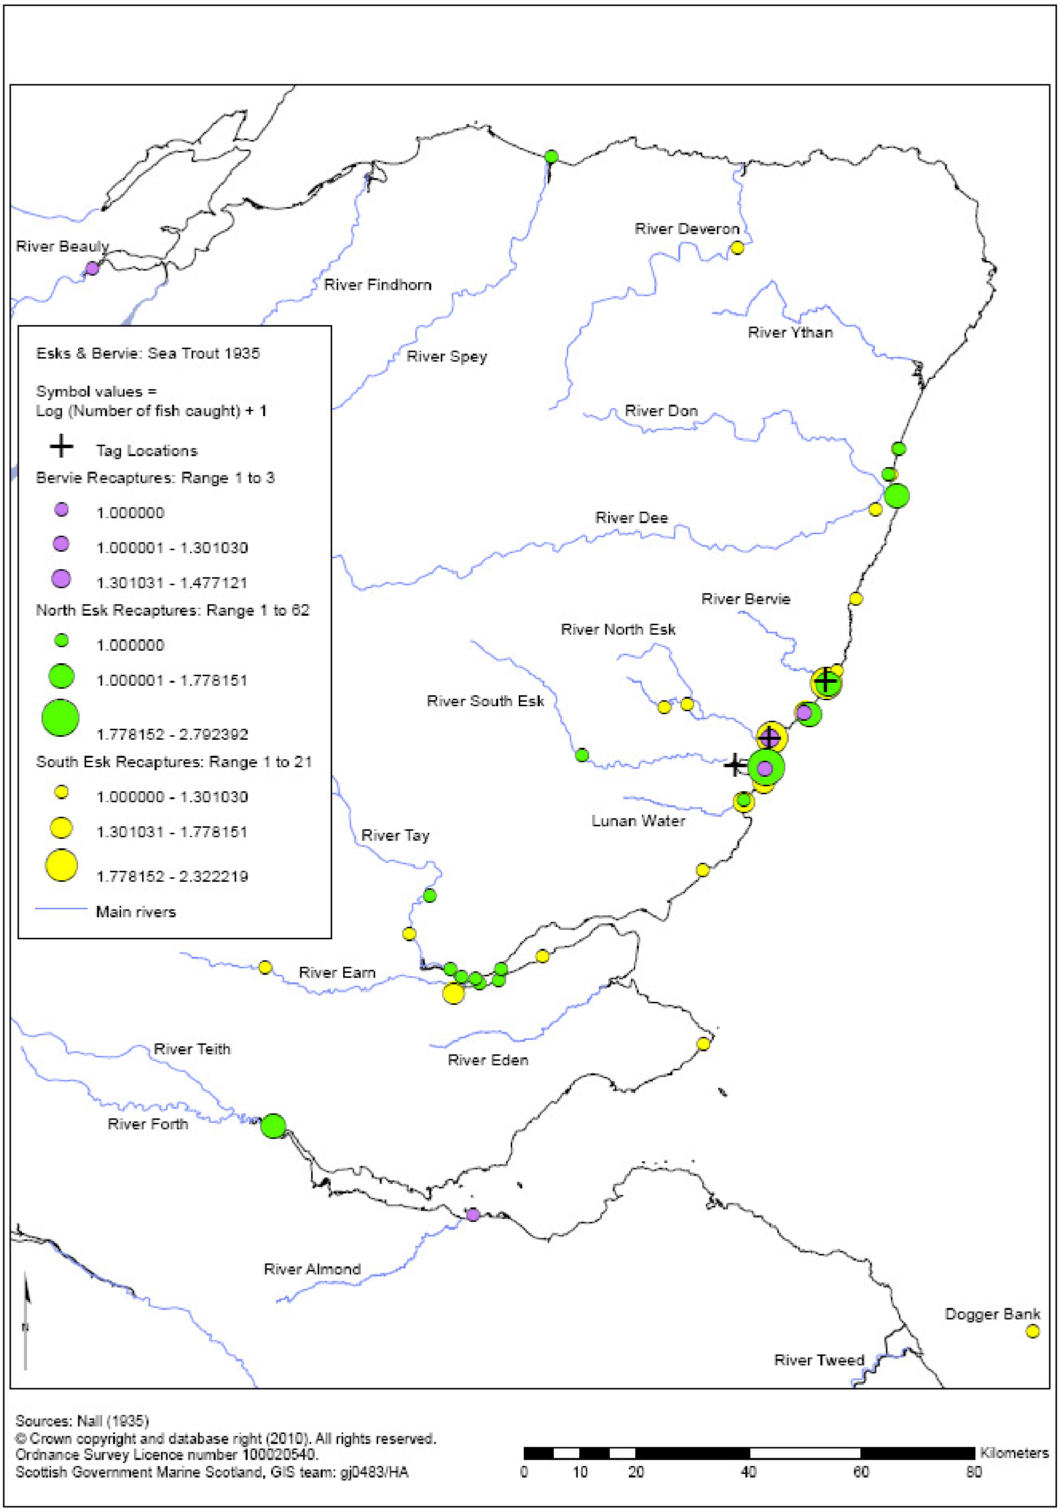

Figure 5.5 Map showing the distribution of sea trout recapture locations from tagging programmes in the rivers North Esk, South Esk and Bervie (Malcolm *et al.,* 2010)

5.3.3 Navigation and Orientation

Olfaction is thought to play an important role in the orientation of salmonids and it is widely accepted that the final phase of the spawning migration is primarily governed by olfactory discrimination of home-stream water (Hasler and Scholz, 1983; Døving *et al*., 1985).

In addition to olfactory stimuli, salmonids are known to be capable of sensing magnetic cues during certain types of spatial activity (Chew and Brown, 1989; Taylor, 1986). In Atlantic salmon, biomagnetic particles, particularly associated with the lateral line, which are of a size suitable for magnetoreception are believed to allow them to follow a rough compass heading, facilitating orientation with respect to the geomagnetic field during the oceanic phase of their migration (Potter and Dare, 2003; Lohmann *et al.,* 2008a).The presence of magnetoreceptors and the ability to use the geomagnetic field for spatial orientation has also been documented in sea trout (Formicki *et al.*, 1997; Formicki *et al.,* 2004).

Based on the ability of salmonids to identify both olfactory and magnetic cues, it has been hypothesised that both olfactory and magnetic mechanisms may play a role in navigation and orientation in salmonids, and that these may function sequentially over different spatial scales (Lohmann *et al*., 2008b).

In line with the above, research carried out in Norway (Hansen *et al.,* 1993) suggest the existence of two phases to the homing migration of maturing Atlantic salmon from the feeding areas to their home rivers; a first phase with crude navigation from the feeding areas toward the Norwegian coast and a second phase with more precise navigation in coastal and estuarine waters towards their home rivers. Similarly, research undertaken in Iceland (Sturlaugsson *et al*., 2009) suggests the existence of behavioural differences in salmon orientation in offshore and inshore areas related to increased use of olfactory sense in inshore areas. The study also found that fixed direction all the way from offshore areas to the home fjord area or home estuary could not explain their migration and it was suggested that shoreline orientation is of importance once the shore has been approached. Based on their findings, the authors recommend the spawning migration of salmon at sea to be divided into three phases in relation to the different orientation behaviour in offshore, inshore and estuarine areas.

It is recognised that there is limited information available to date to describe in detail the navigation and orientation mechanisms used by salmon and sea trout during their marine migration. Furthermore, comprehensive and robust scientific literature specific to salmon and sea trout originating from Scottish rivers is lacking in this field.

5.4 Feeding

Salmon and sea trout seaward migration is thought to be related to increased growth rates at sea derived from the existence of greater feeding opportunities in the marine environment (Haugland *et al.,* 2006; Rikardsen *et al*., 2006). A review of the feeding habits and diet of salmon and sea trout at sea is given below.

5.4.1 Salmon

Atlantic salmon are generalist and opportunistic predators of zooplankton and nekton at the ocean surface (Jacobsen and Hansen, 2001, Lacroix and Knox, 2005, Haugland *et al*., 2006). They feed on a variety of small fish including capelin, herring, sandeels and sprats in addition to other surface-living small components of the zooplankton, principally crustaceans (Mills *et al.,* 2003).

Studies carried out in fjords and coastal areas in Norway suggest salmon start to feed on marine organisms immediately after their transition to saltwater and found salmon post-smolts largely feeding on small fish (0-group), with sandeel and herring being of importance as prey items. Blue whiting was found to be of importance as a prey only in the slope current that transports larvae from its spawning areas west of UK into the North and Norwegian Seas (Haugland *et al*., 2006).

Research based on stomach contents of wild and escaped farmed salmon in the North East Atlantic (Jacobsen and Hansen, 2001) found evidence of selective foraging in salmon. Jacobsen and Hansen (2001) results suggest that fish species were preferred over crustaceans and amphipods over euphausiids. In addition, a relation between sea age and food habits was also found, where larger salmon (3+SW) tended to be more piscivorous than smaller fish.

Research carried out in the Baltic Sea (Karlsson *et al.,* 1999) also suggests seasonal changes in feeding habits, with salmon primarily feeding on sprat in the winter from January to April, and herring and spined stickleback later in the year.

Jacobsen and Hansen (2001) also found seasonal variations in feeding habits, with amphipods, euphausiids and mesopelagic shrimps being the principal food sources in autumn, whilst in the winter mesopelagic fish were important. It has been suggested (Rikardsen *et al*., 2004) that spatial and temporal differences in prey availability may be related to geographical differences in feeding habits in salmon.

5.4.2 Sea Trout

Sea trout at sea feed on a variety of organisms, changing gradually from small crustaceans to small fish such as sandeels and sprat (Potter and Dare, 2003; MSS, 2010a). Food preferences are thought to be dependent on habitat, season and fish size and age (Knutsen *et al*., 2001).

Studies carried out in Mulroy Bay in the Irish Sea, suggest that as sea trout increases in fork length their diet tends to include more fish and fewer crustaceans (Fahy, 1985). Similarly, investigations by Pemberton (1976b) in North Argyll sea lochs found that young fish, principally clupeids and sandeels, featured more in the diet of larger trout (≤21 cm) than in the smaller size range.

Seasonal studies of the feeding of sea trout in fjords in northern Norway (Rikardsen *et al.,* 2006) found sea trout feeding on marine crustaceans and polychaetes during early and late winter, whilst in summer and autumn their principal prey items were small fish such as juvenile herring. This is in line with the findings of Pemberton (1976b), which suggest that benthic feeding (crustacean and annelids) was more important in winter, while midwater and surface organisms (young fish and insects) were preferred in the summer. In addition, Pemberton (1976b) suggested a diel feeding pattern, with bottom feeding being greatest during the day and midwater and surface feeding increasing between sunset and sunrise.

5.5 Conservation Status

Atlantic salmon (*Salmo salar*) is listed in Annexes II and V of the EU Habitats Directive as a species of European importance and Annex III of the Bern Convention. The protection given to salmon through the Habitats Directive, however, is restricted to freshwater habitats, as marine and estuarine sites are excluded from selection. Similarly, salmon at sea is not protected under the Bern Convention.

Through the implementation of the Habitats Directive and as a result of the European importance of Scotland's salmon populations, 11 Scottish rivers have been designated as Special Areas of Conservation (SACs), with salmon being a primary reason for the selection of the site (Figure 5.6). Two of the aforementioned SACs are located within the regional study area: the River Dee and the River South Esk. These rivers' SACs support high quality salmon populations. Furthermore, as a result of a high proportion of the rivers being accessible to salmon, both the South Esk and the Dee support the full range of life-history salmon types found in Scotland with sub-populations of spring, summer salmon and grilse all being present (JNCC, 2010).

In addition to the protection given under the EC Habitats Directive, Atlantic salmon is listed as a UK Biodiversity Action Plan (BAP) priority species and is protected at the international level by the North Atlantic Salmon Conservation Organization (NASCO), an inter-governmental organisation devoted to the conservation, restoration, enhancement and rational management of wild salmon in the North Atlantic (Curd, 2010).

Sea trout (*Salmo trutta*) is not subject to the same level of protection as salmon in Europe, although it is listed as a UK BAP priority species and, in Scotland, is currently protected under the same conservation legislation as Atlantic salmon. This is a result of the definition of the term salmon in the Scottish legislation; under the Salmon (Scotland) Act (1986) salmon means: *"all migratory fish of the species Salmo salar and Salmo trutta and commonly known as salmon and sea trout respectively or any part of any such fish"*

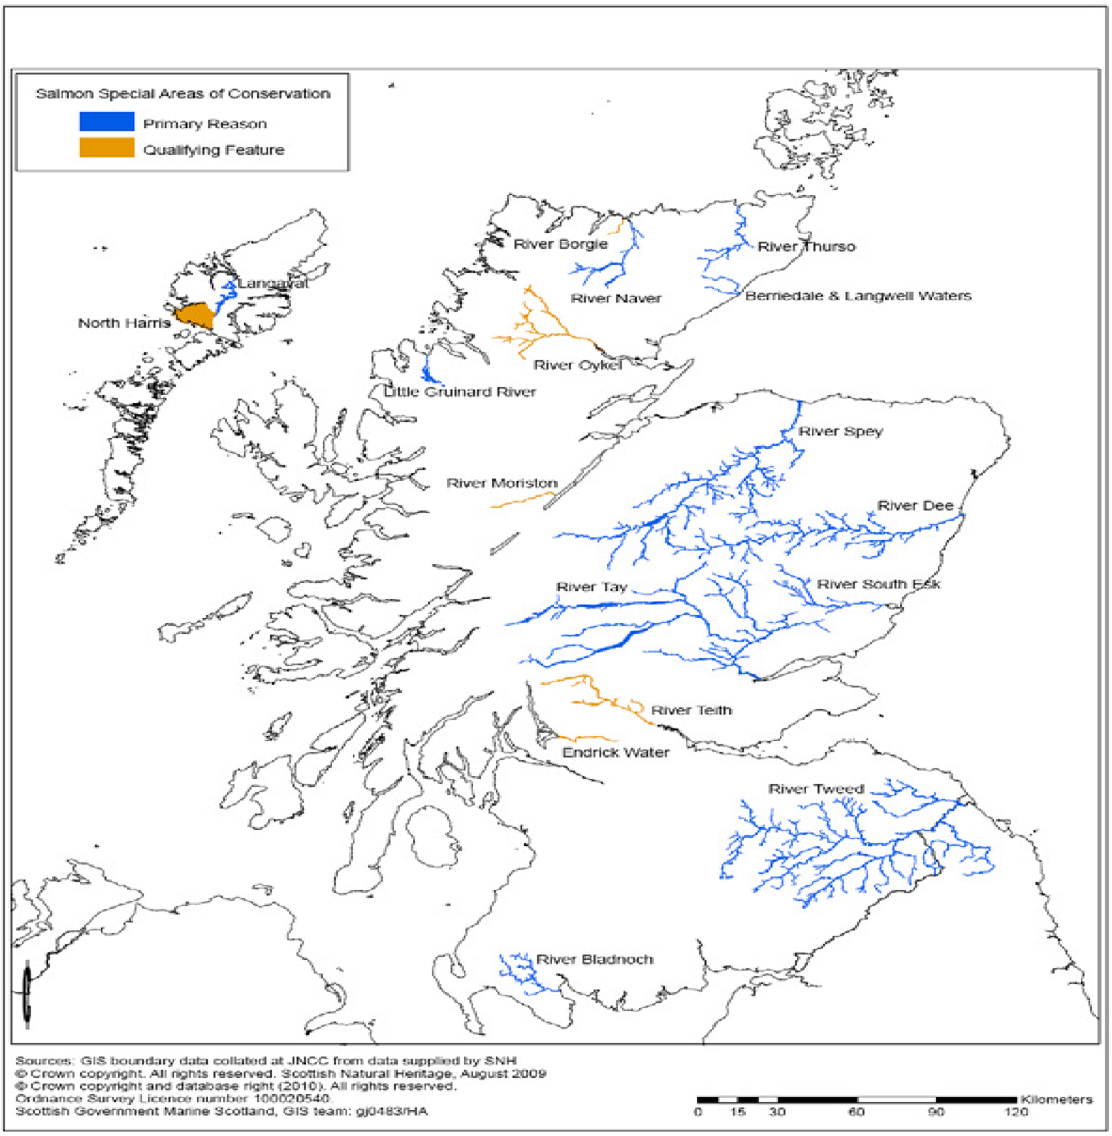

Figure 5.6 Distribution of Special Areas of Conservation (SACs) for Atlantic Salmon (Source: Malcolm *et al.*, 2010)

5.6 Threats to Salmon and Sea Trout

Salmon and sea trout populations are subject to a number of threats in both the freshwater and marine phases. In fresh water, degradation of juvenile and spawning habitat, and land use, in particular intensive agriculture, are thought to be having the greatest effect, whilst in the marine phase, there is concern over the recent decline in post-smolt marine survival rates (Hendry and Cragg-Hine, 2003; ICES, 2009). As a result, Atlantic salmon stocks are currently under threat across their northern hemisphere range and sea trout populations in decline throughout the United Kingdom (Crawley, 2010).

A summary of the main threats that salmon and sea trout are exposed to in the rivers, coastal and marine environments is given below (AST, 2010b; Curd, 2010).

Rivers

- Predation by birds
- Pollution and poor habitat
- Obstructions such as dams, weirs and culverts
- Disease
- Poor angling practices
- Poachers

On the coast

- Interceptory mixed stock nets
- Fish farms - sea lice, disease and escaped farmed salmon
- Pollution

At sea

- Climate changes affecting feeding and survival opportunities (e.g changes in sea surface temperatures)
- Increased predation by seals
- Fishing, including indirectly through over-exploitation of their food resource (e.g sandeel) and directly through unintentional capture when fishing for other species such as herring and mackerel.

The majority of threats to salmon and sea trout in the rivers are being addressed in Scotland through the implementation of river management and water quality schemes, the removal of obstructions, the establishment of fishing codes of practice and other such initiatives.

Efforts made within the rivers to maintain and conserve salmon and sea trout stocks are however limited in their effectiveness as a result of stock management measures implemented in coastal waters and in the high seas and by changes in the status of the stocks caused by sea mortality and other factors. In this context, two aspects of relevance are the persistence of Multi Stock Fisheries (MSFs) in Scotland, which target fish from more than one stock/river (e.g coastal netting), and the current trend of increased post-smolt mortality at sea (Hansen & Queen, 1999).

5.6.1 Multi Stock Fisheries

The exploitation of salmon and sea trout by MSFs holds particular problems to the implementation of management practices. The fisheries can be damaging because they have potential to intercept any salmon or sea trout in their vicinity, regardless of where those fish are heading or the strength of the population in their natal rivers (Crawley, 2010).

5.6.2 Increased Marine Mortality

Increased marine mortalities in post-smolts are thought to be related to climatic variations such as the increase in sea surface temperature (SST) (Beugrand and Reid, 2003; Friedland *et al*., 2009; Friedland *et al.,* 2000; Todd *et al.*, 2008).

Salmon populations are also of concern due to the sharp decline in growth condition observed in recent years in 1SW salmon (grilse) and MSW salmon (Todd *et a*l., 2008; Davidson and Cove, 2010). The growth reductions are thought to be indicative of recent and large-scale ecological shifts in the Easter North Atlantic epipelagic ecosystem and the likely importance of bottom-up control in the food web (Todd *et al*., 2008).

5.6.3 Current Research Initiatives

A number of initiatives have been implemented by NASCO and ICES to improve knowledge about the distribution and migration of salmon at sea, which in turn may help to understand mortality of salmon during their marine phase (ICES, 2009). The international co-operative SALSEA programme, adopted in 2004 was designed to improve the understanding of the migration and distribution of salmon at sea in relation to feeding opportunities and predation. In 2008, the SALSEA-Merge project was launched as part of the SALSEA Programme, aiming to advance understanding of stock specific migration and distribution patterns and overall ecology of the marine life of Atlantic salmon and gain an insight into the factors resulting in recent increases in marine mortality, by merging genetic and ecological investigations.

In line with the SALSEA-Merge project, Rivers and Fisheries Trusts of Scotland (RAFTS), the Scottish Government's Marine Scotland Directorate an all the fisheries Trusts around Scotland, have commenced a collaborative programme of genetic work, "Focusing Atlantic Salmon Management on Populations" (FASMOP), with the aim of understanding the structuring of river stocks of Atlantic salmon into breeding populations. In addition, MSS's Research Project "Development of a General Spatial Model of Within River Population Structuring in Scottish Atlantic salmon (POPMOD), using molecular genetic data on salmon information collected by MS, and through SALSEA-Merge and FASMOP, is anticipated to provide a general model which can be used to predict population structuring within any Scottish salmon river and evaluate the potential for using genetic estimates for monitoring the conservation status of breeding populations.

Research initiatives such as the Moray Firth Sea Trout Project (MFSTP) are also currently in place to address the decline in sea trout stocks and gather further information on the life history and the marine phase of this species.

6.0 Salmon and Sea Trout Fisheries Baseline Assessment

6.1 Introduction

Salmon and sea trout form an important part of Scotland's natural heritage. In addition, they support and maintain the existence of commercial and recreational fisheries which are of importance to the Scottish economy. A study undertaken by the Scottish Executive (Radford *et al.,* 2004) estimated that game and coarse anglers spent a total of £131m in Scotland of which 65% (£73m) corresponded to salmon and sea trout fishing. In 2008, the annual value of salmon fisheries to the Scottish economy was estimated at £120m (ASFB, 2010a).

It should be noted that the definition of salmon under the Salmon Act (1986) includes both Atlantic salmon (*Salmo salar*) and sea trout (*Salmo trutta*). Where applicable, the term may subsequently be used to describe both species.

6.2 Salmon Fishing Rights, Administration and Regulations

6.2.1 Fishing Rights

The right to fish for salmon in Scotland, whether in inland waters or at sea, is a heritable right. The taking of salmon without the right or written permission to do so is prohibited under the Salmon and Freshwater Fisheries (Protection) (Scotland) Act, 1951.

The rights originally belonged to the Crown Estate, however as with land, the Crown Estate has made grants of salmon fishing to others and ownership is now widely distributed among private individuals, companies, local authorities and others. The rights can be bought, sold or leased independently of land except in Orkney and the Shetlands (Williamson, 1991).

The Crown Estate still owns areas along the coast and in rivers, many of which are still let. Since the late 1980s, however, the Crown Estate has supported a policy of conservation by retaining coastal netting stations in hand and unlet. There are therefore, no longer any coastal netting stations let by the Crown Estate and none are actively fished (The Crown Estate, 2010); the existing working netting stations were therefore granted or sold the heritable title by the Crown Estate before the late 1980s (Crawley, 2010).

6.2.2 Fisheries Administration

Salmon fisheries in Scotland, both inland and at sea, are managed by their owner or leaseholder under a framework of regulations laid down by central government.

For the purposes of salmon fishery management Scotland is divided into 54 statutory Salmon Fishery Districts each with a catchment area including a river or group of rivers (ASFB, 2010b). Today, almost without exception, every district has formed a District Salmon Fisheries Board (DSFB) made up of the owners or leaseholders of the fishing rights. These boards manage the rivers and coastal netting zones, being able to appoint bailiffs with the power to enforce regulations and restrictions, as well as establishing other practices for improving and maintaining fish stocks, and monitoring and controlling river conditions. Each salmon fishery in each district has a value, which is calculated by the district assessor (Consultation Meeting, 2010b-c). Individual boards are self-financing and generally raise money by taxing rights' owners within their district. This often works on a sliding scale, according to the number of fish caught. In 1999 the government made a revision to the constitution of the boards to allow for wider representation, by bodies such as the Scottish Environment Protection Agency, Scottish Natural Heritage or others such as local angling clubs and associations (ASFB, 2010b).

Salmon fishery districts as formalised by the Salmon Fisheries (Scotland) Acts 1862-1868, are shown in Figure 6.1. As explained in Section 4.4.2 above, some districts have been joined together and superseded by larger districts, resulting in the current 54 districts.

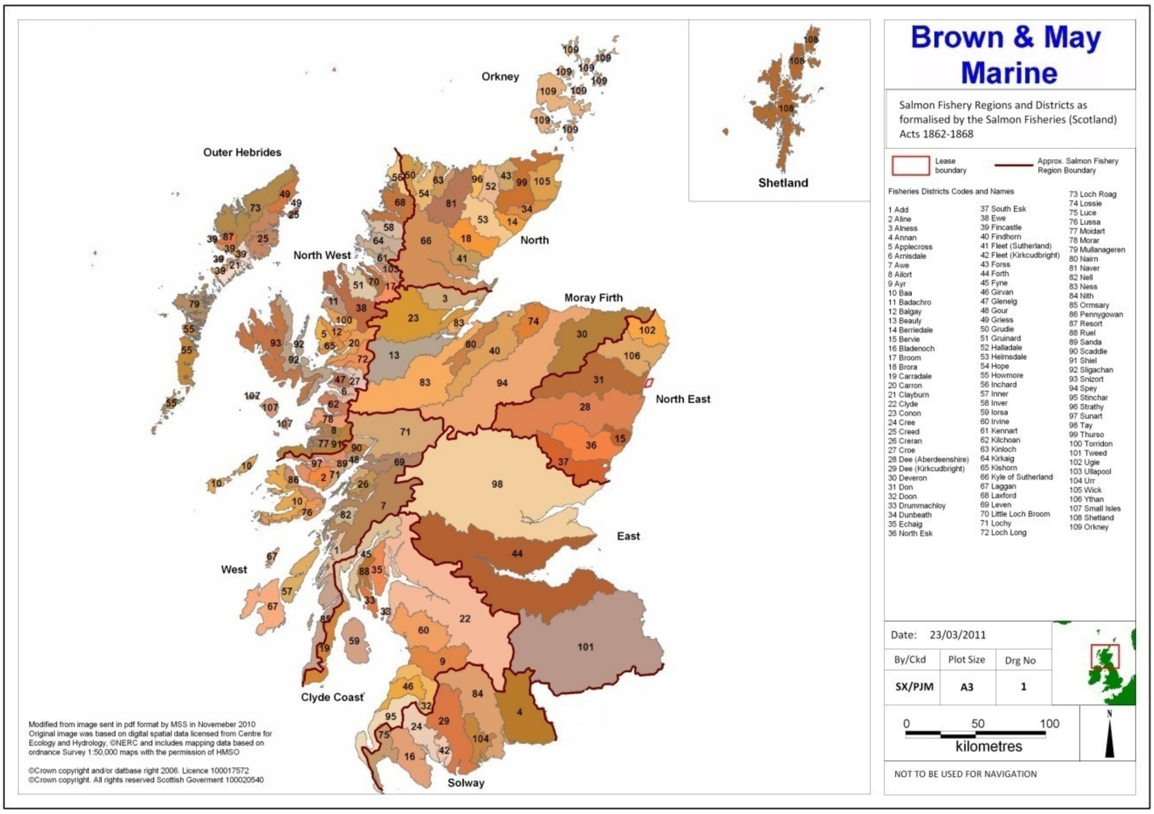

Figure 6.1 Salmon Fishery Regions and Districts in Scotland

Boards hold powers relating to the introduction of new regulations on the fishery, the purchase of property to acquire rod or net fisheries, the imposition of fishery assessments on the fishery proprietors, etc (SPICe, 2000). Whilst the Boards themselves have no ability to make legal restrictions on fishing, applications are made to Scottish Ministers by the boards for changes and new regulations to be introduced.

In addition to the Boards, the Scottish Executive Environment and Rural Affairs Department (SEERAD) oversees the fishery as a whole, promoting legislation and making regulations under the various Salmon and Fisheries Acts passed by the devolved government. The Inspector of Salmon and Freshwater Fisheries monitors the effects of legislation and the operation of the fisheries. Marine Scotland (who has taken on the roles and responsibilities of the former Scottish Fisheries Protection Agency) enforces regulations at sea and helps the District Boards with local, coastal enforcement (Williamson, 1991); Marine Scotland Science's Freshwater Fisheries Laboratory provides scientific advice on salmon and their fisheries.

6.3 Fisheries Regulations

6.3.1 General

All Scottish salmon fisheries are closed for a minimum of 168 days a year. Actual dates may vary but are mostly from late August to mid February, depending upon individual District Board policy.

Angling may continue for a few weeks either side of this. Weekly close times are also nationally enforced, being 24 hours (Sunday) in the case of angling and 60 hours for all other methods.

It is prohibited to take juvenile salmon (not including trout). There is a minimum mesh size of 90mm for nets, to enable smolts to escape.

There is no limitation on fishing effort within open fishing periods. There are however restrictions in place which act as indirect controls: restrictions imposed on the various fishing methods (discussed in Section 6.4); the exclusive right of the salmon fishermen through ownership or tenancy to decide fishing effort in their fishery; and regulations established and enforced by individual District Boards.

Salmon fisheries are saleable and netsmen or companies may acquire fishing rights over relatively large areas. Other interested parties may also purchase rights. For example, the Atlantic Salmon Conservation Trust has historically bought coastal sites to close them down as a conservation measure in order to halt coastal netting activities. Similarly, rod-and-line interests may buy up river netting rights to close them down, often through the district boards.

6.3.2 Inland waters

The only lawful fishing methods in inland waters are rod-and-line and net-and-coble. Fixed nets/engines are prohibited.

6.3.3 At sea

It is prohibited to catch fish by enmeshment. Troll or long-lining is also illegal. Effectively the only lawful methods are net-and-coble, fixed engines (bag and skate nets) or rod-and-line.

6.4 Fishing Methods

The principal legal methods for catching salmon in Scotland are as follows:

- Fixed Engines (Bag and Skate Nets)
- Net-and-coble
- Rod-and-line

In inland waters, salmon can also be caught using a cruive (a sort of trap) where expressly permitted by the Crown Estate. This is however, very rare (SPICe, 2000).

6.4.1 Fixed Engines (Bag and Stake Nets)

Bag and stake nets are the most common types of gear used to catch salmon in Scottish coastal waters and are commonly referred to as fixed engines. Salmon fishing using this method is not permitted in inland waters (rivers above the estuary limits).

Bag nets are set to fish just below the surface in rocky coasts where they will not ebb dry at low tide. They may be set singly or in a line extending seawards from the shore. The entire net or line of nets is not permitted to extend more than 1,300m from the mean low water mark, excluding mooring warps or anchors. The nets must not be operated between 6pm Friday until 6am Monday. Catches are generally removed from the nets at slack tide (Galbraith and Rice, 2004; SI 1992/1974).

No part of the nets may be set with the purpose of catching fish by entanglement. The minimum mesh net size is 90mm. Nets are designed to target fish swimming close to the surface while following the coastline. The gear is made up of two principal elements, the trap and the leader. The trap is approximately 13.5m wide and 4.5m deep at the mouth, tapering to about 3m in width and 2.5m in depth at the head. The leader may not exceed 300m in length.

Stake nets are similar in design and operation to the bag nets except that they are set on sandy beaches, supported on stakes driven into the sand, where the receding tide exposes the nets. The maximum allowed leader length and total gear length are similar to those specified for bag nets. The configuration of a typical bag net is shown in Figure 6.2 below.

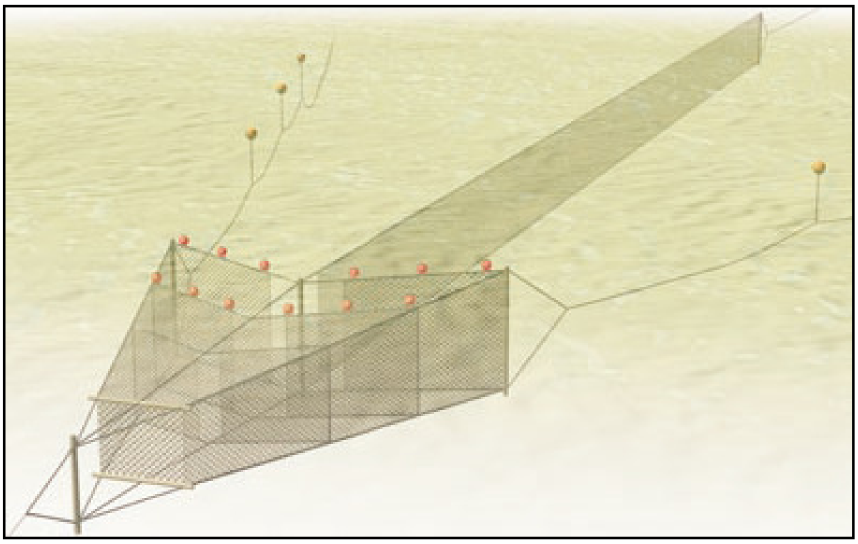

Figure 6.2 Bag Net showing the Trap, the Leader and Moorings

6.4.2 Net-and-Coble

Traditionally nets are operated from cobles, small flat bottomed, open boats, with a shore party assisting in operations. A member of the shore party holds the upstream hauling rope and the net is paid out from the stern of the vessel, as shown in Figure 6.3. The net must not be stationary or allowed to drift at any time and must be constantly 'swept', surrounding the fish and drawing them towards the shore. No other objects or obstructions may be used to aid fishing and adjacent netting operations must be at least 50m apart (Galbraith and Rice, 2004).

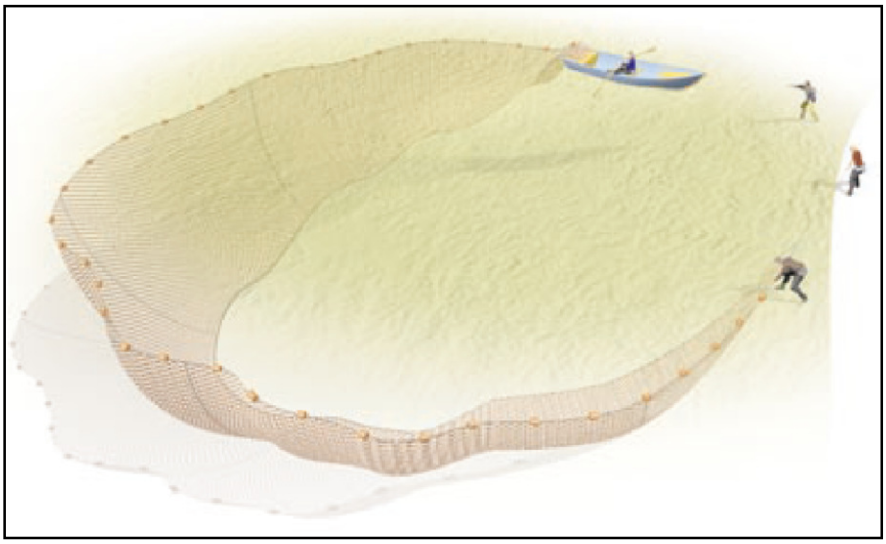

Figure 6.3 Net-and-coble Fishing

Net-and-cobles are generally operated in estuaries and the lower reaches of rivers, although small numbers are also used in coastal waters (Potter and Ó Maoiléidigh, 2006).

6.4.3 Rod and Line

At present, recreational rod-and-line fishing is the most common method of fishing for salmon. The Salmon and Freshwater Fisheries (Consolidation) (Protection) (Scotland) Act 2003, defines rod and line as: "*a single rod and line (used otherwise than as a set line or by way of pointing, or by striking or dragging for fish) with such bait or lure as is not prohibited".* DSFBs can apply to Scottish Ministers for regulations specifying baits and lures that may not be used for rod-and-line fishing in their district to be made whilst in some cases voluntary restrictions are set by the boards. Usually the restrictions prohibit the use of shrimps, prawns or worms as bait and the use of lures bearing multiple sets of hooks (SPICe, 2000). The use of fish roe, fire or light as bait or lure is also prohibited (Salmon and Freshwater Fisheries (Consolidation) (Protection) (Scotland), 2003)

Salmon and sea trout are generally not caught by rod-and-line at sea, but along river beats. Most DSFBs operate and police a catch and release policy. Due to increasing popularity, the sport makes a significant contribution to both local and regional economies.

6.5 Fisheries Data

The information given in this section is principally based on reported catches of salmon, grilse and sea trout recorded from 1952 to 2009 by region and by salmon fishery district within the North East region from 2000 to 2009. These were kindly provided by Marine Scotland Science. In addition, information gathered during the consultation process has also been included in this section where appropriate.

It should be noted that the analysis and interpretation of the fisheries statistics given below is not intended as an assessment of the abundance or state of the stocks but as an indication of the underlying population trends and the relative importance of the salmon and sea trout fisheries by region, fishery district and method.

6.5.1 National

6.5.1.1 Historical Data

This section provides an overview of historical catch data by species for the rod-and-line (including catch and release) and the net fishery (net-and-coble and fixed engines) in Scotland from 1952 to 2009.

Overall current salmon catches by rod-and-line (including catch and release) are in line with historical levels whilst for grilse there has been an increase in the total annual catch, especially during the second half of the data series. It is believed that increases in rod-and-line popularity may have to some extent kept catch values within historical levels. The overall trend in sea trout catches by the rod-and-line fishery, however, appears to be one of a decline (Figure 6.4).

Catches by the net fishery (net-and-coble and fixed engines), have also shown a marked decline in the last decades with respect to historical levels (Figure 6.5). The decline in catches observed for the net fishery is associated with a decrease in fishing effort most likely caused by, the buyout and closure of coastal netting stations, changes in abundance of salmon and the fall in the market price of wild salmon caused by competition from the aquaculture industry, among other factors (MSS, 2008). The decrease in netting effort may also have, to some extent, contributed to the catch levels observed in the rivers by the rod-and-line fishery.

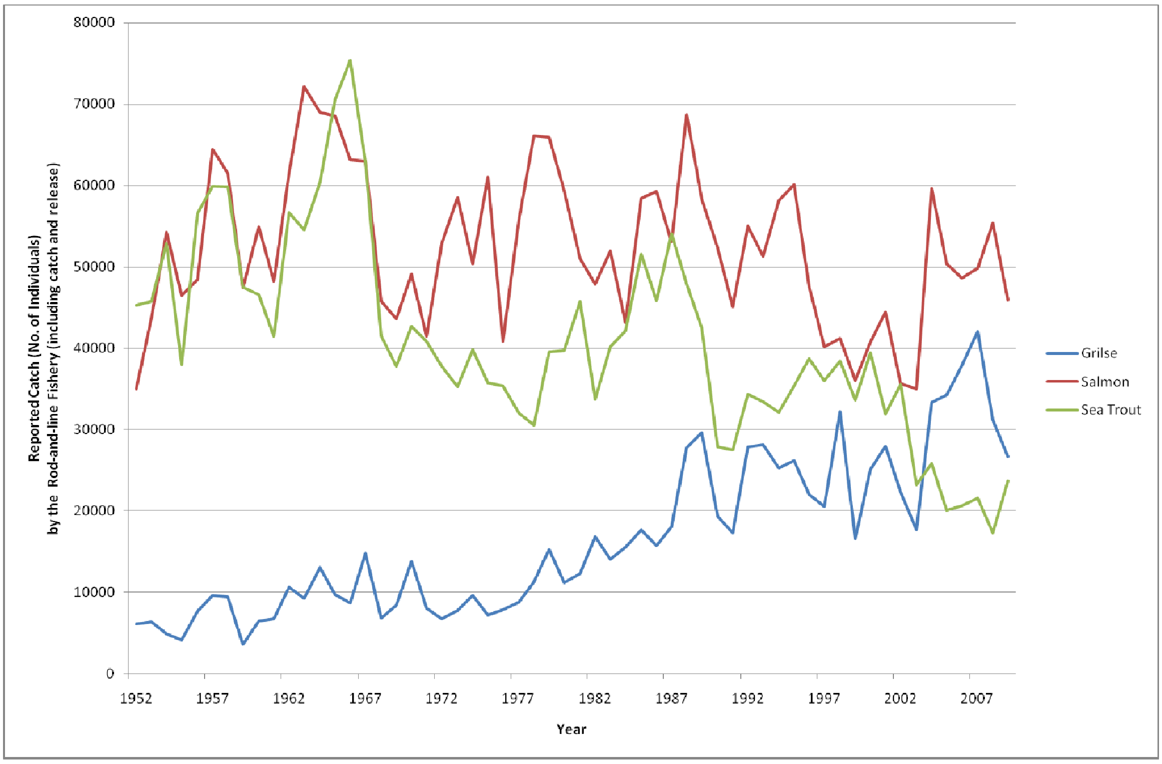

Figure 6.4 Rod-and-line Fishery (including Catch & Release) Reported Catches (1952-2009)

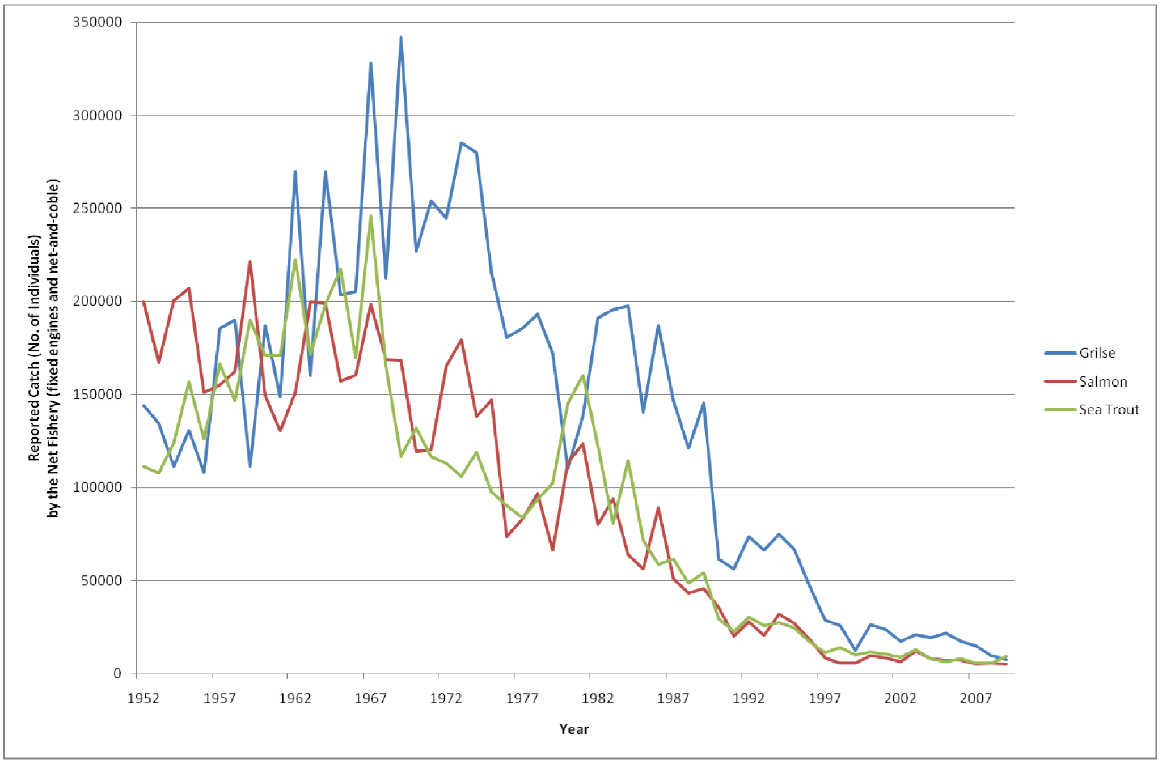

Figure 6.5 Net Fishery (Fixed Engines and Net-and-coble) Reported Catches (1952-2009)

6.5.1.2 Current Trends

An indication of the current salmon, grilse and sea trout catches by fishery region in the national context is given in Figure 6.6 below. This shows annual reported catches (average 2000-2009) for salmon, grilse and sea trout by fishery region.

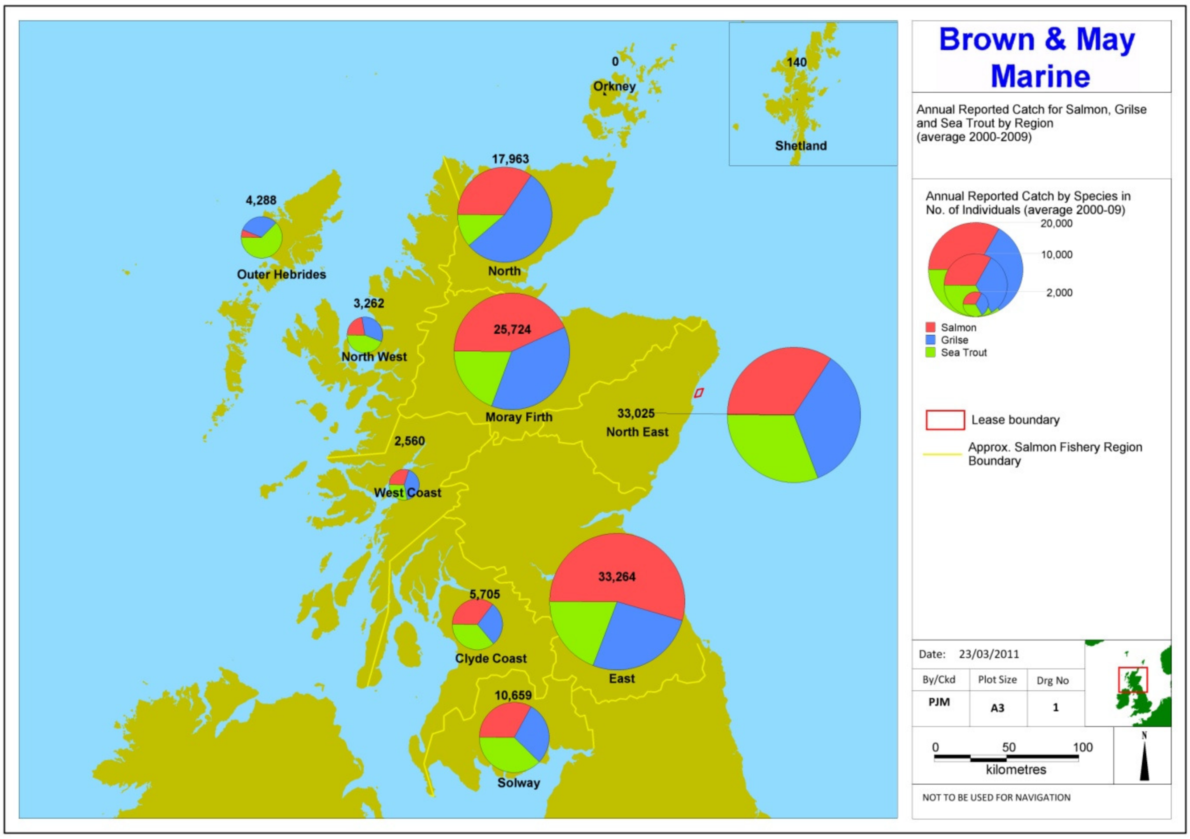

Figure 6.6 Annual Reported Catch (No. of Individuals) by Species and Region (average 2000-2009)

As it is apparent from Figure 6.6, reported catches are greater in the east coast of Scotland. The North East region shows the second highest annual catch (average 2000-2009) in Scotland.

The principal fishing methods used by fishery region are illustrated in Figure 6.7.This shows annual catch (all species combined) by method and region (average 2000-2009). Rod-and-line (including catch and release), accounts for the majority of the average annual catch in most regions, however netting by fixed engines and net-and-coble is also of relevance in some regions.

The netting component of the total catch is of special importance in the North East Region, where the combined catch by fixed engines and net-and-coble accounts for a similar percentage of the total catch (50.3%) than that recorded by the rod-and-line fishery (including catch and release) (49.7%). It should be noted that the majority of the catches by both fixed engines and net-and-coble in this region come from the Esk district. The current netting fishery in the Esk is discussed in further detail in 6.5.3 below.

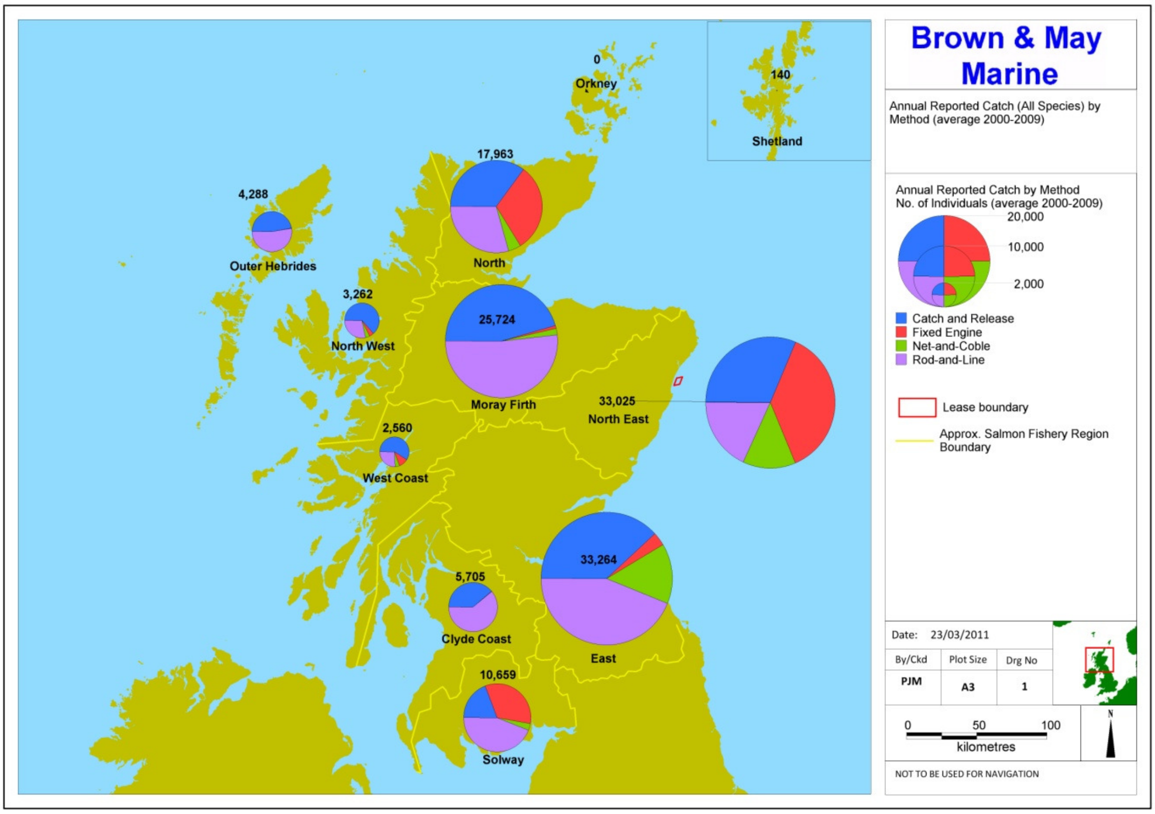

Figure 6.7 Annual Reported Catch (No. of Individuals) by Method and Region (average 2000-2009)

6.5.2 Regional

6.5.2.1 Catches by District

The annual reported catch (average 2000-2009) by salmon fishery district within the North East region is shown in Figure 6.8 and Figure 6.9 by species and method respectively. Note that for the Esk district, catch statistics are broken down by former district (North Esk, South Esk and Bervie).

The Esk and the Dee account for the majority of the catches for all species within the North East region. The Dee shows the highest annual catch for salmon whilst the North Esk and South Esk have the highest grilse catch.

Overall sea trout records catches are similar to those recorded for salmon in the region. In the Ythan and the Ugie, the two districts with the lowest annual catches however, sea trout accounts for a relatively high percentage of the total catch.

Rod-and-line is the principal fishing method in the Dee, the Don and the Ythan, a high percentage of which is by catch and release, particularly in the Dee and the Don.

Fixed engines account for the majority of the catch in the Esk district, especially in the South Esk. In the Don, the Ythan and to a lesser extent the Ugie, fixed engines also account for a relatively important percentage of the total catch. Net-and-coble represents a significant component of the North Esk's and Ugie's annual total catch. The Dee is the only district within the North East region where there is no netting activity, with no reported catches by either fixed engines or net-and-coble.

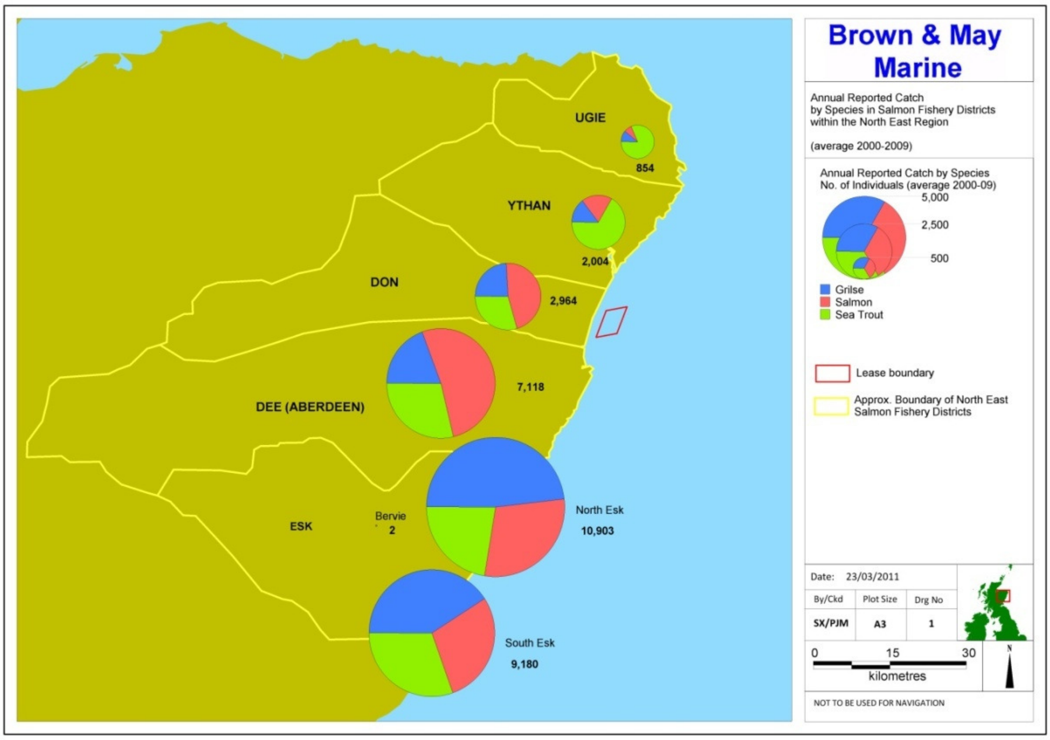

Figure 6.8 Annual Catch (No. of Individuals) by Species in Salmon Fishery Districts within the North East Region (average 2000-2009)

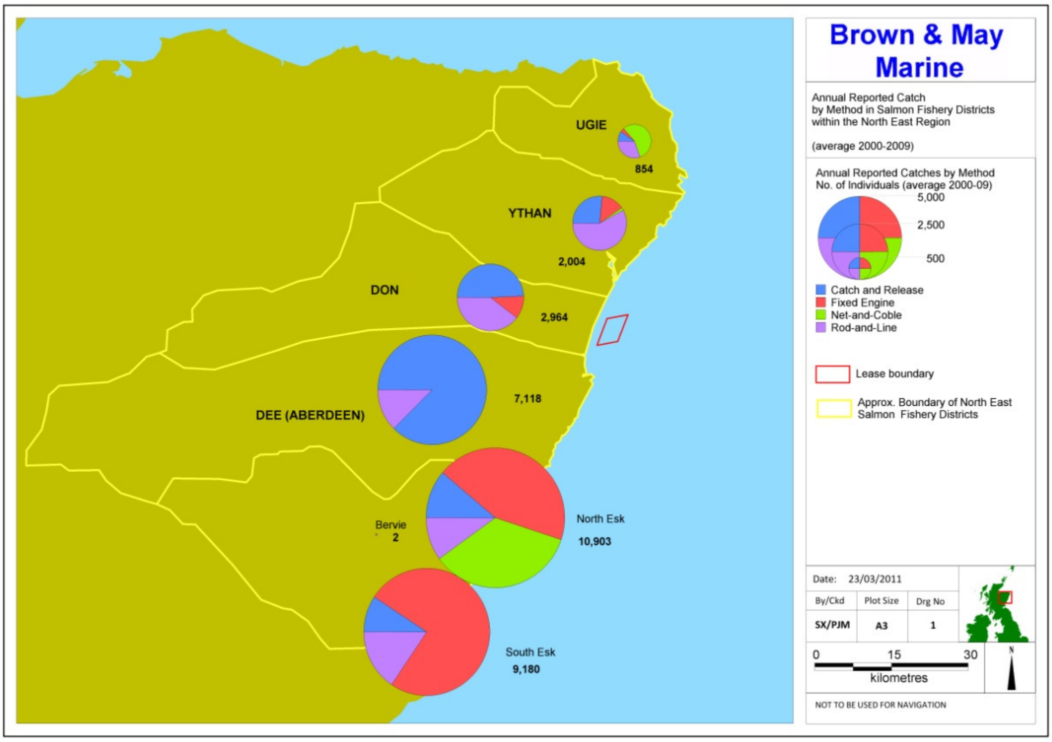

Figure 6.9 Annual Reported Catch (No. of Individuals) by Method in Salmon Fishery Districts within the North East Region (average 2000-2009)

6.5.2.2 Seasonality and Annual Variation

An indication of the seasonality and annual variation of the rod-and-line (including catch and release) and the net fisheries (separated into net-and-coble and fixed engines) by species and district is illustrated in Figure 6.10 to Figure 6.15 below, based on monthly reported catches averaged for the period 2000-2009 and total annual catches for the same period.

Rod-and-line Fishery Seasonality

Salmon catches peak in October in all the districts with the exception of the Dee, where peak catches are recorded in September. In the Dee, relatively high catch values are also shown from March to June, suggesting spring salmon runs to be of importance to the overall rod-and-line fishery in the district. The catch values recorded in the Don, the North Esk the South Esk during the spring also suggest that spring salmon account for a relatively important proportion of the total salmon catch in these districts.

Grilse are principally caught from June to October with peak catches recorded from August to October. Sea trout are caught from May to October with high catches recorded in June, July and August (Figure 6.10).

Rod-and-line Fishery Annual Variation

There has been a marked increase in the rod-and-line catches of salmon and grilse in the Dee. The total salmon catch in 2009 more than doubled that from 2000 in this district.

In the Don, overall, there has been a slight decrease in salmon catches whilst for grilse, catches have remained relatively constant. The highest catches for both salmon and grilse in the Don were recorded in 2004.

In the North Esk salmon catches have shown slight fluctuations over the years, whilst for grilse there has been a significant increase in the total catch by rod-and-line, with 172 grilse caught in 2000 compared to 1,144 in 2009.

Salmon and grilse catches have remained relatively constant in the Ythan and the South Esk from 2000 to 2009, with high values recorded between 2004 and 2005.

The general trend in sea trout catches is one of a decline in all the districts, principally as a result of the decrease in catch values recorded between 2000 and 2003 (Figure 6.11).

Figure 6.11 Annual Variation (2000-2009) of Catches by the Rod-and-Line Fishery (including Catch and Release)

Net-and-coble Fishery Seasonality

As previously mentioned within the North East region, net-and coble principally takes place in the North Esk and to lesser extent in the Ugie and the Ythan (See Figure 6.9 above).

In the North Esk peak catches of salmon are recorded in May, however June, July and August also record relatively high catches. Similarly, grilse catches peak in July and August. The highest sea trout catches are recorded from May to July peaking in June.

In the Ugie the highest salmon and grilse catches are recorded in July and August. Sea trout, the species accounting for the majority of the catch in the district, is caught in relatively high numbers from May to July, peaking in June.

In the Ythan, salmon and grilse catches by net-and-coble are comparatively low. The limited catches recorded by this method in this district, correspond to sea trout principally, and are mainly recorded from May to September with peak catches in August (Figure 6.12).

Net-and-coble Fishery Annual Variation

In the North Esk, salmon catches by net-and-coble have fluctuated from 2000 to 2007, with a significant increase recorded in the last two years. Grilse catches have also changed over the years with peaks in 2000 and 2005, followed by lows in 2004 and 2007. Sea trout catches in this district showed a marked decreased from a peak in 2001 through 2005. The trend has been one of an increase since then, especially in the last year (2009) which records the highest annual catch in the ten year period under consideration.

In the Ugie, no salmon and grilse were caught from 2000 to 2003 by net-and-coble. Since 2004 both species have been caught in relatively low numbers, ranging from 9 to 27 fish per year for salmon and 14 to 127 fish per year for grilse. Sea trout, the principal species in terms of catch in the Ugie, was caught in relatively high numbers from 2000 to 2006 with annual catches ranging from 378 to 782 fish. The catch for this species has however decreased since 2006, with a total of 50 and 66 fish caught in 2008 and 2009, respectively.

In the Ythan, salmon and grilse catches by net-and-coble have been very low from 2000 to 2009, ranging from 0 to 6 fish caught per year. Sea trout catches, have also been relatively low, ranging from 56 to 0 fish caught per year. The lowest sea trout catches within the period under consideration have been recorded in 2008 and 2009 with 6 and 0 individuals caught respectively (Figure 6.13).

Figure 6.13 Annual Variation in Catches by the Net-and-coble Fishery by Species and District

Fixed Engines Seasonality

The principal fixed engine net fishery within North East region takes place in the Esk district, as it was also the case for net-and-coble. The use of fixed engines in the remaining districts appears to be comparatively low, with only the Ythan and the Don recording catches by this method in some numbers.

Overall peak catches by this method are recorded from May to August for salmon, July and August for grilse and May and June for sea trout (Figure 6.14).

Fixed Engines Annual Variation

As it is apparent from Figure 6.15, there has been a strong decline in the total catch by fixed engines in the North Esk over the years, more obvious since 2007. This is a result of the buyout of the North Esk's coastal netting stations by the Esk District Salmon Fishery Board.

Despite the closure of the commercial coastal fishery in the North Esk, fixed engines are still commercially operational in the South Esk. The salmon catch in the South Esk by fixed engines has fluctuated over the ten year period under consideration, whilst for grilse the overall trend has been one of a decline, especially from 2007. Sea trout catches in the South Esk, have also fluctuated during the ten year period under consideration, with 2003 recording the highest catch (3,143 individuals) within the period.

In the Ythan the annual catch by fixed engines for all the species has been variable, with no clear trend shown from 2000 to 2009, whilst in the Don there is a clear trend towards a decrease in the annual total catch by fixed engines from 2004 onwards, with no fish being caught at all by this method in the last two years (2008 and 2009) (Figure 6.15).

Figure 6.15 Annual Variation in Catches by Fixed Engines by Species and District

6.5.3 The Esk District Net Fishery

The annual reported catches of the net fisheries by region in Scotland are illustrated in Figure 6.16 below. The catch in the North East region has been further broken down by individual district. The location of active net fisheries in Scotland in 2009 is also shown on the figure, based on graphical information provided by MSS.

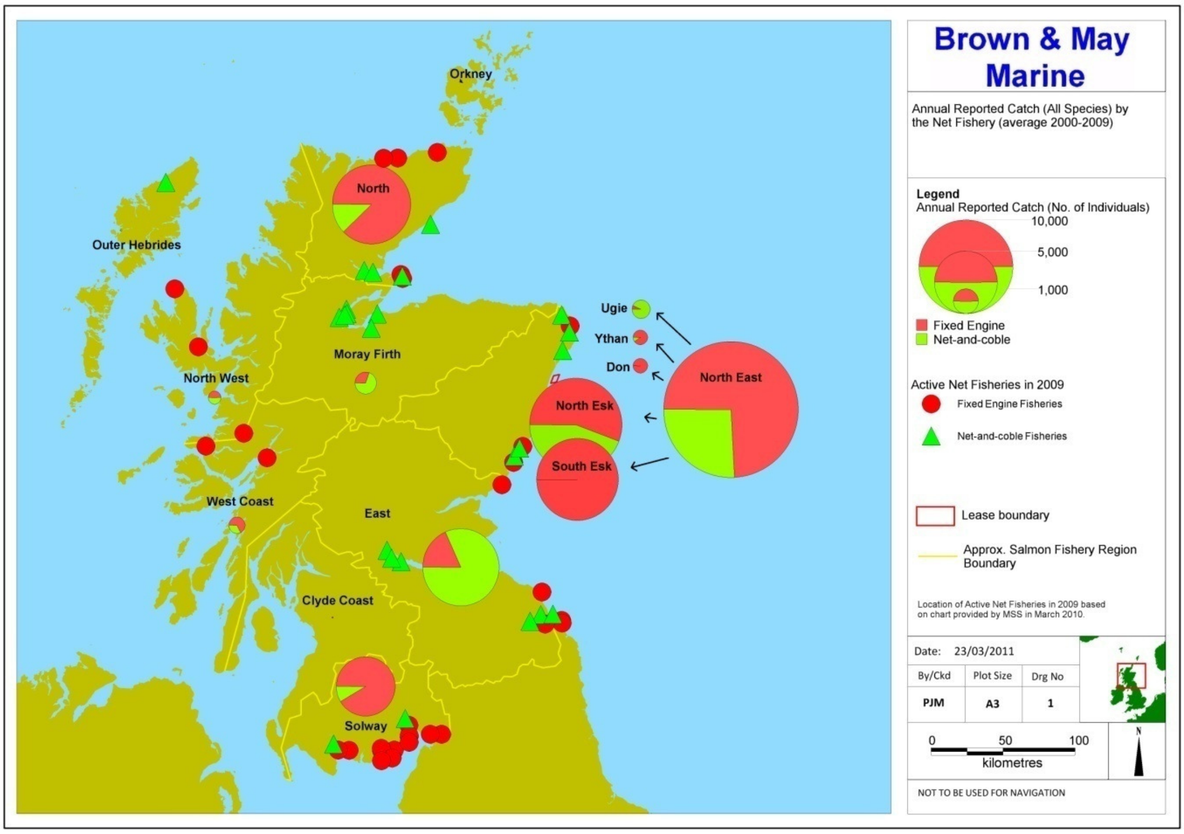

Figure 6.16 Annual (average 2000-2009) Reported Catch of Net Fisheries by Region

As it is apparent from Figure 6.16, the Esk district supports important net fisheries, accounting for the majority of the total net catch recorded in the North East and being of relevance in a national context.

In the South Esk, the principal fixed engine fishery currently active is the Usan Fishery. The Usan's heritable rights stretch between Scurdie Ness lighthouse to the north and Auchmethie Harbour near Arbroath to the south and it operates 8 netting stations. Fish caught by this fishery originate principally from the Tay up to the Dee and the Don (Consultation Meeting, 2011b).

As previously mentioned in Section 6.5.2.2, the fixed engine coastal fishery in the North Esk is currently closed as a result of the buyout of the coastal netting stations by the Esk Salmon Fishery Board. Net-and-coble, however, still takes place in the river. There is a net-and-coble station located at Kinnaber (Consultation Meeting, 2011b).

6.6 Local

6.6.1 Introduction

The following section provides reported catch data for the rod-and-line and the net fishery in the Don, the district located in the immediate vicinity of the proposed EOWDC and incorporates further information gathered through consultation with the Don District Salmon Fishery Board (DDSFB). As previously mentioned, consultation with individual coastal netting right holders will be undertaken once the location of the export cable has been defined.

6.6.2 Fishing Methods in the Don

The distribution of the reported catch (all species combined) in the district by fishing method from 2000 to 2009 is given in Figure 6.17. The majority of the catches in the Don are by rod-and-line, which accounts for 88.9% of the total catch, of which more than a half is by catch and release. The net fishery operates to a lower extent in the district, accounting for only 11.1% of the total reported catch. It should be noted that netting in the Don is only by fixed engines, with no net-and-coble currently taking place, although it existed in the past (Consultation Meeting, 2010c).

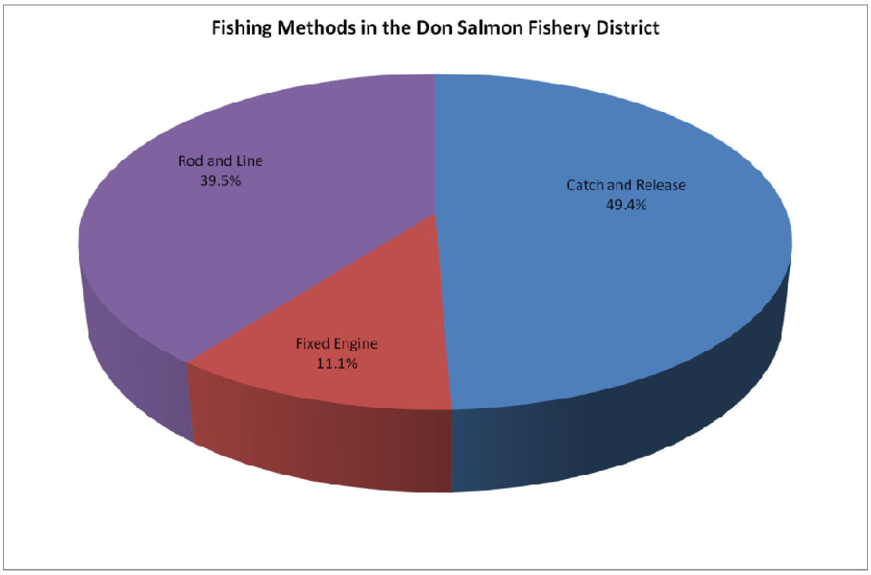

Figure 6.17 Distribution of the Catch by Method in the Don District (2000-2009)

6.6.3 Seasonality of the Fisheries and Main Runs

The netting season in the Don runs from 11th February to 26th August, whilst for rod-and-line the season lasts longer ending on 31st October (Consultation Meeting, 2010c). An indication of the seasonality of the catches by species is shown in Figure 6.18 and Figure 6.19 for the rod-and-line (including catch-and release) and net fishery (fixed engines) respectively, based on average monthly catches for the period 2000-2009.

6.6.3.1 Rod-and-line

The rod-and-line fishery records the highest reported catches from August to October for salmon and grilse, and between June and October for sea trout. It should be noted that earlier fish runs (eg. spring salmon) whilst recording lower catches are also of relative importance to the fishery as they allow for extended fishing seasons (Figure 6.18).

	January	February	March	April	May	June	July	August	September	October	November	December
Grilse	0.0	0.0	0.0	0.7	4.2	22.3	52.9	113.6	177.3	186.3	0.0	0.0
Salmon	0.0	23.3	53.1	105.8	87.6	45.0	48.4	120.3	313.6	495.3	0.0	0.0
Sea Trout	0.0	0.7	3.1	6.7	40.3	179.8	172.6	144.5	154.6	83.4	0.0	0.0

Figure 6.18 Reported Catch by Rod-and-line (including catch and release)

6.6.3.2 Fixed Engines

The seasonality of reported catches in the net fishery is similar to that shown for rod-and-line. The highest catches in fixed engines are however recorded slightly earlier than by rod-and line. The seasonality of the captures by fixed engines reflects to some extent the timing of the coastal migration of adult salmon and sea trout before entering the river to spawn (Figure 6.19).

	January	February	March	April	May	June	July	August	September	October	November	December
Grilse	0.0	0.0	0.0	0.0	0.3	22.1	81.2	54.9	0.0	0.0	0.0	0.0
Salmon	0.0	1.7	3.2	6.1	7.2	17.1	26.9	20.3	0.0	0.0	0.0	0.0
Sea Trout	0.0	0.0	0.0	1.3	18.7	47.6	16.4	3.2	0.0	0.0	0.0	0.0

Figure 6.19 Reported Catch by Fixed Engines

6.6.3.3 Principal Runs

The main runs of salmon and sea trout as specified by the DDSFB (Consultation Meeting, 2010c) in the Don are as follows:

- Spring salmon: mid December to April
- 2SW salmon: May-June
- Grilse: July to Mid October
- Sea trout: June to early August

In addition to the runs detailed above, there are two smolt runs in the Don. The first takes place in May through to early June and the second in September (Consultation Meeting, 2010c).

There has been a change in the timing of the grilse run in recent years. In the past, the bulk of the grilse run used to take place in July, however this now takes place later in the season with the peak run taking place in late August and continuing through until October ((Consultation Meeting, 2010c).

6.6.4 Annual Variation

An indication of the annual changes in the total catch by species from 2000 to 2009 in the Don is given in Figure 6.20 and Figure 6.21 for the rod-and-line fishery (including catch and release) and net fishery (fixed engines), respectively.

6.6.4.1 Rod-and-line

Salmon catches peaked in 2004, with a decline in the following years. 2009 recorded the lowest salmon catch in the district within the ten year period under consideration.

The grilse catch has fluctuated over the years, ranging from a minimum of 419 to a maximum of 887 fish reported per year, peak catches were recorded in 2004. The trend in sea trout catches has been one of a decline, particularly between 2000 and 2003, when a strong decrease in catches for this species was observed (2,253 fish caught in 2000 compared to 445 fish caught in 2003).

	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009
Grilse	419	512	430	556	887	526	675	626	450	492
Salmon	1133	1528	1235	761	2453	2025	1483	786	839	681
Sea Trout	2253	1425	807	445	1011	523	659	294	157	283
Total	3805	3465	2472	1762	4351	3074	2817	1706	1446	1456

Year

Figure 6.20 Annual Variation of the Rod-and-line Catch by Species in the Don District (2000 -2009)

DDSFB's representatives indicated during consultation that the spring stock salmon fishery in the Don has shown a slight improvement two years running and that similarly, the grilse, autumn salmon and sea trout runs have also improved in the past few years (Consultation Meeting, 2010c).

6.6.4.2 Fixed Engines

As it is apparent from Figure 6.21 below, there has been a marked decrease in catches by fixed engines in the Don for all species in the last few years, especially since 2003-2004. It should be noted that no catches have been reported by this fishery in 2008 and 2009.

In line with this, anecdotal evidence suggests that the remaining netsmen in the local area operate on a part–time or hobby basis, with the closest commercial netting stations located to the south, in the Esk District near Montrose (MS, 2007).

	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009
Grilse	128	369	265	350	316	133	23	0	0	0
Salmon	87	118	150	223	134	73	32	8	0	0
Sea Trout	103	49	268	213	164	36	34	5	0	0
Total	318	536	683	786	614	242	89	13	0	0

Year

Figure 6.21 Annual Variation of Fixed Engines Catch by Species in the Don District (2000 -2009)

6.6.5 Coastal Netting Stations in the Don

There are eight coastal netting stations in the Don district located in the immediate vicinity of the Aberdeen Offshore Wind Farm. Their locations and current owners are shown in Figure 6.22.

Three of the eight stations have been bought up by the DDSFB, the Atlantic Salmon Trust and Trump International and are not currently fished (Consultation Meeting, 2010c). The five remaining stations (shown in dark and light blue in Figure 6.22) are owned by two right holders. No catches have been reported in the last two years from these stations, suggesting that they are not currently fished. It should however be recognised that a degree of under-reporting may have occurred. In addition, netting activities may at any time recommence.

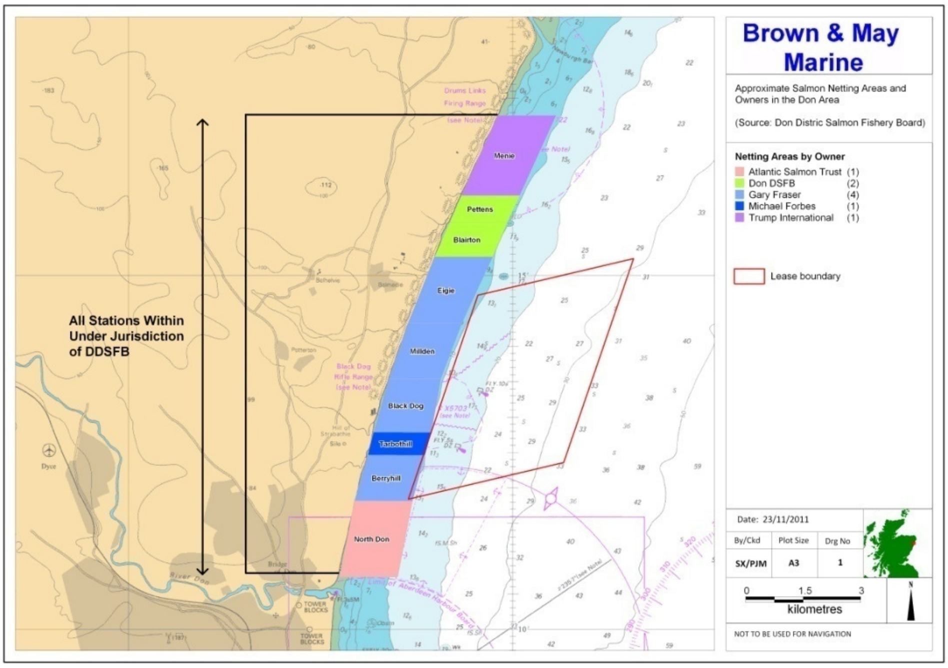

Figure 6.22 Coastal Netting Stations under jurisdiction of the Don District Salmon Fishery Board

6.7 Future Fisheries

As explained in Section 6.3, salmon fisheries are subject to a wide range of regulations and restrictions, from government through to individual districts. All the DSFBs in the North East region are making significant efforts to ensure the future of the industry and specifically the rod-and-line fishery with DSFBs, trusts and conservation groups implementing programmes to maintain and improve upon the number and quality of salmon and sea trout in their rivers. Catch and release policies are also increasingly closely monitored and hatcheries have been developed in some districts.

A priority for the majority of the Boards is the maintenance and development of rod-and-line fishing. It is expected that this trend will continue in the future, in line with the joint aims of the ASFB and other organisations. Parallel to the maintenance and development of the rod-and-line fisheries, a decrease in the costal netting activity in Scotland, either as a result of river and conservation interests buying up coastal stations, as well as increasing restrictions, has been the trend in the last decade. This will likely continue to be the case in the future.

Scotland, together with England, Norway and Northern Ireland has come under increasing international pressure to establish a policy for managing Multi Stock Fisheries (MSFs). This is of particular sensitivity in Scotland, as fishing is prosecuted under heritable property rights, rather than as an activity licensed by Government, as in most salmon producing countries (Crawley, 2010). International advice is that there should be a presumption against operating Multi Stock Fisheries, such as coastal netting, unless they can be shown not to contravene basic conservation policies (ASFB, AST and S&TA, 2009).

It should be noted that there are numerous constraints placed upon the degree to which potential losses and their significance to salmon and sea trout fisheries can be assessed over the operational life of the proposed EOWDC. As is the case with other commercial fishing activities, unpredictable and unrelated influencing variables such as natural fluctuations in stock levels or changes in legislation could significantly alter elements within the baseline.

As discussed in Section 5.6, both salmon and sea trout Scottish populations are currently subject to a number of threats. Whilst conservation measures to protect these species have increased in the last years, it is not possible to be certain of what the outcome of these will be and how this will be affected by natural fluctuations in stock levels during the life time of the proposed EOWDC.

6.8 Main Concerns raised by Fisheries Stakeholders

The main concerns expressed during consultation meetings and in questionnaires by fisheries stakeholders are as follows:

- Potential impact on migratory patterns and disturbance derived from EMFs
- Potential impact on migratory patterns and disturbance derived from underwater noise during construction
- Potential impact of sediment plumes derived from construction activities
- Potential for the proposed EOWDC to alter the path the salmon take to return to home rivers
- Indirect impacts caused by changes in prey availability, principally in relation to sandeels.
- Potential for the turbines to result in a physical barrier to migration

APPENDIX 01- CONSULTATION

Questionnaires

Completed questionnaires have been received from the following fisheries stakeholders:

- District Salmon Fishery Boards
    - Don
    - Ythan
    - Dee
    - Brora
    - Kyle of Sutherland
    - Tweed
    - Caithness
    - Lossie
    - Cromarty
    - Ness/Beauly
    - Helmsdale

- Netsmen/Net Fisheries
    - Kincurdie Salmon Fishings-Patience Family Trust (Ness)
    - Wilkhaven and Castle Salmon Fishery - Ian N. Paterson (Cromarty)

- Moray Firth Sea Trout Project (MFSTP)

Consultation Meetings

Consultation meetings were carried out with the following District Salmon Fishery Boards and net fisheries:

- Ugie District Salmon Fishery Board (26/10/2010)
- Ythan District Salmon Fishery Board (26/10/2010)
- Don District Salmon Fishery Board (27/10/2010)
- Dee District Salmon Fishery Board (17/01/2011)
- Esk District Salmon Fishery Board (27/10/2010)
- Usan Fisheries (Montrose) (17/02/2011)

1.0 Introduction

The following document details the Salmon and Sea Trout Impact Assessment for the European Offshore Wind Deployment Centre (EOWDC).

The primary focus of this report is the assessment of the potential for salmon and sea trout, especially during migration, to be affected by the EOWDC. Given the socio-economic importance of the salmon and sea trout fishery in Scotland, both in rivers and in coastal waters, the potential for the fishery to be directly or indirectly affected has also been evaluated (Section 3.5).

2.0 Methodology

2.1 Key Guidance Documents

In the absence of guidelines specific to the assessment of impacts on salmon and sea trout and in relation to offshore wind farm developments, the following documents have provided guidance:

- Strategic Environmental Assessment (SEA) of Draft Plan for Offshore Wind Energy in Scottish Territorial Waters: Volume 1: Environmental Report. Marine Scotland. 2010
- Habitats Regulations Appraisal Draft Plan for Offshore Wind Energy in Scottish Territorial Waters: Appropriate Assessment Information Review. Marine Scotland .2011
- Offshore Wind Farms guidance note for Environmental Impact Assessment in respect of FEPA and CPA requirements. Version 2- 2004
- EOWDC Marine Scotland Scoping Response (December 2010 and January 2011 update)

2.2 Information and Data Sources

The principal sources of information used for the undertaking of this assessment are as follows:

- Marine Scotland Review of Migratory routes and behaviour of Atlantic salmon, sea trout and European eel in Scotland's coastal environment: Implications for the development of marine renewables (Malcolm *et al*., 2010)
- Scottish Natural Heritage Literature review on the potential effect of electromagnetic fields and subsea noise from marine renewable energy developments on Atlantic salmon, sea trout and European eel (Gill and Barlett, 2010)
- Consultation with District Salmon Fishery Boards and other relevant stakeholders
- Collaborative Offshore Wind Research Into the Environment (COWRIE) Publications
- Monitoring Surveys undertaken in Operational Wind Farms
- Other publically available research literature

2.3 Consultation

Consultation meetings were held with all the salmon fishery boards located within the North East region and with representatives of the netting fishery in the North East.

These were as follows:

- Ugie District Salmon Fishery Board (26/10/2010)
- Ythan District Salmon Fishery Board (26/10/2010)
- Don District Salmon Fishery Board (27/10/2010)
- Dee District Salmon Fishery Board (17/01/2011)
- Esk District Salmon Fishery Board (27/10/2010)
- Usan Fisheries (Montrose) (17/02/2011)

In addition to the above meetings, questionnaires were circulated to all the salmon district fishery boards in Scotland, through the Association of Salmon Fishery Boards (ASFB), and to netsmen, through the Salmon Net Fishing Association of Scotland.

2.4 Data and Information Limitations and Data Gaps

Extensive studies and research concerning the behaviour of salmon, and to a lesser extent sea trout, have been, and are being, undertaken. Despite this, however, the behavioural patterns of the species in the marine environment, particularly on the Scottish east coast, are not fully known and a degree of uncertainty exists regarding salmon and sea trout migratory routes, behaviour in coastal waters, navigation mechanisms and the implication of responses to factors such as noise and EMFs during migration. In light of this, and in order to provide a robust assessment of impacts, a number of assumptions have been made that are further discussed in Section 2.5.7 below.

2.5 Impact Assessment Methodology

The assessment aims to describe the magnitude of effect for each potential impact (i.e. the change created by an activity in terms of its spatial extent, duration and scale) and the sensitivity of each receptor (i.e. the environmental resources that would be affected) based on its importance and recoverability. The effect and sensitivity of the receptor are then used to derive the significance of each potential impact.

2.5.1 Potential Impacts

The potential impacts to be considered are summarised in Table 2.1 below for the construction, operational and decommissioning phases. For the purposes of this assessment and given the uncertainties relating to decommissioning methods at this stage, it has been assumed that the impacts derived from the decommissioning phase will, at worst, be of the same significance as those derived from construction.

Table 2.1 Summary of Key Potential impacts on Salmon and Sea Trout

Development Phase	Source of Impact	Potential Effect
Construction/ Decommissioning	Noise	Direct Impact: Lethal Effects and Hearing Damage
		Disturbance/Delay /Barrier to Migration
		Indirect Impacts: Loss of Key Prey Species
	Increased Sediment Concentrations	Direct Effects
		Disturbance/Delay/Barrier/ to migration
Operation	Noise	Disturbance/Delay /Barrier to Migration
		Indirect Impact: Loss of Key Prey Species
	Physical Presence of Turbines	Disturbance/ Delay/Barrier to Migration
	EMFs	Disturbance /Delay/Barrier to Migration

Given the migratory nature of salmon and sea trout and the potential for the proposed EOWDC to have different impacts on these species depending on the life stage under consideration, for the purposes of this assessment, the receptors have been sub-divided as follows:

- Juvenile salmon (smolts/post-smolts)
- Juvenile sea trout (smolts/post smolts)
- Adult salmon (grilse and Multi-Sea Winter (MSW) salmon)
- Adult sea trout

2.5.2 Assessment Criteria

The criteria used in the assessment are given below:

Spatial Extent of Effect

- A national/international effect
- A regional effect
- A local, site specific effect including within 5km of the site

Duration of Effect

- A long term/permanent effect (more than 10 years)
- A medium effect (existing for 5 to 10 years)
- A short term effect (existing for 1 to 5 years)
- A temporary effect (existing for less than 1 year)

Scale of Effect

- Above accepted standards/guidelines
- Within accepted standards/guidelines
- Where there are no standards/guidelines available, the impact relative to background conditions

Recoverability of the Receptor

- High
- Medium
- Low or None

Importance of the receptor (taking into account international, national and regional legislation, and function within the ecosystem)

- High
- Medium
- Low or None

The impact significance is then given as *MAJOR, MODERATE, MINOR* or *NEGLIGIBLE* guided by the matrix is given in Table 2.2.

Table 2.2 Matrix Used to Guide Significance Ratings of Impacts

		Sensitivity of Receptor			
		VERY HIGH	HIGH	MEDIUM	LOW
Magnitude of Effect (based on spatial, duration and scale)	VERY HIGH	Major	Major	Major	Moderate
	HIGH	Major	Major	Moderate	Minor
	MEDIUM	Major	Moderate	Minor	Minor
	LOW	Moderate	Minor	Minor	Negligible
	NEGLIGIBLE	Minor	Negligible	Negligible	Negligible

2.5.3 Implications of Significance

Where the significance for a potential impact is classified as ***MODERATE to MAJOR*** or ***MAJOR,*** it is considered to be a potentially significant effect. It should be noted however that significant effects may not be unacceptable as their effect may be reversible. A ***NEGLIGIBLE*** significance is assigned to a potential impact if it produces no discernible effect on the environmental resource in question.

2.5.4 Cumulative and In-combination Impact Assessment Methodology

The cumulative and in-combination impact assessments have applied the same methodology and potential impacts outlined above.

In-combination impacts relate to European protected sites that could be affected by the proposed development. These assessments have been addressed within the Habitats Regulations Assessment.

Cumulative impact assessments have been undertaken on those developments and activities which could be reasonably be expected to have an effect.

Other Offshore Wind Farms

The wind farm developments which could contribute to the cumulative impacts are those proposed in the Firth of Forth to the south and the Moray Firth to the north.

Offshore Oil & Gas Developments

Current available information suggests that there is not anticipated to be offshore oil and gas exploration or production activities within the general area of the proposed EOWDC site which could contribute to cumulative effects. This activity has therefore been scoped out of the cumulative assessment process.

Introduction of Marine Protected Areas (MPAs)

The Marine (Scotland) Act has established powers for the development of Marine Protected Areas (MPAs) in the seas around Scotland. These areas, however, have yet to be defined. The introduction of MPA's is not however expected to have any adverse impact on salmon and sea trout and have therefore been scoped out of the cumulative assessment process.

Aggregate Dredging

The Middle Bank licensed dredging area in the Firth of Forth, approximately 150 km from the EOWDC, is the closest licensed dredging area. It should be noted that at present it is not active. This activity has therefore been scoped out of the cumulative assessment process.

Other Offshore Works

Currently there is no information on other offshore works that would contribute to cumulative impacts on salmon and sea trout.

Ocean Laboratory

It is proposed that an Ocean Laboratory may be installed within the site. This will be subject to a separate application and EIA. As such, at this stage, it will only be assessed in terms of its cumulative effect.

2.5.5 Assessment of Impacts against a Changing Baseline

A number of factors unrelated to the proposed EOWDC development may cause changes to salmon and sea trout populations over the life of the project. For instance, increased marine mortality, a trend that has been observed in recent years and thought to be related to environmental factors, could result in a further decline in the numbers of salmon and sea trout in rivers. Furthermore, changes in fishing practices in the coastal and marine environment, and the introduction of further legislation and conservation measures could also impact the state of salmon and sea trout stocks.

2.5.6 Worst Realistic Case

The worst realistic case is assumed to be the installation of 11 turbines, all of which have 8.5 m diameter monopile foundations. The theoretical worst case in terms of cumulative assessment would be the simultaneous construction of the proposed offshore wind developments in the Firth of Forth and in the Moray Firth, coinciding with the proposed EOWDC.

2.5.7 Assumptions

As stated above data gaps exist with respect to the salmon and sea trout baseline and therefore for the purposes of the impact assessment certain assumptions have been made.

Figure 2.1 below shows the location of the EOWDC relative to the principal salmon rivers in the regional area. It can be seen that the Dee, Don and Ythan are closest to the development and the assumption has been made that fish from these rivers are more likely to transit the site. It is also recognised however that fish from other rivers, both within the region (e.g North Esk, South Esk, Ugie) and from other Scottish areas (e.g Moray Firth, North, etc) may on occasions also be present in the vicinity of the development.

Taking a precautionary approach the following assumptions, based on the behavioural patterns of salmon and sea trout, have been made for fish originating in the Dee, Don and Ythan Districts:

- Juvenile salmon and sea trout transit through, or in close proximity to, the site on their seaward migration
- Adult salmon (grilse and MSW) and sea trout transit through, or in close proximity to, the site on their return migration
- Sea trout are present in the vicinity of EOWDC and transit the site as part of their foraging activity

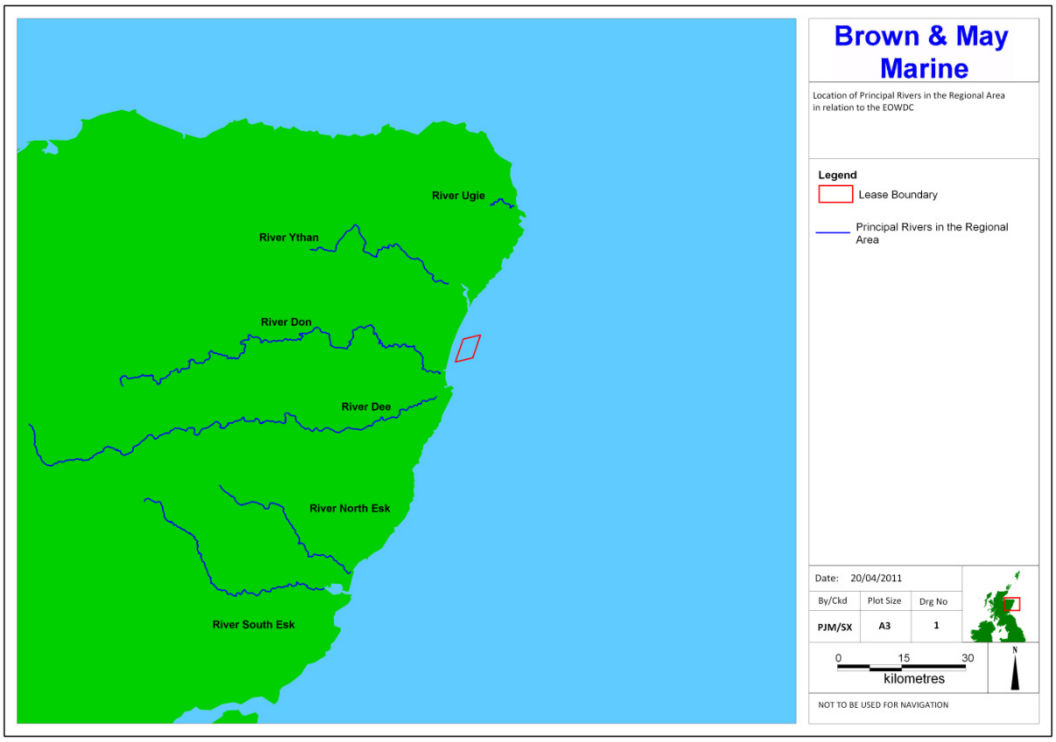

Figure 2.1 Location of the Principal Rivers in the Region in relation to the EOWDC

3.0 Impact Assessment

3.1 Noise and Vibration

3.1.1 Construction and Decommissioning

The principal source of noise during the construction phase will be the possible piling of foundations (monopiles and to a lesser extent jacket structures). Although cable laying and burial, rock placement for scour protection (should it be required) and vessel movements will also result in some levels of noise, these activities will be temporary and localised.

The theoretical maximum number of piling events will be limited to eleven and piling will not be continuous. Under normal conditions, the durations of piling individual foundations for wind farms constructed to date, have typically varied between 20 minutes and thirteen hours. For the purposes of this project, five days is taken as the theoretical maximum duration for the installation of a single foundation within which 24 hours continuous piling is assumed as worst case (further details in Chapter 3, Description of the Proposed Development).

Predicted noise levels from piling activity at the proposed EOWDC were modelled based on piling of 8.5 m diameter piles (worst case) at four different locations (turbines 1, 3, 7 and 11) and taking account of the hearing ability of salmon using the dB_{ht} *(Species)* metric. The model predicts that noise levels which would result in traumatic hearing damage in salmon (130dB_{ht} *(Salmo salar))* could occur at distances of within 20 m of piling (Nedwell *et al.*, 2011). Contour plots of estimated 90dB_{ht} *(Salmo salar)* impact ranges, at which strong behavioural reactions would be expected, were also produced. The results suggest that, at turbine 7 where the 90dB_{ht} impact range was greatest, the average impact range would be 4.2 km (value range 3.6 km- 4.7 km).

An indication of the spatial ranges at which behavioural reactions in salmon may occur for two of the four locations modelled is given in Figure 3.1. This illustrates the estimated 90dB$_{ht}$ *(Salmo salar)* and the 75bB$_{ht}$ *(Salmo salar)* impact ranges contours. It is considered that at 75dB$_{ht}$ levels, 85% of individuals would react to noise although effects will probably be limited due to habituation.

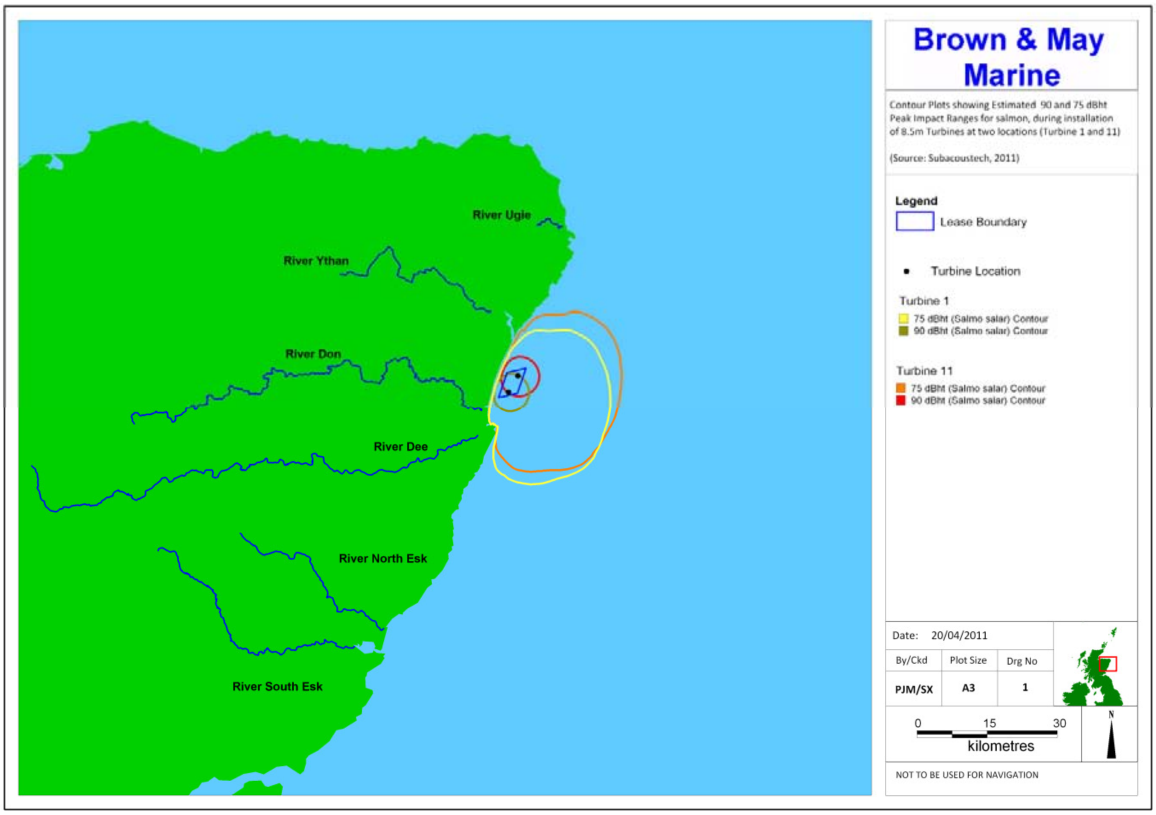

Figure 3.1 Contour Plots showing Estimated 90 and 75dB$_{ht}$ *(Salmo salar)* peak impact ranges during installation of 8.5m diameter Turbines at two locations (Turbine 1 and 11) (Source: Nedwell *et al.*, 2011)

It should be noted that the assessment given below is based on a theoretical worst case scenario, involving piling of 11 monopiles of 8.5 m diameter. As the EOWDC is an experimental development to trial various foundations types, in reality it is expected that less than eleven monopiles will be installed.

Unlike hearing specialists such as herring, salmonids have no direct connection between the swim bladder and the ear and are therefore considered to be hearing generalists.

Salmon have been shown to respond to low frequency sounds (below 380 Hz), with best hearing (threshold 95 dB re 1 μ Pa) at 160 Hz (Hawkins and Johnstone, 1978). The ability of salmonids to respond to sound pressure is regarded as relatively poor with a narrow frequency span, a limited ability to discriminate between sounds, and a low overall sensitivity (Gill and Bartlett, 2010). Based on sound measurements undertaken in the River Dee, Hawkins and Johnstone (1978) concluded that salmon are unlikely to detect sounds originating in air, but may be sensitive to substrate borne sounds.

Research carried out on the effects of piling noise on caged brown trout (*Salmo trutta)* at the Red Funnell's Southampton Terminal (Nedwell *et al*., 2003a) found no behavioural reactions to vibro-piling and no responses to hammer pile operations for fish as close as 50 and 417 m from the source, respectively. Further studies carried out on brown trout (*Salmo trutta*) suggest that the hearing of brown trout is less sensitive than that of salmon. Analysis using the dB_{ht} metric indicated that the noise at the nearest locations during impact piling reached levels at which salmon were expected to react strongly, however, brown trout showed little reaction (Nedwell *et al*., 2006).

For the purposes of this assessment, salmon has been used as a surrogate for sea trout, whilst it is appreciated that the sensitivities of the two species may be different. In addition, it is recognised that juveniles, such as smolts, and small grilse, may also have different sensitivities than adults, being generally considered to be more vulnerable to noise impacts (Hastings and Popper, 2005; MS, 2011). In experimental and river settings they have been found to avoid localised high intensity sounds less than 10 Hz (Sand *et al*., 2001; Knudsen *et al.,* 1992; Knudsen, 1997).

3.1.1.1 Direct Impacts: Lethal Effects and Hearing Damage

Potential Impact

Based on the results of the noise modelling undertaken for salmon (Nedwell *et al.*, 2011), it is expected that lethal noise levels during construction would only occur in the immediate vicinity of areas where piling is being undertaken (< 3 m from the pile).

Similarly the potential for traumatic hearing damage in salmon and sea trout would only take place in localised areas. Using the $130dB_{ht}$ criteria from Nedwell *et al*. (2007), and assuming fish are not deterred from the area, salmon would be expected to suffer traumatic hearing damage within 20-30 m of the piling activity. This distance has been further refined using the fleeing animal model which assumes that animal swim away from the noise source. Using a swim speed of 1 m/s and taking into account the accumulated noise dose near a typical piling operation, the model calculates that fish within 1 m of the piling activity, at the onset of piling, are unlikely to be able to flee before suffering hearing damage.

As lethal/traumatic hearing damage effects are only predicted to occur very close to the pile, and given that soft start piling will deter animals from this area, the magnitude of this impact is considered to be *NEGLIGIBLE*. The receptors, taking the small number of fish potentially present at a given time within the small spatial area where impacts could occur and given their importance as conservation species are considered of *HIGH* sensitivity. The potential direct impacts derived from construction noise on salmon and sea trout are therefore considered of *NEGLIGIBLE* significance.

Mitigation

None other than the use of soft start piling.

Residual Impact

NEGLIGIBLE

Cumulative Impact

None

3.1.1.2 Disturbance/Delay/Barrier to Migration

As illustrated in Figure 3.1 there is potential for behavioural responses to occur in a wider area than just the immediate turbine locations ($95dB_{ht}$ and $75dB_{ht}$ contours). The implications of behavioural responses will depend on the life stage under consideration and the ecology of the species, and on assumptions (Section 2.5.7), rather than definitive research evidence of salmon and sea trout migration routes.

Potential Impact

Salmon and Sea Trout Juveniles (Smolts/Post-smolts)

Information on the behaviour of salmon and sea trout smolts and post-smolts in Scottish waters once they leave the freshwater habitat is limited. Smolts usually leave rivers from April to June and are thought to make limited use of estuarine habitats moving rapidly to the open sea. Research based on salmon suggests post-smolts normally swim in the upper few metres of the water column (1-3m) and do not closely follow nearby shores, having being recorded swimming at distances up to 2-5km from the shore.

Given the close proximity of the Don, Dee and Ythan to the proposed EOWDC, juvenile salmon and sea trout (smolts and post-smolts) originating from these rivers may transit close to or through the proposed EOWDC during their early marine phase. It is also possible that post-smolts originating in other rivers, especially those in the regional study area (Ugie, North Esk and South Esk), may transit close to or through the proposed EOWDC where noise levels could result in strong (90dB_{ht}) or mild (75dB_{ht}) behavioural reactions.

In the case of sea trout, which do not generally venture to distant offshore feeding grounds, there is potential for post-smolts to transit the proposed EOWDC site during their early marine phase as part of their foraging activity.

It is considered that any delay in smolt/post-smolt migration would be extremely short term, given the durations of the worst case piling events (24 hours per pile) and the localised area where strong behavioural reactions are expected to occur (approx. 4 km radius). The magnitude of the impact is therefore considered to be *LOW.* The number of juvenile salmon and sea trout originating from most rivers potentially transiting areas where strong behavioural reactions could occur at any given time is also expected to be low.

The sensitivity of the receptors, particularly those smolts/post-smolts originating in the Dee, Don and Ythan, given the close proximity of the rivers to the proposed EOWDC site is however considered to be *HIGH/VERY HIGH*.

The potential impact of construction noise on juvenile salmon and sea trout (smolts/post-smolts) migration is therefore considered of *MINOR/MODERATE* significance in the case of fish originating in the Dee, Don and Ythan.

Adult Salmon and Sea Trout

On the east coast of Scotland, as far north as the Aberdeenshire coast, the migration of adult salmon in coastal waters is believed to predominantly occur in a northerly direction, potentially starting as far south as the north east coast of England. On this basis, it is likely that adult salmon from the Dee, Don, Ythan and Ugie may migrate through the proposed EOWDC and its vicinity. Fish from other rivers could also transit the site and adjacent areas, principally fish returning to the Esk rivers, and to a lesser extent rivers flowing into the Moray Firth and other Scottish regions, although this would be expected to occur to a lesser extent.

In the case of sea trout, it is expected that adult fish transiting the site both as part of their migration or foraging activity will principally originate from the Dee, Don and Ythan and to a lesser extent other rivers in the regional area (Ugie, North Esk and South Esk). As for salmon, it is possible that sea trout originating in other Scottish regions could also transit the area of EOWDC, as long distance migrations have also been observed.

Adult salmon and sea trout returning to the Dee, Don and Ythan have been reported to remain in estuaries waiting for appropriate conditions to enter the river. Noise levels around the Dee, Don and Ythan estuarine areas are not expected to be above $75dB_{ht}$ *(Salmo salar)* (Figure 3.1), and therefore may, at worst, only cause mild behavioural reactions in salmon and sea trout.

In the absence of specific information on the implications of behavioural responses triggered by noise in pre-spawning adult salmon and sea trout in the marine environment prior to river entry, it is considered that the fish may react in one of the following ways:

- Avoid the area and return to the estuary once construction noise has ceased. Assuming the worst case scenario of 24 hour continuous piling per pile, this would result in a short term delay in upstream migration, similar to that caused by natural factors (e.g waiting for adequate flow conditions).

- Reproductive instinct may overrule behavioural reactions potentially triggered by noise (e.g avoidance reactions) and salmon and sea trout may remain in the estuary and enter the river at the time they would normally do, despite of the noise. For example, research undertaken on herring, a hearing specialist, at a spawning site, concluded that the high priority given to reproductive activities may in some instances overrule avoidance responses (Skaret *et al.,* 2004).

For salmon and sea trout originating in other rivers in the region, if transiting areas where noise levels could cause significant avoidance reactions, it is likely that the implications on their migration will be limited to slight changes in their migratory patterns and potentially, slight delays in river entry.

Taking the worst case scenario, that adult fish migrating into the Dee, Don and Ythan will avoid the area due to noise levels, it is considered that the magnitude of the impact will be *LOW*, on the basis of the relatively short duration of a piling event and the relatively short nature of any delays in migration. Given their importance as species of conservation, especially in the case of salmon in the Dee SAC, and taking account of the relatively small number of fish potentially affected by a piling event, on the basis of the diversity of salmon runs and river entry timing in the case of salmon to take place in some rivers throughout the year, the receptors are considered of *HIGH* sensitivity. The impact due to construction noise on adult salmon and sea trout returning to the Dee, the Don and the Ythan is therefore considered of *MINOR* significance.

Mitigation

Juvenile Salmon and Sea Trout

It is proposed that piling activities be scheduled in consultation with Marine Scotland Science, Scottish Natural Heritage and the Dee, Don and Ythan District Salmon Fishery Boards to ensure minimal disturbance to smolt runs.

The timing of the principal smolt runs in the Ythan, Dee and Don Salmon Fishery Districts as given by the Boards during consultation is given in Table 3.1 below.

Table 3.1 Principal Smolt Runs in the Ythan Dee and Don

District Salmon Fishery Board	Timing of Smolt Runs
Ythan	mid May- end of June
Dee	March-June
Don	May-early June
	September

Adult Salmon and Sea Trout

In light of the different time of river entry in salmon and sea trout originating in different rivers and the diversity and relative importance of salmon and sea trout runs on a river specific basis, the scheduling of piling activities to minimise potential impacts may not be possible for all adult salmon and sea trout migrations. The final piling schedule will however be agreed and defined in consultation with Marine Scotland, Scottish Natural Heritage and the Ythan, Dee and Don District Salmon Fishery Boards.

The timing of the principal salmon and sea trout runs in the rivers located in the proximity of the proposed EOWDC as specified by the Ythan, Don and Dee District Salmon Fishery Boards during consultation are given in Table 3.2 below.

Table 3.2 Principal Salmon and Sea Trout Runs in

District Salmon Fishery Board	Principal Grilse Run	Principal Salmon Run	Principal Sea Trout Runs
Ythan	Autumn	Autumn	May-August
Dee	late May-September	Feb-May (Spring salmon)	May-June
		Summer and Autumn (2SW salmon)	
Don	July-Mid October	mid Dec-April (Spring Salmon)	June- early August
		May-June (2SW salmon)	

Residual Impact

Juvenile Salmon and Sea Trout

Provided that piling operations are scheduled to minimise potential impacts on salmon and sea trout juveniles, it is considered that the residual impact of construction noise on juvenile salmon and sea trout migration will be of *NEGLIGIBLE-MINOR* significance.

Adult Salmon and Sea Trout

The residual impact is expected to be the same as the potential impact (*MINOR)* and possibly *NEGLIGIBLE* depending on final piling schedules, foundation types and installation methods used.

Cumulative Impact

Juvenile Salmon and Sea Trout

The installation of the proposed Ocean Laboratory will involve the piling of a 8.5 m diameter pile, assuming the worst case scenario. This would result in further 24h piling in the area of the EOWDC being undertaken. Given the small area to be affected and the short duration of the noise disturbance, it is not considered that the installation of the proposed Ocean Laboratory will result in a significant cumulative impact in relation to construction noise. In addition, the installation of the Ocean Laboratory, as proposed for the installation of the turbines, would also be scheduled to minimise potential impacts on juvenile salmon and sea trout.

Adult Salmon and Sea Trout

In the case of adult salmon, noise derived from construction activities in the Firth of Forth proposed developments, could result in further impacts on fish migrating towards rivers in the regional area. Taking the worst case scenario, that piling activities in the proposed offshore wind farm developments in the Firth of Forth area are undertaken coinciding with piling operations at the proposed EOWDC, potential direct impacts and avoidance reactions in the Firth of Forth area could result in disturbance to adult salmon migration, further contributing to potential delays in migration/river entry.

Given the limited number of turbines to be installed in the proposed EOWDC in comparison to the offshore wind developments proposed in the Firth of Forth, the contribution of EOWDC to any cumulative impact is likely to be of *NEGLIGIBLE* significance.

3.1.1.3 Key Prey Species

Potential Impact

Noise and vibration during construction could result in a displacement of the food resource if avoidance reactions are triggered in species of importance as prey items to salmon and sea trout. This is relevant in the case of clupeids, such as herring and sprats, as they are hearing specialists and are among the preferred prey species of salmon and sea trout.

Potential impacts derived from prey displacement, if any, are likely to be of greater significance for sea trout than for salmon as they generally remain in coastal areas during their marine phase.

The magnitude of the impact on sea trout through displacement of food resource is considered to be *LOW* on the basis of the spatial scale of the impact and its relatively short duration (theoretical worst case of 11 piling events and 24 hours continuous piling per pile). The sensitivity of the receptor is considered to be *LOW* on the basis of the relatively small number of sea trout potentially feeding in the area from which the food resource could be displaced at a given time, the mobility of sea trout and the availability of other key prey species which are not likely to be disturbed by noise in the wider area (e.g sandeels). The significance of the impact is therefore considered to be *NEGLIGIBLE.*

Mitigation

None required

Residual Impact

Same as the potential impact

Cumulative Impact

There is potential for salmon, in some cases, and more importantly sea trout, to use the Moray Firth and Firth of Forth areas as a feeding ground, principally in relation to the presence of herring and sandeels in these areas.

In view of the limited number of turbines and piling events to be undertaken in the EOWDC in comparison to the developments proposed in the Firth of Forth and the Moray Firth, the contribution by the EOWDC to the any cumulative impact on key prey species due to construction noise would be *NEGLIGIBLE*.

3.1.2 Operation

Noise may arise from a variety of sources during the operational phase of a wind farm, including aerodynamic blade noise, gearbox noise and noise from other machinery (Nedwell *et al.*, 2003b).

Potential Impact

Studies carried out in Denmark on the effect of offshore wind farms on the distribution of fish in areas relevant to the Horns Rev Offshore Wind Farm (Hoffman *et al.,* 2000) found that significant noise levels in the frequency range at which fish typically exhibit a strong response would be expected to be confined to the immediate vicinity of the turbines, within a radius of no more than several hundred of metres. Hoffman *et al.*, 2000 suggested that because of the spatial extent of the low-frequency fields from the turbines, fish would perceive them to be very different compared to the low-frequency fields of other animals. It was therefore concluded that fish species were not expected to be impaired in their ability to detect predators and prey. It was also suggested that the continuous character of the turbine noise was likely to promote habituation in fish species.

In line with this, post-construction monitoring work undertaken in Horns Rev did not find evidence to confirm that fish densities in the general vicinity of the turbines were different from within the ar ray with species such as sandeel, sprat, mackerel and schools of cod recorded in-between the turbines (Hvdt *et al.,* 2006; Hvdt *et al*., 2005). Furthermore, research on species attracted to hard bottom substrates at Horns Rev found that noise and vibration from the turbine generator did not have an impact on the fish communities within the wind farm site (Leonhard *et al*., 2005). Similarly the results of post-construction monitoring fish surveys carried out in the Barrow Offshore Wind Farm and in the North Hoyle Wind Farm did not find significant differences in catch rates during operation in relation to pre-construction catches (BOWind, 2009; RWE npower renewables, 2008), further suggesting that operational noise does not prevent fish from transiting the area of the wind farms.

Walhberg and Westerberg (2005) estimated that Atlantic salmon detect operational turbines at a distance of 0.4 km and 0.5 km at wind speeds of 8 and 13m/s respectively and found that fish are consistently scared away from turbines only at ranges shorter than 4 m, and only at high wind speeds (above 30m/s). The same study concluded that the acoustic impact of wind turbines on fish is restricted to masking communication and orientation signals rather than physiological damage or consistent avoidance reactions.

It should be noted that given the proximity of the proposed EOWDC to major shipping routes into Aberdeen harbour, it is likely that salmon and sea trout transiting the area are habituated to relatively high background noise levels (ANATEC, 2011).

In light of this it is expected that noise generated during operation will not result in a significant impact on the migration of salmon and sea trout juveniles and adult migration neither have an effect on salmon and sea trout feeding and prey availability. The magnitude of the impact and the sensitivity of the receptors are considered to be *LOW*, hence the potential impact of operational noise is considered to be of *NEGLIGIBLE* significance.

Mitigation

None proposed.

Residual Impact

NEGLIGIBLE

Cumulative Impact

None expected.

3.2 Increased Sediment Concentrations

3.2.1 Construction and Decommissioning

Construction activities such as cable laying, piling and rock placement have potential to result in temporary sediment re-suspension increasing turbidity (OSPAR, 2004).

As indicated in the coastal processes section, after installation of the first three turbines, the resulting sediment plume is expected to record a maximum concentration of 35mg/l which extends from Aberdeen harbour to approximately 3 km south of the river Ythan. After installation of 11 foundations, higher concentrations will also remain levelled with Aberdeen Harbour to approximately 3 km of the River Ythan (ABPMER, 2011,). It should be noted that during project specific surveys suspended sediment concentrations found in the area ranged from 0.1 to 43.1 mg/l, with an average value of 20.7 mg/l (ABPMER, 2011a).

Potential Impacts

A wide range of studies have assessed the effect of turbidity levels above natural background on the physiology and behaviour of salmonids. The majority of these are, however, based on freshwater and experimental settings rather than the marine environment. The research indicates that high levels of suspended sediment may be fatal to salmonids while lower levels of suspended sediment and turbidity may cause chronic sub-lethal effects such as loss or reduction of foraging capability, reduced growth, resistance to disease, increased stress and interference with cues necessary for orientation in homing and migration (Bash *et al.,* 2001). Lethal levels of sediment in fish typically range from hundreds to thousands mg/l whilst sub-lethal effects may manifest at significantly lower levels, ranging from tens to hundreds mg/l depending on species specific tolerance (Birtwell, 1999).

A summary of the principal physiological and behavioural effects of turbidity on salmonids is given in Table 3.3.

Table 3.3 Principal Physiological and Behavioural Effect of Turbidity on Salmonids (Bash *et al.,* 2001)

Physiological	Behavioural
Gill trauma	Avoidance
Osmoregulation	Territoriality
Blood Chemistry	Foraging and Predation
Reproduction and Growth	Homing and Migration

Research on the behaviour of juvenile Atlantic salmon has found that initial introduction of sediment (20mg/l) increases foraging activity (Robertson *et al.,* 2007). The same study found a decline in territorial behaviour and avoidance reactions at sediment levels ranging from 60 to 180mg/l. Short term pulses of suspended sediment have also been shown to disrupt feeding behaviour and elicit alarm reactions that may cause fish to relocate downstream to undisturbed areas (Berg and Northcote, 1985)

Whilst physiological and behavioural responses have been observed in a number of studies, salmonids are considered to have the ability to cope with some level of turbidity at certain life stages. Juvenile salmonids are present in turbid estuaries prior migration, as well as in streams with high natural levels of glacial silt, and therefore high turbidity and low visibility (Gregory and Northcote, 1993). In addition salmonids may also encounter naturally turbid conditions during flood events and other natural circumstances (Bash *et al.,* 2001). Measurements undertaken in the River Don (Hillier, 2001), found that concentrations of suspended solids typically ranged from 1 to 10mg/l during base flows, however reached levels up to 150mg/l during high flows.

It should be noted that the potential disturbance through increased sediment concentrations will be short term as once construction works cease, the sediment source for the suspended sediment plume is removed and the tidal regime acts to further reduce the sediment concentrations back to background levels by continual dispersion (ABPMER, 2011).

Based on the relatively short term scale of any potential impact caused by the plume, its relative small spatial extent, and the fact that the expected sediment concentrations within the plume are in line with background levels observed in the area, the magnitude of the impact is considered to be *LOW*. The receptors (adult and juvenile salmon and seat trout), given their tolerance to the expected levels of suspended sediment and their swimming capability, are considered to have a *LOW-MEDIUM* sensitivity in the case of fish originating in the Dee, Don and Ythan, as they are more likely to transit the EOWDC site. The impact of suspended sediments during construction is therefore considered of *NEGLIGIBLE-MINOR* significance.

Mitigation

No mitigation required.

Residual Impact

Same as the potential impact.

Cumulative Impact

In the absence of other offshore activities that could potentially contribute to increased sediment concentrations (e.g. dredging) expected to take place in the vicinity of the proposed EOWDC, no cumulative impacts are expected to take place.

3.3 Electromagnetic Fields (EMFs)

3.3.1 Operation

The magnetic fields anticipated to be produced by the AC cables associated with the proposed EOWDC are small (1.5 µT) in comparison to the Earth's magnetic field (approximately 50 µT). Atlantic salmon are expected to perceive these magnetic fields as new localised additions to the heterogeneous pattern of geomagnetic anomalies already occurring naturally and anthropogenically in the sea (MS, 2011).

Potential Impact

The potential impacts on salmon and sea trout migration derived from the magnetic fields generated by the export and inter array cables could theoretically range from small or large scale disorientation to a barrier to migration.

The Collaborative Offshore Wind Research into the Environment (COWRIE) group has published a number of reviews of current knowledge on the potential impacts of EMFs derived from offshore wind farm developments on electrically and magnetically sensitive species (Gill *et al*., 2009; Gill *et al.,* 2005; CMACS, 2003). The focus of these reports has however been on elasmobranch species, as they are the main group known to be electroreceptive and magnetosensitive (Gill *et al.*, 2009; Gill *et al.*, 2005).

The OSPAR Commission (2008) review of impacts associated with power cables considered that whilst the presence of magnetite in migratory species, including salmonids, suggests that they may use the earth's geomagnetic field for navigation, there is no experimental evidence to determine whether migrating salmon can detect and/or could be affected by anthropogenic magnetic fields of a magnitude comparable to the earth's geomagnetic field. For example, research undertaken on the effect of modified magnetic fields on ocean migration using maturing chum salmon (*Oncorhynchus* *keta*), found no observable effect on the horizontal and vertical movements when the magnetic field was modified (Yano *et al.,* 1997).

In line with the above, Ohman *et al*. (2007) point out that detection of stimuli may not necessarily lead to behavioural responses in fish and that senses that detect magnetic fields are not the only means of spatial orientation, as vision, hearing and olfaction as well as hydrographic and geoelectric information could all be used for spatial orientation. The use of olfaction cues in the final freshwater stage of the homing migration is well documented and it is generally accepted that as salmon approach their natal rivers there is a transition from oceanic orientation mechanisms to mechanisms more appropriate for river migration (Dittman and Quinn, 1996). Ueda *et al.,(*1998) carried out research on the homing mechanisms of sockeye salmon (*Oncorhynchus nerka*) and found that interference of magnetic cues by the attachment of a magnetic ring did not affect the direct return of the fish to the home river and it was concluded that fish returned straight to the vicinity of the natal area using visual cues and finally reach the exact homing point using olfactory cues.

The Environmental report of the Scottish Marine Renewables SEA 2, Environmental Report, 2007 (Section C: Chapter 18- Electromagnetic Fields) states, based on current research and existing cables, that fish species sensitive to magnetic fields such as salmon and eels are not expected to be impacted by the magnetic fields likely to be produced during the operation of device arrays and export cables of tidal and wave energy marine installations proposed in the north coast of Scotland. Similarly, the *Habitats Regulations Appraisal of Draft Plan for Offshore wind Energy in Scottish Territorial Waters: Appropriate Assessment Information Review* (MS, 2011) considers the maximum level of risk in relation to impacts of EMFs on Atlantic salmon to be low.

Gill and Barlett (2010), in a review of the potential impacts of noise and electromagnetic fields from marine renewable installations on salmon, sea trout and European eels, state that there is unclear evidence to assess the overall effect of EMFs from subsea cables on migration and movement behaviour of salmon and sea trout. In addition, it is also stated that whilst physiological responses to EMFs have been demonstrated on laboratory based studies in both salmon and sea trout, there is no evidence on which to determine the effect of a small, local change in magnetic field in the context of their large scale migration or how this may impact their migratory routes.

The magnitude and intensity of the potential movement and behavioural effects on salmonids would be closely linked to the proximity of the fish to the source of the EMF. If there is going to be any effect on their migration, this will be most likely dependent on the depth of water and the proximity of the rivers to the development site (Gill and Barlett, 2010).

The key receptors of potential impacts derived from EMFs would primarily be adult salmon and sea trout returning to the Dee, Don and Ythan, and potentially the Ugie, assuming they transit the site and or the area of the export cable during migration. It should be noted, however, that given the proximity of the EOWDC to the rivers, it is likely that salmon and sea trout may be using olfactory and potentially other types of cues for spatial orientation, in addition to or instead of, magnetic mechanisms, at the time that they will encounter the magnetic fields generated by the EOWDC.

Given the small area of the wind farm and the total cabling involved, a maximum of 13 km for inter array cables and 26 km for the four export cables (1 x 5 km, 1 x 6 km, 1 x 7 km, 1 x 8 km) (further details in Chapter 3, Description of the Proposed Development), the fact that magnetic fields will only be encountered in close proximity to the cables (within tens of metres) and the potential for fish to be using spatial orientation mechanisms other than magnetic navigation, the magnitude of the impact is considered to be *NEGLIGIBLE* to *LOW*. Taking a precautionary approach based on the conservation importance of the species and the lack of definitive evidence in respect of impacts on the migration of salmonids, the receptors, salmon and sea trout originating in rivers within the regional study area, are considered of *HIGH* sensitivity. The impact of EMFs on salmon and sea trout migration is therefore considered to be of *NEGLIGIBLE* to *MINOR* significance.

Mitigation
The cables will be buried. Burial to depth realistically achievable offshore (0.6 m – 3 m) will not make significant difference to the resultant fields or the distance over which they propagate. Cable burial to a depth of at least 1 metre is only likely to provide some mitigation for the possible impacts of the strongest B-fields and induced E-fields that exist within millimetres of the cable (CMACS, 2003).

Residual Impact
Same as the potential impact.

Cumulative Impact
EMF emissions from the proposed offshore wind farm developments in the Firth of Forth and in the Moray Firth could potentially further affect migrating salmon. Assuming the prevalent travelling direction of coastal migration is northerly, there is potential for salmon heading to the rivers in the regional area to be present in the vicinity of the proposed developments in the Firth of Forth at an early stage of their migration. Similarly, there is potential for sea trout to transit both the Moray Firth and the Firth of Forth development areas either during migration or as a result of foraging activity.

Given the relatively small area of the proposed EOWDC and the total cabling used in comparison to the proposed offshore wind developments in the Moray Firth and the Firth of Forth, it is considered that for salmon and sea trout originating in rivers in the regional area the contribution of the EOWDC to any potential cumulative impact would be of *NEGLIGIBLE* significance.

3.4 Physical Presence of the Turbines

3.4.1 Operation

Potential Impact
The physical presence of the turbines could potentially result in disturbance, delays or a barrier to migration. The minimum spacing between turbines assuming installation of 11 turbines would be of 750 m. On the basis of the small total area of the proposed EOWDC, the spacing between turbines, and the ability of salmon and sea trout to overcome obstacles during migration such as dams and other man made obstructions, it is not considered that the physical presence of the turbines will significantly affect salmon and sea trout migration. The impact is considered to be of *LOW* magnitude. The sensitivity of the receptors on the basis of their importance is considered to be *LOW*. The potential impact of the physical presence of the turbine is therefore considered of *NEGLIGIBLE* significance.

Mitigation
None required.

Residual Impact
Same as potential impact.

Cumulative Impact
None expected.

3.5 Impacts on the Salmon and Sea Trout Fisheries

3.5.1 Potential Impacts

The potential impacts that fisheries could theoretically sustain from the EOWDC development are:

- Loss of or restricted access to fishing areas
- Interference to fishing activities
- Loss of or reduction of catch

Loss of or Restricted Access to Fishing Areas

In the case of the local coastal fisheries, given the limited range of netting operations (1300 metres from the shore Low Water), There will be no loss of area or restricted access impacts associated with the construction and operation of the EOWDC and therefore the significance of the impact will be *NEGLIGIBLE.*

Whilst the export cable route has yet to be finalised, taking the worst case scenario that the cable route would pass through a coastal netting station, there could be a small, localised temporary loss of fishing area. As given in the Salmon and Sea Trout Baseline Assessment for the proposed EOWDC, there has been a progressive decline in coastal netting by fixed engines in the local area since 2000 with no reported catches being recorded in the Don District in 2008 and 2009.

Taking the short duration of export cable laying and therefore the short period of exclusion, if the export cable route should pass through a fishing area which was being actively fished, the unmitigated impact is considered to be localised and of *MODERATE* significance.

In the case of rod and line fisheries, due to the distance of both the wind farm site and the export cable route from salmon and sea trout rivers, there will not be any loss of fishing area or restricted access, therefore the impact will be of *NEGLIGIBLE* significance.

Mitigation

Mitigation may well naturally occur whereby the final export cable route will avoid any areas where coastal netting occurs. Similarly, as occurred in 2008 and 2009 in the Don District, fixed engine activity may not occur. The appropriate liaison and consultation will be undertaken with the relevant stakeholders with the objective of minimising potential impacts to *NEGLIGIBLE* significance.

Interference to Fishing Activities

As with loss of, or restricted access to fishing areas, the installation of turbines and intra-field cables will not have any direct impact in terms of interfering with fixed engine, net and coble or rod and line fishing activities. Similarly, apart from a possible temporary loss of access associated with the export cable installation, discussed above, it not expected that any other activity associated with the development will directly affect salmon and sea trout fishing. The impact is therefore predicted to be of *NEGLIGIBLE* significance.

Mitigation

Same as for loss of or restricted access to fishing areas

Loss or Reduction of Catches

The impact of loss or reduction of salmon and sea trout catches, will in effect, be directly related to the effects on the ecology of the two species as assessed above. As given in Table 4.1 below, the significance of the residual impacts is predicted to range from *NEGLIGIBLE* to *MINOR*.

In the case of coastal fisheries, and particularly those which currently appear to not be actively fished, it is expected that the residual impacts will be for the most part *NEGLIGIBLE.* There is however the possibility of *MINOR* impacts, if piling coincides with the migration times of returning adult fish following migration routes along which fishing occurs. An impact would only occur however if construction activities caused the fish to alter their migration routes away from fishing locations as opposed to them only causing a short term delay in migration.

The significance of the impacts on rod and line fisheries, which have a substantially greater overall socio-economic value than the coastal fisheries in the relevant districts, will similarly be dependent upon the short and longer term impacts of the development on salmon and sea trout. As given above, it is considered that the impacts of the construction, operational and decommissioning phases of the EOWDC will range in significance from *NEGLIGIBLE* to *MINOR*. It is however recognised that the scale and magnitude of the potential impacts will vary between districts and will also be related to the relative values of the rod and line fisheries within individual districts and the timing and importance of runs within specific rivers.

With completion of construction activities it is envisaged that the fully operational phase of the development will, with the exception of possible limited EMF related effects, not have any significant effects on salmon and sea trout fisheries. Therefore the potential impacts are, for the most part, considered to be of *NEGLIGIBLE* significance.

3.6 Monitoring

As emphasized above, the assessment of the effects of the construction/decommissioning and operation of EOWDC upon salmonids is constrained by gaps in available baseline information, particularly that describing the behaviour of salmon and sea trout not only in the vicinity of the proposed development but also in the wider marine environment. In addition, there is insufficient direct evidence relating to the potential impacts of offshore wind farms on salmon and sea trout. As a consequence, the precautionary principle has been adopted by taking the 'worst case scenario'.

In practice, however, it is possible that salmon and sea trout may not be adversely affected by the construction and operation of EOWDC, particularly in light of the known obstacles the species overcome during their respective life cycles and the limited number of turbines to be installed. EOWDC will consult with Marine Scotland, Scottish Natural Heritage and the Dee, Don and Ythan Salmon District Fishery Boards in order to identify feasible and relevant monitoring options.

4.0 Summary

The significance level of the impacts derived of the construction, decommissioning and operational phase of the proposed EOWDC, on salmon and sea trout, including cumulative effects, are summarised in Table 4.1 below. A summary of the impacts on salmon and sea trout fisheries is given in Table 4.2.

Table 4.1 Impact Assessment Summary

Salmon and Sea Trout Impact Assessment							
Construction and Decommissioning							
Source of Potential Impact	**Potential Impact**	**Receptor**	**Significance Level**	**Mitigation**	**Residual Significance**	**Cumulative Impact**	**Monitoring**
Noise	Direct Impact	Adult and juvenile salmon and sea trout	Negligible	Soft-start piling	Negligible	None Expected	Appropriate and relevant monitoring will be assessed through discussion with relevant stakeholders and regulators
	Disturbance/ Delay/Barrier to Migration	Salmon and sea trout juveniles	Minor to Moderate	Installation schedule to be discussed with relevant stakeholders and regulators	Negligible to Minor	Negligible	
		Salmon and sea trout adults	Minor	Installation schedule to be discussed with relevant stakeholders and regulators	Negligible to Minor	Negligible	
	Key prey species	Adult sea trout	Negligible	None required	Negligible	None expected	
Increased sediment concentration	Direct effects/ Disturbance/ Delay/Barrier to Migration	Juvenile and adult salmon and sea trout	Negligible to Minor	None required	Negligible to Minor	None expected	None planned
Operational							
Source of Potential Impact	**Potential Impact**	**Receptor**	**Significance Level**	**Mitigation**	**Residual Significance**	**Cumulative Impact**	**Monitoring**
Noise	Disturbance/ Delay/Barrier to Migration	Adult and juvenile salmon and sea trout	Negligible	None required	Negligible	None expected	None planned
	Feeding						
EMFs	Disturbance/Delay/Barrier to Migration	Adult and juvenile salmon and sea trout	Negligible to minor	None other than cable burial	Negligible to minor	Negligible	None planned
Presence of Turbines	Disturbance/ Delay/Barrier to Migration	Adult and juvenile salmon and sea trout	Negligible	None required	Negligible	None expected	None planned

Contents

1.0 Abbreviations

- ACSEF – Aberdeen City and Shire Economic Future
- AOWFL – Aberdeen Offshore Wind Farm Limited
- EOWDC – European Offshore Wind Deployment Centre
- GVA / Gross Value Added – a measure of the economic value of a job or economic activity
- GW – Gigawatt, a measure of electrical generation capacity, equivalent to 1 billion Watts
- LQ / Location Quotient – a measure of industrial specialisation. Location quotients measure whether a region has a particular specialism in an industry or trade, and are calculated by dividing the proportion of employees in a certain industry in the Inner Study Area by the corresponding proportion of employees in the sector in a benchmark area (e.g. Scotland). A location quotient greater than one, indicates that the Inner Study Area has a specialism within that industry, relative to the benchmark area.
- MW – Megawatt, a measure of electrical generation capacity, equivalent to 1 million Watts
- OWIG – Offshore Wind Industry Group
- SIC – Standard Industrial Classification, a system used by the Office of National Statistics to classify economic activities by industry type
- STW – abbreviation for Scottish Territorial Waters

2.0 Information for the Non-Technical Summary

2.1 Aberdeen Offshore Wind Farm Limited (AOWFL) is proposing to develop an offshore wind farm and deployment centre off the coast of Aberdeen, known as the European Offshore Wind Deployment Centre (EOWDC). DTZ has been commissioned by AOWFL to undertake a socioeconomic, recreation and tourism impact assessment of the proposed EOWDC. The scope of the assessment is the Inner Study Area (Aberdeen and Aberdeenshire), Wider Study Area (Scotland), and the UK.

2.2 There is a significant renewable energy resource in Scotland, coupled with a high level of government commitment to renewable energy generation. The Scottish Government is committed to achieving a headline target of 20% of total Scottish energy use from renewable sources by 2020. Scotland has a quarter of Europe's offshore wind potential. The Crown Estate has granted exclusive development rights for 11 offshore wind zones in Scotland. The project has been successful in gaining EU funding of up to €40m from the European Economic Recovery Plan. This award is in recognition of the project's potential role in supporting development of the European offshore wind industry by proving technologies and techniques.

2.3 At a local level, Aberdeen City and Aberdeenshire recognise the importance of the energy sector to the local economy. The 'Energetica' project has been developed which sets out a vision as to how the Inner Study Area can see energy, tourism, other industries and quality of life factors combine to raise the profile and economic performance of the region.

2.4 The Inner Study Area can be characterised as follows:

- A population of 457,300 people in 2009, which has grown by 4.8% since 2003 (a faster rate than the UK or Scotland)
- High levels of employment in the working age population (79.4% of the working age population are employed, compared to 71.9% in Scotland)
- Low level of unemployment (2.8% in the Inner Study Area compared to 7.1% in Scotland)
- A highly qualified workforce (24% of the workforce is degree qualified, compared to 20.5% in Scotland)
- The Inner Study Area is less dependent on public sector employment than other parts of Scotland. The Inner Study Area has a significant Oil and Gas sector – comprising 25,700 workers, and accounting for over 60% of UK employment in the oil and gas industry. This provides a firm foundation for development of new energy sources such as offshore wind, given the complementarity of skills required.
- The three principle ports within the Inner Study Area are Aberdeen, Peterhead, and Fraserburgh. Aberdeen Port is the major supply base for the North Sea oil industry and employs around 11,000 people; whilst Peterhead landed 149,200 tonnes of fish in 2009 valued at £118 million (27% of the total Scottish market).
- 1.5 million tourist trips were made to Aberdeen and Grampian in 2009, contributing £344 million of expenditure to the local economy. The region attracts a high number of Scottish and UK tourists. A relatively high proportion of tourist trips into the region relate to business tourism – almost three quarters of visitors to Aberdeen City are business-related. The most significant tourism investment in the inner study area is the Trump Corporation's investment at Menie Estate which will increase tourist income in coming years.
- The coastline of the Inner Study Area is used for a variety of recreational activities including sailing (although only to a moderate extent relative to other parts of Scotland), sea angling, surfing, canoeing, kayaking, windsurfing and kite surfing. Fraserburgh is a particularly popular surfing location and regularly holds surf competitions and events such as the UK Surf Tour and Fraserburgh Surf Festival.

2.5 Looking forward, the Inner Study Area is expected to experience a weak recovery from the recession. Forecasts show that the economy is expected to grow by an average of 2.7% per annum in the period 2011-2015 in the Inner Study Area, compared to 2.9% in Scotland, and 3.4% in the UK. Employment in the Inner Study Area is expected to decline by 12,100 jobs from 2008 to 2011; after which it is expected that there will be a gradual recovery, with job numbers increasing by 6,000 in the period 2011 to 2018. Over the period 2008-2018 as a whole, the worst affected industries in terms of job losses are expected to be Manufacturing and Oil and Gas industries.

3.0 Introduction

3.1 Aberdeen Offshore Wind Farm Ltd (AOWFL) is proposing to develop an offshore wind farm and deployment centre off the coast of Aberdeen, known as the European Offshore Wind Deployment Centre (EOWDC).

3.2 The proposed project would combine a small commercially operated wind farm with a test and research centre, allowing manufacturers to test "first of run" wind turbines and innovative foundation solutions along with related operation and maintenance access logistics.

3.3 DTZ has been commissioned by AOWFL to undertake a socioeconomic, recreation and tourism impact assessment of the proposed EOWDC. The structure of the assessment can be summarised as follows:

- **Baseline Technical Report (this document)** – this provides a summary of the policy context with regard to offshore renewables in Scotland; and a baseline of indicators related to socioeconomics, recreation and tourism within Aberdeen City and Aberdeenshire.
- **EIA Technical Report** – an assessment of the impact that the proposed EOWDC will have upon socioeconomics, recreation and tourism in the study areas, as described below.

3.4 The scope of this assessment is to consider the impacts of the development across the following areas:

- **Socioeconomic** – employment and economic impacts associated with the construction, operation and decommissioning of the project, including supply chain and income effects
- **Tourism** – considering the impact on tourism in the local area
- **Recreation** – considering the impact on coastal recreational activities
- **Research and Development** – considering the possible impact of the deployment centre on the UK offshore wind industry as a whole, due to the opportunity for research, development and testing of equipment.

3.5 For the purposes of this assessment, the study area has been defined as follows:

- **Inner study area**: the two local authority areas of Aberdeen City and Aberdeenshire, the development will pose direct impacts to this area
- **Wider study area:** Scotland as a whole
- **UK**: potential national impacts, such as the impact on the offshore wind industry as a whole

Consultation

3.6 DTZ consulted with the following individuals in April 2011 (all by phone) to inform the Baseline Assessment and Impact Assessment:

- Colin Parker, Chief Executive, Aberdeen Harbour

- Matt North, Port Manager for the Port of Dundee, Forth Ports
- Steven Paterson, Chief Financial Officer, Peterhead Port Authority
- Eric May, Marine Renewable Section Leader, Marine Scotland
- Robert Forbes, Aberdeen City Council
- Eric Wells, Aberdeenshire Council
- Roddy Mathieson, Aberdeenshire Council
- Alistair Reid, Aberdeenshire Council
- Paul Reynolds, Offshore Wind Development Manager, RenewableUK
- Sara Budge, Project Director, Energetica
- Dr Graham Russell, RYA Scotland

Key Guidance Documents

3.7 This assessment has been undertaken based on the following guidance on economic assessment:

- HM Treasury (2003) Green Book
- BIS (2010) Impact Assessment Guidance
- English Partnerships (2008) Additionality Guide: Third Edition
- BIS (2009) Guidance for Using Additionality Benchmarks in Appraisal
- Surfers Against Sewage (2009) Guidance on Environmental Impact Assessment of Offshore Renewable Energy Development on Surfing Resources and Recreation

Data Information and Sources

3.8 The following key sources of data have been used to inform the baseline assessment:

- Marine Scotland (2011) Economic Assessment of Short Term Options for Offshore Wind Energy in Scottish Territorial Waters: Costs and Benefits to Other Marine Users and Interests
- Office of National Statistics (2003-2009) Mid Year Population Estimates
- Office of National Statistics (2009) Annual Population Survey
- Office of National Statistics (2009) Claimant Count
- Office of National Statistics (2009) Annual Business Inquiry / Business Register and Employment Survey
- Visit Scotland (2009) Visit Scotland Tourism Statistics
- Scottish Government (2010) Scottish Sea Fisheries Statistics 2009

3.9 A full list of documents referenced in this Baseline Assessment is provided in Section 8 below.

4.0 Policy Context

4.1 The Scottish Government (2009a: 5) is committed to achieving a headline target of 20% of total Scottish energy use from renewable sources by 2020. The European Directive on Renewable Energy (2009) and the Climate Change Act (Scotland) 2009 look to reduce carbon emissions and increase the proportion of energy produced from renewable sources.

4.2 In 2009, the Scottish Government published a Renewables Action Plan, which identifies the collective actions of government and its agencies to meet the renewable energy target. The Renewables Action Plan states that offshore wind development will be the key policy focus in the short to medium term, not only for its generation potential, but also in terms of economic opportunities related to manufacturing and infrastructure.

4.3 The Scottish Government states that Scotland can lead the world in the development of renewable energy technologies. The potential for offshore development in Scotland is large, with an estimated 206 GW of offshore wind, wave and tidal resources in Scottish waters - 39% of the UK total (Offshore Valuation Group, 2010: 31).

4.4 According to Scotland's Offshore Wind Route Map (OWIG, 2010: 5), Scotland has a quarter of Europe's offshore wind potential. Scotland's renewable energy capacity stands at 206 GW, however, Scotland's domestic energy requirement stands at 10.5 GW, therefore there is potential for the country to become a significant net exporter of sustainable energy to the rest of the UK and Europe (Scottish Development International, 2011: 5).

4.5 Scotland is currently a stakeholder in the offshore wind market. It is home to the Beatrice wind demonstrator project in the Moray Firth, the world's first deep water offshore wind turbine deployment, and Robin Rigg, E.ON's fully commissioned 180 MW wind farm in the Solway Firth (OWIG, 2010: 5). In 2009 the Crown Estate issued exclusive rights to nine consortia to develop 6.3 GW of offshore wind power in Scottish Territorial Waters (STW) (or up to 1,300 turbines). With strong wind resources, and experience in offshore activities such as oil and gas, Scotland has a competitive advantage and is well positioned to take a global lead in the offshore wind industry.

4.6 The National Renewables Infrastructure Plan (Scottish Enterprise, 2010a: 3) states that total UK expenditure on offshore wind projects is estimated at £72 billion to £84 billion. In Scottish Territorial Waters alone, capital expenditure on offshore wind projects over the period 2010-2020 has been estimated at £15 - £18 billion.

4.7 In 2010, the Crown Estate announced licenses for nine new offshore wind development zones around the UK (under the 'Round 3' licensing process), which aim to deliver a quarter of the UK's electricity needs by 2020. Delivery of this capacity requires massive investment in onshore and offshore energy infrastructure and supply chains. The two Round 3 projects in Scotland are in the Moray Firth (1.3 GW) and the Firth of Forth (3.5 GW).

4.8 In March 2011 the Scottish Government published 'Blue Seas – Green Energy: A Sectoral Plan for Offshore Wind Energy in Scottish Territorial Waters' (Scottish Government, 2011) which sets out the Scottish Government's plan for offshore wind. Scottish Ministers have decided that six of the nine Scottish sites granted exclusive rights by the Crown Estate should be progressed within the plan. Three of the sites previously granted exclusivity licences by The Crown Estate were omitted from consideration in this document as all three are on the Western coast of Scotland. The plan identifies a further 25 sites that should be considered for development between 2020 and 2030.

4.9 As a result of Crown Estate Round 3, STW leasing rounds, and the UK and Scottish Government Climate Change targets, there is a strong expectation that offshore wind programmes will begin large scale installation by 2014/15.

4.10 According to OWIG (2010: 9), offshore renewables represent the biggest opportunity for sustainable economic growth in Scotland for a generation in terms of manufacturing, supply chain, job creation and training opportunities. If Scotland is successful in developing a strong supply chain in offshore renewables, many of the nation's ports and harbours could be involved in related economic activity

(Scottish Enterprise, 2010a: 3).

4.11 RenewableUK (2010: 7) suggests that skills present in the oil and gas sector in the UK (in particular Scotland) will be crucial for the offshore wind industry and will be highly sought after. The Inner Study Area has a sizeable oil and gas industry and the development of offshore wind will provide further employment opportunities for those within Aberdeen City and Aberdeenshire.

4.12 At a local level, Aberdeen City and Aberdeenshire recognise the importance of the energy sector to the local economy. The Energy Review Report (2009) of the local area estimated that almost 40,000 people are directly employed in Aberdeen City and Aberdeenshire's energy sector, with the majority being residents of the area. In order to further enhance the energy sector in the area, Aberdeen City and Aberdeenshire have developed the 'Energetica' project; this public/private partnership aims to create the world's greatest concentration of energy companies on a 30 mile coastal strip between Peterhead and Aberdeen.

4.13 The project has been successful in gaining EU funding of up to €40m from the European Economic Recovery Plan. This award is in recognition of the project's potential role in supporting development of the European offshore wind industry by proving technologies and techniques.

5.0 Baseline Description

Population

5.1 The population of the Inner Study Area (the two local authority areas of Aberdeen City and Aberdeenshire) stood at 457,300 in 2009. Aberdeenshire is the larger of the two local authorities, accounting for 243,500 persons, with the remaining 213,800 residing in Aberdeen City. The population of Aberdeenshire has grown by 6.5% since 2003 – a faster rate than the UK and Scotland averages or Aberdeen City. Population growth in Aberdeen City has been slower, yet still slightly above the Scottish average as illustrated in Table 4.1 below.

Table 4.1: Population Estimates

Region	2003 Population	2009 Population	Population Growth 2003-2009
Aberdeen City	207,500	213,800	3.0%
Aberdeenshire	228,800	243,500	6.5%
Inner Study Area	436,300	457,300	4.8%
Wider Study Area	5,057,400	5,194,000	2.7%
United Kingdom	59,552,200	61,792,000	3.8%

Source: Mid-Year Population Estimates, Office of National Statistics, Downloaded from www.nomisweb.co.uk on 22nd March 2011

5.2 Population projections (General Register Office for Scotland, 2011) state that the population growth rate in Aberdeenshire will continue to be well above the Scottish average; whilst the population of Aberdeen City will continue to grow but at a slower rate. The population of Aberdeenshire is forecast to be 289,900 by 2030; an increase of 19.0% between 2009 and 2030. The population of Aberdeen City is forecast to be 219,800 in 2030; an increase of 4.0% (below the Scottish average of 6.5% for the same period).

5.3 The higher population growth rate projected for Aberdeenshire is expected to be generated from continued outward migration from Aberdeen City, possibly reflecting quality of life factors and better transport links. A potential lack of housing within Aberdeen City (especially family housing) may be another driver in Aberdeenshire's higher projected population growth.

5.4 A relatively high proportion (69.3%) of Aberdeen City's population is of working age (16 to 64 years of age), higher than the corresponding figures of 64.8% for Aberdeenshire, 65.7% across Scotland, and 65.0% across the UK as a whole.

Employment and Economic Activity

5.5 The Inner Study Area has a higher resident employment rate amongst the resident working age population than the Scottish and UK average. Just under 80% of the working age population is in employment, well above the UK average which is closer to 71% as illustrated in Table 4.2 below.

Table 4.2: Resident Employment by Region 2009

Region	Resident Employment Rate	Working Age Population	Employment
Aberdeen City	78.5%	148,100	116,300
Aberdeenshire	80.3%	157,800	126,700
Inner Study Area	79.4%	305,900	242,900
Wider Study Area	71.9%	3,413,100	2,454,000
United Kingdom	70.6%	40,137,100	28,336,800

Source: Annual Population Survey, Office of National Statistics, Downloaded from www.nomisweb.co.uk on 22nd March 2011

5.6 Resident unemployment and claimant count rates (those claiming unemployment benefits) are lower within the Inner Study Area than national average. In 2009 the resident unemployment rate within the Inner Study Area stood at 2.8% of the working age population, much lower than the Scottish average (7.1%).

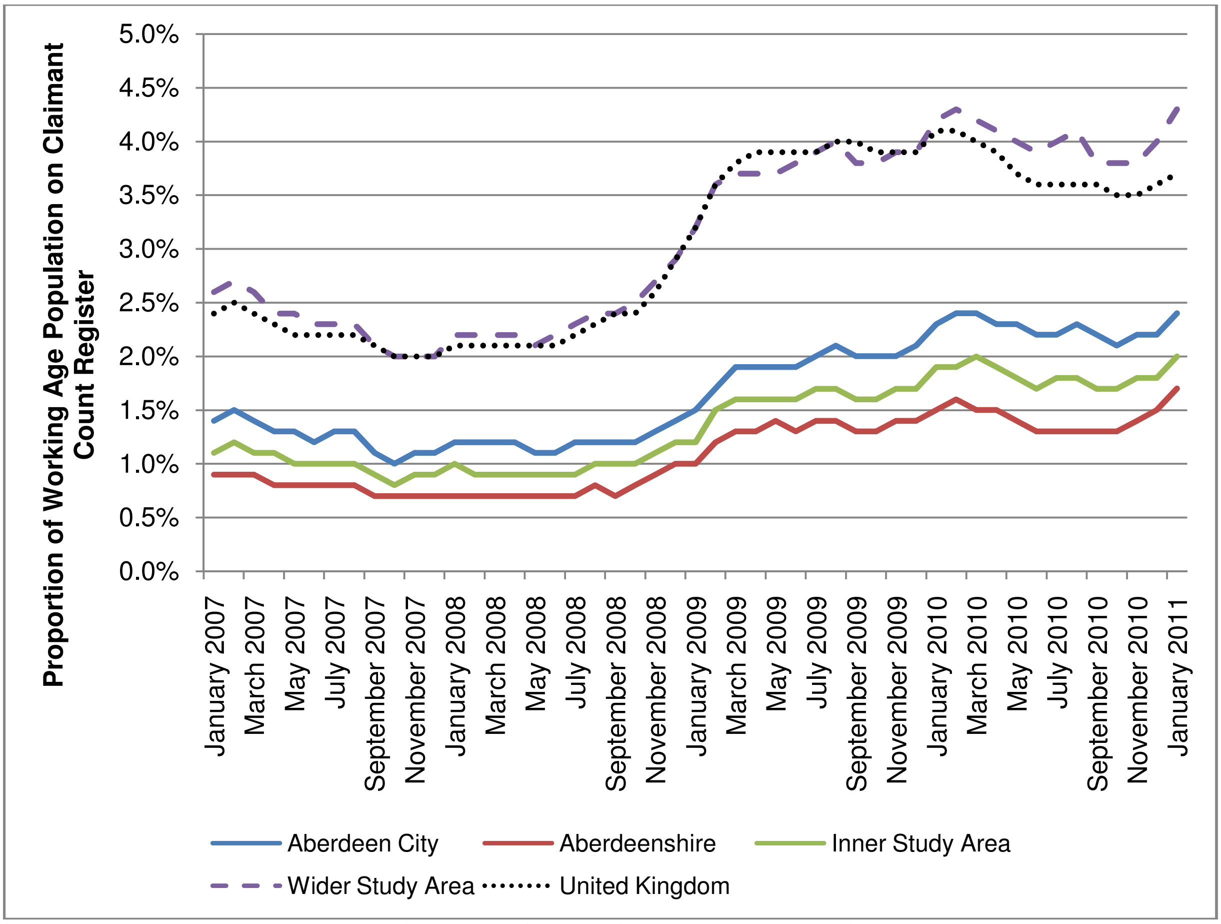
Table 4.3: Resident Unemployment by Region 2009

Region	Resident Unemployment Rate	Working Age Population	Unemployment
Aberdeen City	2.8%	148,100	4,100
Aberdeenshire	2.8%	157,800	4,400
Inner Study Area	2.8%	305,900	8,500
Wider Study Area	7.1%	3,413,100	242,300
United Kingdom	7.8%	40,137,100	3,130,700

Source: Annual Population Survey, Office of National Statistics, Downloaded from www.nomisweb.co.uk on 22nd March 2011

5.7 The claimant count provides much more up to date figures than the unemployment data presented above, and can therefore be used as a proxy for unemployment. As Figure 4.1 illustrates, the claimant count for the Inner Study Area has risen during the recession but remains significantly below the national average. The claimant count in Aberdeen City has been consistently above the Aberdeenshire rate.

Figure 4.1: Claimant Count by Region 2007 to 2011



Source: Jobseeker's Allowance Claimant Count, Office of National Statistics, Downloaded from www.nomisweb.co.uk on 22nd March 2011

5.8 Table 4.4 shows that the economic activity rate in the working age population is higher in the Inner Study Area (81.7%) than Scotland (77.4%) and the United Kingdom (76.5%). A slightly higher proportion of those who are currently economically inactive within the Inner Study Area want a job compared to the national benchmarks.

Table 4.4: Economic Activity by Region 2009

Economic Activity	Aberdeen City	Aberdeenshire	Inner Study Area	Wider Study Area	United Knigdom
Economic Activity	80.8%	82.6%	81.7%	77.4%	76.5%
Economic Inactivity	19.2%	17.4%	18.3%	22.6%	23.5%
Want a job	6.8%	5.5%	6.1%	5.8%	5.5%
Not looking for a job	12.4%	11.9%	12.1%	16.8%	18.0%

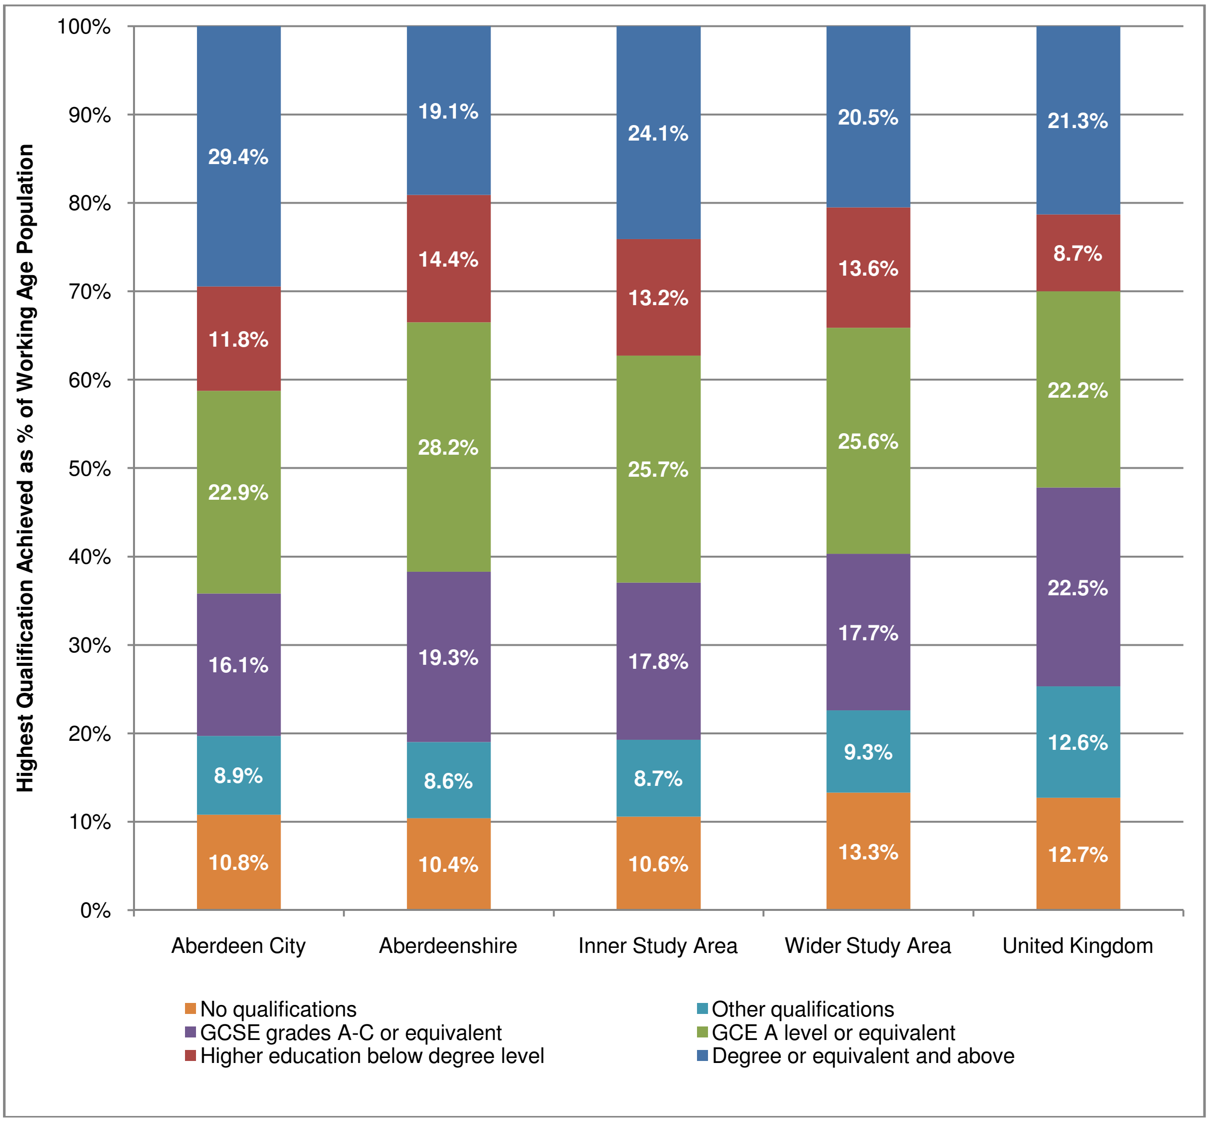
Source: Annual Population Survey, Office of National Statistics, Downloaded from www.nomisweb.co.uk on 22nd March 2011

5.9 Overall, these data show that the Inner Study Area has a relatively tight labour market, with high levels of economic activity and low levels of unemployment.

Qualifications

5.10 The Inner Study Area has a highly skilled working age population: 24.1% of the working age population are educated to degree level or higher, compared to 20.5% in Scotland as a whole. The levels of qualification are particularly high in Aberdeen City, where 29.4% are qualified to degree level, and only 10.8% of people have no qualifications. Aberdeenshire has a qualification profile more like the Scottish average with 19.1% educated to degree level and higher proportions of the working age population holding higher education (but not degree level) and A-Level qualifications than Aberdeen City.

Figure 4.2: Highest Qualification Achieved Profile by Region 2009



Source: Annual Population Survey, Office of National Statistics, Downloaded from www.nomisweb.co.uk on 22nd March 2011

Industrial Structure

5.11 Table 4.5a and Table 4.5b provide employment data from the Annual Business Inquiry/Business Register and Employment Survey, Office of National Statistics. Total employment may be higher than resident employment figures, as the region may support employment for those that live outside of the stated region.

5.12 The Inner Study Area has a higher number of jobs located within the region than the number of residents with jobs; suggesting that the region also provides employment to those commuting in from outside the area. In 2009, there were 263,000 jobs in the Inner Study Area, of which 175,960 were in

Aberdeen City, and 87,080 in Aberdeenshire. Aberdeen City appears to provide employment to many people in Aberdeenshire as well as some outside the region.

5.13 The employment profile of the Inner Study Area is somewhat different to national benchmarks as illustrated in Table 4.5a, as measured by Standard Industrial Classification (SIC). In particular the proportion of those working within Extractive Industries (which includes the oil and gas sector, at 9.8% of total employment, or 25,700 persons) is much higher than the Scottish and Great British average (Annual Business Inquiry/Business Register and Employment Survey does not report UK data, only up to Great Britain level). The vast majority of this employment is related to the extraction of crude petroleum and support activities to the industry. The Energy Review 2009 (ACSEF, 2009: 5) suggests a higher figure of almost 40,000 employees directly related to the energy sector.

5.14 The largest industry within Aberdeen City is human health and social work activities, representing 15.2% of employment in 2009 (26,680 persons), followed by mining and quarrying (21,890 persons; 12.4%, including oil and gas) and professional, scientific and technical activities (23,570 persons; 13.4%), in particular engineering activities and related technical consultancy (15,240 persons).

5.15 The Aberdeenshire employment profile is different to that of Aberdeen City. The oil and gas industry, although proportionally larger than the Scottish and GB average, is smaller than in Aberdeen City. The largest industrial sector within Aberdeenshire is wholesale and retail trade employing 14,420 persons (16.6% of total employment), followed by Manufacturing (10,930 persons; 12.6%) and human health and social work activities (9,860 persons; 11.3%). According to Annual Business Inquiry/Business Register and Employment Survey data at the four digit SIC code level, the largest manufacturing industry in Aberdeenshire is fish processing, employing 1,860 persons.

5.16 Neither Aberdeen City nor Aberdeenshire are overly dependent on the public sector. Although public sector employment (sum of public administration and defence, education and human health and social work activities from Table 4.5a) represents in the region of 25% of employment within the region, this is proportionally lower than the Scottish (31%) and Great British (GB) (28%) averages.

Table 4.5a: Employment Profile by Standard Industrial Classification Section 2009

SIC Sections	Aberdeen City	Aberdeenshire	Inner Study Area	Wider Study Area	Great Britain
Agriculture, forestry and fishing	0.0%	1.2%	0.4%	1.4%	0.8%

5.17 Tables 4.6 and 4.7 identify the location quotient of employment in a number of industrial sectors. Location quotients measure whether a region has a particular specialism in an industry or trade, and are calculated by dividing the proportion of employees in a certain industry in the Inner Study Area by the corresponding proportion of employees in the sector in a benchmark area (e.g. Scotland). A location quotient greater than one, indicates that the Inner Study Area has a specialism within that industry, relative to the benchmark area.

5.18 Oil and Gas support services is a significant specialism within the economy of the Inner Study Area relative to the Scottish and GB benchmarks.

5.19 Annual Business Inquiry/Business Register and Employment Survey data states that employment within the 'Extraction of crude petroleum and natural gas' sector in the Inner Study Area represents 98% of total employment within the industry in Scotland, and 62% of the industry in GB. Similarly, 99% of Scottish and 89% of GB employment in Extractive Industry supporting services is found within the Inner Study Area. Other strong specialisms in the Inner Study Area include: architectural and engineering activities, repair and installation of machinery and equipment, and fishing and aquaculture.

Table 4.6: Location Quotient (LQ), Inner Study Area against Scotland Benchmark 2009

Two-Digit SIC Code	2009 Employment	LQ (Scotland Benchmark)
06 : Extraction of crude petroleum and natural gas	7,020	8.97
09 : Extractive Industry service activities	15,580	8.96
19 : Manufacture of coke and refined petroleum products	N/A	4.69
71 : Architectural and engineering activities	23,320	4.08
33 : Repair and installation of machinery and equipment	2,610	2.45

Table 4.7: Location Quotient, Inner Study Area against Great Britain Benchmark 2009

Two-Digit SIC Code	2009 Employment	LQ (GB Benchmark)
09 : Extractive Industry service activities	15,580	88.4
06 : Extraction of crude petroleum and natural gas	7,020	55.1
03 : Fishing and aquaculture	1,170	17.9
71 : Architectural and engineering activities	23,320	5.6
02 : Forestry and logging	260	2.8

Source: Annual Business Inquiry/Business Register and Employment Survey, Office of National Statistics, Downloaded from www.nomisweb.co.uk on 22nd March 2011

5.20 In 2009, according to Annual Business Inquiry/Business Register and Employment Survey data 1,170 persons were employed within the two digit SIC code '03 : Fishing and aquaculture', representing 27.9% and 18.0% of the Scottish and Great British fishing industry respectively.

5.21 There are three principal ports within the Inner Study Area (Aberdeen, Peterhead, and Fraserburgh), plus a number of smaller ports and harbours used for commercial and fishing activities such as Banff, Buckie, Gourdon, Johnshaven, Macduff, Portsoy, and Stonehaven. Aberdeen is the major supply base for the North Sea oil industry and employs around 11,000 people, a large number of which are oil related (Marine Scotland, 2011: 27). Peterhead is the UK's largest fishing port and is also a major oil industry support base. 140,000 passengers a year travel on Northlink ferries from Aberdeen and Lerwick and Kirkwall, which gives considerable economic and social benefits to both port and harbour operators as well as the surrounding areas (Marine Scotland, 2011: 27).

5.22 Marine Scotland (2011: 10) states that: "Scotland is one of the largest fishing nations in Europe and the Scottish fleet is responsible for landing 66% of the total UK volume of fish. The fishing sector contributed around £144 million gross value added (GVA) to the Scottish economy in 2009, and total of £443 million of fish was landed in Scotland".

5.23 The Inner Study Area is home to the most valuable district in terms of the value of fish landed in Scotland: Peterhead landed 149,200 tonnes of fish in 2009 valued at £118 million (27% of the total Scottish market). Other important ports in the study area for landing fish are Fraserburgh (37,500 tonnes), Aberdeen (3,500 tonnes) and Buckie (1,900 tonnes) (Marine Scotland, 2011: 12-13).

Renewable Energy Sector

5.24 Innovas (2010: 43) valued the UK renewable energy sector at £31.3 billion in 2007/08, of which Scotland accounted for £2.6 billion (8.3%). Scotland's renewable energy sector was the fifth largest in the UK, behind English regions such as London, South East, North West and the West Midlands. UK employment within the sector stood at 265,700 in 2007/08, of which Scottish employment stood at 22,200 (8.4%).

5.25 As of February 2011, Scottish Renewables stated that renewable energy generation capacity in Scotland stood at 4,405 MW, of which wind was the largest contributor with 2,562 MW, followed by hydro (1,395 MW) and biomass heat (225 MW). Offshore wind is relatively new to Scotland as the majority of offshore wind development has so far taken place off English and Welsh coasts. Scotland currently has two operational offshore wind sites, the Beatrice wind demonstrator project with two 5 MW turbines and Robin Rigg with a total capacity of 180 MW. However, Scottish Renewables (2011: 1) estimate that the proposed offshore wind developments in Scotland may create around 28,000 direct jobs by 2020.

5.26 Aberdeen Renewable Energy Group (AREG) was set up by Aberdeen City Council to help develop the region as a centre of excellence in renewable technologies. AREG are developing the Energy Futures Centre in Aberdeen, which aims to lead the way nationally and globally in R&D of renewable technology, bringing together the key players from across the energy sector. Other projects include a new Renewables Research Centre in partnership with the two universities based in the city (University of Aberdeen and Robert Gordon University).

5.27 A number of onshore wind farms are located within the Inner Study Area including Glens of Foundland Wind Farm (26 MW), Dummuies Wind Farm (10MW) and Boyndie Wind Farm Cooperative (14 MW). There are also a number of smaller developments within the Inner Study Area such as three turbines generating 2.5MW of electricity at Mackie's ice cream factory near Inverurie and in 2007 Cults Primary School became the first school in Scotland to use wind generated power (ACSEF, 2009: 20-21). The Inner Study Area is also home to a number of biomass projects including Aboyne Academy, one of the first schools in Scotland to have installed a biomass heating system.

Business Base

5.28 Table 4.8 provides an overview of the size of businesses by employment number bands. Nearly 83% of businesses in the Inner Study Area employ 10 or fewer people. Aberdeenshire has a larger proportion of small businesses, those employing ten or less employees, than Aberdeen City. Aberdeen City has a higher number of larger employers, perhaps reflecting the industrial structure of employment, and the Oil and Gas sector.

Table 4.8: Business by Employment Band 2009

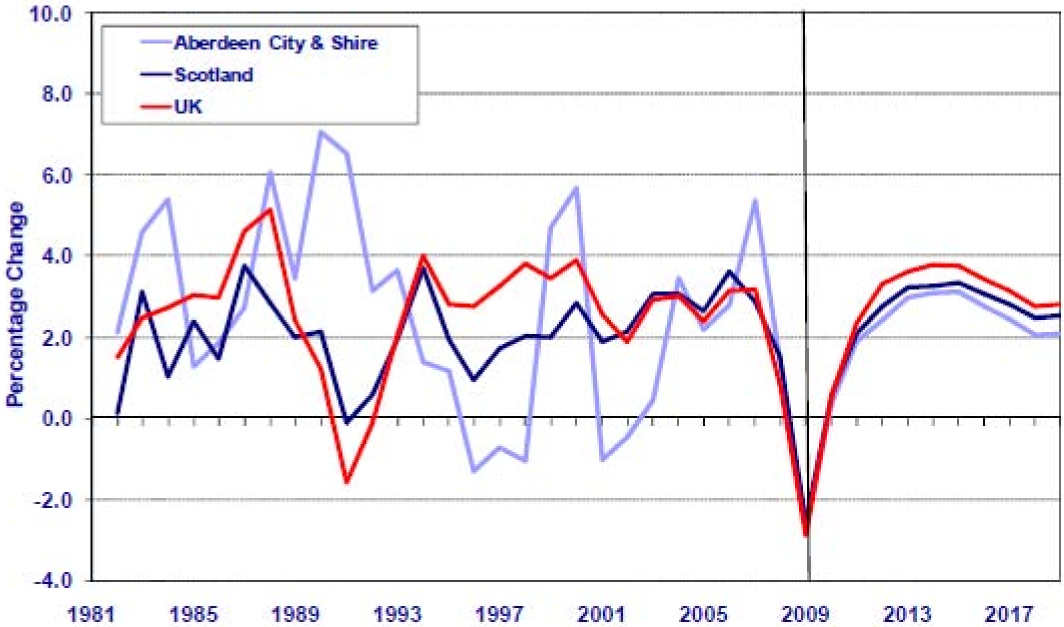
Region	Businesses	1 to 10	11 to 49	50 to 199	200 Plus
Aberdeen City	9,680	77.8%	16.1%	5.0%	1.2%
Aberdeenshire	11,280	87.4%	10.3%	2.0%	0.4%
Inner Study Area	20,960	82.9%	12.9%	3.4%	0.7%
Scotland	181,470	81.4%	14.4%	3.4%	0.8%
Great Britain	2,446,020	85.0%	11.5%	2.8%	0.7%

Source: Annual Business Inquiry/Business Register and Employment Survey, Workplace Analysis, Office of National Statistics, Downloaded from www.nomisweb.co.uk on 22nd March 2011

Future Performance

5.29 Scottish Enterprise (2009) provides an overview of the structure of the region's economy and forecasts for the future direction of the economy. The review suggests that the recovery from the current downturn is likely to be largely service sector led. The Inner Study Area will experience a weaker upturn than most other regions in Scotland and the UK. Average annual gross value added (GVA) growth between 2011 and 2015 is expected to be 2.7% in the Inner Study Area, compared with 2.9% in Scotland and 3.4% in the UK (Scottish Enterprise, 2009: 73).

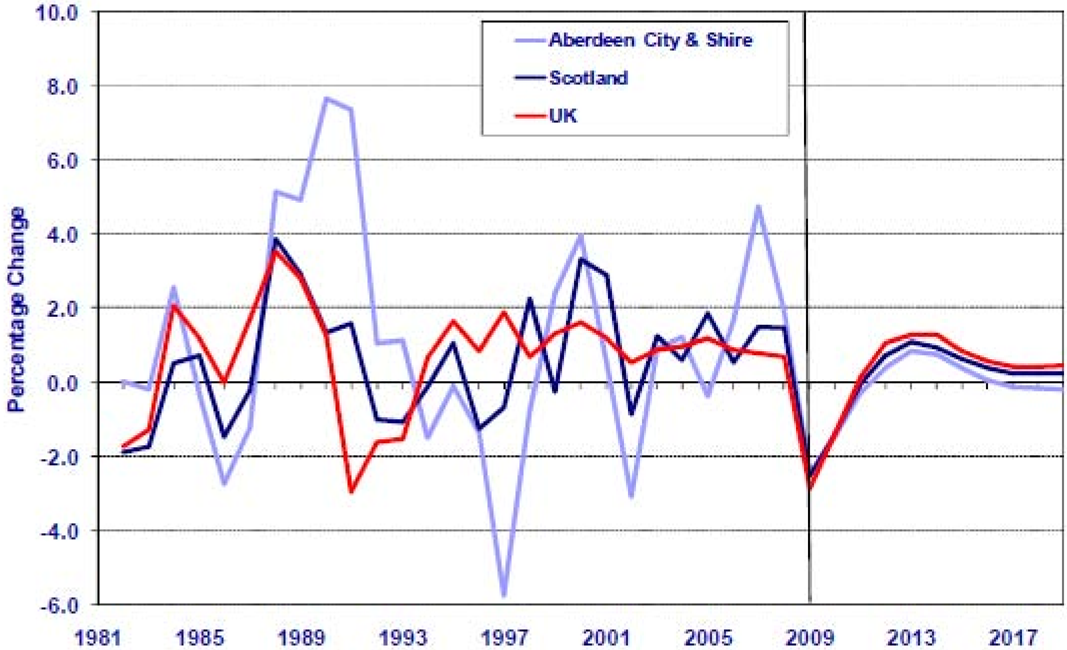
Figure 4.3: GVA Growth 1981 to 2019



Source: Scottish Enterprise Aberdeen City & Shire Economic Review 2009, Oxford Economics

5.30 Scottish Enterprise (2009) suggests that overall employment in the Inner Study Area will contract over the period 2008 to 2018, with a loss of around 6,000 jobs (Scottish Enterprise, 2009: 73). An estimated 12,100 jobs will be lost between 2008 and 2011, with a recovery between 2012 and 2018 creating 6,000 jobs (Scottish Enterprise, 2009:73). It is estimated that 2008 employment levels will not be regained until beyond 2018 as highlighted in Figure 4.4.

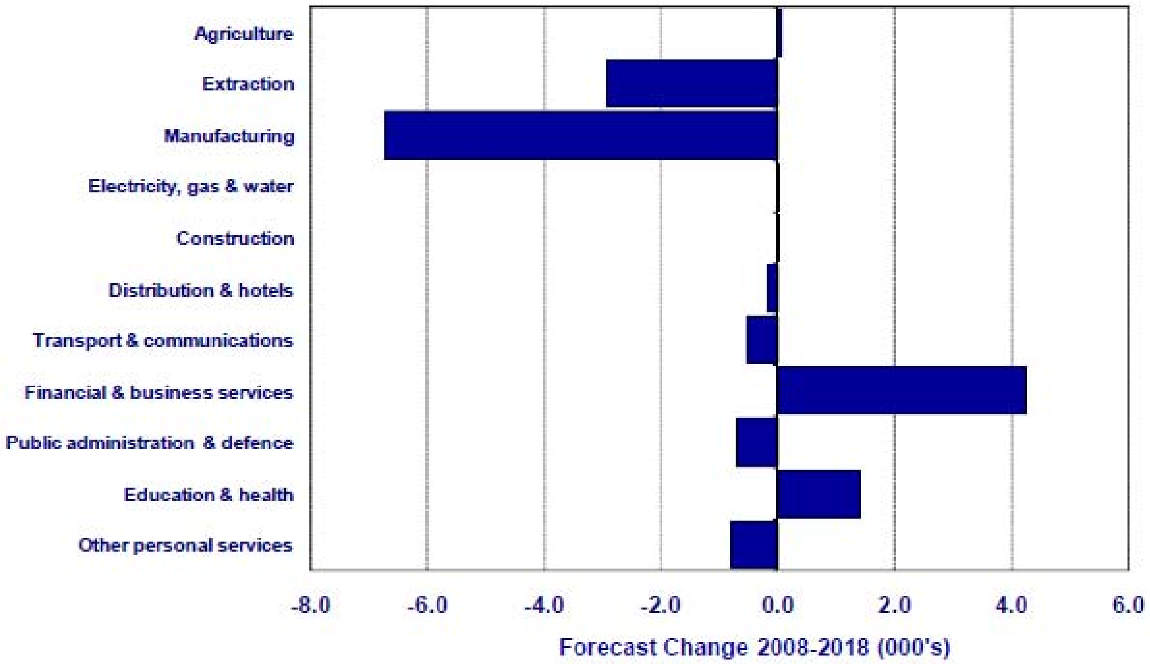
Figure 4.4: Employment Growth Forecast



Source: Scottish Enterprise Aberdeen City & Shire Economic Review 2009, Oxford Economics

5.31 The worst affected sectors will be Manufacturing and Extractive Industries (such as Oil and Gas), with estimated losses of 6,700 and 2,900 jobs by 2018 respectively. The only sectors that are expected to grow between 2008 and 2018 are Education and Health, and Financial Services, as illustrated in Figure 4.5.

Figure 4.5: Employment Change by Sector, 2008 to 2018



Source: Scottish Enterprise Aberdeen City & Shire Economic Review 2009, Oxford Economics

Tourism

5.32 In 2009, around 15 million overnight tourism trips were taken in Scotland, for which expenditure totalled over £4 billion (Visit Scotland, 2010a: 3).

5.33 It is estimated that in 2009, tourists made around 1.5 million trips to Aberdeen & Grampian, staying for 6.1 million nights and spending a total of £344 million as illustrated in Table 4.9 (Visit Scotland, 2010b: 3). On the basis of tourist numbers, therefore, the Aberdeen and Grampian area accounts for around 10% of the total tourism sector in Scotland. Aberdeenshire's tourist industry is growing in importance, with its major natural assets the Cairngorms and coast, supplemented by visitor attractions based on Aberdeenshire's heritage.

Table 4.9: Visit Scotland Tourism Statistics 2009

Tourist Metric	Aberdeen & Grampian		Scotland	
	UK visitors	Overseas Visitors	UK visitors	Overseas Visitors
Trips[a]	1.25 million	0.24 million	12.5 million	2.6 million
Nights[b]	4.38 million	1.67 million	46.1 million	21.9 million
Spend[c]	£246 million	£98 million	£1,249 million	£1,259 million

Source: Visit Scotland, Scotland – The Key Facts on Tourism in 2009; Visit Scotland, Tourism in Northern Scotland 2009

a: Stay of one or more nights away from home for holidays, visits to friends, business and conference or any other purpose other than boarding education of semi-permanent employment.

b: Nights spent away from home using any type of accommodation or in transit on a tourist trip.

c: Spending incurred while away from home on a tourist trip and advance payments for such items as fares and accommodation. For overseas visitor statistics, the cost of travel to the destination is excluded.

5.34 Of the 1.5 million trips made by tourists to Aberdeen and Grampian, 50% were made by Scottish visitors - much higher than the Scottish average of 39%. Overseas visitors represented 240,000 trips to the region in 2009, staying for 1.67 million nights and spending around £98 million. Germany and the USA were the largest markets for the region, making up a quarter of all international visits and spend between them (Visit Scotland, 2010b: 3).

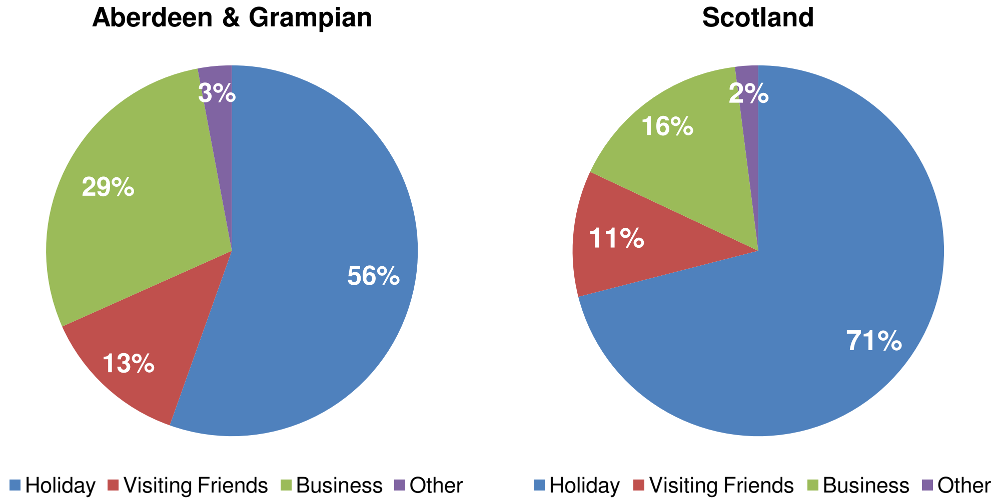
Table 4.10: Tourist Numbers by Country of Residence 2009

Toursit Residence	Aberdeen & Grampian		Scotland	
England	450,000	30.2%	5,980,800	39.9%
Scotland	750,000	50.3%	5,856,200	39.0%
Northern Ireland	25,000	1.7%	373,800	2.5%
Wales	25,000	1.7%	249,200	1.7%
Outside UK	240,000	16.1%	2,540,000	16.9%

Source: Visit Scotland, Scotland – The Key Facts on Tourism in 2009; Visit Scotland, Tourism in Northern Scotland 2009

5.35 Figure 4.3 provides an overview of UK visitor type to both the Aberdeen & Grampian region and Scotland. The Inner Study Area is more reliant upon business tourism than the Scottish average (29% of tourist trips versus the Scottish average of 16%), whilst tourist trips are of relative less importance in Aberdeen and Grampian (56%) than Scotland as a whole (70%). The proportion of business tourism in Aberdeen is close to that of Glasgow (27%) (Visit Scotland, 2010c: 1), but above that of Edinburgh (22%) (Visit Scotland, 2010d: 1).

Figure 4.3: Tourist Trip by UK Visitor Type 2009



Source: Visit Scotland, Scotland – The Key Facts on Tourism in 2009; Visit Scotland, Tourism in Northern Scotland 2009

5.36 Aberdeen City and Shire is recognised as an area of outstanding natural beauty and unique attractiveness. Scottish Enterprise (2010b: 4) states that the region is an attractive region for hotel operators and developers. The report identifies two concerns, especially for those targeting the business tourism market which is important to the Inner Study Area: current demand from the business market is not always met by the current stock especially if there is need for larger capacity bookings; the leisure tourist offering requires to be developed further in order to more strongly position the Inner Study Area as a competent visitor destination (Scottish Enterprise, 2010b: 6).

5.37 Scottish Enterprise (2010b: 12) estimate that business tourism accounts for a higher proportion of visitor trips and spend than the Visit Scotland figures (Visit Scotland, 2010b: 3). Scottish Enterprise estimates that over half of visitors to Aberdeenshire, and almost three quarters of visitors to Aberdeen City were business related. Business tourism is estimated to be worth £137 million per year to the local economy (Scottish Enterprise, 2010b: 12).

5.38 Scottish Enterprise (2010b) identified a number of key tourism developments within the Inner Study Area which are described in Table 4.11. In addition, the Menie Estate development by the Trump organisation is the most significant tourism investment ever to take place in Aberdeenshire and will see several hundred million pounds of investment into the local economy.

Table 4.11: Key Developments in Tourism and Infrastructure- Aberdeen City & Shire

Attraction	Development
Royal Deeside & Cairngorms	SE's Destination Plan estimated to increase tourism income by £30 million. Identifying sites for resort and accommodation development.
Banffshire Coast	A number of initiatives underway to boost tourist income by £5 million a year, mainly through art and boat festivals.
Golf Tourism	The Inner Study Area is one of the main beneficiaries from £177 million Scottish golf market. A number of championship links golf courses are in the pipeline which will significantly impact the local economy.
Food Tourism	Current key attraction such as Deans of Huntly Visitor Centre and distillery projects will continue to grow. A number of events showcasing local produce will also attract tourists in the future.
Business Tourism	Despite the economic downturn, business tourism will continue to be of importance to the region. Major industry conferences such as Society of Petroleum Engineers (SPE) Offshore Europe Oil & Gas Conference & Exhibition are significant to the local economy.
City Centre Retail	The £275 million Union Square retail and leisure development opened in October 2009. The 700,000 sq ft centre includes a cinema, shops and restaurants and is integrated with the city's bus and rail stations.

Source: Scottish Enterprise, Aberdeen City & Shire Hotel Accommodation Report Feb 2010

5.39 Table 4.12 lists the top five visitor attractions in Aberdeen & Grampian. None of the Aberdeen-based visitor attractions feature in the Scottish top ten list, with David Welch Winter Gardens (313,217 visitors) below the tenth placed Scottish visitor attraction: National War Museum, Edinburgh (494,213). The top ten list is dominated by attractions in Glasgow and Edinburgh.

Table 4.12: Top Visitor Attractions, 2009

Aberdeen & Grampian			Scotland		
Rank	Visitor Attraction	Visitor Numbers	Rank	Visitor Attraction	Visitor Numbers
1	David Welch Winter Gardens (Aberdeen)	313,217	1	Kelvingrove Art Gallery & Museum, Glasgow	1,368,096
2	Johnston's Cashmere Visitor Centre (Elgin)	202,200	2	Edinburgh Castle	1,196,481
3	Aberdeen Art Gallery	178,344	3	The National Gallery Complex, Edinburgh	890,361

Recreation

5.40 The Scottish coast, in particular the West coast, is identified as one of the World's best destinations for sailing. According to the Royal Yachting Association (RYA), recreational boating and sailing tourism contributes about £300 million to the Scottish economy (Marine Scotland, 2011: 38). Sailing off the east coast of Scotland is concentrated in the Firth of Tay and Firth of Forth and further south. Recreational use is moderate along the coastline of the Inner Study Area. The inner Moray Firth is an important area for recreational sailing. The value of sailing area from Helmsdale to Peterhead stood at £10.1 million in 2010, and the corresponding figure for the coastline of Peterhead to Berwick is £7.9 million (Marine Scotland, 2011: 40).

5.41 Sea angling takes place along most of the Scottish Coast. The Scottish Government estimates that 125,200 adults and 23,450 children went sea angling in Scotland in 2008, with a total expenditure of £141 million (Marine Scotland, 2011: 42). Sea angling supported 3,148 FTE Scottish jobs in 2008 (Scottish Government, 2009b: 8).

5.42 There are a number of other widespread water-borne recreational activities of importance. British Marine Federation (BMF, 2009: 31) estimates that across Scotland, 52,869 adults participate in surfing, 23,952 in windsurfing and 37,416 in canoeing. Fraserburgh, located within the Inner Study Area, is a particularly popular surfing location and regularly holds surf competitions and events such as the UK Surf Tour and Fraserburgh Surf Festival. There are a number of popular surfing and windsurfing sites along the coast of the Inner Study Area including: Lossiemouth, Spey Bay, Sandend Bay, Cullen, Banff, Pennan, Aberdeen Beach, Aberdeen Harbour, Stonehaven and St Combs.

6.0 Summary

6.1 AOWFL is proposing to develop an offshore wind farm and deployment centre off the coast of Aberdeen, known as the European Offshore Wind Deployment Centre (EOWDC). DTZ has been commissioned by AOWFL to undertake a socioeconomic, recreation and tourism impact assessment of the proposed EOWDC.

6.2 There is a significant renewable energy resource in Scotland, coupled with a high level of government commitment to renewable energy generation. The Scottish Government is committed to achieving a headline target of 20% of total Scottish energy use from renewable sources by 2020. Scotland has a quarter of Europe's offshore wind potential. The Crown Estate has granted exclusive development rights for 11 offshore wind zones in Scotland.

6.3 At a local level, Aberdeen City and Aberdeenshire recognise the importance of the energy sector to the local economy. The 'Energetica' project has been developed which sets out a vision as to how the Inner Study Area can see energy, tourism, other industries and quality of life factors combine to raise the profile and economic performance of the region.

6.4 The Inner Study Area can be characterised as follows:

- A population of 457,300 people in 2009, which has grown by 4.8% since 2003 (a faster rate than the UK or Scotland)
- High levels of employment in the working age population (79.4% of the working age population are employed, compared to 71.9% in Scotland)
- Low level of unemployment (2.8% in the Inner Study Area compared to 7.1% in Scotland)
- A highly qualified workforce (24% of the workforce is degree qualified, compared to 20.5% in Scotland)
- The Inner Study Area is less dependent on public sector employment than other parts of Scotland. The Inner Study Area has a significant Oil and Gas sector – comprising 25,700 workers, and accounting for over 60% of UK employment in the oil and gas industry. This

provides a firm foundation for development of new energy sources such as offshore wind, given the complementarity of skills required.

- The three principle ports within the Inner Study Area are Aberdeen, Peterhead, and Fraserburgh. Aberdeen Port is the major supply base for the North Sea oil industry and employs around 11,000 people; whilst Peterhead landed 149,200 tonnes of fish in 2009 valued at £118 million (27% of the total Scottish market).
- 1.5 million tourist trips were made to Aberdeen and Grampian in 2009, contributing £344 million of expenditure to the local economy. The region attracts a high number of Scottish and UK tourists. A relatively high proportion of tourist trips into the region relate to business tourism – almost three quarters of visitors to Aberdeen City are business-related. The most significant tourism investment in the inner study area is the Trump Corporation's investment at Menie Estate which will increase tourist income in coming years.
- The coastline of the Inner Study Area is used for a variety of recreational activities including sailing (although only to a moderate extent relative to other parts of Scotland), sea angling, surfing, canoeing, kayaking, windsurfing and kitesurfing. Fraserburgh is a particularly popular surfing location and regularly holds surf competitions and events such as the UK Surf Tour and Fraserburgh Surf Festival.

6.5 Looking forward, the Inner Study Area is expected to experience a weak recovery from the recession. Forecasts show that the economy is expected to grow by an average of 2.7% per annum in the period 2011-2015 in the Inner Study Area, compared to 2.9% in Scotland, and 3.4% in the UK. Employment in the Inner Study Area is expected to decline by 12,100 jobs from 2008 to 2011; after which it is expected that there will be a gradual recovery, with job numbers increasing by 6,000 in the period 2011 to 2018. Over the period 2008-2018 as a whole, the worst affected industries in terms of job losses are expected to be Manufacturing and Oil and Gas industries.

1.0 Information for the Non-Technical Summary

1.1 Aberdeen Offshore Wind Farm Limited (AOWFL) is proposing to develop an offshore wind farm and deployment centre off the coast of Aberdeen, known as the European Offshore Wind Deployment Centre (EOWDC). DTZ has been commissioned by AOWFL to undertake a socioeconomic, recreation and tourism impact assessment of the proposed EOWDC. The scope of the assessment is the Inner Study Area (Aberdeen and Aberdeenshire), Wider Study Area (Scotland), and the UK.

1.2 The project has been successful in gaining EU funding of up to €40m from the European Economic Recovery Plan. This award is in recognition of the project's potential role in supporting development of the European offshore wind industry by proving technologies and techniques. It also has an excellent strategic fit with local and national policy, as described in the Baseline Report. The Scottish Government is committed to achieving a headline target of 20% of total Scottish energy use from renewable sources by 2020, and Scotland has a quarter of Europe's offshore wind potential. At a local level, Aberdeen City and Aberdeenshire recognise the importance of the energy sector to the local economy. The 'Energetica' project has been developed which sets out a vision as to how the Inner Study Area can see energy, tourism, other industries and quality of life factors combine to raise the profile and economic performance of the region.

1.3 The impacts considered in this assessment are the direct and supply chain impacts of construction, operation and decommissioning activities; impacts on tourism; impacts on recreational activities; and impacts on the offshore wind energy sector. A range of assumptions have been developed in consultation with AOWFL in order to assess the socioeconomic impact of the development, and are set out in the report. For the purposes of this assessment, it has been assumed that the capacity of the EOWDC will be 84 MW across 11 turbines.

1.4 Total capital expenditure during the two-year **Construction Phase** has been estimated at £260.4 million. As shown in the summary table, it has been estimated that this will support 738 job-years worth of employment, and £40m of Gross Value Added (GVA) in Scotland; of which 296 job-years and £16 million of GVA will be in the Inner Study Area (Aberdeen and Aberdeenshire). The impact related to the Inner Study Area will relate mainly to the construction and assembly of turbines and foundations, whilst the additional impact in the rest of Scotland will relate to the manufacture of project components such as foundations and potentially also wind turbines.

Table 1.1: Summary of Impact: Construction Phase (2 years)

Total Employment (job-years)	Direct & Indirect	Induced	Total
Inner Study Area	248	48	296
Wider Study Area (Scotland)	531	207	738
UK	955	n/a	n/a
Gross Value Added (£ million, discounted)	**Direct & Indirect**	**Induced**	**Total**
Inner Study Area	£13.8	£2.3	£16.1
Wider Study Area (Scotland)	£29.5	£10.0	£39.6
UK	£53.1	n/a	n/a

The Crown Estate lease has a limit of 22 years within which construction and decommissioning must also take place. In terms of the Operational Phase of the project – this is anticipated to be up to 22 years in duration, and therefore a 'Long-term' effect. Once fully deployed, it is anticipated that the EOWDC will require a local team of around 25 jobs for operational and maintenance activities. Over the up to 22 year operational life of the development, this will support 768 job-years worth of employment and £23m of GVA at the Scotland level as summarised below.

Table 1.2: Summary of Operational Impacts over lifetime of project (22 years)

Total Employment (job-years)	Direct & Indirect	Induced	Total
Inner Study Area	553	108	661
Wider Study Area (Scotland)	553	216	768
UK	693	n/a	n/a
Gross Value Added (£ million, discounted)	Direct & Indirect	Induced	Total
Inner Study Area	£17.4	£3.0	£20.4
Wider Study Area (Scotland)	£17.4	£5.9	£23.4
UK	£21.9	n/a	n/a

1.5 The **Decommissioning Phase** is expected to be temporary, lasting for up to 5 months. It has been estimated that the total expenditure on decommissioning will be £33.3m, and this will support 248 job-years of employment and £7.7m of GVA at the Scotland level.

Table 1.3: Summary of Impacts from Decommissioning Phase (up to 5 months)

Total Employment (job-years)	Direct & Indirect	Induced	Total
Inner Study Area	178	35	213
Wider Study Area (Scotland)	178	69	248
UK	178	n/a	n/a
NPV of GVA	**Direct & Indirect**	**Induced**	**Total**
Inner Study Area	£5.8	£1.0	£6.8
Wider Study Area (Scotland)	£5.8	£2.0	£7.7
UK	£5.8	n/a	n/a

1.6 The impact of other offshore wind farm projects in the vicinity of the proposed development is likely to be very significant. Around 7.5GW of offshore wind capacity is planned for the East coast of Scotland, which will require capital investment in the order of £23 billion[1] up to 2020 supporting 28,000 jobs and having a major impact on ports such as Leith, Dundee, Nigg, Aberdeen, Peterhead, and Fife Energy Park. Consultees felt that this project would have a significant role in supporting the development of the industry as there is an identified need for more proving sites for turbines (RenewableUK).

1.7 The impact of the proposed development on **Tourism** is considered to be of **negligible significance.**

1.8 The impact of the proposed development on **Recreational** activities is considered to be of **negligible significance.**

1.9 The impact of the proposed development on **Research and Development and the Offshore Wind industry** has also been considered at both a local and national level. The view of consultations was that the proposed deployment centre would have a **positive impact** on the offshore wind sector. The following quotations highlight the significance of that impact:

- *'The development of offshore wind still faces many challenges to commercial deployment. The operation of the EOWDC will make a strong contribution to knowledge sharing for new components, designs and access methodologies for construction, operations and maintenance to be executed in the marine environment.'* **Chris Bronsdon, Chief Executive, Scottish European Green Energy Centre (SEGEC)**
- *'The European Offshore Wind Deployment Centre will provide invaluable opportunities for R&D, helping the industry to grow with real confidence. Innovative projects such as this will*

[1] i.e. 7,460MW of capacity multiplied by a CAPEX figure of £3.1 million per MW

help the UK to maintain its position as the world leader in offshore wind. This will in turn encourage more investors to come forward, creating thousands of jobs in the rapidly-expanding offshore wind sector.' **Maria McCaffery, Chief Executive of RenewableUK**

- *'This is potentially a great opportunity for Scotland's research community to actively engage in the development of an important means to generate low carbon electricity. Particularly important will be the deployment of the Ocean Laboratory, a wide range of turbines and support structures as possible and access to these for independent evaluation in order to aid future developments.'* **Professor Paul Mitchell of the University of Aberdeen's School of Engineering**

- *'The EOWDC is a major component of ACSEF's flagship project, Energetica. As a pioneering offshore wind project, it will be at the cutting edge of the development of new technologies and presents significant opportunities for Aberdeen City and Shire to build a viable, robust supply chain around offshore wind, particularly in the areas of development, operation and maintenance'* **Sara Budge, project manager for Energetica, Aberdeen City and Shire Economic Future (ACSEF)**

- *'This is a real opportunity for Aberdeen and the North-east [of Scotland] to place itself at the forefront of this aspect of the renewables industry. There is fierce completion not just in Scotland but across the rest of Europe to gain recognition as a leader in the field and this project will provide an extremely valuable testing site for manufacturers to demonstrate their products and to gather vital data on performance.'* **Bob Collier, Chief Executive of Aberdeen & Grampian Chamber of Commerce**

1.10 Overall, the assessment demonstrates that the project will have a significant positive impact on the economy of the Inner Study Area and the remainder of Scotland. **Including construction, operation and decommissioning, it is estimated that the project will support over 1,750 job-years worth of employment in Scotland, and over £70 million of Gross Value Added**. It will also provide benefits to the wider offshore wind energy sector by providing opportunities for testing, research and development, and training. This will accelerate the deployment of offshore wind projects progressing through The Crown Estate's 'Round 3' and Scottish Territorial Waters licensing processes by providing the opportunity to demonstrate new equipment in the marine environment.

2.0 Introduction

2.1 AOWFL is proposing to develop an offshore wind farm and deployment centre off the coast of Aberdeen, known as the European Offshore Wind Deployment Centre (EOWDC).

2.2 The proposed project would combine a small commercially operated wind farm with a test and research centre, allowing manufacturers to test "first of run" wind turbines and innovative foundation solutions along with related operation and maintenance access logistics.

2.3 The project has been successful in gaining EU funding of up to €40m from the European Economic Recovery Plan. This award is in recognition of the project's potential role in supporting development of the offshore European wind industry by proving technologies and techniques.

2.4 DTZ has been commissioned by AOWFL to undertake a socio-economic, recreation and tourism impact assessment of the proposed EOWDC. The structure of the assessment can be summarised as follows:

- **Baseline Technical Report** – this provides a summary of the policy context with regard to offshore renewables in Scotland; and a baseline of indicators related to socio-economics, recreation and tourism within Aberdeen City and Aberdeenshire.

- **EIA Technical Report (this document)** – an assessment of the impact that the proposed EOWDC will have upon socio-economics, recreation and tourism in the study areas, as described below.

2.5 The scope of this assessment is to consider the impacts of the development across the areas listed below. The scope of the assessment has been informed through a benchmarking exercise (see Section 6) which identified the key socio-economic impacts which have been considered in previous Environmental Impact Assessments of comparable offshore wind schemes.

- **Socioeconomic** – employment and economic impacts associated with the construction, operation and decommissioning of the project, including supply chain and income effects
- **Tourism** – considering the impact on tourism in the local area
- **Recreation** – considering the impact on coastal recreational activities
- **Research and Development** – considering the possible impact of the deployment centre on the UK offshore wind industry as a whole, due to the opportunity for research, development and testing of equipment.

2.6 For the purposes of this assessment, the study area has been defined as follows:

- **Inner study area**: the two local authority areas of Aberdeen City and Aberdeenshire, the development will pose direct impacts to this area
- **Wider study area:** Scotland as a whole
- **UK**: potential national impacts, such as the impact on the offshore wind industry as a whole

Consultation

2.7 DTZ consulted with the following individuals in April 2011 (all by phone) to inform the Baseline Assessment and Impact Assessment:

- Colin Parker, Chief Executive, Aberdeen Harbour
- Matt North, Port Manager for the Port of Dundee, Forth Ports
- Steven Paterson, Chief Financial Officer, Peterhead Port Authority
- Eric May, Marine Renewable Section Leader, Marine Scotland
- Robert Forbes, Aberdeen City Council
- Eric Wells, Aberdeenshire Council
- Roddy Mathieson, Aberdeenshire Council
- Alistair Reid, Aberdeenshire Council
- Paul Reynolds, Offshore Wind Development Manager, RenewableUK
- Sara Budge, Project Director, Energetica
- Dr Graham Russell, RYA Scotland

Key Guidance Documents

2.8 This assessment has been undertaken based on the following guidance on economic assessment:

- HM Treasury (2003) Green Book
- BIS (2010) Impact Assessment Guidance
- English Partnerships (2008) Additionality Guide: Third Edition
- BIS (2009) Guidance for Using Additionality Benchmarks in Appraisal

- Surfers Against Sewage (2009) Guidance on Environmental Impact Assessment of Offshore Renewable Energy Development on Surfing Resources and Recreation

Data Information and Sources

2.9 The main sources of information for this assessment (aside from consultations) are the following:

- BWEA (2009) UK Offshore Wind: Charting the Right Course
- Ernst & Young (2009) Cost of and financial support for offshore wind
- Marine Scotland (2011) Economic Assessment of Short Term Options for Offshore Wind Energy in Scottish Territorial Waters: Costs and Benefits to Other Marine Users and Interests
- Scottish Enterprise (2010) National Renewables Infrastructure Plan
- Scottish Renewables (2010) Scottish Offshore Wind: Creating an Industry
- Technip (2011) Rochdale Envelope Requirements for the European Offshore Wind Development Centre
- The Crown Estate / BVG Associates (2010) Guide to an Offshore Wind Farm

Impact Methodology

2.10 The overall impact methodology is primarily based on a quantitative assessment of the economic impacts in terms of job and Gross Value Added (GVA), in line with HM Treasury (2003) Green Book guidance.

2.11 The level of significance is assessed as follows:

Table 2.1: Impact Methodology

Magnitude of the Effect (based on spatial extent, duration, and scale)		
Spatial Extent of Effect, assessed at the level of • Inner Study Area (Aberdeen & Aberdeenshire) • Wider Study Area (Scotland) • UK	**Duration of Effect** • Long-term/ permanent (more than 10 years) • Medium-term (existing for 5 to 10 years) • Short-term (existing for 1 to 5 years) • Temporary effect (existing for less than a year)	**Scale of Effect:** As there are no specific standards or guidelines, the impacts have been assessed relative to baseline conditions, or a 'No Development' scenario
Sensitivity of the Receptor		
The sensitivity of the receptor is typically assessed in terms of the recoverability of the receptor and importance of the receptor. However this method of assessment does not perform well in terms of socio-economic impacts (particularly beneficial impacts), where the receptor is assumed to be the economy, population, businesses and workforce in the study area. In the case of job creation (or job losses), the sensitivity has been judged in terms of the level of unemployment in the area.		

2.12 Impacts are assigned a rating of major, moderate, minor or negligible, based on the magnitude of the effect and sensitivity of the receptor, as follows:

Table 2.2: Matrix for Significance of Impact

Magnitude of Effect based on spatial, duration and scale of effect	Sensitivity of Receptor Very High	High	Medium	Low
Very High	Major	Major	Major	Moderate
High	Major	Major	Moderate	Minor
Medium	Major	Moderate	Moderate	Minor
Low	Moderate	Minor	Minor	Negligible
Negligible	Minor	Negligible	Negligible	Negligible

Cumulative and In-combination Impact Assessment Methodology

2.13 The core development under consideration within this assessment is the offshore works associated with the European Offshore Wind Deployment Centre (EOWDC). Other cumulative developments which need to be considered are: the onshore works associated with the project, the Ocean Laboratory element of the project, and any other potential offshore wind energy projects in the area.

2.14 The onshore works will be subject to a separate Environmental Impact Assessment, however they have been considered briefly within this assessment as a cumulative development.

2.15 The cumulative impact assessment has also considered the interaction with other offshore wind developments on the East coast of Scotland. There are two clusters of offshore wind farm developments planned for the East coast of Scotland totalling around 7.5GW of capacity, as follows:

- **Moray Firth** – Beatrice project (920MW) and Moray Firth Round 3 project (1,300 MW)
- **Firth of Forth** – Inch Cape (905MW), Neart na Gaoithe (420MW), Forth Array (415MW), and Firth of Forth Round 3 project (3,500MW)

Worst Realistic Case

2.16 In conducting this assessment, consideration has been given to the possible range of impact scenarios, based around the following key aspects of the project:

- **Scale** (capacity deployed) and timing of the project - the larger scale the project and the sooner it takes place, the greater the beneficial economic impacts
- **Sourcing of components** – higher levels of local sourcing will increase beneficial impacts in the Inner and Wider study areas.
- **Usage of local ports for construction and operational activities** – using a local port such as Peterhead or Aberdeen will increase beneficial impacts in the inner study area.

2.17 For the purposes of this assessment, a central scenario has been developed reflecting the most likely outcome; although it is recognised that there is some uncertainty around the key project parameters above, and that the actual impact may be higher or lower.

Scale and timing of the project

2.18 The level of capacity deployed within the EOWDC is one of the key variables for the socioeconomic assessment; as this determines the scale of capital and operational expenditure and the resulting socioeconomic impact. The development will comprise 11 turbines of between 4MW and 10MW each (although The Crown Estate Lease limits the overall capacity to 100 MW). However, following further consultation with the developer, it appears that the most likely outcome is towards the midpoint of this range rather than the extremes, as the development is likely to involve a mix of different turbine designs and sizes. For the purposes of this assessment, DTZ has used an indicative total capacity figure of **84MW**, based on the following assumptions:

- 4 x 6 MW turbines installed in 2013
- 4 x 7.5 MW turbines plus 3 x 10 MW turbines installed in 2014

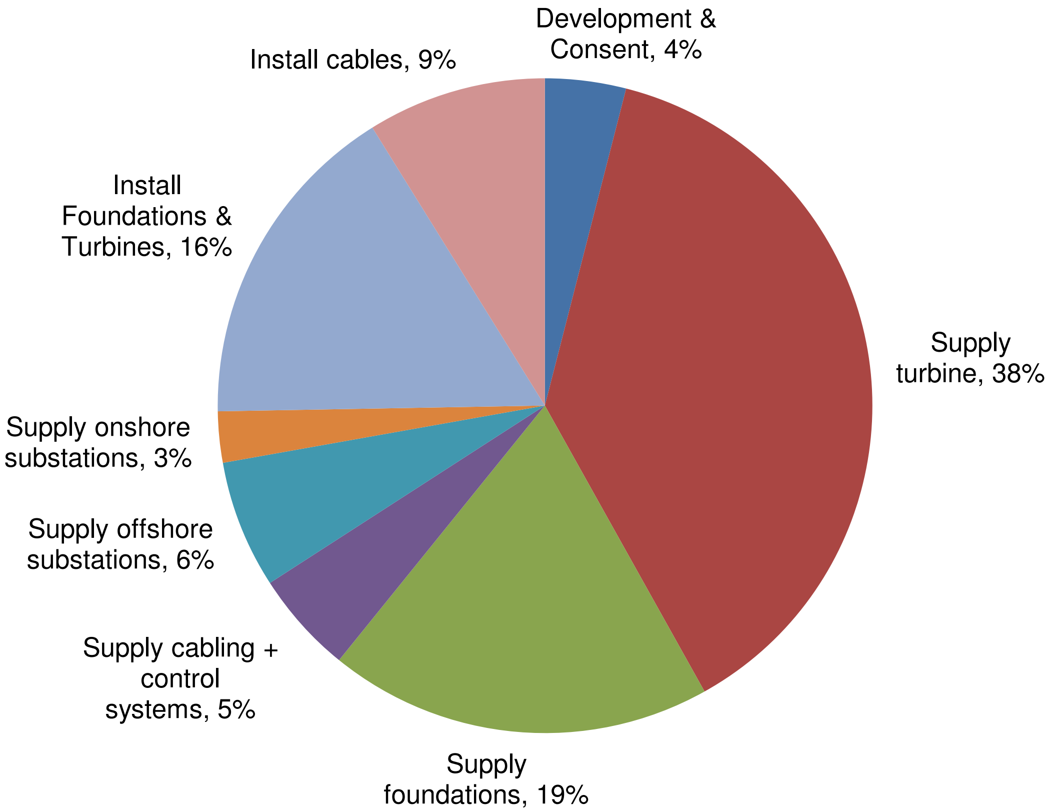
2.19 It is anticipated that the project will be constructed over a two year period, and will be operational for up to 22 years.

Sourcing of Project Components

2.20 Another key aspect in determining the socioeconomic impact during the construction phase is the extent to which project-related capital expenditure is captured by businesses within the study area. This can be assessed by breaking the total CAPEX into its constituent elements; and then making assumptions as to the likelihood of each element of expenditure remaining within the study area.

2.21 A report produced by BVG Associates for The Crown Estate (2010) provides a breakdown of the CAPEX for a typical offshore wind farm, based on industry benchmarks, which DTZ has analysed as shown in Figure 2.3. As can be seen, the largest single element is the cost associated with the supply of the wind turbine generator (38%), followed by the supply of foundations (19%), and the installation of foundations and turbines (16%). Installation activities account for 25% of the total CAPEX, whilst supply of project components comprises 71% of the total CAPEX (the remaining 4% relates to Development and Consenting).

Figure 2.3: Breakdown of Capital Cost for a Typical Offshore Wind Farm (Source: Crown Estate / BVG Associates, 2010)



2.22 DTZ has considered where the main project elements are likely to be sourced from, in consultation with AOWFL and wider consultees, and bearing in mind the actual locations of potential suppliers for each element. The assumptions are shown in Table 2.4:

Table 2.4: Assumptions on Sourcing of Components

Project Element (% of CAPEX)	Assumption	Comments
Turbines (38% of CAPEX)	Assume: 25% Wider Study Area 25% Rest of UK 50% Non-UK	The key manufacturers of offshore wind turbines are currently located in Continental Europe and Asia. A number of manufacturers (e.g. Siemens, GE, Clipper Windpower, Mitsubishi, Vestas, Gamesa, Doosan) are considering the development of manufacturing bases for offshore turbines in the UK. Of these, Doosan and Gamesa are considering investing in Scotland, but not in the Inner Study Area.[2] Given that the project proposes to use a mix of turbines, it is likely that they will be sourced from a number of distinct companies and locations.
Foundations (19% of CAPEX)	Assume: 50% Wider Study Area 50% Rest of UK	There are a number of suppliers of foundations for offshore wind projects in the UK, including some within the Wider Study Area (but not Inner Study Area) such as BiFab. Given the physical size of foundations it is preferable to source locally if possible. Given that there will be a mix of foundations used within the development, it is possible that they will be sourced from a range of different locations
Cabling & control systems (11%)	Assume: 50% Rest of UK 50% Non-UK	The probable source for this element is the UK or Scandinavia. No offshore substation is proposed so this element is included within cabling.
Development & Consenting (4%)	Assume: 33% Inner Study Area 33% Wider Study Area 33% Rest of UK	Includes project development work, which in this case will be split between Technip, AOWFL and any associated contractors/advisors. Also includes survey work which is likely to be carried out locally.
Onshore Substation (3%)	Note: this element falls outside the scope of this assessment, as the assessment only covers offshore works. The impact of this element is considered in the section on Cumulative Impacts below.	

Usage of Local Ports

2.23 Another main factor which will influence the scale of socioeconomic impacts is the choice of port used during the construction and operational phases – and whether this is within the Inner Study Area, Wider Study Area, or further afield – as this is a key factor in the location of impact.

2.24 The final decision on which port(s) are to be used has not yet been made, although current intentions are as follows:

- Potential utilisation of Aberdeen Port for small vessels during the construction phase, and for operational activities
- Potential utilisation of Peterhead Port as a construction port

2.25 DTZ has conducted an independent high-level review of a number of major ports in close proximity to the proposed development site (see Section 6), including Aberdeen and Peterhead, in order to assess their suitability for construction and operational activities. This review found that Aberdeen and Peterhead ports are likely to be sufficient for construction activities in relation to the EOWDC, although noting that these ports may not be suitable for the construction of larger offshore wind projects in their current state, due to space constraints.

[2] Doosan in Renfrew, near Glasgow, and Gamesa in Dundee

2.26 The review also found that Aberdeen and Peterhead have sufficient infrastructure in order to be used during the operational phase, and offer good facilities and may be chosen due to the requirement for an operational port in close proximity to the development site.

2.27 Overall, the conclusions of DTZ's review of ports are consistent with the preferences of the project, as indicated above. For the purposes of this assessment, it has therefore been assumed that the both the construction port and operational port will be located within the Inner Study Area (i.e. Peterhead and Aberdeen).

3.0 Impact Assessment

Direct and Supply Chain Impacts

Construction Phase

Potential Impacts

3.1 The construction of an offshore wind farm can potentially generate socioeconomic benefits related to the direct employment of staff in manufacturing and construction activities, and indirect knock-on impacts on the supply chain for the construction project.

3.2 As identified in Section 2 above, the **duration** of the construction phase will be for two years (2013-2014), and is therefore viewed to be a **short-term effect**.

3.3 In assessing the **scale** of the impact it is important to first consider the level of capital expenditure (CAPEX) related to the project. As detailed costings have not yet been finalised for the project, DTZ has estimated the total capital cost based on the likely capacity and industry benchmarks for the level of CAPEX per Mega Watt (MW).

3.4 BWEA (2009) identifies that the capital cost offshore wind projects currently stands at £3.1 million per MW. This ratio has increased markedly in recent years, due to changes in commodity prices, foreign exchange rates, and supply constraints. BWEA (2009) provides a range of forecasts for CAPEX, concluding that there is some uncertainty as to whether CAPEX will increase or decrease in the short to medium term. On this basis, DTZ has used the current figure of £3.1 million per MW in order to model the likely CAPEX associated with the EOWDC.

3.5 Based on a total capacity of 84 MW, this results in an estimated capital cost of **£260.4 million**, as shown in Table 3.1.

Table 3.1: Capital Cost estimates for the EOWDC

	2013	2014	Total
Capacity Deployed in year	24	60	84
CAPEX per MW (£m)	3.1	3.1	
Total CAPEX	74.4	186.0	260.4

3.6 Based on the assumptions on sourcing of project components (as set out in Figure 2.4) and excluding the onshore elements, the proportion of CAPEX retained within the study area is estimated to be as follows:

Table 3.2: Assumptions of CAPEX retained in study area

Project component	% of CAPEX	Inner Study Area	Wider Study Area (inc Inner Study Area)	UK (Inc Wider Study Area)
Development & Consent	4.0%	1.3%	2.7%	4.0%
Supply turbine	38.0%		9.5%	19.0%
Supply foundations	19.0%		9.5%	19.0%
Supply cabling & control systems	11.4%			5.7%
Install Foundations & Turbines	16.5%	16.5%	16.5%	16.5%
Install cables	8.9%			4.4%
Total CAPEX retained (% of total)		17.8%	38.1%	68.56%
Total CAPEX retained (£m)		£46.3	£99.2	£178.5

3.7 As shown in Table 3.2, it has been assumed that 38% of CAPEX will be retained in the Wider Study Area (Scotland), of which 18% will be retained in the Inner Study Area. This translates into £99m of expenditure captured in the Wider Study Area, of which £46m will be captured in the Inner Study Area.

3.8 The next steps in calculating the impact are described as follows, and summarised in Table 3.3:

- The number of job-years supported directly or indirectly by project expenditure can be calculated by dividing the total expenditure by the average turnover per worker in a relevant industrial sector – which in this case would be the 'Construction of Civil Engineering Projects'[3] sector, with a turnover per head of £187,000 (Source: Annual Business Inquiry 2008, Office for National Statistics). As shown in Table 3.3, the project is estimated to support 531 job-years worth of employment in the Wider Study Area, of which 248 job-years worth of employment will be in the Inner Study Area.

- The Gross Value Added (GVA) supported by the expenditure can be estimated by multiplying the number of job-years by the average GVA per worker in the sector - £59,000 (Source: Annual Business Inquiry 2008, Office for National Statistics; Construction of Civil Engineering Projects sector). HM Treasury (2003) Green Book guidance recommends that where possible, economic impacts which occur over differing timescales are expressed in Net Present Values (NPV) terms using an appropriate discount rate (the guidance suggests 3.5%). As shown in Table 3.5, the GVA supported (directly or indirectly) by the proposed development in the Wider Study Area is estimated to be £29.5m, of which £13.8m will be in the Inner Study Area.

- The direct and indirect employment supported will increase household incomes and expenditure in the local area, which will support additional jobs. This is known as an induced or income multiplier effect. At a Scotland level, estimates have been made for the scale of the income multiplier effect in the Scottish Input-Output tables (the latest set of data relates to 2007). For the construction sector the induced multiplier is 0.39 for employment, or 0.34 for GVA. In the absence of any corresponding estimates of multiplier effects for the Inner Study Area, we have assumed that the multiplier effects on the local economy will be half as great as for Scotland as a whole (i.e. 0.195 for employment, and 0.17 for GVA).

[3] As defined in the Office for National Statistics Standard Industrial Classification (SIC) system

Table 3.3: Summary of Impact: Construction Phase

Total Employment (job-years)	Direct & Indirect	Induced	Total	Magnitude of Impact
Inner Study Area	248	48	296	Medium
Wider Study Area (Scotland)	531	207	738	High
UK	955	n/a	n/a	Very High
NPV of GVA (£m)	**Direct & Indirect**	**Induced**	**Total**	
Inner Study Area	£13.8	£2.3	£16.1	Medium
Wider Study Area (Scotland)	£29.5	£10.0	£39.6	High
UK	£53.1	n/a	n/a	Very High

3.9 The receptors of the above economic impacts have been assumed to be the economy, population, businesses, and workforce of the Inner Study Area and Wider Study Area. One way of assessing the sensitivity of the receptors is in terms of the relative level of unemployment – as the creation of jobs associated with the proposed project will be of benefit in reducing unemployment in the area, and partially offsetting the anticipated contraction in employment in other sectors such as oil and gas and manufacturing (see Baseline Report, Figure 4.5). As described in the baseline report, the current level of unemployment is 2.8% in the Inner Study Area, and 7.1% in the Wider Study Area (compared to a UK benchmark of 7.8%).

3.10 Another factor in assessing the sensitivity of the receptors is in terms of the wider catalytic impact the development could have in supporting the development of renewable energy sector. This is particularly true of the Inner Study Area, where the project will have a strong linkage with other local initiatives such as the Energetica project described in the Baseline Report. **Overall, the sensitivity of the receptors has been assessed as 'Medium' in both the Inner Study Area and the Wider Study Area.**

3.11 The impact on the Inner Study Area has been assessed of Medium (positive) magnitude, Medium sensitivity and therefore of **Moderate (positive) significance**. In the Wider Study Area, the potential impact has been assessed of High (positive) significance, Medium sensitivity, and therefore of **Moderate (positive) significance.**

Mitigation

3.12 The impacts of the development in terms of direct employment and supply chain impacts have been assessed to be of Moderate positive significance. Therefore no mitigation of negative impacts is required.

3.13 The consultations with stakeholders including Aberdeen City and Shire Councils and Scottish Enterprise, including the Energetica Project, highlighted the anticipated positive impacts of the project on the economy in both the Inner Study Area and Wider Study Area.

3.14 However, it is acknowledged that there is some uncertainty as to the scale of impact, as set out in Section 2. Actions which should be taken in order to maximise the beneficial impacts of the development include the following:

- Work with the major ports within the Inner Study Area to ensure that they can be utilised during the construction, operational, and decommissioning phases; identifying any necessary infrastructure upgrades at the earliest possible opportunity.
- Identify suitable local businesses which could provide components of the project. Engage with these companies and make them aware of the opportunities available where possible. Actively encourage these businesses to bid for contracts related to the project. Scottish Enterprise has been engaged in activities of this kind.

Residual Impacts

3.15 Not applicable – no mitigation measures

Cumulative Impacts

3.16 This assessment covers the offshore works for the proposed project only: onshore works will be considered separately in the assessment as part of the application for the onshore works. In terms of socioeconomic impact, the onshore works such as a substation are viewed to be of negligible significance on their own. The rationale for this is that the total capital expenditure on this element will be relatively modest (3% of total CAPEX), and that components are likely to be sourced from outside the Inner Study Area or Wider Study Area. However, consultees have highlighted the benefits of locating onshore works at the Science and Energy Park in order to support a cluster of offshore wind related businesses. If this can be achieved, the cumulative beneficial impacts will be greater.

3.17 The impact of other offshore wind farm projects in the vicinity of the proposed development is likely to be very significant. As described in Section 2, there is around 7.5GW of offshore wind capacity planned for the East coast of Scotland, which will require capital investment in the order of £23 billion[4] and will be constructed on a phased basis between now and around 2020. A study by Scottish Renewables (2010) showed that the offshore wind sector in Scotland could directly support 28,000 full time equivalent jobs by 2020. Offshore wind projects on the East coast of Scotland will have a major impact on ports in the area - a report by Scottish Enterprise & HIE (2010a) concluded that the most likely ports/locations to be used for offshore wind manufacturing and construction in the area are Leith, Dundee, Nigg, Aberdeen, Peterhead, and Fife Energy Park. Consultees felt that this project would have a significant role in supporting the development of the industry as there is an identified need for more proving sites for turbines (RenewableUK).

Operational Phase

3.18 The operation of an offshore wind farm can potentially generate socioeconomic benefits related to the direct and indirect employment of staff in operations and maintenance (O&M) activities.

3.19 The **duration** of the operational phase is 22 years, and is therefore judged to have a **long-term** effect.

3.20 In order to assess the **scale** of the effect, it is necessary to consider the total level of Operational Expenditure (OPEX); the proportion of this which will be retained locally; and the employment which this will support. The following assumptions have been used, with the results shown below:

- Total OPEX can be estimated based on the total installed capacity (i.e. 84MW by end of 2014) multiplied by a ratio of £79,000 per MW per annum (Source: Ernst & Young, 2009). This means that once all capacity has been installed in 2014, the total OPEX will be around £6.6 million per annum.
- The proportion of total OPEX which will be retained locally has been estimated in a number of studies. A report by Scottish Renewables (2010) estimated that of total OPEX related to offshore wind projects in Scottish Territorial Waters, 45% would be retained in Scotland, and 56% in the UK. The local impact will relate to the operations and maintenance team, which will typically be located in a port proximate to the wind farm site to minimise transfer times. DTZ's review of port infrastructure (see Section 6) concluded that there are two ports in the Inner Study Area (Aberdeen and Peterhead) which would be suitable for use as an Operations and Maintenance base. The project has confirmed the utilisation of Aberdeen Port during this phase of development. On this basis, it can be assumed that the 45% of OPEX which falls within the Wider Study Area would relate to the Inner Study Area and not the remainder of Scotland.

[4] i.e. 7,460MW of capacity multiplied by a CAPEX figure of £3.1 million per MW

- Direct and Indirect GVA impacts can be estimated using a ratio of OPEX to GVA of 2.27 to 1 (Source: Scottish Renewables, 2010).
- The level of direct and indirect employment can be estimated from GVA using a suitable ratio for the total cost per operations and maintenance job, which Scottish Renewables (2010) estimated at £52,000.
- As with the construction phase above, the induced multiplier effect has been calculated through reference to the Scottish Input Output tables. At Scotland level, the induced multiplier for the construction sector is 0.39 for employment, or 0.34 for GVA. It has been assumed that the corresponding multiplier effects for the Inner Study Area are 0.195 for employment, and 0.17 for GVA.

Table 3.4: Operational Impacts (per annum, once all capacity deployed)

	OPEX (£m p.a.)	Jobs supported directly & indirectly	GVA (£m p.a.)
Inner Study Area	3.0	25	1.3
Wider Study Area (Scotland)	3.0	25	1.3
UK	3.7	31	1.6

Table 3.5: Total Operational Impacts over lifetime of project (22 years)

Total Employment (job-years)	Direct & Indirect	Induced	Total	Magnitude of Impact
Inner Study Area	553	108	661	High
Wider Study Area (Scotland)	553	216	768	High
UK	693	n/a	n/a	High
NPV of GVA	**Direct & Indirect**	**Induced**	**Total**	**Magnitude of Impact**
Inner Study Area	£17.4	£3.0	£20.4	High
Wider Study Area (Scotland)	£17.4	£5.9	£23.4	High
UK	£21.9	n/a	n/a	High

3.21 As shown in Table 3.4, O&M activities will (directly and indirectly) support 25 jobs and £1.3 million of GVA per annum in the Inner Study Area. Over the 22 year operational phase of the project, the project will directly or indirectly support £17.4 million of GVA in the Inner Study Area, or £20.4 million once induced effects have been taken into account. The impact is viewed to be of High significance at both the level of the Inner Study Area and Wider Study Area.

3.22 The sensitivity of receptors is as described above in relation to the Construction phase– i.e. 'Medium' in both the Inner Study Area and Wider Study Area.

3.23 In the Inner Study Area, the potential impact has been assessed of High (positive) magnitude, Medium sensitivity and therefore of **Moderate (positive) significance**. In the Wider Study Area, the potential impact has been assessed of High (positive) significance, Medium sensitivity, and therefore of **Moderate (positive) significance**.

Mitigation

3.24 The above section demonstrates that the impact of the development during the operational phase is of Moderate positive significance. Therefore no mitigation of negative impacts is required.

Residual Impacts

3.25 No change from pre-mitigation position.

Cumulative Impacts

3.26 This assessment covers the offshore works for the proposed project only: onshore works will be considered separately. In terms of socio-economic impact, the onshore works such as substations are viewed to be of negligible significance, as OPEX related to these elements will be minimal. However, as already identified, the siting of these elements on the Energy Park north of Aberdeen could, in the opinion of consultees, support a cluster of offshore wind related companies and be used as part of the demonstration and training aspects of the project. This would have knock-on beneficial impacts for the local economy.

3.27 The impact of other offshore wind farm projects in the vicinity of the proposed development during the operational phase is likely to be very significant. As described in Section 2, there is around 7.5GW of offshore wind capacity planned for the East coast of Scotland, which will require operational expenditure of nearly £600 million per annum[5] for the lifetime of these projects. This will support a large number of permanent jobs in operations and maintenance, which are likely to be located in operations and maintenance ports on the East Coast of Scotland.

Decommissioning Phase

3.28 The decommissioning of an offshore wind farm can potentially generate socioeconomic benefits related to the removal, disassembly, and disposal of wind farm components. It is anticipated that foundations and turbines will be cut/lifted and removed by a self-elevating crane vessel. Cables will be left in situ where possible, with exposed ends cut and/or buried.

3.29 The **duration** of the decommissioning phase is estimated to be up to 5 months, and is therefore judged to be a **temporary** effect.

3.30 In order to assess the **scale** of the effect, it is necessary to consider the total level of expenditure on decommissioning; the location of this expenditure; and the employment which this will support. The following assumptions have been used:

- Ernst and Young (2009) recommend that the costings for offshore wind projects build in a contingency equivalent to £18,000 per MW per annum for decommissioning; which for a project with a lifetime of 22 years equates to a total figure of £396,000 per MW of capacity.
- This figure has been multiplied by the total capacity (84 MW) to give a total decommissioning cost of **£33.3 million**.
- It has been assumed that the decommissioning phase takes place in 2036/7, assuming a 22 year lifetime of the project.
- It has been assumed that the construction port would be used for decommissioning activity – which as described above, has been assumed to be in the Inner Study Area. The economic activity associated with decommissioning activity will be associated with the decommissioning port.
- The number of job-years directly or indirectly supported by expenditure on decommissioning can be calculated by dividing the total expenditure by the average turnover per worker in a relevant industrial sector – which in this case would be the 'Construction of Civil Engineering Projects'[6] sector, with a turnover per head of £187,000 (Source: Annual Business Inquiry 2008, Office for National Statistics).
- The Gross Value Added (GVA) supported by the expenditure on decommissioning activity can be estimated by multiplying the number of job-years by the average GVA per worker in the sector of £59,000 (Source: Annual Business Inquiry 2008, Office for National Statistics;

[5] i.e. 7,460 MW multiplied by £79,000 per MW per annum
[6] As defined in the Office for National Statistics Standard Industrial Classification (SIC) system

Construction of Civil Engineering Projects sector).

- HM Treasury (2003) Green Book guidance recommends that where possible, economic impacts which occur over differing timescales are expressed in Net Present Values (NPV) terms using an appropriate discount rate (the guidance suggests 3.5%).
- As with the construction phase above, the induced multiplier effect has been calculated through reference to the Scottish Input Output tables. At Scotland level, the induced multiplier for the construction sector is 0.39 for employment, or 0.34 for GVA. It has been assumed that the corresponding multiplier effects for the Inner Study Area are 0.195 for employment, and 0.17 for GVA.

3.31 Overall, the analysis shows that the total expenditure on decommissioning will be £33.3 million. This will directly or indirectly support 178 job-years of employment within the Inner Study Area, generating £5.8 million of GVA. Once induced effects have been taken into consideration, this will support £6.8 million worth of GVA in the Inner Study Area.

Table 3.6: Summary of Impacts from Decommissioning Phase

Total Employment (job-years)	Direct & Indirect	Induced	Total	Magnitude of Impact
Inner Study Area	178	35	213	Medium
Wider Study Area (Scotland)	178	69	248	Medium
UK	178	n/a	n/a	Medium
NPV of GVA	**Direct & Indirect**	**Induced**	**Total**	**Magnitude of Impact**
Inner Study Area	£5.8	£1.0	£6.8	Medium
Wider Study Area (Scotland)	£5.8	£2.0	£7.7	Medium
UK	£5.8	n/a	n/a	Medium

3.32 As with the impacts associated with construction and operation, the **sensitivity of the receptors** has been assessed as 'Medium' in the Inner Study Area and Wider Study Area.

3.33 In the Inner Study Area, the impact has been assessed to be of Medium magnitude, Medium sensitivity, and therefore of **Moderate (positive) significance.** In the Wider Study Area, the impact has been assessed of Medium magnitude, Medium sensitivity and therefore of **Moderate (positive) significance**.

Mitigation

3.34 The above section demonstrates that the impact of the development during the decommissioning phase is of Moderate positive significance. Therefore no mitigation of negative impacts is required.

Residual Impacts

3.35 No change from pre-mitigation position.

Cumulative Impacts

3.36 This assessment covers the offshore works for the proposed project only: onshore works will be considered separately.

3.37 The impact of other offshore wind farm projects in the vicinity of the proposed development during the decommissioning phase is likely to be very significant. As described in Section 2, there is around 7.5GW of offshore wind capacity planned for the East coast of Scotland. The expenditure on decommissioning on these projects could total nearly £3 billion[7], and is likely to take place around 25 years from commissioning (which on the East coast projects is likely to occur between now and

[7] i.e. 7,460 MW of capacity multiplied by around £400,000 per MW (assuming a 22 year project lifetime)

2020). This will create a large number of temporary jobs for the duration of the decommissioning phase. The £7m of GVA associated with this project will be a very small part of the wider cumulative impacts.

Impact on Tourism

3.38 Marine Scotland (2011) highlight that offshore wind projects can have a range of potential impacts on tourism, including positive and negative impacts:

- Visual effects on the landscape and seascape deterring visitors to an area or deterring tourism investment;
- Disturbance or injury to coastal or marine wildlife interests (e.g. for wildlife watching) during construction or operation of the wind farm;
- Disruption to site access for tourism operations; and
- Visual effects on landscape and seascape during operation creating tourism opportunities, providing add-on benefits to existing wildlife excursions and attracting visitors to an area.

3.39 The Marine Scotland assessment cites a survey by Riddington et al (2008), which estimates the impacts of *onshore* wind farm development on tourism expenditure in Scotland (Note: there is no corresponding survey looking at the impact of offshore wind projects on tourism, but this is taken to be a reasonable proxy). The survey found that the vast majority of visitors (93-99%) who had seen a wind farm suggested that the experience would not have any effect on their decision to return to the area; in fact there were some tourists for whom the experience increased the likelihood of a return visit rather than decreasing it.

3.40 The assessment by Marine Scotland suggests that the seascapes in the East and North East of Scotland (i.e. the area around the proposed development site) are less sensitive than the West coast of Scotland (citing Scott et al, 2005); and that the effects of offshore wind development on general tourism in these regions has therefore been considered to be negligible.

3.41 Commercial wildlife boat trips such as whale watching trips have the potential to be impacted directly by the physical presence of the wind farms by making access difficult to routes often used by the boats or by interrupting lines of sight while scanning for wildlife with scopes or binoculars. However the report by Marine Scotland (2011) found these effects to be negligible.

3.42 Overall, the assessment by Marine Scotland (2011) suggests that the impact of offshore wind farms on tourism is of negligible significance. This view is supported in a study by Glasgow Caledonian University for the Scottish Government (2008), which concluded that 'even using a worst case scenario, the impact of current [wind farm] applications [on tourism] would be very small.'

3.43 The views of consultees supported this view, though the close proximity of the Trump Development at Menie Estate has been noted. Construction of new golf courses is well underway at Menie and the EOWDC lies to the south east of the estate. Consultees also highlighted the high levels of business tourism. The baseline report highlighted Visit Scotland and Scottish Enterprise statistics showing that nearly three quarters of tourist trips to Aberdeen are for business. The EOWDC will clearly support and potentially grow this important market segment, which is estimated by Scottish Enterprise to be worth £137 million per annum.

3.44 The assessment by Marine Scotland (2011) suggests that offshore wind farms can have positive impacts on tourism – particularly where the wind farm has an associated visitor centre. For example, a report by BWEA (2006) reviewed numerous studies and surveys assessing the impacts of wind farms on tourism in the UK, including two operational offshore wind farms in England and Wales. The report stated that E.ON UK's Scroby Sands Information Centre welcomed 30,000 people in the first six months (from May 2004), and in 2009, 42,000 people visited the centre (Marine Scotland, 2011). .

3.45 Furthermore, there may be positive effects on the local tourism economy associated with temporary workers during the construction phase. It is often the case on offshore wind construction projects, that workers are employed on a shift pattern system – for example one week of work on an offshore vessel, followed by one week of shore leave. Workers on shore leave are likely to have a (modest) impact on the local tourist economy, through expenditure on accommodation and subsistence. The extent of this impact varies from development to development, and has not been quantified in this case.

3.46 Overall, the potential impact on tourism has been assessed to be of **negligible significance**. The EOWDC may have a minor beneficial effect on business tourism.

Impact on Recreation

3.47 The assessment of Offshore Wind projects in Scotland by Marine Scotland (2011) highlights that in general, offshore wind projects may have impacts on recreational boating; and surfing, windsurfing and kayaking.

3.48 The EOWDC is seen by consultees to be too far offshore to prevent surfing or bathing. In terms of the potential impact on recreational boating, a number of potential impacts have been considered such as: safety, changes to recreational boating behaviour or activity levels, and increased steaming distances to avoid offshore wind farms. There are known to be jet skiers in the area.

3.49 However, the assessment by Marine Scotland concludes that the presence of an offshore wind farm will not have any significant negative impacts in terms of changes to recreational boating behaviour or activity levels, or collision risk/navigation. A position statement by the European Boating Association (EBA) states that “there is no danger to a vessel under 24 metres in length navigating through the farm taking reasonable care” – a position which is supported by the RYA Scotland (Marine Scotland, 2011, pg 73). The report also suggests that (with the exception of one offshore wind development in the West of Scotland) there would not be any impacts in relation to the loss of essential routes to anchorage points. Consultation with RYA further reveals that normal sailing routes for large craft are several miles offshore at that point in order to avoid Aberdeen Harbour traffic. Any small craft (e.g. dingy sailing) would, on the other hand, sail around and in between the turbines quite safely.

3.50 The only impact quantified in the assessment by Marine Scotland relates to the negative impact (increased cost) associated with increased steaming distances to avoid wind farms, for which a number of scenarios are identified (High, Medium, and Low Impact). However even in the High Impact scenario, the overall impact associated with increased steaming is £33,000 per annum for the 10 offshore wind farms in Scottish Territorial Waters combined. Given the relatively small area affected by the proposed development (26 sq km) compared to the projects considered in the Marine Scotland report (1,233 sq km combined), the impact associated with the proposed development is likely to be of **negligible significance**.

3.51 In terms of the potential impact on surfing, windsurfing and kayaking, the assessment by Marine Scotland (2011) identifies that the main impact of offshore wind developments is related to the deterioration of surf wave quality due to the presence of foundations. However, the assessment concludes, based on evidence from existing wind farm developments, that there have been no significant changes in wave quality at the shoreline as a result of other offshore wind projects. On this basis, it has been assumed that the proposed development will not have a significant impact on surfing, windsurfing or kayaking activity.

3.52 Overall, the potential impact on recreation has been assessed of **negligible significance**.

Impact on the Offshore Wind sector / R&D impacts

3.53 The EOWDC has the potential to create benefits for the offshore wind energy sector at a local and national level, through its role as a deployment and research and development centre. Key features of the EOWDC in this regard are that it will involve the deployment of different foundation and turbine designs; and the inclusion of the Ocean Laboratory within the overall development, which will provide both training and environmental monitoring opportunities.

3.54 Deployment centres are needed to allow manufacturers to test turbines, foundation designs and other components in the offshore environment. Given the large number of manufacturers expressing an interest in UK manufacture of offshore turbines, a large number of turbine test locations will be required.

3.55 The EOWDC will be the second largest of four current deployment centres in the UK. The others are at Blyth (National Renewable Energy Centre) with up to 99 MW of capacity (20 turbines) in development; and two smaller deployment centres each comprising two turbines (Gunfleet sands, Kent and 2B Energy at Methil, Fife). The four current centres will collectively provide the opportunity to test 35 turbines, of which 11 (or 30%) would be at the EOWDC. RenewableUK identifies a further two sites as being required to support industry development in the current round of licensing plus more sites in future rounds.

3.56 The deployment centres will allow manufacturers to improve reliability and reduce costs through testing. Extensive data will be generated that will be of benefit to all of the industry. RenewableUK has identified a need for 10 new UK factories to produce the 23 GW required by 2020. Sites such as the EOWDC will be critical in the UK securing this new manufacturing base and the associated jobs. Its location off Aberdeen will allow the lessons of the oil and gas industry to be transferred to offshore wind reinforcing the region's position in energy. Turbine manufacturers from China, France, Korea, USA and Japan have already shown keen interest in the EOWDC as a possible route into supplying Round 3 projects.

3.57 Stakeholders have expressed their strong support for the scheme, and the significant impact it will have in supporting the development of the offshore wind energy sector at a national level through the R&D opportunities it provides:

- 'The development of offshore wind still faces many challenges to commercial deployment. The operation of the EOWDC will make a strong contribution to knowledge sharing for new components, designs and access methodologies for construction, operations and maintenance to be executed in the marine environment.' **Chris Bronsdon, Chief Executive, Scottish European Green Energy Centre (SEGEC)**
- 'The European Offshore Wind Deployment Centre will provide invaluable opportunities for R&D, helping the industry to grow with real confidence. Innovative projects such as this will help the UK to maintain its position as the world leader in offshore wind. This will in turn encourage more investors to come forward, creating thousands of jobs in the rapidly-expanding offshore wind sector.' **Maria McCaffery, Chief Executive of RenewableUK**
- 'This is potentially a great opportunity for Scotland's research community to actively engage in the development of an important means to generate low carbon electricity. Particularly important will be the deployment of the Ocean Laboratory, a wide range of turbines and support structures as possible and access to these for independent evaluation in order to aid future developments.' **Professor Paul Mitchell of the University of Aberdeen's School of Engineering**

3.58 Consultees in the Inner Study Area saw the EOWDC as a key part of the Energetica project (discussed in the Baseline Report), underlining the capability of the area in energy and renewables and helping to attract inward investment. For example, if the onshore elements could be co-located with the Energy Park (Bridge of Don) it would help to create a cluster of energy and engineering companies in one location. Sara Budge, project manager for Energetica, Aberdeen City and Shire Economic Future (ACSEF), commented:

"The EOWDC is a major component of ACSEF's flagship project, Energetica. As a pioneering offshore wind project, it will be at the cutting edge of the development of new technologies and presents significant opportunities for Aberdeen City and Shire to build a viable, robust supply chain around offshore wind, particularly in the areas of development, operation and maintenance

"Energetica is a highly ambitious, dynamic proposal at the heart of our efforts to promote Aberdeen City and Shire as a global energy hub. In addition to the EOWDC, the hydrogen corridor, airport development zone and Peterhead's decommissioning and emerging marine renewable sector along with links to the region's two universities and research base are also key to Energetica's success.

"Energetica may have the potential for a Smart Grid system to transport and deliver electricity, a pump storage facility to store any excess electricity produced through wind generation, test and research facilities for other forms of renewable energy and high quality, low carbon commercial and industrial accommodation."

3.59 Bob Collier, Chief Executive of Aberdeen & Grampian Chamber of Commerce commented:

"This is a real opportunity for Aberdeen and the North-east [of Scotland] to place itself at the forefront of this aspect of the renewables industry. There is fierce completion not just in Scotland but across the rest of Europe to gain recognition as a leader in the field and this project will provide an extremely valuable testing site for manufacturers to demonstrate their products and to gather vital data on performance."

3.60 Overall, the consultees and stakeholders have expressed a high level of support for the project. They identified that the proposed project will be an important contributor to the offshore wind industry as a whole, in particular benefitting the rollout of Round 3 projects, and benefitting the local area / Inner Study Area.

3.61 Whilst it is not possible to precisely quantify the scale, magnitude or duration of this effect, **DTZ's view is that this effect is of Moderate/Major (positive) significance to the Inner Study Area, and of Moderate (positive) significance to the Wider Study Area and the UK.**

4.0 Summary of Impact Assessment

4.1 The following tables provide a summary of the Impact Assessment at the level of the Inner Study Area and Wider Study Area.

Table 4.1: Impact Assessment: Inner Study Area

Potential Impact / Activity	Sensitivity of Receptor	Scale	Duration	Spatial Extent	Magnitude of Effect	Significance	Significance after Mitigation
Direct & Supply Chain impacts							
Construction	Medium	Medium (positive)	Short-term	Local	Medium (positive)	Moderate (positive)	Moderate (positive)
Operation	Medium	High (positive)	Long-term	Local	High (positive)	Moderate (positive)	Moderate (positive)
Decommissioning	Medium	Medium	Temporary	Local	Medium (positive)	Moderate (positive)	Moderate (positive)
Tourism	Medium	Low (positive)	Long-term	Local	Negligible	Negligible	Negligible
Recreation	Low	Low (positive)	Long-term	Local	Negligible	Negligible	Negligible
R&D	High	Medium (positive)	Long-term	Local / National / International	High (positive)	Moderate / Major (positive)	Moderate / Major (positive)

Table 4.2: Impact Assessment: Wider Study Area

Potential Impact / Activity	Sensitivity of Receptor	Scale	Duration	Spatial Extent	Magnitude of Effect	Significance	Significance after Mitigation
Direct & Supply Chain impacts							
Construction	Medium	High (positive)	Short-term	Regional	High (positive)	Moderate (positive)	Moderate (positive)
Operation	Medium	High (positive)	Long-term	Regional	High (positive)	Moderate (positive)	Moderate (positive)
Decommissioning	Medium	Medium (positive)	Temporary	Regional	Medium (positive)	Moderate (positive)	Moderate (positive)
Tourism	Low	Negligible	Long term	Regional	Negligible	Negligible	Negligible
Recreation	Low	Negligible	Long term	Regional	Negligible	Negligible	Negligible
R&D	High	Medium (positive)	Long term	Local / National / International	Medium (positive)	Moderate (positive)	Moderate (positive)

5.0 Appendix 1: Port Assessment

5.1 The construction, operation and decommissioning of the European Offshore Wind Deployment Centre will require the use of port facilities. The extent to which ports will be required will vary depending on various factors such as the technical specification of the wind farm, the location of the development site and the level of ongoing maintenance required. This appendix briefly explores the port specifications needed to deliver each phase of the proposed wind farm development, and seeks to identify at high level which ports in the local area could be suitable.

5.2 The following ports have been assessed. These ports were chosen on the basis that they are the nearest major ports to the development site and are of sufficient size to support at least part of the construction and / or operational phases.

- Aberdeen
- Peterhead
- Cromarty Firth (including Nigg and Invergordon)
- Dundee

5.3 Aberdeen and Peterhead are located within the Inner Study Area, whilst Cromarty Firth and Dundee are outside of the Inner study area but within the Wider Study Area.

Port Requirements

Construction and Decommissioning Activity

5.4 The National Renewable Infrastructure Plan (NRIP) produced by Scottish Enterprise and Highlands and Islands Enterprise (2010a) sets out the priorities for investment in infrastructure to ensure that the Scottish economy benefits from the growth potential of the renewable energy sector. The report identifies sites suitable for offshore wind construction, ranking them according to their potential.

5.5 The NRIP draws upon research carried out by BVG Associates for DECC (2009), which identified that the typical requirements for a construction port with the capacity to deploy 100 turbines a year is:

- At least 80,000 sq m (8 hectares) suitable for laydown and pre-assembly
- 200-300 m of quayside length with high load baring capacity and adjacent access
- Water access to accommodate vessels up to 140 m in length, 45 m beam and 6 m draft with no tidal or other access restrictions
- Overhead clearance of 100 m minimum to allow for the vertical transportation of towers
- Sites with weather restrictions could require additional lay down space, up to 300,000 sq m (30 hectares)

5.6 Whilst the DECC (2009) report identifies the infrastructure required to deploy 100 turbines per year, the proposed project is much smaller at only 11 turbines. On this basis, it is possible that some of the infrastructure requirements such as the extent of lay-down space could be scaled back given the need to handle fewer turbines at any one point in time (depending on the exact method of construction). The Project has indicated that approximately 20,000 sq m (2 hectares) of laydown space will be required at the construction port.

5.7 However, the requirements for harbour access, draft, quayside length and vessel dimensions are likely to be as per the DECC (2009) assessment, since it is anticipated that the proposed project will utilise standard jackup crane vessels (as per the DECC, 2009 assessment).

Operational Phase

5.8 The DECC (2009) report describes the need for ports to act as bases for operations and maintenance activities. The main factors in choosing an operations and maintenance port are proximity to the offshore wind farm (in order to minimise transfer times), uninterrupted access, and adequate berthing for maintenance vessels.

5.9 As a result of the oil and gas industry there is already a wide range of locations which are able to service the operations and maintenance of wind farm operations, particularly along the east coast of Scotland.

Port specifications

Aberdeen

5.10 The Port of Aberdeen is the closest major port to the proposed development site. It is the principal commercial port in Northern Scotland dealing with general cargo, roll-on/roll-off and container traffic. There a total of six deep water berthing areas in Aberdeen Harbour. Consultations with Aberdeen Harbour have identified Telford Dock as being the most suitable for construction and / or assembly of wind farm components. Telford dock has 520 m of berthing space available, a heavy lifting area and two transit sheds. The two sheds have a total space of 4,700 sq m (0.47 ha). This could make them suitable for storing parts such as turbine blades. It is possible that the construction phase could take place at Aberdeen, although there are some constraints in terms of the amount of space available.

5.11 Aberdeen has expressed an interest in becoming the operations port for the EOWDC development. The port has over 40 years experience in delivering similar support services for the oil and gas industry. It also benefits from being the closest location to the wind farm site, reducing the time taken to transfer between the wind farm and the port. The port has confirmed that it would be possible for operations activities to take place alongside existing port activities.

5.12 The NRIP Stage 2 document (Scottish Enterprise, 2010b) states that Aberdeen has the 'potential [to be used] for distributed manufacturing and service and maintenance [of offshore wind farms], and expertise in offshore industries which could be diversified.'

5.13 Aberdeen Harbour recently made the following statement in support of the proposed development:

> *"We welcome today's announcement and subsequent planning application; both crucial steps in driving forward the European Offshore Wind Deployment Centre (EOWDC).*
>
> *"Renewable energy, and in particular the offshore wind industry, has the potential to generate significant levels of traffic for Aberdeen Harbour in the future, while offering considerable economic opportunities that will benefit the whole region. Vessels involved in surveying and drilling bore holes for offshore wind farms are, for example, already utilising the port's facilities.*
>
> *"The EOWDC is a facility that has the potential to substantially develop the north east's burgeoning renewables sector. The harbour's future role as an operations and maintenance base for the Scottish renewables industry is something we will embrace as we build on the excellent reputation we have already established within the existing oil and gas industry."*

Peterhead

5.14 Peterhead port is located to the north of the proposed wind farm site. Based upon consultations with representatives of the Peterhead Port Authority, Smith Embankment is the facility which is most likely to be able to service any wind farm related construction activity. This newly developed facility has a 200 m berthing area, with 10 m draft, heavy lifting equipment and no tidal restrictions. Attached to the Smith Embankment is 16,000 sq m (1.6 ha) of working area which is specified as being suitable for offshore and onshore renewable developments. There is the potential to reclaim a further 50,000 sq m (5 ha) from the harbour if the phase 2 development goes ahead.

5.15 Peterhead has experience in delivering ongoing support to the oil and gas industry and would be a suitable base for the operations base for the proposed wind farm. It is possible that part of the ASCO facility to the south of the port area could be redeployed to support the offshore renewable industry.

Cromarty Firth

5.16 Cromarty Firth is a trust port. The Cromarty Firth Port Authority (CFPA) has authority over the shipping and navigation across the whole of the Firth up to a limit of two miles offshore. The CFPA own several facilities within the Firth such as the Invergordon Service Base, whilst some other assets such as those at Nigg are owned by other parties.

5.17 Nigg is a 96 hectare facility majority owned by KBR Ltd. Its facilities include a dry dock, large fabrication / warehouse buildings, 725 m of quayside with load-out areas up to 1,000 tonnes. It is accessible in all states of wind and tide, with extensive deep water and sheltered anchorage. Existing buildings on site include fabrication units of 17,000 sq m, assembly of 17,000 sq m and warehousing of 22,000 sq m. The NRIP Stage 2 report (Scottish Enterprise, 2010b) identifies that the site is suitable for large scale integrated manufacturing of offshore wind components, construction, and operations activities, particularly in conjunction with the site at Invergordon. The turbines used for the Beatrice offshore wind demonstrator project were assembled at Nigg. Nigg has the potential to be used for construction activities relating to the Aberdeen Offshore Project.

5.18 The Invergordon Service Base (ISB) has around 450 m of quayside space with water depth varying between 5.5 and 12 m. The ISB has many years experience supporting the oil and gas sector and has developed a strong supply chain. Therefore, ISB would have many of the necessary skills and expertise to be involved as an operations facility for the Aberdeen Offshore Wind project, once in place. The main downside is that the distance between Cromarty Firth and the proposed development site is significant, meaning that there may be other closer ports to the development site which are more suitable overall.

Dundee

5.19 The port of Dundee currently offers around 27 hectares of development land available for the renewable sector, all of which is in the ownership of Forth Ports. Other sites have been identified within the City of Dundee for renewable energy activities which do not require waterside access. The port itself offers about 1,800m of quayside in a sheltered location with access to the North Sea unrestricted by either air draft or vessel width. The water depth along the quay is up to 9.5m. Facilities include heavy lift equipment and required space to accept jack-up rigs. Potential exists for a rail freight terminal within the port estate.

5.20 The NRIP Stage 2 report (Scottish Enterprise, 2010b) identifies that there ‘is potential for a major turbine manufacturing facility and a tower manufacturing facility to co-locate on the site.’ Further capacity could exist for supply chain operations within the existing site.

5.21 In theory Dundee would have the required facilities and experience to act as either a construction or operations port for the Aberdeen Wind Farm development. However, as with Cromarty Firth, the distance between the port and the development site may prove to be a significant drawback in terms of operations activities.

Summary of Port Suitability

5.22 Table 5,1 below summarises the capability of the four chosen ports for construction activity, based upon the high-level assessment we have conducted.

Table 5.1: Summary of Port Suitability – Construction Activities

	Suitability as a construction port	Suitability as an operational port	Comments
Aberdeen	✔	✔	Some constraints in space available, but potentially sufficient for the EOWDC project. Proximate to the development site.
Peterhead	✔	✔	Some constraints in space available, but plans to expand capacity in the future. Proximate to the development site.
Cromarty Firth (Nigg)	✔	x	Highly ranked by the NRIP as a site to support the development of offshore wind in Scotland. Distance from site means it is less likely to be chosen for operational activity.
Dundee	✔	x	Large amounts of development space available. Highly ranked by the NRIP as a site to support the development of offshore wind in Scotland. Distance from site means it is less likely to be chosen for operational activity.

5.23 On the basis of this assessment, it appears that both of the ports in the Inner Study Area (Aberdeen and Peterhead) could be utilised in the construction phase of the proposed project; particularly given the relatively small scale of the EOWDC development relative to other commercial wind farm projects.

5.24 In terms of operations and maintenance activities, the most likely scenario is that one of the major ports in the Inner Study Area (Aberdeen or Peterhead) would be utilised. The rationale for this is that whilst other ports meet the requirements in terms of port infrastructure, the ports in the Inner Study Area benefit from proximity to the development site (which is a particular advantage for operational activities).

6.0 Appendix 2: Benchmarking of Offshore Wind Projects

6.1 The purpose of this section is to highlight the range of socio-economic impacts which have been considered in previous Environmental Impact Assessment studies for other comparable offshore wind projects around the UK, to inform the scope of the Impact Assessment. This assessment has been made through reference to completed Environment Impact Assessments of the following offshore wind projects, as summarised in Table 6.1:

- North Hoyle
- Beatrice
- Gwynt Y Mor
- Kentish Flats

6.2 In summary, the main socio-economic impacts identified across all of the case studies are:

- Direct employment during the Construction, and Operations and Maintenance phases
- Value of the construction project
- Supply chain effects

- Impact on tourism and recreation
- Impact on other marine activities such as fishing and shipping

Table 6.1: Summary of Socio-Economic Impacts of Benchmark Offshore Wind Projects

Details of the development:	North Hoyle	Gwynt Y Mor	Kentish Flats	Beatrice Demonstrator
Location	North Wales	North Wales	Thames Estuary	Moray Firth
Capacity / number of turbines	60 MW 30 turbines	576MW 160 turbines	129MW 30 turbines	10MW 2 turbines
Timescale	Constructed in 2002	Installation 2011-2014	Constructed 2004	Constructed 2006
Scope of assessment:				
Direct employment during the Construction, and Operations and Maintenance phases	✔	✔	✔	✔ #
Value of construction project	✔	✔	✔	✔ #
Supply chain effects	✔	✔	✔	✔ #
Impact on tourism and recreation	✔	✔	✔	✔
Impact on other marine activities such as fishing and shipping	✔	✔	✔	✔
Impact on offshore wind industry	✔		✔	
Community benefits		✔

- GVA / Gross Value Added – a measure of the economic value of a job or economic activity
- GW – Gigawatt, a measure of electrical generation capacity, equivalent to 1 billion Watts

- Ha – hectare (10,000 square metres)
- MW – Megawatt, a measure of electrical generation capacity, equivalent to 1 million Watts
- STW – abbreviation for Scottish Territorial Waters

European Offshore Wind Deployment Centre
Environmental Statement

Appendix 24.1: In Air Noise Baseline Technical Report

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

1 IN – AIR NOISE BASELINE TECHNICAL REPORT

1 This baseline technical report describes the measurement of the background noise and derivation of noise limits at various locations along the shoreline near the proposed European Offshore Wind Deployment Centre (EOWDC) to the north of Aberdeen.

1.1 Information for the Non-Technical Summary

2 A baseline noise survey has been carried out in order to establish the existing background noise at the four closest residential properties to the proposed offshore wind farm and at a further two locations representative of properties further inland where the influence of noise from the sea will be lower. The measurement locations were agreed with the Environmental Health Departments at Aberdeen City and Aberdeenshire Council. This document summarises the findings.

3 The measured background noise levels are influenced by sea noise and by traffic noise, especially that from the A90. Noise levels also show a correlation with increasing wind speed.

4 The results are used to derive the noise limits for the proposed EOWDC according to the UK Department of Trade & Industry's ETSU-R-97, *The Assessment and Rating of Noise from Wind Farms* (DTI, 1996).

1.2 Introduction

5 An assessment has been carried out of the existing noise environment at locations along the shoreline closest to the proposed development to the north of Aberdeen.

6 The baseline survey has been carried out to derive noise limits for the proposed development according to guidance normally used for onshore wind farms. This guidance has been used as there is currently a lack of Planning Policy Guidance for offshore wind farms with respect to noise impact on onshore residential properties.

7 This approach has been agreed with the Environmental Health Officers from Aberdeen City and Aberdeenshire Councils.

1.2.1 Methodology Consultation

8 Aberdeen Offshore Wind Farm Limited (AOWFL) submitted a Request for an Environmental Impact Assessment (EIA) Scoping Opinion in August 2010. Chapter 6.9 deals with in-air noise assessment. None of the responses received identified specific requirements for in-air noise assessment for residential properties onshore.

9 The Environmental Health Officers of Aberdeen City Council and Aberdeenshire Council have been consulted regarding the assessment methodology and the choice of measurement locations for the baseline noise survey:

- Andrew Gilchrist, Aberdeen City Council (110106)
- John Dawson, Aberdeenshire Council (110106)

1.2.2 Key Guidance Documents

10 The following key documents have been used in the assessment:

- Scottish Executive (2011). Planning Advice Note PAN 1/2011: Planning and Noise
- Scottish Executive (2010). Web based 'renewables advice'
- DTI Working Group on Noise from Wind Turbines (1996). The Assessment and Rating of Noise from Wind Farms ETSU-R-97
- Aberdeenshire Council (2005). Use of Wind Energy in Aberdeenshire: Guidance for Developers – Supplementary Planning Guidance Part 1
- Bowdler et al (2009). Institute of Acoustics (IOA) Bulletin Vol 34 no 2, March/April 2009 Prediction and Assessment of Wind Turbine Noise

11 The documents listed above have all been written for the purpose of assessing onshore wind farm developments but have been adopted for this project as providing suitable guidance on assessing background noise and deriving noise limits for the onshore residential properties.

1.2.3 Data Information and Sources

12 Background noise data was measured at 6 locations for three weeks. Wind speed was simultaneously measured with a SoDAR (Sound Detection and Ranging) remote sensing device on a field at Easter Hatton. This onshore wind data has been translated to the offshore wind farm location as described in (Oldbaum 2011).

- Oldbaum Services Limited (2011a). Wind speed data spatial translation – Method Statement for Aberdeen Offshore Windfarm Limited (Appendix 3).
- Hayes McKenzie Partnership Ltd. (2011). Measurement of background noise data and rainfall.
- Oldbaum Services Limited (2011b). Wind speed data spatial translation – Wind data analysis for Aberdeen Offshore Windfarm Limited (Appendix 4).

1.3 Baseline Description

1.3.1 Legislative and Planning Context

Planning Advice Note PAN1/2011, Planning and Noise

PAN1/2011 indentifies two sources of noise from wind turbines; mechanical noise and aerodynamic noise. It states that '*Good acoustical design and siting of turbines is essential to minimise the potential to generate noise*'. It refers to the '*web based planning advice*' on renewables technologies for onshore wind turbines.

Scottish Executive Web Based Planning Advice, Onshore Wind Turbines

13 The web based Planning Advice, Onshore Wind Turbines refers to ETSU-R-97, *Assessment and Rating of Noise from Wind Farms* (DTI, 1996a), as the document that *'should be followed by applicants and consultees and used by planning authorities to assess and rate noise from wind energy developments*'. There is no equivalent guidance for offshore wind farms, but there is no reason why the ETSU-R-97 guidance should not apply. ETSU-R-97 contains noise limits designed to protect external amenity during the day and sleep disturbance at night. These limits are derived from baseline noise measurements carried out at potentially affected properties around the proposed development site.

ETSU-R-97, The Assessment and Rating of Noise from Wind Farms

14 ETSU-R-97, *The Assessment and Rating of Noise from Wind Farms* (DTI 1996a), presents the recommendations of the Working Group on Noise from Wind Turbines, set up in 1993 by the DTI as a result of difficulties experienced in applying the noise guidelines existing at the time to wind farm noise assessments. The group comprised independent experts on wind turbine noise, wind farm developers, DTI personnel and local authority Environmental Health Officers. In September 1996 the Working Group published its findings by way of report ETSU-R-97. This document describes a framework for the measurement of wind farm noise and contains suggested noise limits, which were derived with reference to existing standards and guidance relating to noise emission from various sources.

15 The form of the noise limits proposed in ETSU-R-97 is that noise should be limited to X dB L_{A90} or 5 dB above the ‘prevailing background noise level’, whichever is the greater.

16 For night-time (2300-0700) the value of ‘X’ is given as 43, to protect against sleep disturbance indoors with a window open. The prevailing background noise is that acquired during the same night-time hours.

17 For day-time hours (evenings and week-ends) ‘X’ is given as 35-40 with the actual value in the range dependant on:

- The number of dwellings in the neighbourhood of the wind farm.
- The effect of noise limits on the number of kWh generated.
- The duration and level of exposure.

The prevailing background noise is that acquired during the quiet day-time hours, as defined in ETSU-R-97.

18 A simplified limit of 35 dB L_{A90} for 10 m height wind speeds up to 10 m/s is specified for smaller or more remote schemes obviating the need for background noise measurements in such cases. This also provides a useful tool for determining the extent of baseline monitoring required for any proposal.

19 It is stated that the $L_{A90,10min}$ noise descriptor should be adopted for both background and wind farm noise levels and that, for the wind farm noise, this is likely to be between 1.5 and 2.5 dB less than the L_{Aeq} measured over the same period. The $L_{Aeq,t}$ is the equivalent continuous 'A' weighted sound pressure level occurring over the measurement period t. It is often used as a description of the average noise level. Use of the L_{A90} descriptor for wind farm

noise allows reliable measurements to be made without corruption from relatively loud, transitory noise events from other sources.

20 ETSU-R-97 also specifies that a penalty should be added to the predicted noise levels, where any tonal component is present. The level of this penalty is described and is related to the level by which any tonal components exceed audibility.

Lord Hunt's Response to Environmental Protection UK

21 In October 2009, The Rt Hon Lord Hunt of Kings Heath OBE (Minister of State, DECC) wrote to Environmental Protection UK in response to their claim that a review of ETSU was due. He states:

'You're quite right that modern turbines are generally larger than those on which the ETSU-R-97 guidance was based. Noise outputs from these larger turbines have also, however, reduced in that time. Since the ETSU-R-97 derived noise limits are a function of background noise, there is currently no evidence to suggest that the larger turbines are any more likely to cause a noise impact than earlier and smaller designs. Similarly, there is currently no evidence to suggest that the small incidence of Amplitude Modulation (AM) that is reported to occur at a few sites is as a result of turbine size'.
'In essence, therefore, we continue to support the approach set out in Planning Policy Statement (PPS) 22 - Renewable Energy, including the use of ETSU-R-97 to "ensure that renewable energy developments have been located and designed in such a way to minimise increases in ambient noise levels".

Use of Wind Energy in Aberdeenshire: Supplementary Planning Guidance Part 1

22 A variation to the lower fixed noise limits described by ETSU-R-97, (see above). Aberdeenshire Council specify lower noise limits at 38 dB $L_{A90,10min}$ during night-time and 35 dB $L_{A90,10min}$ during day-time for very quiet locations. Theses lower fixed noise limits are valid for measurements carried out externally and have been applied to this study.

Institute of Acoustics Bulletin Article, Prediction and Assessment of Wind Turbine Noise, March/April 2009

23 Institute of Acoustics Bulletin Vol 34 no. 2 (Bowdler et al., 2009) contains an agreement, jointly authored by a number of consultants working in the wind turbine sector for both developers, local authorities and third parties, on an agreed methodology for addressing issues not covered by ETSU-R-97. This includes a methodology for dealing with vertical wind shear (which is the difference of the wind speed at different heights).

24 It should be noted that this article is written in the context of onshore wind farms, but the recommendation for dealing with wind shear is also applicable for offshore wind farms.

1.3.2 Baseline Conditions

Measurement Positions

25 Noise measurements were agreed to be carried out at six measurement locations, representing the four closest dwellings to the proposed

development site and two locations further inland, as indicated on Figure 1, Appendix 1 and as described below.

Four Winds (E395191, N814956)

26 Four Winds is a property to the west of the proposed development roughly 1,530 m from the shore and 470 m to the west of the A90. The equipment was located in the eastern corner of the garden, closest to the proposed wind farm site and near to the amenity area, as shown in Photographs 1. The principal source of noise at this location was road traffic during installation, and road traffic and wind in the trees during collection of the equipment.

Photographs 1 Four Winds Baseline Noise Measurement Position

16 Chapelwell Wynd, Balmedie (E396968, N817138)

27 16 Chapelwell Wynd is a property to the west of the proposed development roughly 575 m from the shore and 645 m to the east of the A90. The equipment was located in the rear garden, by a pond so that the house was shielded from sea noise and in the amenity area, as shown in Photographs 2. The principal sources of noise at this location were road traffic, the sea, helicopters and the trickling of the pond (which was being drained by the owner to prevent future noise) during installation, and the sea, helicopters and wind in the trees during collection of the equipment.

Photographs 2 16 Chapelwell Wynd Baseline Noise Measurement Position

Easter Hatton (E396245, N816102)

28 Easter Hatton is a property to the west of the proposed development roughly 915 m from the shore and 65 m to the east of the A90. The equipment was located in the side garden, in the middle of the lawn amenity area, as shown in Photographs 3. The principal sources of noise at this location were road traffic and the sea during installation, and road traffic, the distant sea, aeroplanes and wind in the trees during collection of the equipment.

Photographs 3 Easter Hatton Baseline Noise Measurement Position

Hareburn House (E396294, N813979)

29 Hareburn House is a property to the west of the proposed development roughly 180 m from the shore and 780 m to the east of the A90. The equipment was located in the rear garden, between the house and the bushes in the amenity area, as shown in Photographs 4. The principal sources of noise at this location were the sea and distant road traffic during installation, and the sea, helicopters and wind in the bushes during collection of the equipment.

Photographs 4 Hareburn House Baseline Noise Measurement Position

3 Tarbothill Farm Cottages (E395696, N813430)

30 3 Tarbothill Farm Cottages is a property to the west of the proposed development roughly 680 m from the shore and 330 m to the east of the A90. The equipment was located in the side garden, in the amenity area, as shown in Photographs 5. The principal sources of noise at this location were the sea and distant road traffic during installation, and road traffic, the distant sea, distant farm machinery and wind in the bushes during collection of the equipment.

Photographs 5 3 Tarbothill Farm Cottages Baseline Noise Measurement Position

16 Dubford Gardens, Bridge of Don (E393913, N812140)

31 16 Dubford Gardens is a property to the west of the proposed development roughly 2,070 m from the shore and 720 m to the west of the A90. The equipment was located in the middle of the rear garden, in the amenity area, as shown in Photographs 6. The principal sources of noise at this location were road traffic and rain noise during installation, and road traffic and wind in the trees during collection of the equipment.

Photographs 6 16 Dubford Gardens Baseline Noise Measurement Position

Measurement Procedure

Instrumentation

32 The baseline noise measurements were made with four Larson Davis model LD-820 Precision Integrating Sound Level Meters fitted with 1/2" microphones, one Larson Davis model LD-831 and one Larson Davis model LD-824, which comply with the type 1 standard in IEC 651-1:1979. The microphones were fitted with 45 mm radius foam ball windshields surrounded by secondary windshields of 40 mm thickness, in line with recommendations in ETSU W/13/00386/REP, Noise Measurements in Windy Conditions (DTI, 1996b), and were mounted on tripods at a height of 1.2 m. Pre-calibration was carried out using a Bruel & Kjaer model 4231 acoustic calibrator (s/n 2218188). The calibration of each meter was checked at the end of the monitoring period using the same acoustic calibrator.

33 Noise monitoring equipment was left at the measurement positions for a period of 21 days from 15th February to 8th March 2011. The meters were programmed to measure a number of statistical noise indices, including the L_{A90}, together with the maximum and minimum levels and the L_{Aeq} (the Equivalent Continuous A-Weighted Sound Pressure Level) over consecutive 10-minute periods. Results were automatically stored at 10-minute intervals, synchronised to wind speed measurements from the on-site SoDAR to allow for later correlation between the two.

34 Calibration of the noise measurement equipment was carried out before the monitoring period commenced and was checked at the end. A drift of no more than 1.2 dB was noted at any location.

35 Wind speed and direction measurements were made with the AQ500 SoDAR unit installed at East Hatton, Balmedie (NGR E396714, N815608) at various heights up to 200 m agl (above ground level) during the course of the noise measurement. This data has been translated to the proposed EOWDC location as described in (Oldbaum 2011a and 2011b).

36 Rain data for the site has been obtained from the Met Office Central Climate Unit for the background noise survey. Periods with recorded rainfall from the Met Office data have been excluded from any further assessment.

Wind Shear

37 It is now well established that wind speed experienced by a wind turbine cannot be correctly predicted from 10 m height wind speed measurements and ground roughness conditions alone. Hub height wind speed, and hence the wind speed experienced by the wind turbine, may be under-predicted under these conditions and hence the output noise level may be under-predicted. To correctly account for this in the assessment methodology, background noise is referenced to hub height wind speed, as described in the agreement published in the Institute of Acoustics Bulletin (Bowdler et al., 2009).

38 Wind speed and direction was measured with an AQ500 SoDAR remote sensing device at Easter Hatton, Balmedie, an onshore location near the coastline. The data was recorded in 5 m steps from 50 m to 200 m. This data has been translated to the location of the offshore wind farm as described in (Oldbaum 2011b). For the assessment, the measured data correlating to hub height wind speed is used.

39 This translated hub height wind speed has then been corrected to 'standardised' 10 m height wind speed, as required by the method described in the IoA Bulletin using the same methodology as is used by the manufacturers to produce noise data for 'standardised' 10 m height wind speed, i.e.:

$$V_{10} = V_h \cdot \frac{\ln\left(\frac{h_{10}}{z_0}\right)}{\ln\left(\frac{h_h}{z_0}\right)}$$

40 Where V_{10} and V_h are the 'standardised' 10 m height (h_{10}) and hub height (h_h) wind speeds respectively, and z_0 is the standardised ground roughness length (= 0.05 m).

41 This standardisation is not intended to reflect actual 10 m height wind speed conditions and does not affect the relationship between turbine noise, background noise, and the derived noise limits.

Results of Noise Measurements

42 Raw data results of the noise measurements are not included in this chapter due to the relatively large amount of information gathered. Figures are, however, available on request which show the $L_{A90,10min}$ and $L_{Aeq,10min}$ in periods of 24 hours from midday to midday, at the measurement location, together with wind speed.

43 The noise limits are derived in accordance with ETSU-R-97 and the Aberdeenshire Supplementary Planning Guidance, as agreed with Aberdeen City Council and Aberdeenshire Council Environmental Health Officers.

44 Due to a technical error, the sound level meter at Hareburn House only recorded data for 3 days. During that period background noise levels were between 40 and 58 dB L_{A90} at 3 m/s and 52 and 59 dB L_{A90} at higher wind speeds during amenity hours and 42 and 55 dB L_{A90} at 3 m/s and 52 and 55 dB L_{A90} at higher wind speeds during night hours. Comparing the measured noise level of Hareburn House with the noise levels obtained at 3 Tarbothill Farm and 16 Chapelwell Wynd leads to the conclusion that background noise levels are generally higher at Hareburn House due to the proximity of the sea. The approach taken to use the noise limits derived from the measurement at Chapelwell Wynd as a substitute for Hareburn House is considered conservative as lower noise levels were recorded at this property compared to Tarbothill Farm. It is also assumed that using those noise limits is more representative for the houses in Blackdog which are further back from the shoreline as Hareburn House and would therefore receive less sea noise than Hareburn House.

45 Although the measured background noise data show a strong influence from the sea and the traffic noise of the A90 at all locations except Dubford Gardens, it also shows a correlation with increasing wind speed.

Noise Limits

46 Plots have been produced of the measured L_{A90} background noise levels against wind speed at six locations representing the four closest residential properties to the wind farm site and two more distant properties representative of properties further inland where the influence of noise from

the sea will be lower. The derived noise limits are based on the lower ETSU-R-97 day time limit and the night time limit of 38 dB L_{A90} or background noise level plus 5 dB, whichever is the greater. The plots for these locations also show the upper ETSU-R-97 day time limit for completeness.

47 The measured background noise correlated with equivalent offshore wind speed and subsequently derived noise limits according to ETSU-R-97 are shown in Chart X.1 to X.10 in Appendix 2 for the night hours and quiet day-time hours periods for the representative residential locations.

Other Residential Properties

48 The assessments carried out for the background noise measurement locations are generally representative of the properties most likely to be affected in each area. This has been determined by considering distance from the sea, distance from the A90, and the type of residential area.

49 Generally all other properties in the area being represented receive a lower predicted noise level and, assuming background noise is similar, will receive a lower impact than the assessed location.

50 The only area to which this doesn't apply is 16 Dubford Gardens. This is due to the measurement being chosen for being both further from the A90, and on the edge of the Aberdeen suburb of Bridge of Don. Although there are properties closer to the wind farm site, which will therefore have a higher predicted noise level from the wind farm, these properties will equally have a higher background noise than that of 16 Dubford Gardens, due to their proximity to the A90, sea and being in a more built-up region. 16 Dubford Gardens was therefore chosen to represent this area due to its location balancing these factors.

1.4 Summary

51 An assessment of the existing background noise at properties near the proposed EOWDC has been performed. The guidance contained within ETSU-R-97 has been used to derive noise limits at these properties.

52 Background noise measurements were made at six locations representative of those likely to be most affected by noise from the proposed development. These locations were agreed with the Environmental Health Officers for the Local Planning Authorities from the Aberdeen City and Aberdeenshire Councils.

53 Analysis of the measured data has been performed in accordance with ETSU-R-97 to determine the existing background noise environment at these six locations.

1.0 Scope

The following method statement details the process to be undertaken to translate data from the AQ500 SoDAR deployment at Easter Hatton to the position of the proposed Aberdeen Offshore Windfarm.

The installation at Easter Hatton is detailed in the following reports, which are available upon request:

Method Statement: MSVFALL002-151210

Risk Assessment: RAVFALL002-261110

Install Report: IFVFLL002-120111

The coastal location represents a good compromise to onsite data acquisition for offshore wind farms.

Given the flat terrain nature of the installation, the SoDAR (Sound Detecting And Ranging) location should experience similar flow conditions to that of the offshore wind farm.

From the primary wind direction, the wind will approach the wind farm and SoDAR location from onshore (South West – Westerly being the predominant direction). As the wind translates from onshore to offshore, a new internal boundary layer will form, and develop until new free stream flow conditions are developed. Typically this can be in the order of 15km – 20km from the coastline, depending on local conditions. Therefore it can be expected that the offshore wind farm location will feel the effect of the onshore constraints.

From offshore, easterly winds, the flow can be thought of as open sea conditions. Again a coastal location is a good compromise for these conditions, as the close proximity of the installations to the coast line means that local roughness effects have had very little time and space to modify the flow such that the SoDAR will experience significantly different conditions from that seen offshore.

Section 2 introduces the AQ500 SoDAR system in general terms, with typical validation results, acquired in Scottish conditions, shown in Annex 1.

Section 3 states the methodology used to translate the data series spatially from the install location to the proposed wind farm installation. The technique shown can be thought of as standard industry practice, minimising any increase in uncertainty in wind speed.

2.0 Instrumentation

The following section introduces the technology used to capture wind speed data. The AQ500 SoDAR system is a well respected reliable unit which has been in use since 2002 in the wind industry. There are now over 200 units in operation, providing accurate wind speed data for a variety of roles within the wind industry sector.

2.1 AQ500 SoDAR system

Figure 2.1 shows the AQ500 system on site in Sweden, housed within its own trailer unit.

The system is designed to be primarily powered by PV input, but has the energy security of a small generator back-up system which is intelligently controlled to help maintain the voltage level in the 600Ah of battery storage.

The system is flexible, relatively easy to deploy, and has a good track record in the wind industry. As a first look system the AQ500 has an unprecedented track record in terms of data quality, system reliability, and customer base within the wind industry.

Figure 2.1: In deployment in Sweden with Thnadners attachment

Table 2.1 summarises the specification of the SoDAR system. Figure 2.2 shows the actual AQ500 antenna housed within the trailer unit. The whole setup is designed to minimise side-lobe sound propagation, i.e noise pollution, and to minimise broadband loud noise interference with the return signal.

Item	Specification	Range
1	Height Range	20-200m
2	Height Resolution	5m
3	Accuracy Wind Speed	0.1m/s
4	Antenna Arrangement	3-beam
5	Antenna Height	1.2m
6	Antenna Width	1m
7	Antenna Weight	70kg
8	Data Transfer	GSM
9	Data Format	ASCII via SODWIN Software

10	Operating Frequency	3144Hz
11	Temperature Range	-40 ^{o}C to +60 ^{o}C
12	Humidity Range	10 to 100% RH

Table 2.1: AQ500 system specification

The AQ500 is unique on the market in that it is a three beam arrangement rather than the more common phased array type approach. The main benefit of this technique is that the system has generally better data availability statistics throughout the height range (typically greater than 95% at 90m), is less prone to background noise issues, and is less prone to error in rain conditions. Rain intensifies the scatter of the output sound signal, meaning the return signal is generally at a lower level. As the AQ500 is capable of emitting 300W peak pulses, the system is capable of returning values even in rain periods. Annex 1 gives some indicative values of an AQ500 in comparison with a Met mast station.

Figure 2.2: AQ500 antenna in standalone setup – most systems now deployed in trailer unit

2.1.1 Power Supply

Power supply integrity is the achilles' heel of most remote sensing systems, specifically when looking to operate in cold climate conditions. The AQ500 has a robust well trialled system which provides an intelligent, always-on, stability to the system. Over 200 systems currently operate within the UK and Europe with little or no system failures due to power system failure. The main mode of non-system availability is in prolonged no solar period with fuel running out. This is generally due to running the system in a low fuel configuration for quick and easy re-deployment depending on measurement campaign.

Table 2.2 specifies the AQ500 trailer and power supply solution.

Item	Specification	Range
1	Solar Input	480W
2	Generator	5kW
3	Battery Storage	600Ah
4	SMS notification	Via GSM
5	Trailer Height	2m
6	Trailer Width	1.4m
7	Trailer weight (incl. SoDAR)	1100kg
8	Fuel Tank Size	200 l
9	Power Consumption	30-50W
10	Pulse Power (max)	300W (user set or adaptive according to SNR)
11	Acoustic Power	17W (Max)
12	Electrical heating	240V AC user defined thermostat

Table 2.2 Power Supply specification

2.1.2 Health and Safety and System Security

The AQ500 is a self contained unit with little or no user intervention required in the setup of the system.

Prior to every installation a full risk assessment is carried out by Oldbaum Services to ensure that all risks have been identified and mitigated. This is done in conjunction with the client to ensure the clients HSE policy is adhered to.

The system is fully self contained with no potential for environmental impact. All systems can be fully isolated with a central kill on/off switch available. All systems are provided with fire extinguishers as required.

Security is handled by an integrated GPS vehicle tracking system, high grade hitch lock, wheel lock, and if required all wheels can be removed allowing the system to be fully supported on the four corner levelling legs.

3.0 Methodology

In order to translate the data form onshore to offshore conditions, numerical modelling techniques will be employed which are standard within the wind industry.

For this project, the most appropriate software is the WAsP (Wind Atlas analysis and application Programme) software developed by the Danish Technical University at RISOE, Roskilde. WAsP 10.0 will be used for this analysis, which has been specifically updated to help with coastal boundaries in the numerical domain, and the transition from onshore to offshore conditions.

To provide the noise study with the required data, the change in flow characteristics will be obtained and reported as a series of speed ups, or coefficients generated within WAsP to be applied to wind speed values to show the effect of moving the data acquisition point from onshore to offshore.

It should be noted that it is not possible to translate the full resolution time series as the change in wind speed will be reported and summarised by a directional sector bin. Typically this is a bin of 30 degrees width, and therefore 12 sectors are reported. The reporting of data in directional sector bins is standard practice in the wind industry.

Therefore a speedup value will be calculated for each sector bin, and this will be applied to each wind speed value within the bin. This will have no negative impact on the wind shear profile derived from this process.

The procedural methodology for the Aberdeen Offshore Windfarm is:

1. AQ500 data received and quality checked using Oldbaum standard practice for SoDAR data;
2. Data analysed and summarised to show mean wind speed, profile by sector, turbulence by sector and both wind speed and wind direction distributions;
3. Data summarised and collated into 30 degree sector bins;
4. Definition of numerical run within WAsP, including importing of local terrain maps;
5. Import of data series and summary of data acquisition point within WAsP;
6. Plausibility check of WAsP values with initial analysis values reported in 2;
7. Data summary of wind speed coefficients at the Aberdeen Offshore Wind development area;
8. Modification of SoDAR time series using WAsP calculated coefficients.

The output will be a wind speed timeseries consistent with industry best practice and suitable for use within the noise measurement campaign.

5.0 About Oldbaum

Oldbaum Services is a wind energy consultancy, with roots tracing back to 2003. In 2003 Technical Director Andy Oldroyd won a Green Energy Award whilst working for Chillwind for introducing a new measurement technique (Sound Detecting and Ranging or SoDAR) to the wind industry sector.

Andy, and his fellow Director Monica Griesbaum have continued to bring innovation and rigour to the wind industry, pioneering quality control and wind sensor use with such novel techniques as LiDAR and SoDAR.

Our company and experience has continued through involvement in innovative high profile projects such as the Beatrice offshore wind demonstrator, and has been recognised by Oldbaum Services winning an EC FP7 bid for the NORSEWInD Programme, with Andy Oldroyd as Coordinator.

NORSEWInD is a 7 million Euro project designed to deliver offshore wind atlases for the Baltic, Irish and North Sea areas based on physical data. The data is acquired from Met masts, LiDAR's located offshore and satellite based datasets. The result is a highly innovative project reducing uncertainty in offshore development by easing access to data for offshore developers.

Oldbaum are recognised experts in remote sensing and in particular data acquisition in offshore wind developments. This knowledge and understanding of the wind energy sector will prove invaluable in terms of understanding fully the nature of the challenges ahead, delivering the outputs defined in the feasibility study, and ultimately delivering a useable, innovative and necessary marine energy development tool.

Oldbaum Services are part of the Leosphere Wind Experts programme, and have been working with all forms of LiDAR since 2005. Oldbaum have designed acceptance tests and measurement campaigns for all forms of LiDAR (Continuous wave or pulse) and have therefore a unique perspective and experience in the unique challenges posed by each system type.

Annex 1.0: AQ500 validation results

The following is an extract of a test undertaken at Myers Hill in Scotland. The data IS FORM a well instrumented 80m met mast as reference, with the AQ500 being located 300m to the South West of the system. No filters have been applied apart form directional filters to exclude the influence of the 1MW NEG MICON WTG's located to the North East and South East of the met mast.

Full test results can be downloaded here: http://www.aqs.se/wordpress/wp-content/uploads/2009/12/AQSMH001_221209.pdf (large file)

Annex 1.0: Data Availability

Annex 1.0: Correlation Results

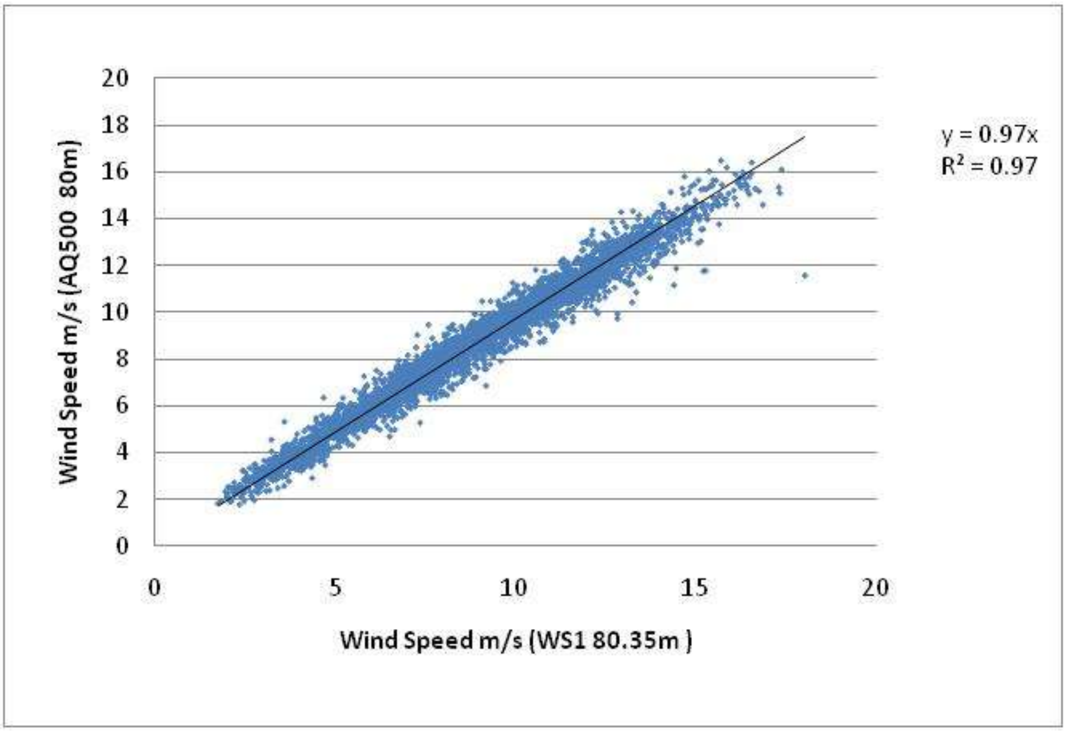

Figure A1.2: Overall correlation with 80m mast @ 80m, 300m Separation. Direction filter applied

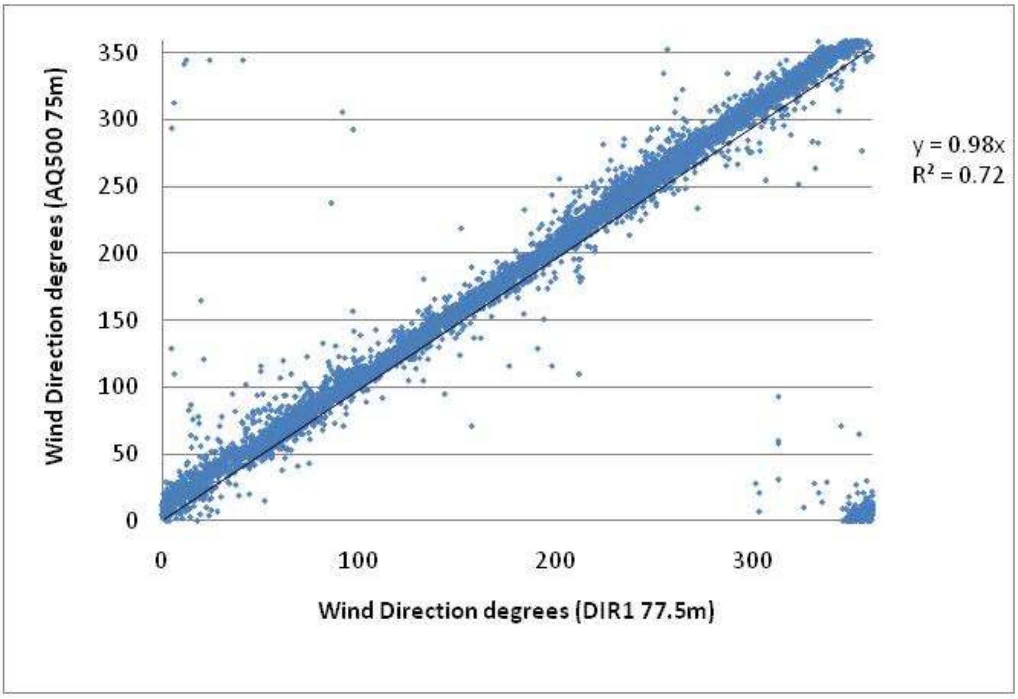

Figure A1.3: Direction Correlation – No applied filter

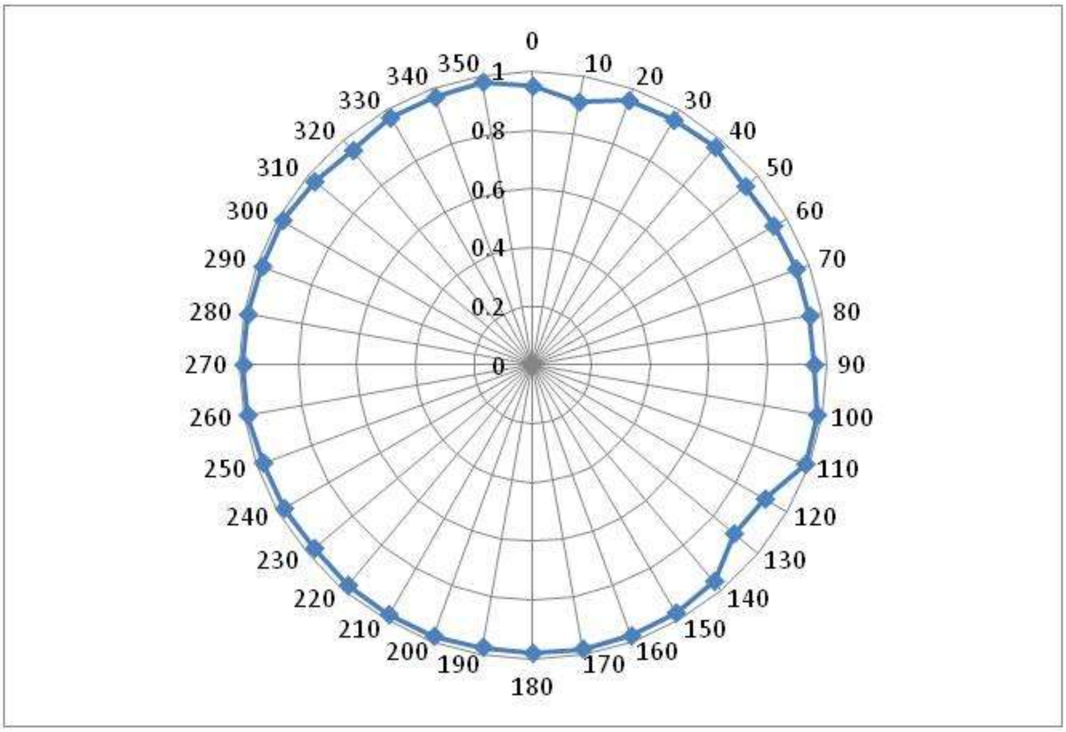

Figure A1.4: Correlation by Direction. Kinks show location of NEG Micon systems

Annex 1.0: Shear Profile Results

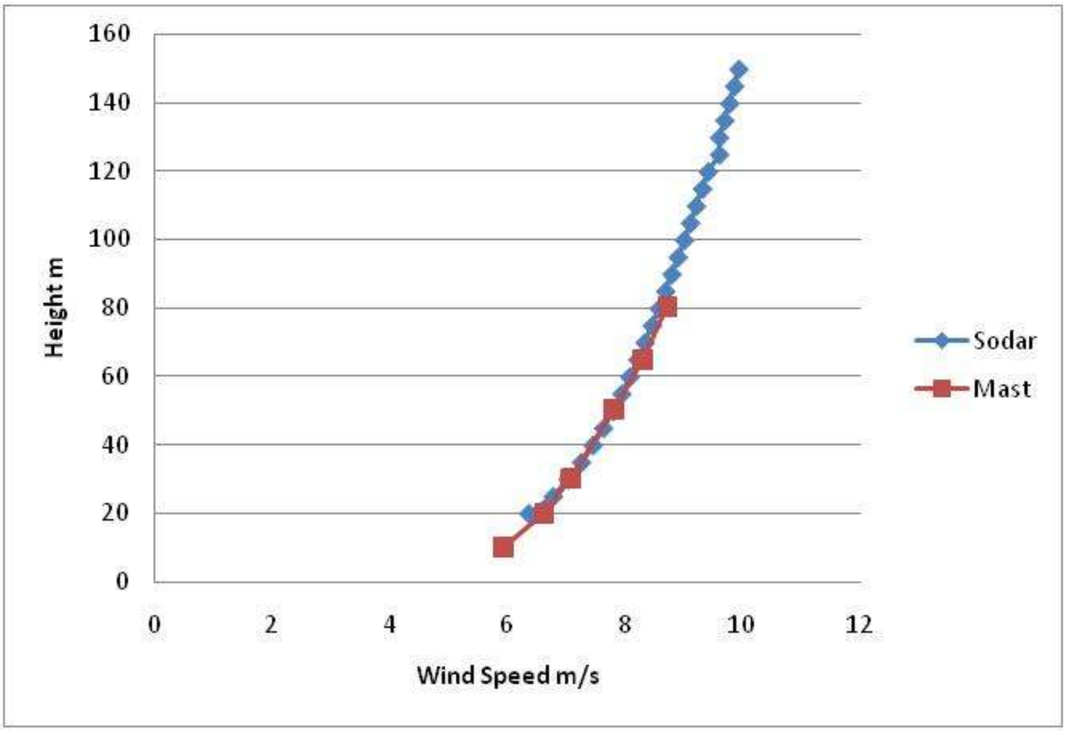

Figure A1.5: Shear profile Direction filter applied

	Mast	Sodar
c	0.0017	0.0026
b	4.9921	4.8059
α	0.2003	0.2081
R^2	0.9944	0.9979

Table A1.1: Regression analysis output equation of form cx^b .

Annex 1.0: turbulence Intensity

All RS systems have issue with turbulence through spatial and temporal averaging, or in some cases systematic filtering of the turbulence spectrum. IN this case we advocate the use of bin averaged values. Time series turbulence should be treated with caution, however Bin averaging shows the ability of the system for site classification.

Contents

1.0 Scope

The following report details the process undertaken to translate data from the AQ500 SoDAR deployment Easter Hatton to the position of the proposed Aberdeen Offshore Windfarm.

The installation at Easter Hatton is detailed in the following reports, which are available upon request:

Method Statement: MSVFALL002-151210

Risk Assessment: RAVFALL002-261110

Install Report: IFVFLL002-120111

The coastal location represents a good compromise to onsite data acquisition for offshore wind farms.

The location to be used as the wind farm site is: **400533, 814777.**

Given the flat terrain nature of the installation, the SoDAR (Sound Detecting And Ranging) the assumption is that the wind farm location should experience similar flow conditions to that of the offshore wind farm.

From the primary wind direction, the wind will approach the wind farm and SoDAR location from onshore (South West – Westerly being the predominant direction). As the wind translates from onshore to offshore, a new internal boundary layer will form, and develop until new free stream flow conditions are developed. Typically this can be in the order of 15km – 20km from the coastline, depending on local conditions. Therefore it can be expected that the offshore wind farm location will feel the effect of the onshore roughness.

From offshore, easterly winds, the flow can be thought of as open sea conditions. Again a coastal location is a good compromise for these conditions, as the close proximity of the installations to the coast line means that local roughness effects have had very little time and space to modify the flow such that the SoDAR will experience significantly different conditions from that seen offshore.

Section 2 introduces the AQ500 SoDAR system in general terms, with typical validation results, acquired in Scottish conditions, shown in Annex 1.

Section 3 states the methodology used to translate the data series spatially from the install location to the proposed wind farm installation. The technique shown can be thought of as standard industry practice, minimising any increase in uncertainty in wind speed.

Section 4 summarises the results of the analysis.

.0 Instrumentation

The following section introduces the technology used to capture wind speed data. The AQ500 SoDAR system is a well respected reliable unit which has been in use since 2002 in the wind industry. There are now over 200 units in operation, providing accurate wind speed data for a variety of roles within the wind industry sector.

2.1 AQ500 SoDAR system

Figure 2.1 shows the AQ500 system on site in Sweden, housed within its own trailer unit.

The system is designed to be primarily powered by PV input, but has the energy security of a small generator back-up system which is intelligently controlled to help maintain the voltage level in the 600Ah of battery storage.

The system is flexible, relatively easy to deploy, and has a good track record in the wind industry. As a first look system the AQ500 has an unprecedented track record in terms of data quality, system reliability, and customer base within the wind industry.

Figure 2.1: In deployment at Easter Hatton with Thnadners attachment

Table 2.1 summarises the specification of the SoDAR system. Figure 2.2 shows the actual AQ500 antenna housed within the trailer unit. The whole setup is designed to minimise side-lobe sound propagation, i.e noise pollution, and to minimise broadband loud noise interference with the return signal.

Item	Specification	Range
1	Height Range	20-200m
2	Height Resolution	5m
3	Accuracy Wind Speed	0.1m/s
4	Antenna Arrangement	3-beam
5	Antenna Height	1.2m
6	Antenna Width	1m
7	Antenna Weight	70kg

2.1.2 Health and Safety and System Security

The AQ500 is a self contained unit with little or no user intervention required in the setup of the system.

Prior to every installation a full risk assessment is carried out by Oldbaum Services to ensure that all risks have been identified and mitigated. This is done in conjunction with the client to ensure the clients HSE policy is adhered to.

The system is fully self-contained with no potential for environmental impact. All systems can be fully isolated with a central kill on/off switch available. All systems are provided with fire extinguishers as required.

Security is handled by an integrated GPS vehicle tracking system, high grade hitch lock, wheel lock, and if required all wheels can be removed allowing the system to be fully supported on the four corner levelling legs.

3.0 Methodology

In order to translate the data from onshore to offshore conditions, numerical modelling techniques will be employed which are standard within the wind industry.

For this project, the most appropriate software is the WAsP (Wind Atlas analysis and application Programme) software developed by the Danish Technical University at RISOE, Roskilde. WAsP 10.0 will be used for this analysis, which has been specifically updated to help with coastal boundaries in the numerical domain, and the transition from onshore to offshore conditions.

To provide the noise study with the required data, the change in flow characteristics will be obtained and reported as a series of speed ups, or coefficients generated within WAsP to be applied to wind speed values to show the effect of moving the data acquisition point from onshore to offshore.

It should be noted that it is not possible to translate the full resolution time series as the change in wind speed will be reported and summarised by a directional sector bin. Typically this is a bin of 30 degrees width, and therefore 12 sectors are reported. The reporting of data in directional sector bins is standard practice in the wind industry.

Therefore a speedup value will be calculated for each sector bin, and this will be applied to each wind speed value within the bin. This will have no negative impact on the wind shear profile derived from this process.

The procedural methodology for the Aberdeen Offshore Windfarm is:

1. AQ500 data received and quality checked using Oldbaum standard practice for SoDAR data;
2. Data analysed and summarised to show mean wind speed, profile by sector, turbulence by sector and both wind speed and wind direction distributions;
3. Data summarised and collated into 30 degree sector bins;
4. Definition of numerical run within WAsP, including importing of local terrain maps;
5. Import of data series and summary of data acquisition point within WAsP;
6. Plausibility check of WAsP values with initial analysis values reported in 2;
7. Data summary of wind speed coefficients at the Aberdeen Offshore Wind development area;
8. Modification of SoDAR time series using WAsP calculated coefficients.

4.0 Analysis results

Section 4 summarises the data analysis as used to generate the final output time series. The terrain file used to generate the wind analysis in WAsP is shown in Figure 4.1:

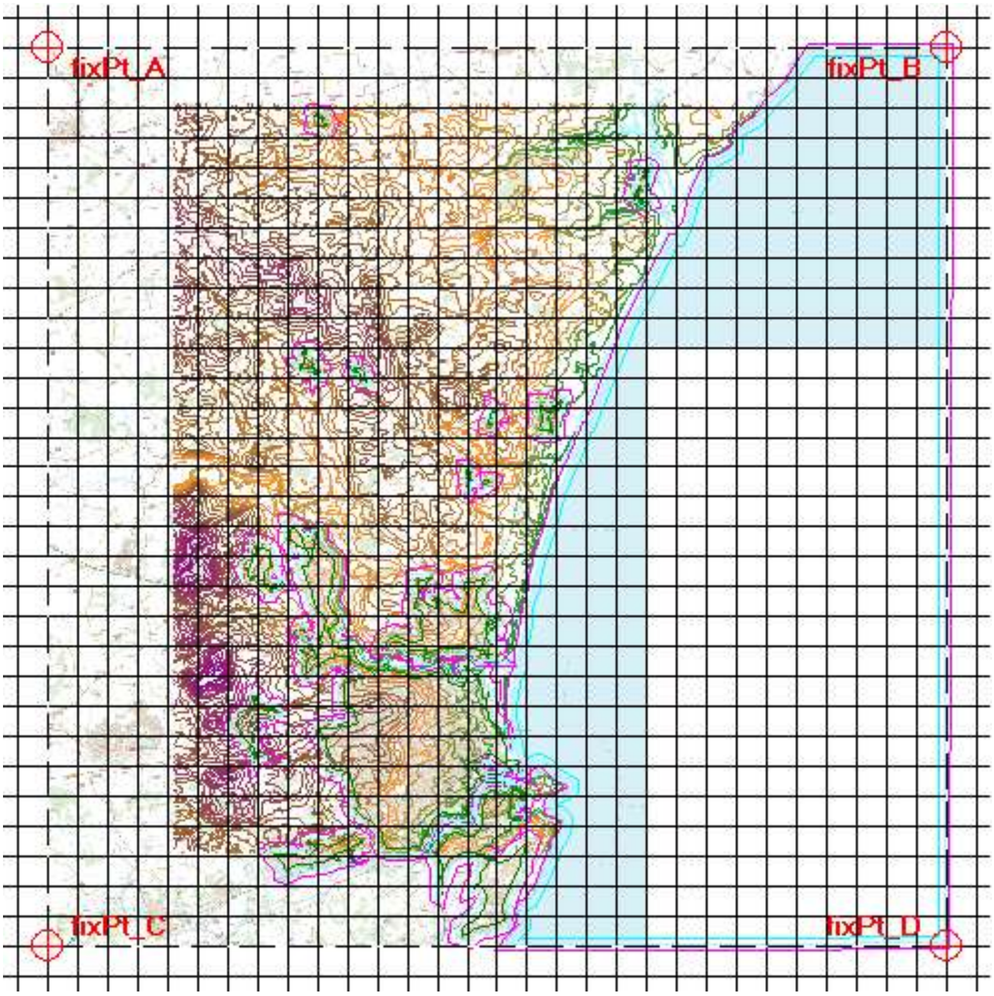

Figure 4.1: Contour map showing 10m height contours with roughness used for calculation.

4.1 Data filtering

SoDAR data can be prone to some errors in measurement which can be eliminated through careful filtering. These errors can include:

- Fixed echo;
- Low signal to noise ratio;
- Data loss through high background noise levels.

In this case the following data filters were used to clean the dataset prior to analysis:

- Data screened for null values (e.g. “9999”)

Wind speed data spatial translation

- Data with low signal to noise ratio (S:N < 50) removed.

The data period covered is from the 17th December 2010 (00:00) till 10th March 2011 (23:50).

4.2 Easter Hatton Summary

Figure 4.2 shows the wind speed data analysis output from WAsP.

A reference height of 120m was chosen by the client as being the hub height reference for this project, and is therefore used to summarise the data analysis.

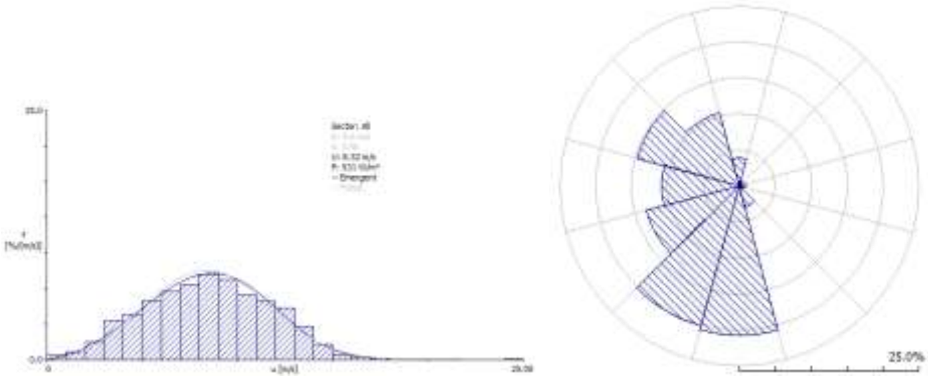

Figure 4.2: WAsP summary of SoDAR output at 120m (A=9.6, k=3.06, U=8.57m/s)

Figure 4.2 clearly shows the wind speed within the analysis period rarely came from easterly sectors, with the predominant direction being southerly during this period.

Figure 4.3 shows the site characteristic turbulence as a function of wind speed

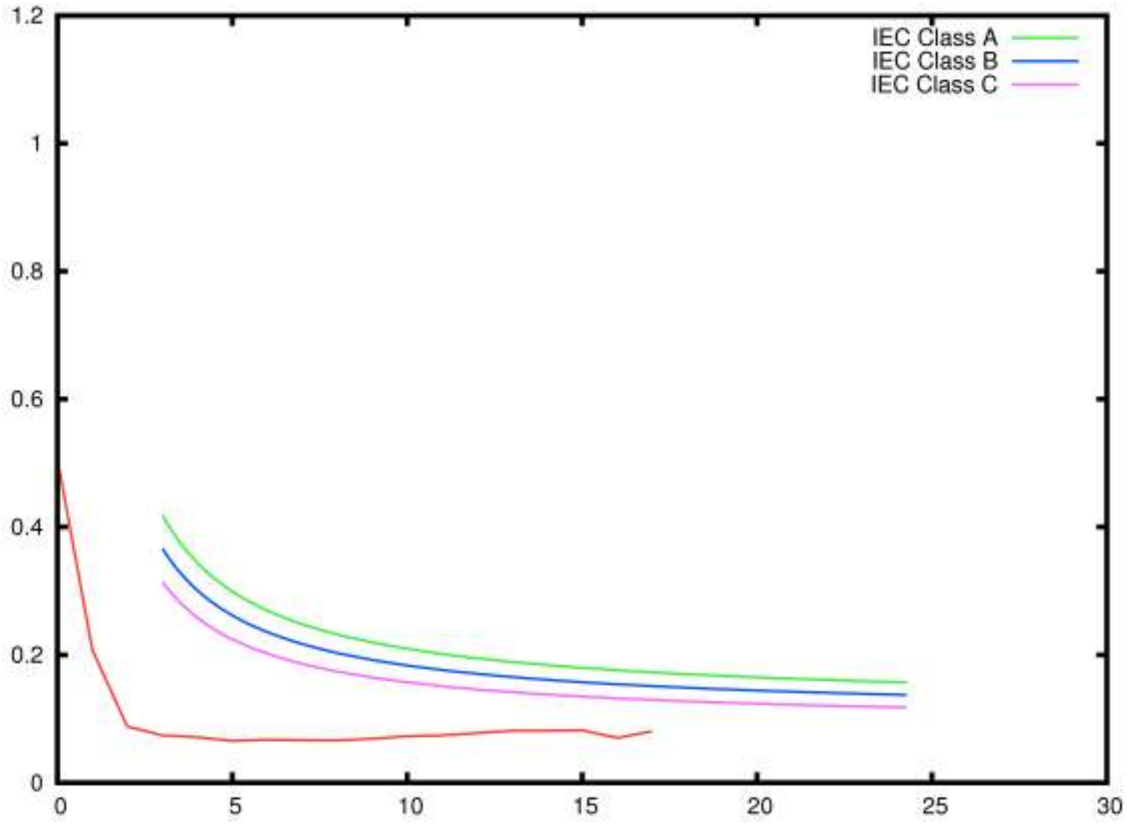

Figure 4.3: Site characteristic wind speed on data submitted.

Figure 4.4 shows the turbulence by sector with Table 4.1 showing the shear profile by sector.

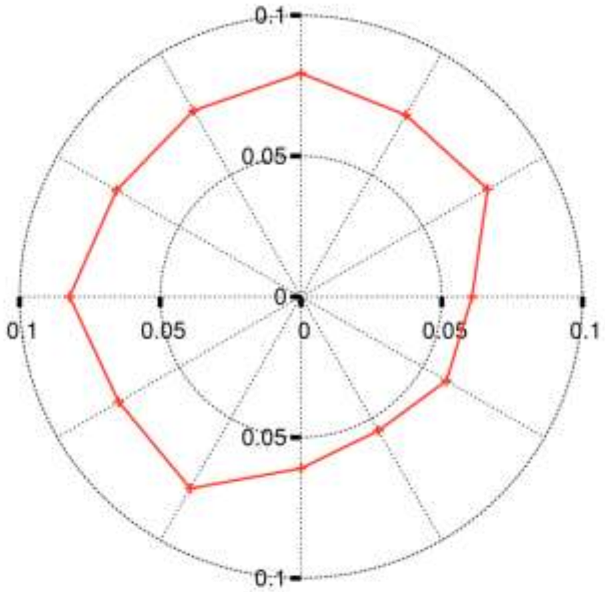

Figure 4.4: Turbulence intensity Rose

	Direction Sector	Mean Exponent
1	345-15	0.438
2	15-45	0.753
3	45-75	--
4	75-105	--
5	105-135	--
6	135-165	--
7	165-195	0.140
8	195-225	0.295
9	225-255	0.248
10	255-285	0.282
11	285-315	0.337
12	315-345	0.295

Table 4.1: Shear mean exponent by sector

The Turbulence rose shows a consistent level of turbulence by sector, supporting the little effect of local features on the SoDAR site. There is however high shear from Sector 2, which is most likely, a function of very few data points in these sectors as opposed to being physical.

The mean shear profile is 0.205, with a reported turbulence intensity of 8.02% at 15m/s. This is a typical value for offshore supporting the suitability of the location for providing data for the offshore project.

4.4 Wind Farm data Summary

Figure 4.5 shows the WAsP wind speed predicted output at the Wind Farm location.

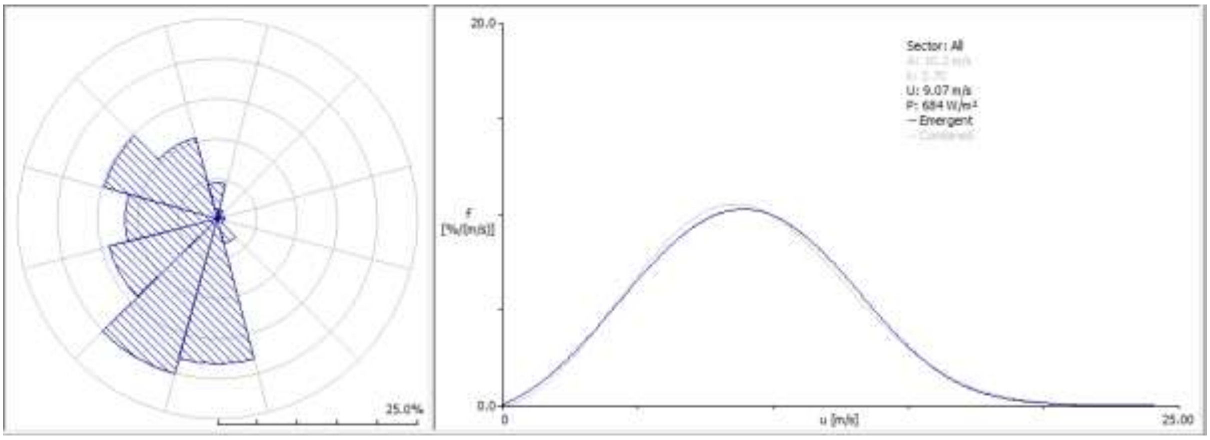

Figure 4.5: WAsP output at 120m (A=10.2m/s, k=2.7; U=9.07m/s)

Figure s 4.6 and 4.7 shows the shear output for the onshore SoDAR and offshore location respectively where the shear has reduced as the flow has migrated from onshore to offshore. This is to be expected, and supports the method used.

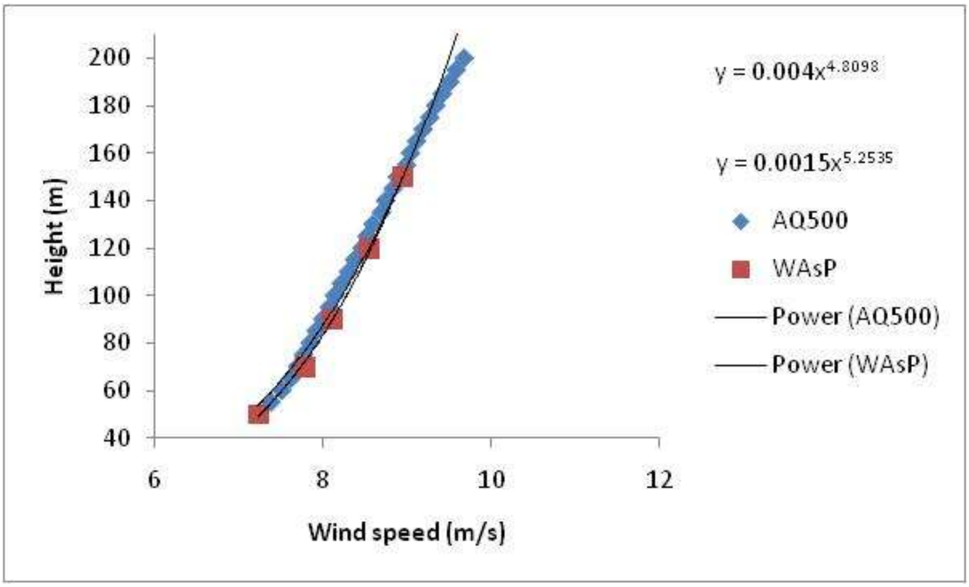

Figure 4.6: SoDAR and WAsP derived Shear Profile for Easter Hatton

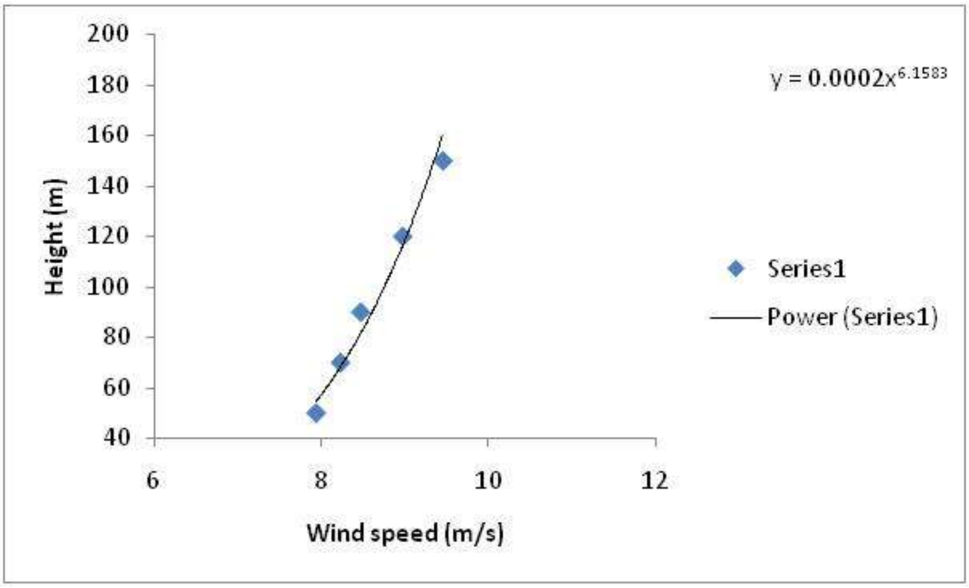

Figure 4.7: WAsP Predicted hear profile (0.16)

The wind speed predicted has increased slightly from 8.57m/s to 9.07m/s at 120m

The predicted WAsP climate was calculated at 5 heights (50m, 70m, 90m, 120m, and 150m), and the resultant wind speed ratio between the WAsP predicted output and the actual SoDAR recorded value was used to calculate a coefficient.

The WAsP values are also used to generate the predicted shear profile, which in turn is used to give a flow modification coefficient for each height level recorded by the SoDAR.

Table 4.3 summarises the 5 calculated coefficients, and table 4.4 the coefficients used to modify the time series.

Height	OWC wind speed from WAsP	Wind climate at reference site from WAsP	Scaling factor
50	7.23	7.95	1.099585
70	7.78	8.33	1.070694
90	8.11	8.6	1.060419
120	8.55	9.07	1.060819
150	8.94	9.51	1.063758

Table 4.4: Modified SoDAR shear profile for all heights

The coefficients are then used to modify the SoDAR time series at all heights and the resultant time series generated is the output of this report.

Figure 4.8 shows the final shear profile generated from the modified SoDAR time series.

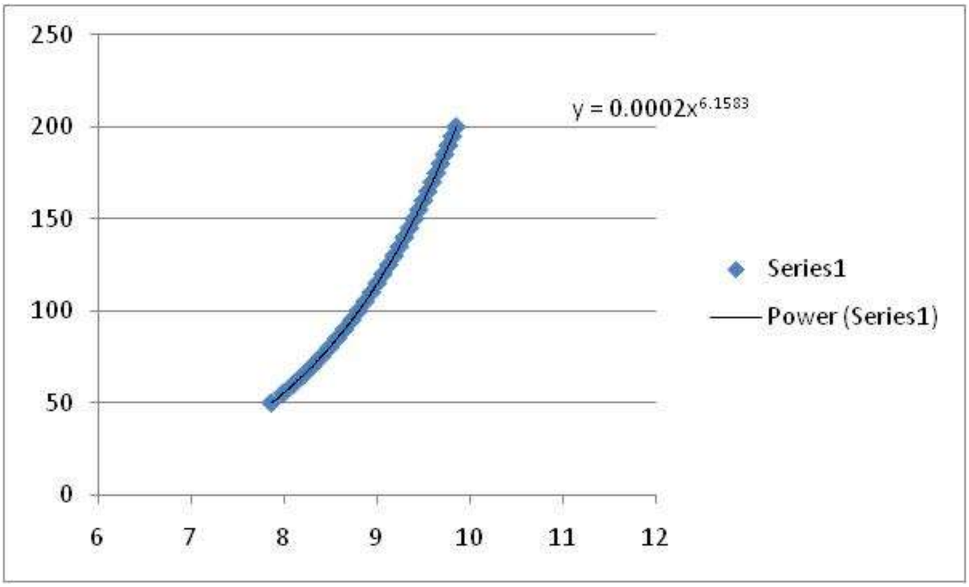

Figure 4.8: modified SoDAR data now representing the offshore wind farm climate (Shear =0.16)

5.0 Summary

An analysis has been performed to translate locally acquired onshore SoDAR data form an AQ500 system to a location offshore.

The onshore dataset has been characterised into a climate file suitable for WAsP and used to generate a predicted wind speed value at the wind farm location. This was done for 5 heights.

The resultant predicted wind shear and speed up effect was then used to calculate the speed up coefficients for all heights, ranging from 50m – 200m in 5m increments.

The output is a modified time series which is sent in accompaniment to this report.

The reference height was 120m, and the resultant wind speed increased from 8.57m/s to 9.07m/s.

6.0 About Oldbaum

Oldbaum Services is a wind energy consultancy, with roots tracing back to 2003. In 2003 Technical Director Andy Oldroyd won a Green Energy Award whilst working for Chillwind for introducing a new measurement technique (Sound Detecting and Ranging or SoDAR) to the wind industry sector.

Andy and his fellow Director Monica Griesbaum have continued to bring innovation and rigour to the wind industry, pioneering quality control and wind sensor use with such novel techniques as LiDAR and SoDAR.

Our company and experience has continued through involvement in innovative high profile projects such as the Beatrice offshore wind demonstrator, and has been recognised by Oldbaum Services winning an EC FP7 bid for the NORSEWInD Programme, with Andy Oldroyd as Coordinator.

NORSEWInD is a 7 million Euro project designed to deliver offshore wind atlases for the Baltic, Irish and North Sea areas based on physical data. The data is acquired from Met masts, LiDAR's located offshore and satellite based datasets. The result is a highly innovative project reducing uncertainty in offshore development by easing access to data for offshore developers.

Oldbaum are recognised experts in remote sensing and in particular data acquisition in offshore wind developments. This knowledge and understanding of the wind energy sector will prove invaluable in terms of understanding fully the nature of the challenges ahead, delivering the outputs defined in the feasibility study, and ultimately delivering a useable, innovative and necessary marine energy development tool.

Oldbaum Services are part of the Leosphere Wind Experts programme, and have been working with all forms of LiDAR since 2005. Oldbaum have designed acceptance tests and measurement campaigns for all forms of LiDAR (Continuous wave or pulse) and have therefore a unique perspective and experience in the unique challenges posed by each system type.

Annex 1.0: AQ500 validation results

The following is an extract of a test undertaken at Myers Hill in Scotland. The data IS FORM a well instrumented 80m met mast as reference, with the AQ500 being located 300m to the South West of the system. No filters have been applied apart from directional filters to exclude the influence of the 1MW NEG MICON WTG's located to the North East and South East of the met mast.

Full test results can be downloaded here: http://www.aqs.se/wordpress/wp-content/uploads/2009/12/AQSMH001_221209.pdf (large file)

Annex 1.0: turbulence Intensity

All RS systems have issue with turbulence through spatial and temporal averaging, or in some cases systematic filtering of the turbulence spectrum. IN this case we advocate the use of bin averaged values. Time series turbulence should be treated with caution; however Bin averaging shows the ability of the system for site classification.

European Offshore Wind Deployment Centre
Environmental Statement

Appendix 24.2: In Air Noise EIA Technical Report

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

1 IN - AIR NOISE IMPACT ASSESSMENT

1 This chapter describes the effects of noise at onshore locations along the shoreline north of Aberdeen from the proposed European Offshore Wind Deployment Centre (EOWDC) due to the construction and operation of the wind turbines.

2 Noise emissions associated with the construction and operation of the wind turbines will also be radiated into the water. The effects upon the marine environment due to noise being transmitted from the wind turbine support structure or pile into the water are dealt with within the underwater noise chapter.

1.1 Information for the Non-Technical Summary

3 The noise impact due to the operation of the proposed European Offshore Wind Deployment Centre on residential properties on land is assessed.

4 The operational noise assessment has been carried out according to ETSU-R-97, *Assessment and Rating of Noise from Wind Farms*, as specified in Scottish Government web based planning advice on onshore wind turbines referred to in PAN 1/2011, *Planning and Noise*, as there is no equivalent guidance for offshore wind farms affecting properties on land. The more stringent Aberdeenshire Council noise limits have also been taken into account.

5 Predictions of the typical noise levels likely to result from the operation of the wind farm were carried out based on generic noise data for a wind turbine with a rated power of up to 10 MW and a hub height of 100 m.

6 The assessment shows that predicted operational noise levels would meet the ETSU-R-97/Aberdeenshire Council night-time noise limits and lower day-time noise limits under all conditions.

7 It is assumed that piling with a hydraulic hammer causes the highest noise levels of all foundation types. The prediction of the construction noise has therefore been carried out for pile driving with assumed sound power level based on piling noise measurements elsewhere.

8 The noise limits for the construction noise have been derived from measurements of existing noise level in accordance with BS5228-1:2009 *Code of practice for noise and vibration control on construction and open sites – Part 1: Noise*. The predictions show exceedance of the night-time noise limits for piling activities. It is proposed that piling activities should be restricted to daytime hours from 07:00 to 19:00 hours only, unless otherwise agreed with Aberdeen City and Aberdeenshire Council or if significant levels of mitigation can be applied during night time hours.

9 A cumulative noise assessment of the operational wind farm noise and the diesel generator located on the potential ocean laboratory platform has been carried out. The additional noise from the diesel generator results in no increase of the predicted operational wind farm noise.

1.2 Introduction

10 An assessment has been carried out that takes into account the predicted noise immissions from the proposed EOWDC wind turbines using a generic worst case sound power level and the existing noise environment at locations along the shoreline north of Aberdeen.

11 The generic wind turbine assumed for the noise predictions has a hub height of 100 m and a maximum sound power level (SWL) of 112 dB(A) at 9 m/s at standardised 10 m height wind speed. The anticipated hub height for the EOWDC is between 100 m and 120 m. Noise predictions have been carried out for a wind turbine with a 100 m hub height as this represents the worst case in terms of source height.

12 As part of the proposed EOWDC development it is possible that an Ocean Laboratory may also be developed which could include a diesel generator for power supply, this development would be subject to a separate consent application. A prediction of the cumulative noise levels due to the combined operation of the generator and the wind turbines has been carried out.

13 An assessment has been performed of the construction noise associated with piling operations for the wind turbine foundations when using a monopile construction.

1.2.1 Methodology Consultation

14 Aberdeen Offshore Wind Farm Limited (AOWFL) submitted a Request for an Environmental Impact Assessment (EIA) Scoping Opinion in August 2010. Chapter 6.9 deals with airborne noise assessment. None of the responses received identified specific requirements for airborne noise assessment for residential properties onshore.

15 The Environmental Health Officers of Aberdeen City Council and Aberdeenshire Council have been consulted regarding the operational noise assessment methodology and the choice of measurement locations for the baseline noise survey:

- Andrew Gilchrist, Aberdeen City Council (110106)
- John Dawson, Aberdeenshire Council (110106)

1.2.2 Key Guidance Documents

16 The following documents have been used in the assessment:

- Scottish Executive (2011). Planning Advice Note PAN 1/2011: Planning and Noise
- Scottish Executive (2010). Web based ‘renewables advice’
- Department of Trade and Industry (1996). The Assessment and Rating of Noise from Wind Farms ETSU-R-97
- Aberdeenshire Council (2005). Use of Wind Energy in Aberdeenshire: Guidance for Developers – Supplementary Planning Guidance Part 1
- Institute of Acoustics Bulletin Vol 34 No 2, March/April 2009 Prediction and Assessment of Wind Turbine Noise

- British Standards Institution (BSI) (2009). BS 5228:2009 Code of practice for noise and vibration control on construction and open sites – Part 1: Noise
- The Scottish Government (2011). Technical Advice Note – Assessment of Noise

17 The documents listed above have all been written for the purpose of assessing onshore developments but have been adopted for this project as providing suitable guidance on assessing background noise and deriving noise limits for the onshore residential properties.

18 Advice on long-range sound propagation over sea has been taken from:

- Mathieu Boué (2007). Report for Swedish Energy Agency: Long-range sound propagation over the sea with application to wind turbine noise.

1.2.3 Data Information and Sources

19 Background noise monitoring was carried out at 6 locations for three weeks. The results of this survey and the derivation of the noise limits is described in the baseline technical report *Measurement of background noise data and rainfall (Hayes McKenzie Partnership Ltd (HMPL), 2011)*.

20 Wind speed was simultaneously measured with a SoDAR (Sound Detection and Ranging) remote sensing device on a field at Easter Hatton, Balmedie, an onshore location near the coastline. This onshore wind data has been translated to the offshore wind farm location as described in (Oldbaum 2011).

- Oldbaum Services Limited (2011a). Wind speed data spatial translation – Method Statement for Aberdeen Offshore Windfarm Limited
- Hayes McKenzie Partnership Ltd. (2011). Measurement of background noise data and rainfall.
- Hayes McKenzie Partnership Ltd. (2011). Baseline Technical Report for European Offshore Wind Deployment Centre.
- Oldbaum Services Limited (2011b). Wind speed data spatial translation – Wind data analysis for Aberdeen Offshore Windfarm Limited

1.2.4 Impact Assessment Methodology

21 Planning Policy Guidance associated with the development of wind farms currently only deals with onshore developments regarding airborne noise. In the absence of detailed Planning Guidance on the development of Offshore Wind Farms and noise immissions, the best current practice for onshore developments as been referred to.

22 When wind speeds are high any noise is masked by wind induced noise effects, particularly that of the trees being blown. Noise from the sea and the traffic noise from the A90 will also contribute to the masking of noise from the proposed EOWDC wind turbines but this will be more significant at lower wind speeds when wind induced background noise may be low. Wind turbine noise increases with wind speed up to rated power with very low levels of noise being generated at lower wind speeds.

23 Noise levels are normally expressed in decibels. Noise in the environment is measured using the dB(A) scale which includes a correction for the response of the human ear to noises with different frequency content. Planning Advice Note PAN 1/2011, *Planning and Noise* (Scottish Executive, 2011) states that:

'For noise of a similar character, a change of 3 dB(A) is the minimum perceptible under normal conditions, and a change of 10 dB(A) corresponds roughly to halving and doubling the loudness of a sound'.

24 It also provides examples of noise levels from certain activities as shown in Table 1 (below).

Table 1: Examples of Indicative Noise Levels*

Source/Activity	Indicative noise level dB (A)
Unsilenced pneumatic drill (at 7 m distance)	95
Heavy diesel lorry (40km/h at 7 m distance)	83
Modern twin-engine jet (at take-off at 152 m distance)	81
Passenger car (60 km/h at 7m distance)	70
Office environment	60
Ordinary conversation	50
Quiet bedroom	35

* Based on information in PAN 1/2011, Planning and Noise

1.2.4.1 Legislative and Planning Context

***Planning Advice Note PAN1/2011, Planning and Noise* (Scottish Executive, 2011)**

25 PAN1/2011 replaces PAN56 *Planning and Noise*. It identifies two sources of noise from wind turbines; mechanical noise and aerodynamic noise. It states that '*Good acoustical design and siting of turbines is essential to minimise the potential to generate noise*'. It refers to the '*web based planning advice*' on renewable technologies for onshore wind turbines.

26 PAN1/2011 states that the Control of Pollution Act 1974 and the Pollution and Prevention Control Act 1999 are suitable to limit noise from temporary construction sites.

***Scottish Executive Web Based Planning Advice, Onshore Wind Turbines* (Scottish Executive, 2010)**

27 The web based Planning Advice, Onshore Wind Turbines refers to ETSU-R-97, *Assessment and Rating of Noise from Wind Farms* (DTI, 1996a), as the document that *'should be followed by applicants and consultees, and used by planning authorities to assess and rate noise from wind energy developments*'. There is no equivalent guidance for offshore wind farms, but there is no reason why the ETSU-R-97 guidance should not apply. ETSU-R-97 contains noise limits designed to protect external amenity during the day and sleep disturbance at night. These limits are derived from baseline noise measurements carried out at potentially affected properties around the proposed development site.

***ETSU-R-97, The Assessment and Rating of Noise from Wind Farms* (DTI, 1996a)**

28 ETSU-R-97, *The Assessment and Rating of Noise from Wind Farms*, presents the recommendations of the Working Group on Noise from Wind Turbines, set up in 1993 by the Department of Trade and Industry (DTI) as a result of difficulties experienced in applying the noise guidelines existing at the time to wind farm noise assessments. The group comprised independent experts on wind turbine noise, wind farm developers, DTI personnel and local authority EHOs. In September 1996 the Working Group published its findings by way of report ETSU-R-97. This document describes a framework for the measurement of wind farm noise and contains suggested noise limits, which were derived with reference to existing standards and guidance relating to noise emission from various sources.

29 It is recommended that noise limits should be applied to external locations used for relaxation or where a quiet environment is highly desirable. These limits should be set relative to background noise and should reflect the variation in both wind turbine source noise and background noise with wind speed. It is not, however, necessary to use a margin above background in particularly quiet areas as such low limits are not necessary to offer a reasonable degree of protection to wind farm neighbours.

30 Separate noise limits should apply for day-time and for night-time as during the night the protection of external amenity becomes less important and the emphasis should be on preventing sleep disturbance.

31 The form of the noise limits proposed in ETSU-R-97 is that noise should be limited to X dB L_{A90} or 5 dB above the ‘prevailing background noise level’, whichever is the greater.

32 The $L_{A90,T}$ is the A-weighted sound pressure level exceeded for 90% of a given time period T. Background noise is commonly measured using this index. The $L_{Aeq,T}$ is the equivalent continuous A-weighted sound pressure level determined as an energetic average during a certain time interval T. The A-weighting curve is based on the inverted 40 phon equal loudness curve and is designed to mimic the human hearing over a certain frequency range.

33 For night-time (2300-0700) the value of ‘X’ is given as 43, to protect against sleep disturbance indoors with a window open. The 43 dB(A) lower limit is based on a sleep disturbance criteria of 35 dB(A) with an allowance of 10 dB for attenuation through an open window and 2 dB subtracted to account for the use of L_{A90} rather the L_{Aeq}. The prevailing background noise is that acquired during the same night-time hours.

34 For day-time hours (evenings and week-ends) ‘X’ is given as 35-40 with the actual value in the range dependant on:

- The number of dwellings in the neighbourhood of the wind farm
- The effect of noise limits on the number of kWh generated
- The duration and level of exposure

The prevailing background noise is that acquired during the quiet day-time hours, as defined in ETSU-R-97.

35 The prevailing background noise level is set by calculation of a best fit curve through values of background noise plotted against wind speed as measured during the appropriate time period with background noise measured in terms of L_{A90}. The L_{A90} is the noise level which is exceeded for 90% of the measurement period ‘t’. It is recommended that at least 1 week’s worth of measurements is required.

36 It is stated that the $L_{A90,10min}$ noise descriptor should be adopted for both background and wind farm noise levels and that, for the wind farm noise, this is likely to be between 1.5 and 2.5 dB less than the L_{Aeq} measured over the same period. The $L_{Aeq,t}$ is the equivalent continuous 'A' weighted sound pressure level occurring over the measurement period t. It is often used as a description of the average noise level. Use of the L_{A90} descriptor for wind farm noise allows reliable measurements to be made without corruption from relatively loud, transitory noise events from other sources.

37 ETSU-R-97 also specifies that a penalty should be added to the predicted noise levels, where any tonal component is present. The level of this penalty is described and is related to the level by which any tonal components exceed audibility.

***Use of Wind Energy in Aberdeenshire: Supplementary Planning Guidance Part 1* (Aberdeenshire Council, 2005)**

38 As a variation to the lower fixed noise limits described by ETSU-R-97, (see above), Aberdeenshire Council specifies the lower noise limits at 38 dB $L_{A90,10min}$ during night-time and 35 dB $L_{A90,10min}$ during day-time for very quiet locations. These lower fixed noise limits are valid for measurements carried out externally.

Institute of Acoustics Bulletin Article, Prediction and Assessment of Wind Turbine Noise, March/April (IoA Bulletin 34, 2009

39 Institute of Acoustics (IoA) Bulletin Vol 34 no. 2 contains an agreement, jointly authored by a number of consultants working in the wind turbine sector for both developers, local authorities and third parties, on an agreed methodology for addressing issues not covered by ETSU-R-97. This includes a methodology for dealing with wind shear.

40 It should be noted that this article is written in the context of onshore wind farms, but the recommendation for dealing with wind shear is also applicable for offshore wind farms.

Blade Swish (Aerodynamic Modulation)

41 The noise limits prescribed in ETSU-R-97 take into account the fact that all wind turbines exhibit the character of noise described as blade swish, to a certain extent. *The Measurement of Low Frequency Noise at Three UK Wind Farms* (DTI, 2006), concluded that *'the common cause of complaints associated with noise at all three wind farms is not associated with low frequency noise, but is the audible modulation of the aerodynamic noise, especially at night'*. It suggests that *'it may be appropriate to re-visit the issue of aerodynamic modulation (AM) and the means by which it should be assessed'*.

42 As a result, Salford University carried out a study, jointly commissioned by the Department for Food, Environment and Rural Affairs (Defra), Department for Business, Enterprise and Regulatory Reform (BERR, formerly the DTI) and the Department for Communities and Local Government (DCLG), to investigate AM of wind turbine noise. The results were published by way of report NANR233 *Research into Aerodynamic Modulation of Wind Turbine Noise*, which concluded that AM was only considered to be a definite factor at four, and a possible factor at eight, out of the 133 sites (all the sites in the UK operational at the time of the study) considered. At the four sites, it was considered that conditions associated with AM might occur between about 7% and 15% of the time.

43 In a statement accompanying the published report, BERR states that it *'continues to support the approach set out in Planning Policy Statement (PPS) 22 – Renewable Energy. This approach for local planning authorities to ensure that renewable energy*

developments have been located and designed in such a way to minimise increases in ambient noise levels, through the use of the 1996 report by ETSU to assess and rate noise from wind energy developments.' PPS 22 is the relevant English planning advice covering onshore wind turbines, equivalent to the Scottish PAN 45.

44 Renewable UK, the trade body representing the wind and marine energy industry, has recently commissioned a research project involving two university departments specialising in noise issues, two independent UK consultancy practices and a well respected researcher in the field of source localisation on wind turbine blades to carry out further research into this issue.

45 The above effects are described for onshore wind farms. It has yet to be determined whether these affects arise for offshore wind farms.

Infrasound

46 Infrasound is defined as noise occurring at frequencies below that at which sound is normally audible, i.e. at less than 20 Hz, due to the significantly reduced sensitivity of the ear at such frequencies. In this frequency range, for sound to be perceptible, it has to be at a very high amplitude and it is generally considered that when such sounds are perceptible then they can cause considerable annoyance.

47 Wind turbines have been cited as significant producers of infrasound. This has, however, been due to the high levels of such noise, as well as audible low frequency thumping noise, occurring on older 'downwind' wind turbines of which many were installed in the USA prior to the large scale take up of wind power production in the UK. Downwind wind turbines are configured with the blades downwind of the tower such that the blades pass through the wake left in the wind stream by the tower resulting in a regular audible thump, with infrasonic components, each time a blade passes the tower. Virtually all wind turbines which have been installed in the UK, however, have been of the upwind design; that is with the blades up wind of the tower, such that this effect is eliminated.

48 The DTI (2006) report concluded that '*Infrasound noise emissions from wind turbines are significantly below the recognised threshold of perception for acoustic energy within this frequency range. Even assuming that the most sensitive members of the population have a hearing threshold which is 12 dB lower than the median hearing threshold, measured infrasound levels are well below this criterion'*. It goes on to state that, based on information from the World Health Organisation that '*there is no reliable evidence that infrasounds below the hearing threshold produce physiological or psychological effects'* it may be concluded that *'infrasound associated with modern wind turbines is not a source which may be injurious to the health of a wind farm neighbour'*.

Low Frequency Noise

49 Noise from modern wind turbines is essentially broad band in nature in that it contains similar amounts of noise energy in all frequency bands from low to high frequency. As distance from a wind farm site increases the noise level decreases as a result of the spreading out of the sound energy but also due to air absorption which increases with increasing frequency. This means that although the energy across the whole frequency range is reduced, higher frequencies are reduced more than lower frequencies with the effect that as distance from the site increases the ratio of low to high frequencies also increases. This effect may be observed with road traffic noise or natural sources such as the sea where higher frequency components are diminished relative to lower frequency components at long distances. The DTI study showed that low frequency noise could be measurable on occasion but was below

the low frequency noise criterion published in DEFRA Project Report NANR45, Proposed Criteria for the Assessment of Low Frequency Noise Disturbance.

1.2.4.2 Construction Site Noise Planning Policy Guidance

***BS 5228, Code of Practice for Noise and Vibration Control on Construction and Open Sites* (British Standards Institution, 2009)**

50 British Standard BS5228 was re-issued in 2009 as BS5228: 2009, *Code of Practice for Noise and Vibration Control on Construction and Open Sites*.

51 The Control of Pollution Act 1974 provides a legal framework for the control of construction noise. Example criteria for the assessment of construction noise effects and a method for prediction of noise levels from construction activities are given in BS5228. Two example methods are provided for assessing the impact of construction activities.

52 The first is based on the use of criteria defined in Department of the Environment (DoE) Advisory Leaflet (AL) 72, *Noise Control On Building Sites* (DoE, 1976) which sets a fixed limit of 70 dB(A) in rural suburban and urban areas away from main roads and traffic and 75 dB(A) in urban areas near main roads in heavy industrial areas. Noise levels are generally taken as façade L_{Aeq} values with free-field levels taken to be 3 dB lower giving an equivalent noise criterion of 67 dB L_{Aeq} and 72 dB(A) respectively.

53 The second is based on noise change but applies minimum criteria of:

- 45 dB L_{Aeq}: night-time (2300-0700)
- 55 dB L_{Aeq}: evening and weekends (1900-2300 weekdays, 1300-2300 Saturdays and 0700-2300 Sundays)
- 65 dB L_{Aeq}: daytime (0700-1900) including Saturdays (0700-1300)

These criteria are applicable when existing noise levels are low, and subject to a construction period of one month or more. The threshold values are based on measured background data and give limits in three categories A, B and C, depending on the magnitude of the background noise levels. It should be noted that the time period to which each limit applies also defines the time averaging period for the calculated L_{Aeq}.

1.2.4.3 Sleep Disturbance Criteria

54 International Guidance concerning the effects of noise upon sleep are covered in a number of documents discussed within ETSU-R-97. In general, if internal noise levels are limited to a range of no more than 30 - 35 dB L_{Aeq}, then sleep disturbance and any adverse effects of noise upon sleep will be minimised. Since the issue of ETSU-R-97 further guidance has been issued by the World Health Organisation (WHO): *Guidelines for Community Noise* in March 2000 and *Night Noise Guidelines for Europe* in 2009.

55 The Guidance within BS 8233: 1999 *Sound Insulation and Noise Reductions for Buildings – Code of Practice* (BSI, 1999) follows the advice contained within the WHO (2000) Report on Community Noise which states that unoccupied indoor ambient noise levels within bedrooms are a “good “ design when in the range of

around 30 dB L_{Aeq} and “reasonable” when around 35 dB L_{Aeq}. Individual noise events should also be limited to no more than 45 dB L_{Amax}. This internal noise level criterion is not relevant for operational wind turbine noise as it refers to individual, discrete noise events, but is applicable for driving piles into the seabed for wind turbine foundations.

56 The WHO World Health Organisation (WHO) *Night Noise Guidelines for Europe* advises as to what is an acceptable external noise level to a bedroom and gives a value of $L_{night,outside}$ = 40 dB below which no effect harmful to health has been observed and this level is therefore recommended as night noise guideline. It should be noted that this is an average noise level over a period of 8 hours per night over a whole year. Due to the nature of the averaging, events with higher and lower short-term noise level can occur during this period.

1.2.4.4 Prediction of Wind Turbine Noise Levels

57 Noise predictions were carried out using International Standard ISO 9613, Acoustics – Attenuation of Sound During Propagation Outdoors (International Organization for Standardization, 1996) but with an adjustment added to allow for long distance propagation over the sea surface. The propagation model described in Part 2 of this standard provides for the prediction of sound pressure levels based on either short-term downwind (i.e. worst case) conditions or long term overall averages up to 1000 m. Only the downwind condition has been considered in this assessment, that is for wind blowing from the proposed development site towards the nearby houses. When the wind is blowing in the opposite direction noise levels will be significantly lower, especially if there is any shielding between the site and the houses. Therefore, the results of the assessment should be considered as the ‘worst case’ in that they any impacts identified will only be present for a limited duration when winds are blowing onshore.

58 The ISO propagation model calculates the predicted sound pressure level by taking the source sound power level for each wind turbine in separate octave bands and subtracting a number of attenuation factors according to the following:

Predicted Octave Band Noise Level = $L_w + D – A_{geo} - A_{atm} – A_{gr} - A_{bar} - A_{misc}$

59 The predicted octave band levels from each of the wind turbines are summed together to give the overall ‘A’ weighted predicted sound level from all the wind turbines acting together. These factors are discussed in detail below.

L_W - Source Sound Power Level

60 The sound power level of a noise source is normally expressed in dB re: 1pW (10^{-12} Watt). Noise predictions have been based on source sound power levels of a typical 3 MW class offshore wind turbine with a 4 dB margin added to represent a generic 10 MW wind turbine. This approach has been adopted so that predictions are higher than the sound power level of currently operational offshore wind turbines and therefore assumed to be worst case. The noise levels for different wind speeds are shown in Table 2.

Table 2: Wind Turbine Source Sound Power Levels for a Generic 10 MW Wind Turbine with 100 m Hub Height

Standardised Wind Speed at 10 m height (m/s)	Sound Power Level (dB L_{Aeq} re 1 pW)
4	99.5
5	109.6
6	111.5
7	112.0
8	112.0
9	112.0
10	112.0

61 The noise spectrum used is shown in Table 3. This data is based on typical octave band spectra of a 3 MW class wind turbine for 8 m/s (referenced to 10 m height) and has then been normalised to the overall sound power level at each integer wind speed.

Table 3: Normalised Noise Spectrum for Maximum Sound Power Level for a Generic 10 MW Wind Turbine with Hub Height 100 m

Octave Band Centre Frequency (Hz)	Normalised Octave Band Sound Power Level (dB L_{Aeq} re 1 pW)
63	91.6
125	100.9
250	105.9
500	107.0
1k	106.6
2k	99.9
4k	89.7
8k	76.8

D – Directivity Factor

62 The directivity factor allows for an adjustment to be made where the sound radiated in the direction of interest is higher than that for which the sound power level is specified. In this case the sound power level is measured in a down wind direction, corresponding to the worst case propagation conditions considered here and needs no further adjustment.

A_{geo} – Geometrical Divergence

63 The geometrical divergence accounts for spherical spreading in the free-field from a point sound source resulting in attenuation depending on distance. It has been found

in various publications (e.g. Boué, 2007 and Søndergaard, 2005) that for sound propagation at sea, spherical spreading is only applicable up to a certain distance. Measurements of piling activities carried out by Hayes McKenzie Partnership Ltd have found that the prediction correlates well with a distance of 800 m for the spherical spreading term:

$A_{geo} = 20 \cdot \log(800) + 11$

64 At distances beyond 800 m the propagation is modelled with cylindrical spreading:

$A_{geo} = 10 \cdot \log(d/800)$

where d = distance from the wind turbine.

65 Each of the wind turbines may be considered as a point source beyond distances corresponding to one rotor diameter.

***A_{atm}* - Atmospheric Absorption**

66 Sound propagation through the atmosphere is attenuated by the conversion of the sound energy into heat. This attenuation is dependent on the temperature and relative humidity of the air through which the sound is travelling and is frequency dependent with increasing attenuation towards higher frequencies. The attenuation depends on distance according to:

$A_{atm} = d \cdot \alpha$

where d = distance from the wind turbine
α = atmospheric absorption coefficient in dB/m.

67 Published values of 'α' from ISO 9613 Part 1 (International Organization for Standardization, 1992), corresponding to a temperature of 10ºC and a relative humidity of 70% have been used for these predictions. These are the values specified in the Acoustics Bulletin article *Prediction and Assessment of Wind Turbine Noise* (IoA, 2009), which give relatively low levels of atmospheric attenuation, and subsequently worst case noise predictions as shown in Table 4.

Table 4: **Frequency dependent Atmospherical Absorption Coefficients (10°C and 70% Humidity)**

Octave Band Centre Frequency (Hz)	Atmospheric Absorption Coefficient (dB/m)
63	0.00012
125	0.00041
250	0.00104
500	0.00193
1k	0.00366
2k	0.00966
4k	0.0328
8k	0.117

A_{gr} - Ground Effect

68 Ground effect is the interference of sound reflected by the ground interfering with the sound propagating directly from source to receiver. The prediction of ground effects is inherently complex and depends on the source height, receiver height, propagation height between the source and receiver and the ground conditions. The ground conditions are described according to a variable G, which varies between 0 for 'hard' ground (includes paving, water, ice, concrete and any sites with low porosity) and 1 for 'soft' ground (includes ground covered by grass, trees or other vegetation). The predictions have been carried out using a source height corresponding to the proposed height of the wind turbine nacelle, a receiver height of 4 m and an assumed ground factor G = 0 for the water surface.

A_{bar} - Barrier Attenuation

69 The effect of any barrier between the noise source and the receiver position is that noise will be reduced according to the relative heights of the source, receiver and barrier and the frequency spectrum of the noise. The barrier attenuations predicted by the ISO 9613 model have, however, been shown to be significantly greater than that measured in practice under down wind conditions. The results of a study of propagation of noise from wind farm sites carried out for ETSU (DTI, 2000) concludes that an attenuation of just 2 dB should be allowed where the direct line of site between the source and receiver is just interrupted and that 10 dB should be allowed where a barrier lies within 5 m of a receiver and provides a significant interruption to the line of site. It should be noted that no barrier attenuation has been used in any of the noise predictions carried out here.

A_{misc} – Miscellaneous Other Effects

70 ISO 9613 includes effects of propagation through foliage, industrial plants and housing as additional attenuation effects. These have not been included here and any such effects are unlikely to significantly reduce noise levels below those predicted.

Tonality

71 No allowance has been made for the character of the noise emitted by the wind turbines. In general, wind turbines exhibit little tonality within the radiated noise. However, an appropriate method to control such a character is through the imposition of a Planning Condition which limits the level of tonality that a site may emit. ETSU-R-97 defines a method by which tonality may be assessed and proposes a penalty system for any tonality which might be measured.

Wind Shear

72 It is now well established that wind speed experienced by a wind turbine cannot be correctly predicted from 10 m height wind speed measurements and ground roughness conditions alone. Hub height wind speed, and hence the wind speed experienced by the wind turbine, may be under-predicted under these conditions and hence the output noise level may be under-predicted. To correctly account for this in the assessment methodology, background noise is referenced to hub height wind speed, as described in the agreement published in the IoA Bulletin (IoA, 2009).

73 Wind speed and direction was measured with an AQ500 SoDAR remote sensing device at Easter Hatton, Balmedie, an onshore location near the coastline. The data was recorded in 5 m steps from 50 m to 200 m. This data has been translated to the location of the proposed EOWDC as described in (Oldbaum 2011b). For the assessment, the measured data correlating to hub height wind speed is used.

74 This translated hub height wind speed has then been corrected to 'standardised' 10 m height wind speed, as required by the method described in (IoA, 2009) using the same methodology as is used by the manufacturers to produce noise data for 'standardised' 10 m height wind speed, i.e.:

$$V_{10} = V_h \cdot \frac{\ln\left(\frac{h_{10}}{z_0}\right)}{\ln\left(\frac{h_h}{z_0}\right)}$$

75 Where V_{10} and V_h are the 'standardised' 10 m height (h_{10}) and hub height (h_h) wind speeds respectively, and z_0 is the standardised ground roughness length (= 0.05 m).

76 This standardisation is not intended to reflect actual 10 m height wind speed conditions and does not affect the relationship between wind turbine noise, background noise, and the derived noise limits.

1.2.4.5 Prediction of Construction Noise Associated with Wind Turbine Erection

77 Noise associated with the construction of the wind turbines will be caused by the following sources:

- Noise associated with the insertion of the wind turbine tower foundation
- Noise associated with the erection of the wind turbine tower and nacelle/rotor assembly
- Noise associated with boat movements to and from shore
- Noise associated with onsite activities such as cable laying at the point the cable comes ashore.

78 The potentially noisiest activity associated with these potential sources is related to the installation of the wind turbine foundation. The method of foundation construction that will generate the greatest level of noise is associated with a monopile foundation system.

79 Drilling of the monopile would minimise the noise emissions from this construction operation, however, it may be necessary to drive the pile into the seabed. If this is the case, then there is the potential for impulsive piling noise to occur.

80 Specifically, if the monopile is driven into the sea bed, levels associated with this method of pile insertion can generate measured sound pressure levels as high as 105 dB L_{Amax} and 93 dB $L_{Aeq,1\ minute}$ measured at a distance of 55 metres from the pile. This is equivalent to a source noise level of L_{WAmax}=151 dB re: 1 pW and L_{WA}=139 dB re: 1 pW respectively.

1.2.4.6 Spatial Extent of Effect

81 The construction of the proposed EOWDC will have a regional effect. The piling noise levels will be greater than 65 dB $L_{Aeq,1minute}$ for up to 1.6 km distance from the piling location. The piling will still be audible at a greater distance further inland especially when background noise is low and the influence of the surf and the A90 traffic noise decrease.

82 The operational noise will have a local effect on the nearest properties along the shore in the vicinity of the proposed EOWDC.

1.2.4.7 Duration of Effect

83 The highest construction noise due to the piling process is expected to last 24 hours per location at a maximum, i.e. 11x 24 hours. It is expected that there are breaks inbetween, when the vessel is relocated and the next monopile lifted in position. Therefore this will have a temporary effect on the residents.

84 The Crown Estate lease for the proposed EOWDC is 22 years, the project will therefore have a long-term effect. It is assumed that the wind farm will be decommissioned after its operational span of life has been reached so that the effect is not considered permanent.

1.2.4.8 Scale of Effect

85 Table 5 is taken from the Technical Advice Note (TAN Noise) on the Assessment of Noise issued by The Scottish Government in association with PAN 01/2011.

Table 5: Classification of Magnitude on Noise Impacts according to TAN *Assessment of Noise* (Table 2.2)

Descriptor for Magnitude of Impact	Generic Criteria of Descriptor
Major adverse	Loss of resource and/or quality of resource; severe damage to key characteristics, features or elements
Moderate adverse	Loss of resource, but not adversely affecting the integrity; partial loss of/damage to key characteristics, features or elements
Minor adverse	Some measurable change in attributes, quality or vulnerability; minor loss of, or alteration to, one (maybe more) key characteristics, features or elements
Negligible adverse	Very minor loss or detrimental alteration to one or more characteristics, features or elements
No change	No loss or alteration of characteristics, features or elements; no observable impact

1.2.4.9 Recoverability of the Receptor

86 Due to the limited time of 11 days with high noise levels from the piling noise, it is expected that the receptor, i.e. the residents in the affected area, will fully recover from any effects.

1.2.4.10 Importance of the Receptor

87 The receptor, i.e. the affected residents near the shore, is considered of high importance.

1.2.5 Implications of Significance

88 The receptors closest to the shore and the A90 are considered of medium sensitivity as background noise is relatively high. Further inland with fewer other noise sources, the sensitivity increases.

89 Schools, hospitals/residential care homes, residential properties with low background noise, conference facilities and quiet outdoor areas used for recreation are considered to have a high sensitivity to noise.

1.2.6 Cumulative Impact Assessment Methodology

90 Cumulative impact assessments have been undertaken on all existing and any reasonably foreseeable project/development activities. The possible development of an Ocean Laboratory has been considered as having the potential to contribute to cumulative impacts and has been assessed.

1.2.7 Worst Case

91 At this stage of the project, no decision has been made on which wind turbine foundation type will be adopted. The noise associated with a hydraulic hammer driving monopiles into the seabed is assumed to be the loudest of all foundation types. It is also the loudest activity of the construction process itself. The prediction of construction noise from piling 8.5 m diameter monopiles is therefore considered worst case.

92 There is no information available about the sound power level of potential candidate wind turbines. Some of the wind turbine types in the offshore market are still in the development stage and the manufacturer can therefore not yet issue information about the sound power level. Generic sound power level data has been assumed based on source sound power levels of a typical 3 MW class offshore wind turbine with an added margin of 4 dB which is considered worst case for currently available offshore wind turbine models. The anticipated hub height for the EOWDC is between 100 m and 120 m. Noise predictions have been carried out for a wind turbine with a 100 m hub height as this represents the worst case in terms of source height.

93 A worst case cumulative noise assessment that considers a possible ocean laboratory has been carried out for the construction and operational phases of the proposed EOWDC. This includes the possible installation of an additional 8.5 m diameter monopile and a diesel generator during the operational phase. It is possible that if the ocean laboratory is developed a diesel generator may not be required.

1.3 Impact Assessment

1.3.1 Deployment of 11 Wind Turbines

1.3.1.1 Construction Phase

Potential Impacts

94 The noise limits for the construction period are based on Table E.1 in BS5228 – Part 1 (BSI, 2009), derived from the average measured LAeq from the background noise survey as displayed Table 6. Sound pressure levels measured at wind speeds >5m/s have been removed from further assessment. This is in accordance with BS4142:1997 Method for Rating industrial noise affecting mixed residential and industrial areas and BS7445 Description and measurement of environmental noise (BSI, 1991).

95 For the purpose of assessing the noise generated by the construction of the proposed EOWDC, hours are defined as follows:

- daytime: 07:00-19:00 weekdays
07:00-13:00 Saturdays
- evenings and weekends: 19:00-23:00 weekdays
13:00-23:00 Saturdays
07:00-23:00 Sundays
- night-time: 23:00-07:00

Table 6: Arithmetic averaged measured Sound Pressure Level at Measurement Locations

Location	Easting	Northing	Average Measured Day L_{Aeq}, dB	Average Measured Evenings and Weekends L_{Aeq}, dB	Average Measured Night L_{Aeq}, dB
Four Winds	395191	814956	54	53	44
16 Chapelwell Wynd	396968	817138	49	45	40
Easter Hatton	396245	816102	61	57	52
Hareburn House*	396294	813979	57	55	53
3 Tarbothill Farm Cottages	395696	813430	56	51	48
16 Dubford Gardens	393913	812139	49	41	32

*data only available for 3 days

96 Table 7 shows the suggested noise limits for the construction activities based on the average measured background at each property. BS5228 (BSI, 2009) gives threshold values for a whole period, e.g. an $L_{Aeq,day}$ for a period of 12 hours.

Table 7: Noise Limits derived from Table E.2 in BS 5228 – Part 1 at the Measurement Locations.

Location	Easting	Northing	Noise Limit Day L_{Aeq}, dB	Noise Limit Evenings and Weekends L_{Aeq}, dB	Noise Limit Night L_{Aeq}, dB
Four Winds	395191	814956	65	60	45
16 Chapelwell Wynd	396968	817138	65	55	45
Easter Hatton	396245	816102	65	60	55
Hareburn House*	396294	813979	65	60	55
3 Tarbothill Farm Cottages	395696	813430	65	55	55
16 Dubford Gardens	393913	812139	65	55	45

*data only available for 3 days

97 Predictions of the incident noise levels at the shore-line have been performed using the same method as for noise from an operational wind farm. The noise spectrum was taken from a measurement during piling activity carried out by HMPL. The highest equivalent sound pressure level measured at a distance of 55 metres from the pile was 93 dB $L_{Aeq,1minute}$. This is equivalent to a source noise level of L_{WA}=139 dB re: 1 pW. The predicted noise levels for the same six locations as for the operational wind farm assessment are detailed in Table 8 below.

Table 8: Predicted Noise Levels $L_{Aeq,1minute}$ associated with driven Monopile Activity at Wind Turbine Locations and potential Ocean Laboratory

Location	WT location											
	1	2	3	4	5	6	7	8	9	10	11	Ocean Lab
Four Winds	63	64	64	62	63	63	62	62	62	61	61	63
16 Chapelwell Wynd	63	64	66	63	64	65	63	64	65	63	63	63
Easter Hatton	64	65	66	63	64	65	63	63	64	62	62	64
Hareburn House	66	66	66	65	65	65	63	63	63	62	62	66
3 Tarbothill Farm Cottages	65	65	65	64	64	63	62	62	62	61	61	65
16 Dubford Gardens	62	62	61	61	62	60	60	60	59	59	58	62

98 As it is proposed that pile insertion for the tower support structures may occur during any period of the day or night, it is appropriate to consider the worst-case noise impact that may occur, i.e. the potential for sleep disturbance of residents within dwellings facing the site. Therefore, the potential for construction noise is evaluated against the criterion of 45 dB $L_{Amax,inside}$ for night time operations. Assuming an attenuation of 10 dB, the outside level above which sleep of the residents is likely to be disturbed is 55 dB L_{Amax}.

99 Table 9 shows the predicted $L_{Amax,outside}$ based on the maximum sound power level determined during a measurement of a 30 minute piling operation carried out by HMPL.

100 The maximum sound pressure level measured at a distance of 55 metres from the pile was 105 dB L_{Amax}. This is equivalent to a source noise level of L_{WAmax}=151 dB re: 1 pW.

Table 9: Predicted Noise Levels $L_{Amax,outside}$ associated with Driven Monopile Activity at Wind Turbine Locations and potential Ocean Laboratory

Location	WT location											
	1	2	3	4	5	6	7	8	9	10	11	Ocean Lab
Four Winds	75	76	76	74	75	75	74	74	74	73	73	76
16 Chapelwell Wynd	75	76	78	75	76	77	75	76	77	75	75	75
Easter Hatton	76	77	78	75	76	77	75	75	76	74	71	76
Hareburn House	78	78	78	77	77	77	75	75	75	74	74	78
3 Tarbothill Farm Cottages	77	77	77	76	76	75	74	74	74	73	73	77
16 Dubford Gardens	74	74	73	73	73	72	72	72	71	71	70	74

101 As there is only limited information available about the foundation type(s) that could be used for the proposed EOWDC it has not yet been decided which equipment will be used for the construction period, the relevant sound power level has had to be assumed for this assessment. The predicted piling noise is based on measurements previously carried out by HMPL for an offshore piling noise assessment.

102 The predicted $L_{Aeq,1minute}$ in Table 8 exceeds the suggested daytime noise limits in Table 7 by 1 dB at the three closest locations to the development. At Chapelwell Wynd and Easter Hatton this would only be the case for the piling at location 3. At Hareburn House this would be the case for turbine location 1-3 and at the potential ocean laboratory location.

103 The predicted $L_{Aeq,1minute}$ would, however, comply with the noise criterion of proposed noise limit of 67 dB L_{Aeq} for rural and suburban areas as suggested in the Environment Advisory Leaflet 72, *Noise Control On Building Sites* (DoE, 1976).

104 Comparing the predicted noise levels in Table 8 with the evening and weekend noise limits in Table 7 shows that the noise limits are exceeded at all locations by a minimum margin of 4 dB at Four Winds and a maximum margin of 11 dB at 16 Chapelwell Wynd.

105 The night-time noise limits in Table 7 are exceeded at all locations by a minimum margin of 10 dB at 3 Tarbothill Farm Cottages and by a maximum margin of 21 dB at 16 Chapewell Wynd.

106 Table 10 shows the highest predicted $L_{Aeq,1minute}$ for each property and a comparison with the adopted criterion.

Table 10: Comparison of highest Predicted Noise Level $L_{Aeq,1minute}$ at each Property with adopted Noise Limits, yes / no indicate if value is within the noise limit, values in brackets indicate exceedance above the noise limit.

Location	Highest predicted $L_{Aeq,1minute}$, dB	DoE AL 72 Noise Limit (67 dB L_{Aeq})	BS 5228 – Part 1 Noise Limits (see Table 7)		
			Day L_{Aeq}, dB	Evenings/ Weekends L_{Aeq}, dB	Night L_{Aeq}, dB
Four Winds	64	Yes	Yes	No (+4 dB)	No (+19 dB)
16 Chapelwell Wynd	66	Yes	No (+1 dB)	No (+11 dB)	No (+21 dB)
Easter Hatton	66	Yes	No (+1 dB)	No (+6 dB)	No (+11 dB)
Hareburn House*	66	Yes	No (+1 dB)	No (+6 dB)	No (+11 dB)
3 Tarbothill Farm Cottages	65	Yes	Yes	No (+10 dB)	No (+10 dB)
16 Dubford Gardens	62	Yes	Yes	No (+7 dB)	No (+17 dB)

107 It should be noted that the noise levels measured by HMPL decreased during the piling operation by 8 dB within half an hour due to the immersion of the hydraulic hammer into the water.

108 The maximum sound pressure levels are considerably higher due to the impulsive nature of the piling operation with a hammer. Comparing the highest predicted maximum sound pressure level of 78 dB L_{Amax} in Table 9 with the WHO noise level for sleep disturbance of 55 dB L_{Amax} for outside the bedroom window shows that the sleep disturbance criterion is exceeded by up to 23 dB at the closest locations.

109 With regard to the impact from piling noise during the daytime it is expected that the noise from driving a pile into the seabed has a minor adverse impact on the residents during the daytime at those properties where background noise is already high due to the noise from the surf and the A90. It is assumed that due to the repetitive nature of the piling noise and slight exceedance of the daytime noise limits, the noise will be noticeable (mildly intrusive) and may cause small changes in behaviour such as closing the windows or turning up the volume of the TV/radio (see Table 5 above and Table 2.5 in (TAN Noise)). At properties further away from the A90 and the coast and therefore with lower background noise, effects may increase and have a minor to moderate adverse impact for a limited time as the piling noise will be more noticeable and may be perceived as disruptive.

110 Due to the limited period of time it is expected that the residents will fully recover from any disturbance during the day-time. The recovery period after disturbed sleep for up to 12 nights would, in all likelihood, be longer. A full recovery is expected once the construction phase is completed. The impact on the closest neighbours of the proposed EOWDC due to piling noise during evenings/weekends is expected to be between minor and major adverse depending on the prevailing background noise and the distance to the development. The repetitive nature and the magnitude may be perceived as mildly intrusive up to very disruptive if the noise impact requires a significant change in behaviour such as keeping windows closed at all times, or not being able to use the garden in the evenings.

111 The impact from piling noise during the night-time, the impact is expected to be between minor and major adverse for the L_{Aeq}, depending on the location, i.e. distance to the development, and the prevailing background noise. For the closest properties it may result in loss of regular sleep and increased stress due to the magnitude of the noise levels and the nature of the noise (repetitive). It is considered to be major adverse impact for these properties. Depending on prevailing background noise and increasing distance to the piling activity, the impact will be reduced.

112 The impact on undisturbed sleep will be major adverse for the closest properties but would also affect a wider area when assessing the maximum sound pressure level against the adopted sleep disturbance criteria due to the magnitude of the noise levels. The generated noise levels will be well above the recommended criterion for undisturbed sleep and therefore prevent regular sleep.

113 The predicted piling noise will have a major and thus significant impact on the residents during evenings/weekends and during the night through temporary loss of amenity and likelihood of disturbed sleep during the driving of the monopiles.

114 Due to the limited period of the piling operation to 12 days, the effect on the surrounding properties during the day is regarded to be less significant than for the evening/weekend or night-time. BS 5228-1:2009 (BSI, 2009) states in Appendix E.3.2 that '*if the total noise level exceeds the appropriate category value* (i.e. noise limit), *then a significant effect is deemed to occur*.' The exceedance of the noise limits occurs only during a very limited period at the beginning of the piling process and a limited number of properties on a limited number of days (i.e. when piling the closest locations). This is a potential significant effect but is considered reversible and only of limited duration. Therefore the effect is expected to be acceptable.

Mitigation

115 It is impossible to calculate the reduction of noise levels due to proposed noise mitigation measures as very little data is available for airborne noise reduction of offshore piling operation and currently it is uncertain which machinery will be used.

116 Suggestions for the noise reduction of onshore building construction sites is available but it should be noted that those piles are much smaller in diameter and therefore much less energy is needed to drive them and thus a lower noise emission is produced. It is possible that suggested measures might not be practically feasible at sea.

117 Potential mitigation measures at the source could include enclosing the hammer head and the top of the pile in an acoustic screening or using a resilient pad between hammer head and pile to prolong the impulse/contact time and thus reduce the peak sound power level. If hammer driver monopiles are to be installed, consideration will be given to the selection of the hammer and potential dampening techniques to abate in-air emissions.

118 Using vibration pile driving reduces the sound power level compared to impulse pile driving, especially the peak level. This technique, however, is normally only used for small piles and is limited to a certain type of soil. It therefore may not be suitable for the proposed EOWDC.

119 The duration of high noise levels can be reduced when pile driving is limited to the necessary amount to achieve necessary penetration depth and mechanical boring is used when applicable.

120 It is recommended that a stringent noise management policy is designed to ensure the noise levels at nearby dwellings are kept to a minimum at all times. It is recommended that regular meetings are held with one or more elected resident's representatives to ensure noise levels do not become excessive. A 24hr contact telephone number should be made available and publicised for surrounding receptors in case noise levels become excessive.

121 To reduce annoyance and hostility, potentially affected residential areas should be notified well before the piling operations start and be informed about the expected impacts and the duration of the construction phase. A neighbourhood comment and complaint system should be developed to record and deal with complaints.

122 In order to mitigate the effects on sleep disturbance during the night and periods used for relaxation at the weekends, it is proposed to restrict the pile driving operation to the following periods:

- Mondays – Fridays 07:00 until 19:00
- Saturdays 07:00 until 13:00
- Sundays and bank holidays no noisy equipment should operate

Residual Impacts

123 If piling is not carried out during the night there will be no noise impact on the residents during this time and the impact will be negligible.

124 By introducing a noise management policy that includes regular meetings with local resident representatives and facilitates the dissemination of information on the expected timing and duration of piling it is expected that the impact during daytime hours will be minor. As the construction period associated with high noise levels is only for a limited time and as methods to screen the sound at source could potentially be employed this impact could be reduced even further.

125 By following the same mitigation as is proposed for daytime hours above it is felt that the impacts during evenings and weekends will also be moderate adverse.

Cumulative Impacts

126 The installation of the potential Ocean Laboratory has been assessed as a cumulative impact. Table 9 highlights that the worst case predicted noise levels associated with installing the potential Ocean Laboratory will be similar to those associated with installing the worst case wind turbine on the site. Additional time spent installing the structure would increase the time local residents could be exposed to noise. However, as the additional time that noise will be generated will only be of a short, temporary duration the cumulative impact is assessed as being of minor significance.

Monitoring

127 It is vital to monitor the construction noise at least at the beginning of the pile driving phase. This is essential to establish the real sound power level of the pile driving activity, verify the propagation calculation and check the efficiency of the mitigation measures.

128 It is suggested to measure the sound pressure level as close to the piling operation as possible to calculate the sound power level of this noise source.

129 Further monitoring should be carried out at the locations where the background noise monitoring has been done. It might be advisable to choose one location at a greater distance inland (2-3 km) to establish how far inland the noise could cause complaints, especially in areas where there is not much road traffic and surf noise.

130 During the monitoring noise mitigation measures could also be tested and it could be established whether sufficient mitigation is in place to allow for night-time piling as well.

1.3.1.2 Operational Phase

131 To determine the potential impact of the proposed development when operating, wind turbine noise has been assessed in accordance with the guidance contained within ETSU-R-97.

132 Following discussions with the relevant EHOs noise predictions were carried out for the four locations representing the closest residential properties to the proposed EOWDC and two locations further inland. The predictions assume down wind propagation from all sources simultaneously, which cannot occur in practice. The predicted noise levels are summarised in Table 11 below.

Table 11: Highest predicted Wind Farm Noise Level at the assessed Properties

Location	**Highest predicted wind farm noise level L_{A90}, dB**
Four Winds	39.5
16 Chapelwell Wynd	40.9
Easter Hatton	40.7
Hareburn House	41.3
3 Tarbothill Farm Cottages	40.2
16 Dubford Gardens	37.2

Potential Impacts

133 Plots have been produced of the measured L_{A90} background noise levels against wind speed at six locations representing the closest residential properties to the proposed EOWDC site. The derived noise limits are based on the lower ETSU-R-97 daytime limit and the Aberdeenshire night-time limit of 38 dB L_{A90} or background noise level plus 5 dB, whichever is the greater. The plots for these locations also show the upper ETSU-R-97 day time limit for completeness.

134 All the data points corresponding with recorded incidences of rainfall were removed.

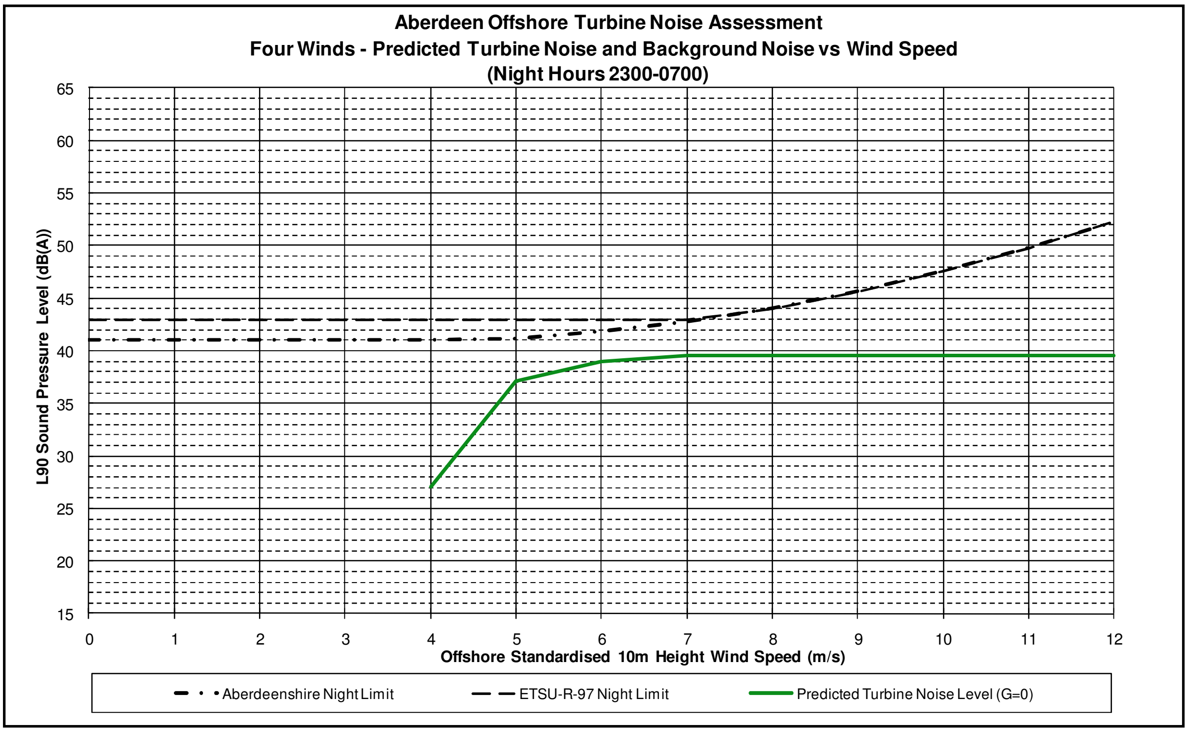
135 The assessment plots are shown in Chart 1 to 12 for the night hours and daytime hours for the representative residential locations.

136 Due to a technical error, the sound level meter at Hareburn House only recorded data for 3 days. During that period background noise levels were between 40 and 58 dB L_{A90} at 3 m/s and 52 and 59 dB L_{A90} at higher wind speeds during amenity hours and 42 and 55 dB L_{A90} at 3 m/s and 52 and 55 dB L_{A90} at higher wind speeds during night hours. Comparing the measured noise level of Hareburn House with the noise levels obtained at 3 Tarbothill Farm and 16 Chapelwell Wynd leads to the conclusion that background noise levels are generally higher at Hareburn House due to the proximity of the sea. The approach taken to use the noise limits derived from the measurement at Chapelwell Wynd as a substitute for Hareburn House is considered conservative as lower noise levels were recorded at this property compared to Tarbothill Farm. It is also assumed that using those noise limits is more representative for the houses in Blackdog which are further back from the shoreline as Hareburn House and would therefore receive less sea noise than Hareburn House.

137 The ETSU-R-97 noise limits assume that the wind turbine noise contains no audible tones. Where tones are present, a correction should be added to the measured or predicted noise level before comparison with the recommended limits. The audibility of any tones can be assessed by comparing the narrow band level of such tones with the masking level contained in a band of frequencies around the tone called the critical band. The ETSU-R-97 recommendations suggest a tone correction, which depends on the amount by which the tone exceeds the audibility threshold. A warranty will be sought from the manufacturer of the wind turbines for this site, once the model has been chosen, that the noise output will not require a correction under the ETSU-R-97 scheme.

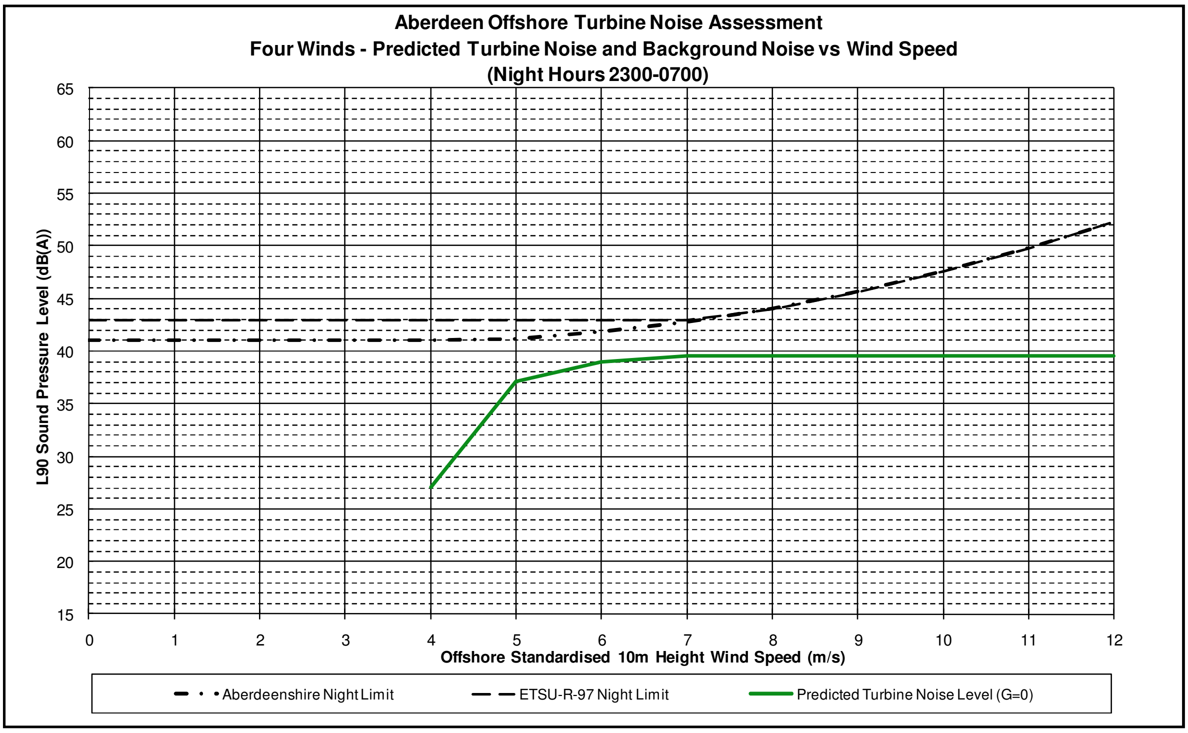
Four Winds

Chart. 1



138 Chart 1 shows that at Four Winds, the typical predicted wind turbine noise level meets the night noise limit by a minimum margin of 2.8 dB. The typical predicted wind farm noise level is below the prevailing background noise for wind speeds above 8.5 m/s.

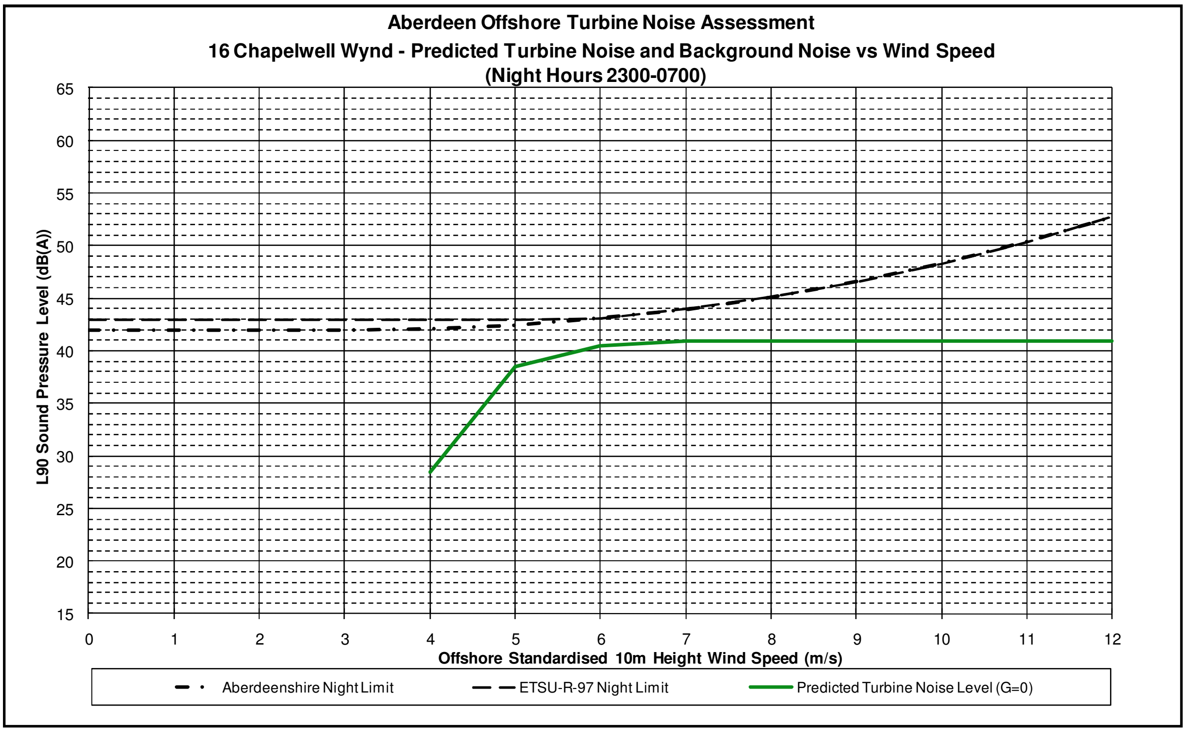
Chart. 2



139 Chart 2 shows that at Four Winds, the typical predicted wind turbine noise level meets the ETSU-R-97 day-time noise limit by a minimum margin of 14.2 dB. The typical predicted wind farm noise is below the prevailing background noise for all wind speeds.

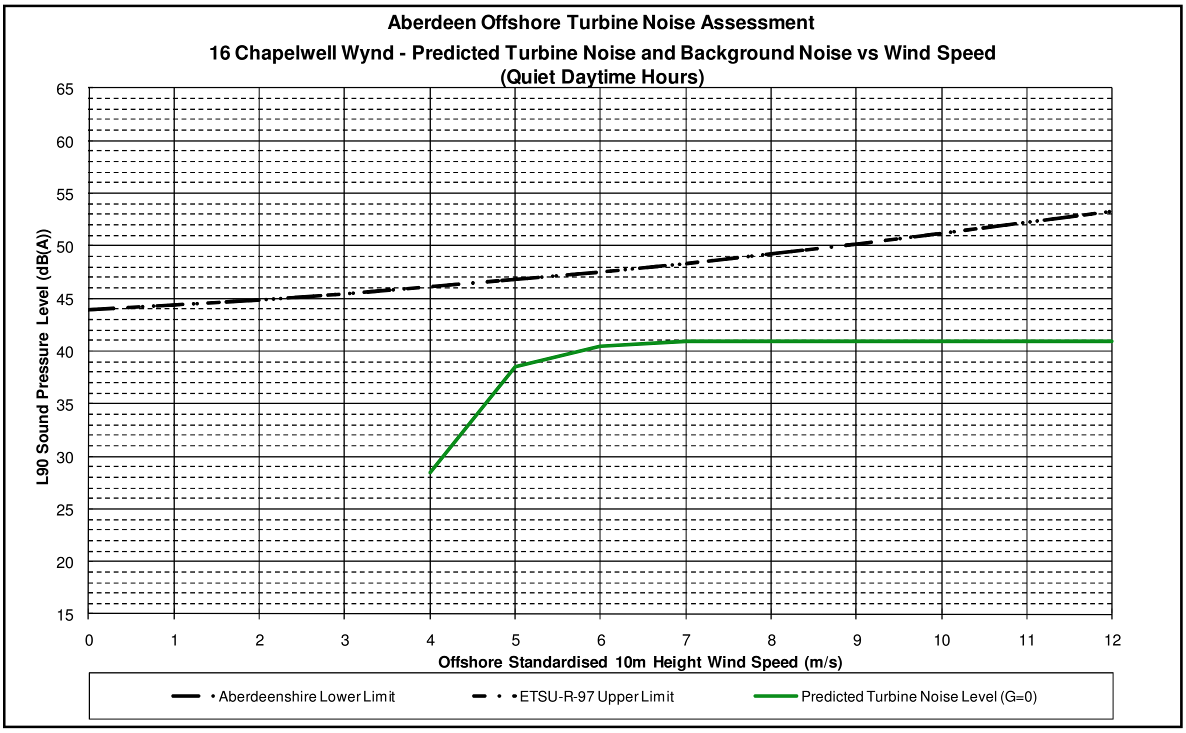
16 Chapelwell Wynd

Chart. 3



140 Chart 3 shows that at 16 Chapelwell Wynd, the typical predicted wind turbine noise level meets the night noise limit by a minimum margin of 2.7 dB. The typical predicted wind farm noise level is below the prevailing background noise for all wind speeds above 8.5 m/s.

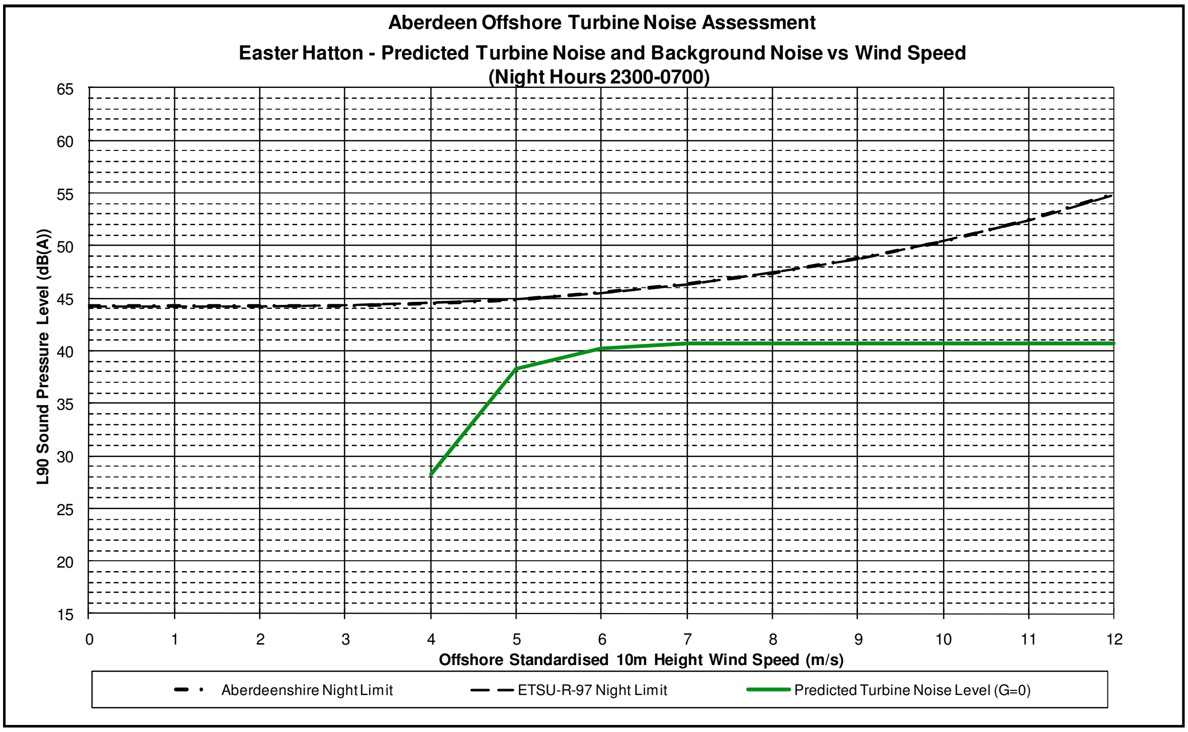
Chart. 4



141 Chart 4 shows that at 16 Chapelwell Wynd, the typical predicted wind turbine noise level meets the ETSU-R-97 day-time noise limit by a minimum margin of 7.1 dB. The typical predicted wind farm noise is below the prevailing background noise for all wind speeds.

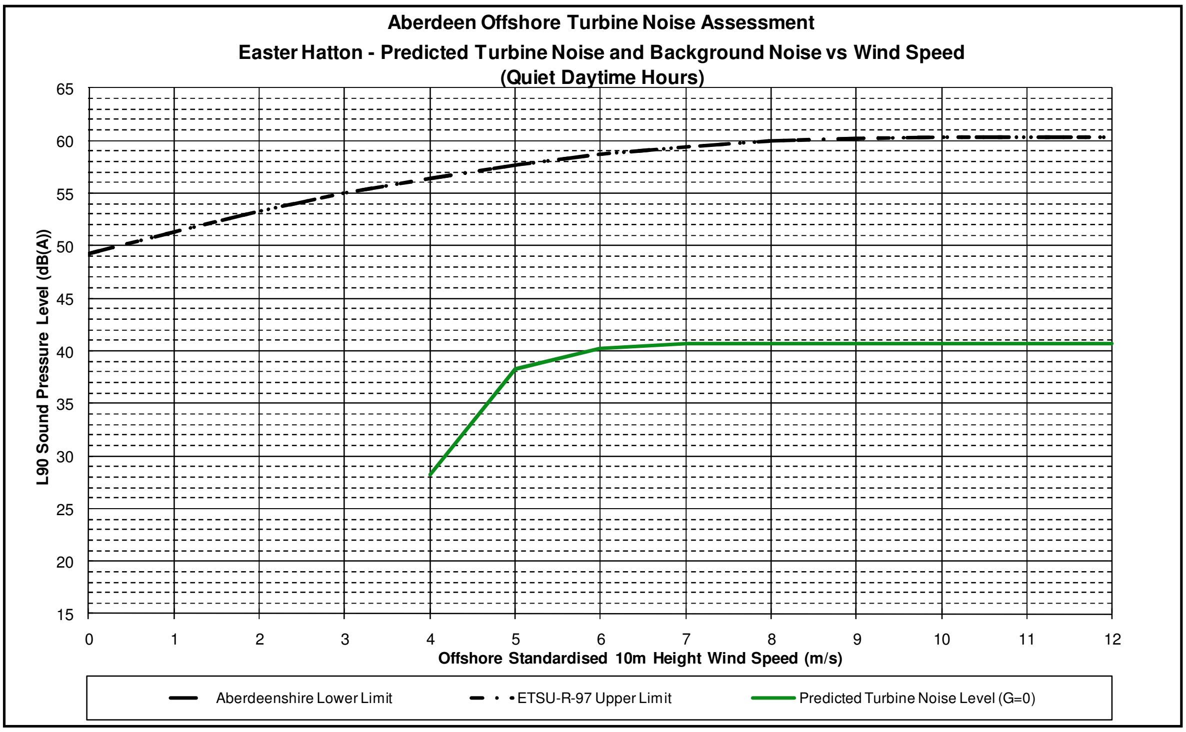
Easter Hatton

Chart. 5



142 Chart 5 shows that at Easter Hatton, the typical predicted wind turbine noise level meets the night noise limit by a minimum margin of 5.3 dB. The typical predicted wind farm noise level is below the prevailing background noise for all wind speeds.

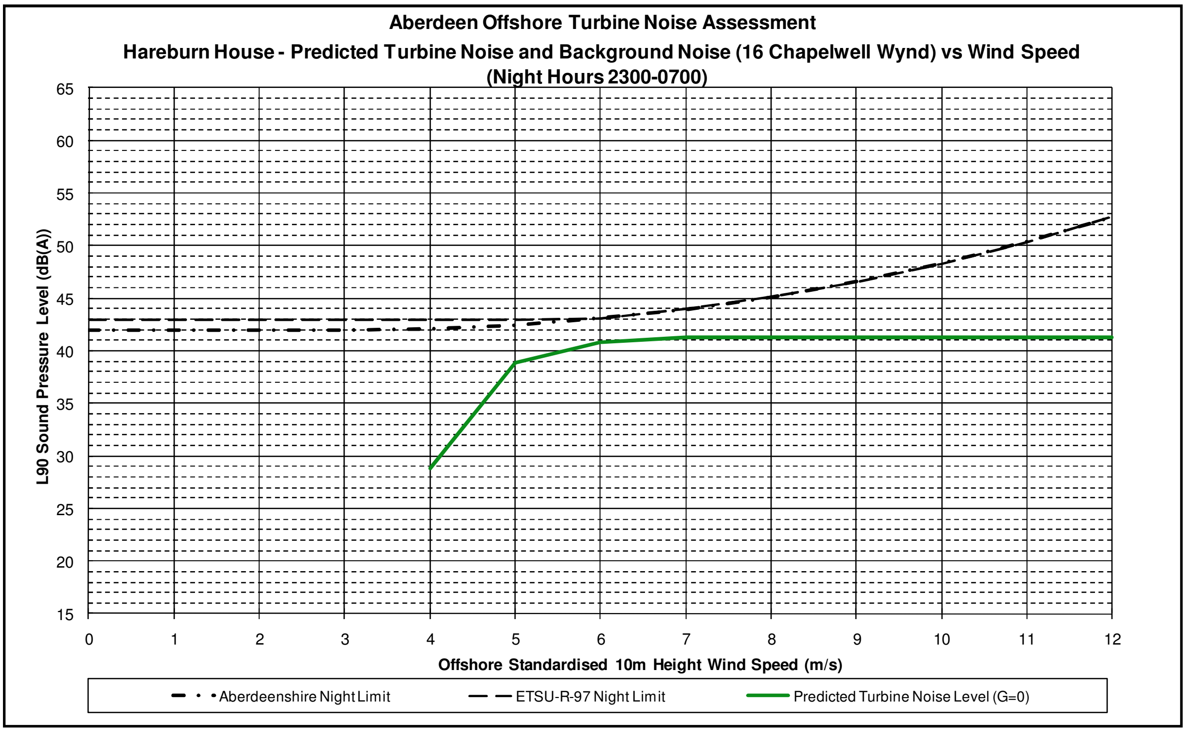
Chart. 6



143 Chart 6 shows that at Easter Hatton, the typical predicted wind turbine noise level meets the ETSU-R-97 day-time noise limit by a minimum margin of 18.5 dB. The typical predicted wind farm noise is below the prevailing background noise for all wind speeds.

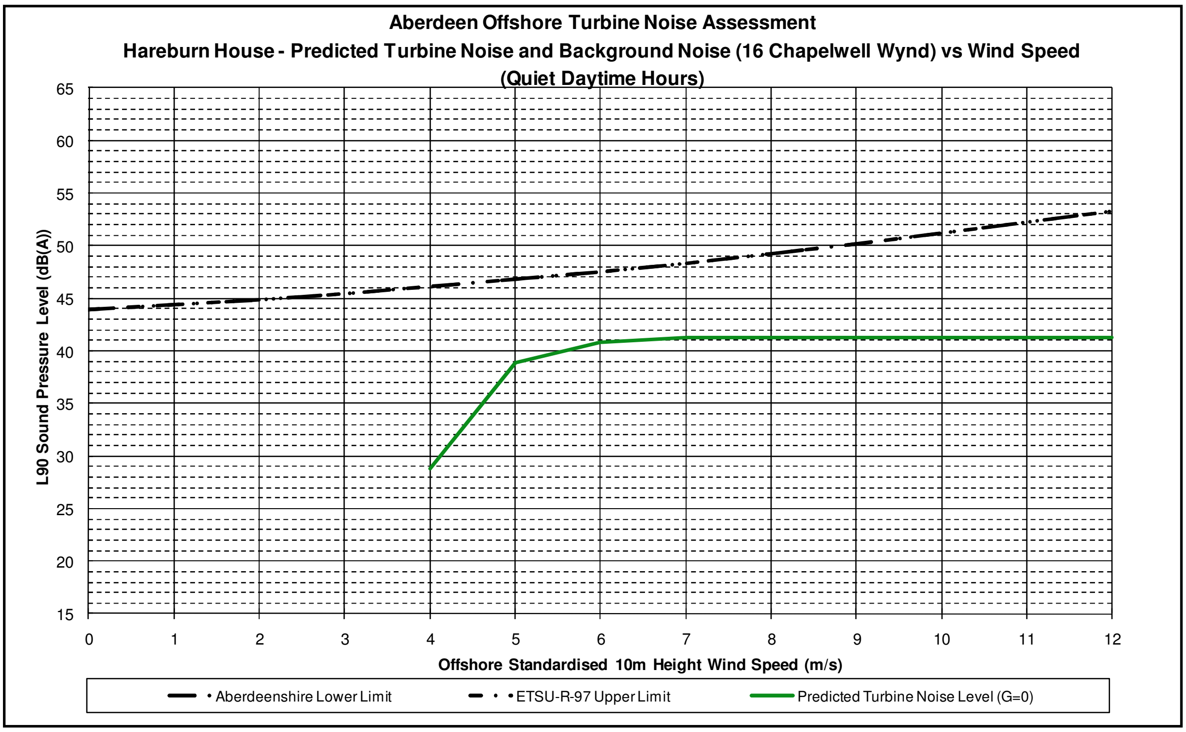
Hareburn House

Chart. 7



144 Chart 7 shows that at Hareburn House, the typical predicted wind turbine noise level meets the night noise limit, based on the background noise measurements at 16 Chapelwell Wynd, by a minimum margin of 2.3 dB.

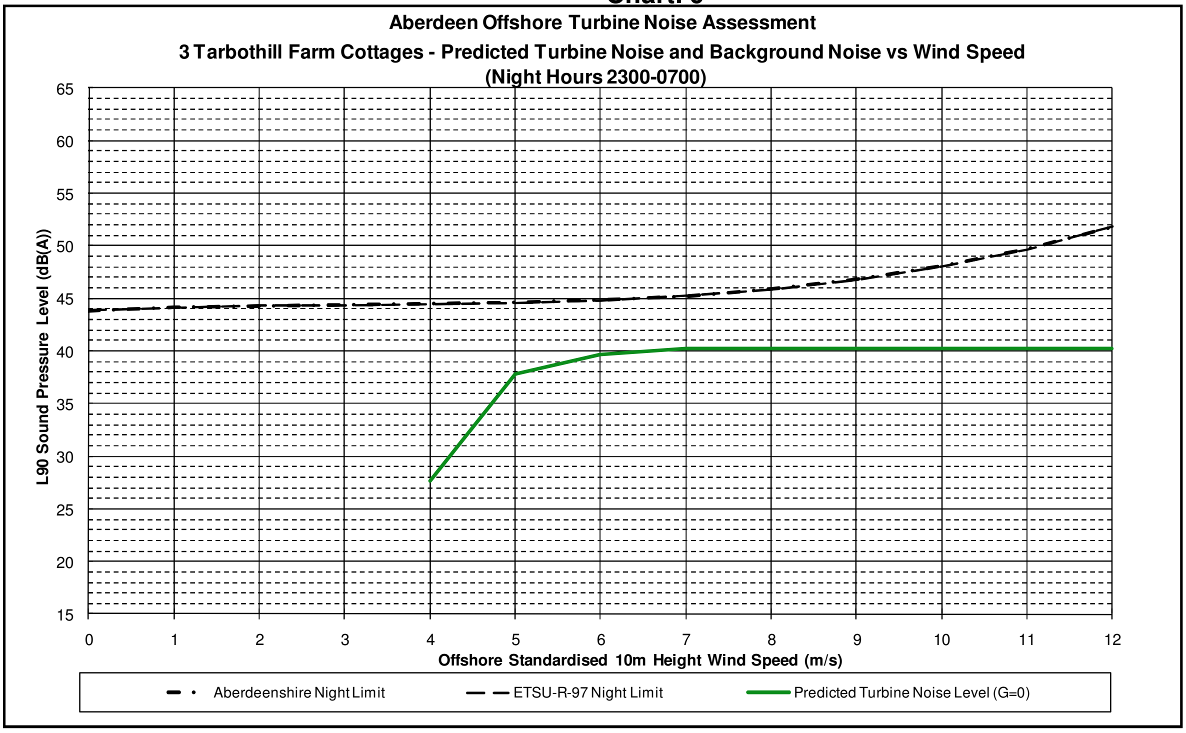
Chart. 8



145 Chart 8 shows that at Hareburn House, the typical predicted wind turbine noise level meets the ETSU-R-97 day-time noise limit assigned from 16 Chapelwell Wynd by a minimum margin of 6.7 dB.

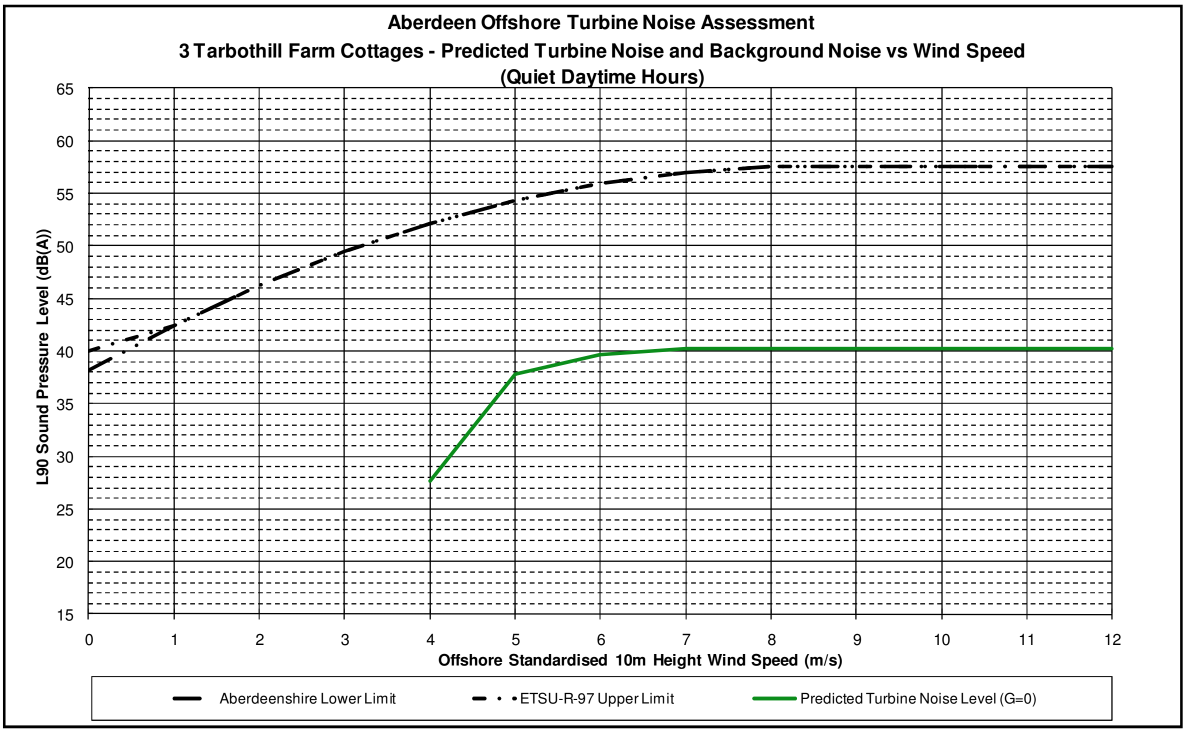
3 Tarbothill Farm Cottages

Chart. 9



146 Chart 9 shows that at 3 Tarbothill Farm Cottages, the typical predicted wind turbine noise level meets the night noise limit by a minimum margin of 5 dB. The typical predicted wind farm noise level is below the prevailing background noise for all wind speeds.

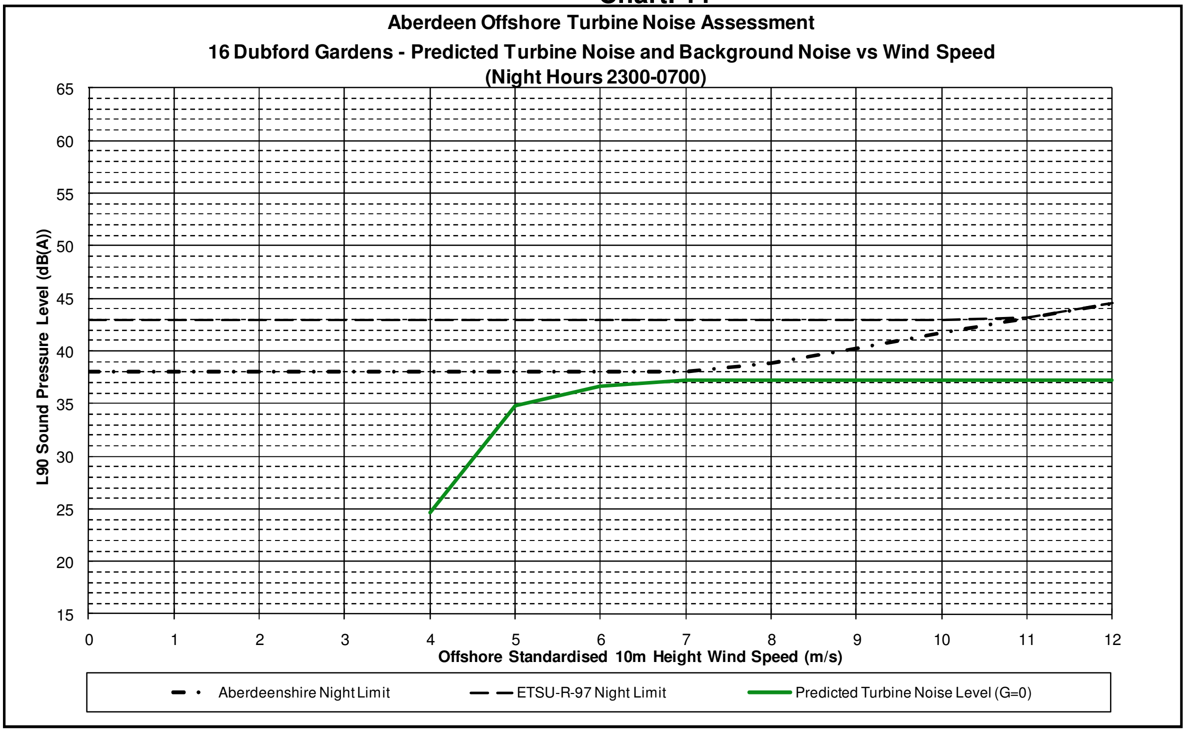
Chart. 10



147 Chart 10 shows that at 3 Tarbothill Farm Cottages, the typical predicted wind turbine noise level meets the ETSU-R-97 day-time noise limit by a minimum margin of 16.2 dB. The typical predicted wind farm noise is below the prevailing background noise for all wind speeds.

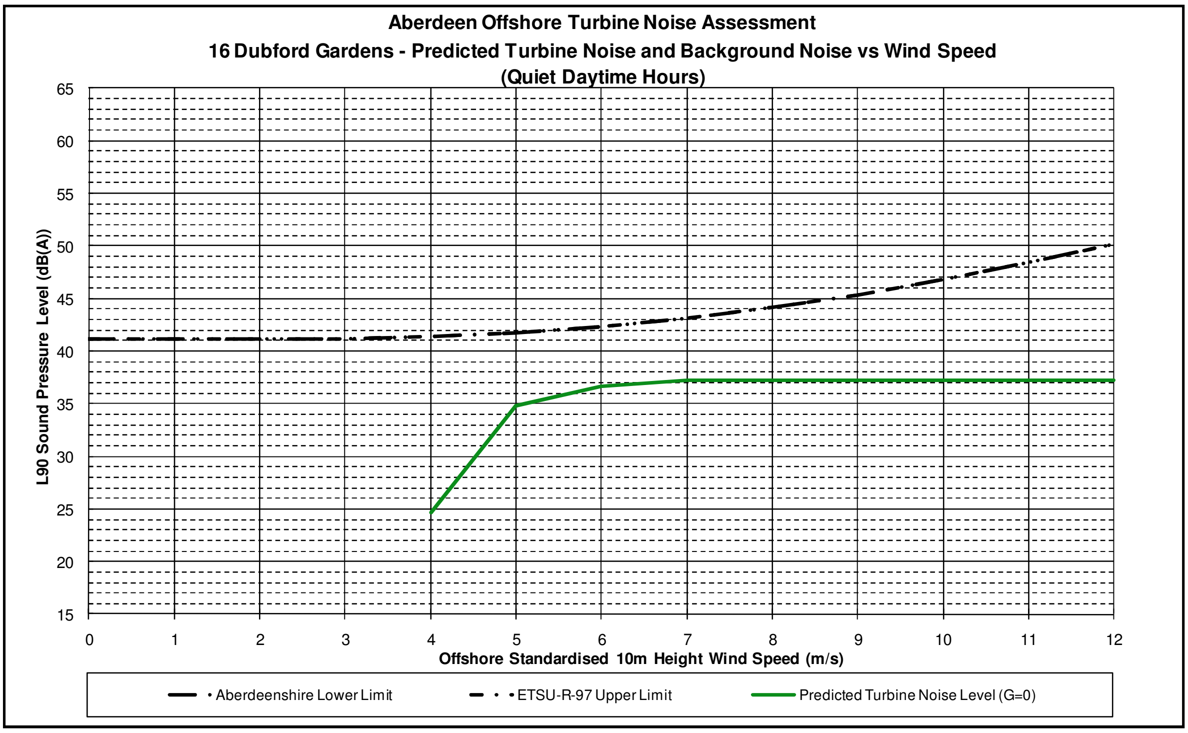
16 Dubford Gardens

Chart. 11



148 Chart 11 shows that at 16 Dubford Gardens, the typical predicted wind turbine noise level meets the night noise limit by a minimum margin of 0.8 dB. The typical predicted wind farm noise level is below the prevailing background noise for wind speeds above 10.5 m/s.

Chart. 12



149 Chart 12 shows that at 16 Dubford Gardens, the typical predicted wind turbine noise level meets the ETSU-R-97 lower day-time noise limit by a minimum margin of 5.7 dB. The typical predicted wind farm noise is below the prevailing background noise for all wind speeds.

1.3.1.3 Other Residential Properties

150 The assessments carried out for the background noise measurement locations are generally representative of the most affected properties in each area. This has been determined by considering distance from the sea, distance from the A90, and the type of residential area. Generally all other properties in the area being represented receive a lower predicted noise level and, assuming background noise is similar, will receive a lower impact than the assessed location.

151 The only area to which this doesn't apply is 16 Dubford Gardens. This is due to the measurement being chosen being both further from the A90, and on the edge of the Aberdeen suburb of Bridge of Don. Although there are properties closer to the proposed EOWDC site, which will therefore have a higher predicted noise level from the wind farm, these properties will equally have a higher background noise than that of 16 Dubford Gardens, due to their proximity to the A90, sea and being in a more built-up region. 16 Dubford Gardens was therefore chosen to represent this area due to its location balancing these factors.

152 The operational wind farm is predicted to be within the noise limits set by ETSU-R-97, the accepted guideline for onshore wind farm noise which has been adopted in this assessment and is therefore considered to have a negligible impact in terms of ETSU-R-97 noise limits.

Mitigation

153 None required

Residual Impacts

154 As no mitigation is required the residual impact will be negligible.

Cumulative Impacts

155 The proposed EOWDC may be supplemented by the installation of a diesel generator on the potential Ocean Laboratory Platform for electricity generation for the laboratory. The operational wind farm noise has been assessed together with the operation of the diesel generator of the potential ocean laboratory as a cumulative impact.

156 The height of the ocean laboratory is proposed to be 18 – 20 m above sea level. This has been assumed as source height. The source noise level of 90 dB(A) at 1 m distance for the diesel generator has been given in chapter 3, Description of the Proposed Development. Table 12 shows the assumed octave band sound power level based on octave band information from BS5228:2009 Appendix C, Table C.4 normalised to 90 dB(A).

Table 12: Normalised Noise Spectrum for a Diesel Generator at 1 m

Octave Band Centre Frequency (Hz)	Normalised Octave Band Sound Power Level (dB L_{Aeq})
63	88.8
125	81.8
250	76.8
500	72.8
1k	69.8
2k	65.8
4k	66.8
8k	59.8

157 The results of the cumulative assessment showed no change in predicted noise levels at all. The operation of the diesel generator has no effect on the predicted noise levels of the operational EOWDC, the cumulative impact has therefore been assessed as negligible.

Monitoring

158 Due to the magnitude of the prevailing background noise compared to the predicted EOWDC noise especially during the daytime, it might be difficult or impossible to distinguish between the two during a measurement especially if the wind turbines cannot be stopped for an additional background noise measurement during the survey.

159 If the Planning Permission requires a compliance test nevertheless, it is proposed to carry out the measurement at the same locations as previously, according to the methodology proposed in ETSU-R-97, measuring the $L_{A90,10minute}$ of the total noise and background noise with the wind turbines stopped if possible, and compare the measured sound pressure level with the noise limits proposed in this EIA chapter.

160 Should complaints arise due to the operational noise of the EOWDC, it is suggested that monitoring should be carried out at the affected properties with the results compared to the limits derived for the nearest relevant property where background noise monitoring was carried out.

1.3.1.4 Decommissioning Phase

Potential Impacts

161 The decommissioning phase is not expected to cause any significant effect as noise levels from shipping and taking down the wind turbine parts will be significantly lower than the piling noise from the construction phase.

1.3.2 **Additional Potential Noise Generating Activities**

1.3.2.1 Construction Phase

Potential Impacts

162 Noise from shipping activities is not considered significant and has not been assessed here.

163 The main noise source of the cable laying process is assumed to be from the activity of ploughing, trenching or jetting. Neither the machinery nor the exact cable route is known at this stage and therefore no accurate assessment could be carried out. It is expected that the effect, if at all, would be where the cable route comes to shore but due to the duration of the activity and the machinery potentially under water for most of the works, a negligible impact on the closest residential properties is expected. No further assessment has been carried out here.

164 To ensure compliance with the noise limits adopted from BS5228-1:2009 it is suggested to carry out measurements during the period, when the cable lying activity is closest to the nearest properties. For any other times, noise levels would be lower and thus comply with the noise limits.

Mitigation

165 None required.

Residual Impact

166 As no mitigation is required the residual impact will be negligible.

1.3.2.2 Operational Phase

Potential Impacts

Additional noise generated from ongoing operation and maintenance (for example vessel movements) is not considered significant and has not been assessed here.

Mitigation

167 None required.

Residual Impact

168 None.

1.3.3 EOWDC Future Research and Monitoring Opportunities

1.3.3.1 Offshore Piling

169 As only limited noise data is available for the offshore piling activity it is suggested to carry out sound measurements at the source and simultaneously at two receiver locations, one near the shore and one further inland. The sound source measurements would provide sound power level for future offshore projects which involve piling and would also be useful to verify the data that has been used for this assessment.

170 The noise measurements onshore in combination with the simultaneous sound source measurements can be used to verify the propagation model for long-range propagation at sea and also to verify the noise reduction measures for local residents during the construction phase. Those measurements are also essential to show compliance with the construction noise limits.

171 Furthermore, the measurements can also be used to refine the sound propagation model especially to investigate the influence of ground absorption for locations further inland.

1.3.3.2 Offshore Wind Turbines

172 Many new offshore wind turbine types have been developed in the last few years but there is still not much noise data available, partly because some of the wind turbine types are still in the development state. Sound source measurements at the offshore wind turbines can fill this gap and provide essential information for a correct sound propagation calculation.

173 Simultaneous noise measurements at the same receptors for which background noise measurements have been carried out can be used to verify the propagation model and also show compliance with the derived noise limits.

174 Long-term noise measurement onshore could be used to investigate the effects certain weather conditions on the propagation and audibility of offshore wind farm noise at onshore receptor locations. This could result in a study where measured noise level are compared with the perception of local residents to get a better understanding of the effects of offshore wind farm noise on residents living near the coast and further inland where the masking noise of the sea noise will be less.

1.4 Summary

175 An assessment of the potential noise impact from the European Offshore Wind Deployment Centre has been performed. The guidance contained within ETSU-R-97 has been used to assess the potential noise impact of the proposed development, as specified in Scottish Government web based planning advice on onshore wind turbines as referred to in PAN 1/2011 (Scottish Executive, 2011), *Planning and Noise*.

176 Background noise measurements were taken at six locations neighbouring the proposed EOWDC. These locations were agreed with the Environmental Health Officers (EHO) for the Local Planning Authorities of Aberdeen City and Aberdeenshire Council.

177 Analysis of the measured data has been performed in accordance with ETSU-R-97 to determine the pre-existing background noise environment at these six locations.

178 Predictions of wind turbine noise have been made, based upon a generic sound power level typical for a 10 MW generating capacity wind turbine. The calculation procedure adopted is considered to be worst-case.

179 A warranty will be sought from the manufacturer of the wind turbine for this site such that any tonal noise output from the wind turbines will not require a correction under the ETSU-R-97 scheme.

180 The predicted levels and measured background noise levels indicate that for all dwellings located onshore, wind turbine noise will meet the amenity and night-time noise criteria proposed within ETSU-R-97.

181 Predictions of noise associated with the possible diesel generator, associated with the potential ocean laboratory indicate that this noise source will result in no audible noise at onshore receptor locations and the sleep disturbance due to this noise source will not occur.

182 Cumulative assessment of the operational EOWDC noise and the possible diesel generator resulted in no change of the operational EOWDC noise.

183 Prediction of the pile driving noise during the construction phase shows exceedance of the night-time noise limits adopted from BS5228:2009 Part 1 (BSI, 2009) at all properties. It has therefore been proposed that construction times should be limited to daytime hours unless suitable noise mitigation can be found and verified by measurements.

184 Prediction of the pile driving noise during daytime shows exceedance of the L_{Aeq} daytime noise limits adopted from BS5228:2009 Part 1 (BSI, 2009) at three assessed properties by 1 dB. With a suitable noise management policy it is expected that the impact during daytime hours will be minor adverse. As the construction period with high noise levels is only for a limited time and as methods to screen the sound at source could potentially be employed this impact could be reduced even further.

185 A summary of the impacts is provided in Table 13.

Table 13: Impact Assessment Summary Table

Potential Impact	Significance Level	Mitigation	Residual Significance	Monitoring
Sleep disturbance during piling night	Major	No piling during night	Negligible	No
Stress, annoyance during piling daytime	Minor to Moderate	Screens and good information policy	Minor	Yes, to determine real sound levels and check efficiency of potential mitigation measures.
Exceedance of noise limits during operation day	Negligible	Not required	Negligible	No
Exceedance noise limits operation night,	Negligible	Not required	Negligible	No
Construction noise from other machinery	Negligible	Not required	Negligible	No
Operational noise from diesel generator	Negligible	Not required	Negligible	No

European Offshore Wind Deployment Centre

Environmental Statement

Appendix 28.1: Draft EMP

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

1 INTRODUCTION

1 This document provides the Environmental Management Plan (EMP) for Aberdeen Offshore Wind Farm Limited's (AOWFL) proposed European Offshore Wind Deployment Centre (EOWDC) for the three phases of offshore construction, operational and decommissioning.

2 Due to the nature of the proposed project (a test centre) and the stage at which this document has been produced it has not been possible to fully address every element. For the purposes of this document a list of likely outline method statements has been produced and an example outline provided. As further information is made available so these documents will be updated.

1.1 Aim of the Environmental Management Plan (EMP)

3 The aim of the EMP is to ensure that all aspects of environmental management are carried out in accordance with relevant legislation and best practice guidelines.

4 This is to be achieved by taking a fully integrated approach to project management through the complete cycle of preparation, planning, action, monitoring, checking and review.

5 The EMP will be implemented prior to construction and in consultation with statutory authorities, with a suite of complementary management plans corresponding to different aspects of the construction activity. The documents will be tailored specifically to ensure compliance with the consent conditions for the project and current environmental best practice. The following documents would be incorporated into a final EMP:

- Monitoring Protocol (as per statutory consents)
- Incident Reporting and Non Conformance Procedure
- Emergency Response Plan
- Collision Risk Management Plan
- Marine Pollution Contingency Plan
- Dropped Objects and Materials Recovery Plan
- Archaeology Plan
- Noise, Dust and Vibration Management Plan
- Waste Management Plan

6 The final EMP would be in place well before construction begins to take full account of all pre-construction monitoring requirements.

1.2 Structure of this Document

7 This EMP is divided in to three sections:

a. **Part 1** provides background and supporting information for the EMP.

b. **Part 2** details in a series of summary briefing notes, the environmental impacts identified to date and the associated commitments made with regard to environmental management, impact mitigation measures and consent conditions, all of which AOWFL is obliged to carry out. These commitments derive from the EOWDC Environmental Statement.

c. **Part 3** provides an introduction to outline construction method statements.

8 It should be noted that further commitments could be contained in any consent granted to the project. At such time these commitments would be fully incorporated in to the EMP.

PART 1

2 POLICY

9 Suitable and effective safety, health and environmental management would be in place for the duration of the project.

10 A health and safety plan would be prepared covering all aspects relating to health and safety.

11 A manager would be appointed responsible for the overall safety, health and environmental policy. It would be the joint responsibility of all employees to ensure this policy is implemented via collective and individual responsibilities set out within the policy document.

3 PLANNING REQUIREMENTS

3.1 Environmental Aspects

12 An environmental aspect is any element of an activity that could interact with the environment and that may have the potential to have an environmental impact.

13 The following documents were used to formulate the draft EMP and contain information on potential environmental impacts and environmental aspects of the EOWDC proposal:

- European Offshore Wind Development Centre Environmental Statement of which this document forms Appendix of Chapter 28
- aspects identified in good practice
- Marine Scotland Guidance

14 This draft EMP focuses upon the key offshore environmental aspects with detail provided in outline briefing notes.

15 This information may be supplemented as additional studies may be undertaken throughout the phases of the development and would be taken into account as appropriate.

3.2 Legal and Other Requirements

16 It is important that all elements and activities associated with the development in all its phases comply with all relevant environmental legislation.

17 Lead responsibility for delivering compliance with relevant environmental obligations and legal statues is set out below.

- before issue of construction contracts: The applicant development team
- construction: Construction Contractor
- operation: Operations Contractor
- decommissioning: Decommissioning Contractor

18 Responsibility to identify and adhere to specific and current environmental legal requirements will lie with the main contractor.

3.3 Objectives, Targets and Programme

19 At the heart of the EOWDC project is the interaction between a research and potential test and training centre with a small, highly innovative, commercially operated and highly instrumented and monitored offshore wind farm. The site will offer potential opportunities for commercial R&D, testing and dissemination including long-term environmental monitoring and improvement. This future monitoring should play a key role in the development of the EMP.

20 Long-term improvement goals would be identified for the project. These would be compatible with the policy for the development and consider the relevant environmental impacts.

21 The applicant is committed to the following environmental objectives:

- exemplary performance in all aspects of environmental management
- a proactive attitude to environmental protection
- no prosecutions
- monitoring
- collision risk for key species less than predicted
- a target of no reportable environmental incidents at any stage in the project
- minimum ornithological and ecological disturbance commensurate with building an operational wind farm
- regular reporting and communication on environmental performance with statutory bodies and the local community

22 To support the long-term goals, a series of environmental targets, focusing upon the short-term actions would be developed. These would be supported by a programme that sets out how the targets are to be achieved (eg resources, specific actions and timescales). Action may take the form of the following:

- development of improvement strategies in particular areas, one-off actions, such as establishment of an environmental component to the website, introduction of technological solutions to resolve/improve environmental issues
- on-going actions that could be tracked over time, eg tonnage of waste disposed (or recycled)

23 The long-term objectives, the short-term targets and progress against these would be reviewed on a regular basis. This would form part of the management review and meetings with the independent Environmental Management Committee.

24 The review would continue through all phases of the development with the objectives, targets and management programme reflecting the key issues for the activities being undertaken and the lead responsibilities.

4 IMPLEMENTATION

4.1 Resources, Roles, Responsibility and Authority

25 The overall project management team would have the responsibility of delivering the EMP. In this way environmental management would be fully integrated into the running of the project. This team's roles would include:

- review of all method statements and review against all management plans and checking that work is carried out accordingly
- ensuring monitoring in accordance with all management plans is carried out and reviewed; and
- reporting as required by the management plans

26 In order to implement the management plans identified above and to ensure the monitoring procedures outlined in the briefing notes are implemented, the project management team would employ a number of skilled experts during the construction, operation and decommissioning periods. This could include:

- ornithologist
- marine mammal observer
- marine ecologist
- fisheries expert
- archaeologist

4.1.1 Incorporation of EMP into Contracts

27 The EMP would be incorporated into all contracts. Incentives and/ or penalties would be introduced where appropriate to ensure that the EMP is adhered to throughout the development process.

4.1.2 Day to Day Responsibility

28 During construction, operation and decommissioning, a client representative would be on-site or on-call and able to respond to any incident. They would have the authority to halt or modify work in response to environmental concerns and the responsibility to ensure that all monitoring and checks are carried out in accordance to the relevant schedules. They would also have the necessary training and authority to direct the emergency response team to deal with environmental incidents.

4.2 Competence, Training and Awareness

4.2.1 Evaluation of Contractors and Subcontractors

29 When contractors are assessed consideration would be given to organisational environmental management systems and ability to implement the EMP.

4.2.2 Training

30 Suitably trained staff would be employed to manage this EMP and fulfil the roles identified in this document. Any contractors working on studies would be selected taking into account their environmental awareness and where appropriate their experience in the implementation of EMPs.

31 For construction, all senior project management staff would undergo environmental awareness training, such as the IOSH five day course. Specific members of the team would have appropriate professional environmental training as would consultants and advisors.

32 The emergency response team would be trained to carry out their work (in the unlikely event of an incident happening) with high environmental awareness to minimise the impact of any response.

4.2.3 Site Induction

33 Environmental awareness would feature prominently in the induction for all workers and site visitors.

4.3 Communication

4.3.1 Contractors and Subcontractors

34 During pre-construction surveys and then during construction, operation and decommissioning, there would be regular project meetings, including a review of environmental issues and current sensitivities.

35 Part of the review of all method statements would include an environmental audit.

4.3.2 Workforce

36 Information would also be provided to the workforce via Construction Design and Management Pre-Construction Information, the workforce would also be informed of specific areas of sensitivity and generally reminded of the sensitivity of the site through toolbox talks, posters and in method statements. They would be encouraged to report any concerns on environmental issues immediately to the project management team. All issues and actions taken would be reviewed by the project management team as a minimum on a weekly basis.

4.3.3 Meetings Programme

37 Health, safety and environment would be on the agenda of every regular project meeting.

4.4 Documentation

38 During construction, thedocumentation would include up to date records of the site and all environmental issues so that the project management team has current information available.

39 The 'documents' available could include:

- GIS Constraints Register
- design risk register
- all method statements
- all briefing notes
- all risk assessments
- commitments register

40 All records would be kept and maintained during the operation phase so that management plans could be adapted in response to changing circumstances and so that they are available for decommissioning.

4.5 Control of Documents

41 A document management system would be in place prior to construction. All method statements, risk assessments, audits, monitoring records, reviews and meeting minutes would be recorded in this system.

4.6 Operational Control

42 Before construction, records would be maintained of all activities and assessments (risk assessments, pre-construction surveys). It would be ensured that they are properly controlled and the results are passed on to the construction and operation teams later.

43 Day to day control of the project during construction would involve:

- constraints register
- working time
- time of year working
- working areas
- project planning
- preparation and monitoring of overall plan – six months, one year, total project
- preparation of detailed plan – one month ahead
- checks against constraints register
- method statements
- risk assessments
- commitments register

5 CHECKING

5.1 Monitoring and Measurement

5.1.1 Pre-construction

44 All surveys would be monitored for compliance with EOWDC specifications and appropriate management plans.

5.1.2 During Construction

45 The following monitoring checks are examples of checks that could be carried out during construction:

- water quality
- pollution control measures
- noise (in air/ sub-acoustic)
- traffic (vessels)
- scour protection

5.1.3 During Operation

46 The following monitoring checks are examples of checks that could be carried out during operation:

- water quality
- pollution control measures
- noise (in air/ sub-acoustic)
- traffic (vessels)
- scour protection

5.1.4 Monitoring Plan Timetable

47 Monitoring plans will be agreed within a specific timetable as agreed with all relevant parties.

5.2 Evaluation of Compliance

48 Full records of all measurements, shipments and transfers would be kept to demonstrate compliance with licenses and permits. The recording systems would be prepared in advance and regularly audited and reviewed.

5.3 Non-conformity, Corrective Actions and Preventative Action

49 All non-conformity would be investigated and reported to the project management team if necessary. All corrective actions would be recorded with dates for action. An overall register would be kept and regularly reviewed by the project management team and shared with other parent

projects for trend spotting. It is possible that incidents would also be required by law to be reported to industry.

5.4 Control of Records

50 Records would be controlled through the document management system and the project management team would have responsibility to ensure this is done.

5.5 Internal Audit

51 Regular internal audits would be carried out in accordance with a schedule agreed with the management team.

6 MANAGEMENT REVIEW

6.1 Project Team Review

6.1.1 Regular Review of EMP

52 This document would be reviewed regularly.

6.1.2 Preparation of Reports

53 The relevant project management team would be responsible for the preparation and presentation of reports to the relevant stakeholders.

PART 2

7 OUTLINE BRIEFING NOTES

54 This section of the draft EMP contains outline briefing notes which are relevant to all phases of the EOWDC (ie construction, operation, maintenance and decommissioning). The purpose of the briefing notes is to provide information about the environmental aspects and set out the measures necessary to reduce the environmental impact of the development during the construction stage. Outline briefing notes have been prepared for the following areas:

- Outline Briefing Note 1: General Obligations
- Outline Briefing Note 2: Ornithology
- Outline Briefing Note 3: Marine Mammals
- Outline Briefing Note 4: Marine Ecology
- Outline Briefing Note 5: In-Air Noise
- Outline Briefing Note 6: Offshore Archaeology
- Outline Briefing Note 7: Coastal Processes
- Outline Briefing Note 8: Commercial Fisheries
- Outline Briefing Note 9: Salmon and Sea Trout
- Outline Briefing Note 10: Commercial Shipping and Navigation

55 These outline briefing notes are intended for use upon consenting of the proposed EOWDC. During the initial post consent period they would be refined and finalised. During the pre-construction phase they outline the pre-construction monitoring and surveys required, and during the construction phase they outline procedures to be followed.

56 Compliance with the measures outlined in the resultant briefing notes and the method statements supporting them is mandatory via contractual obligation.

57 The outline briefing notes are intended for use by project team members and contractors responsible for construction.

58 In order to ensure compliance with many of the measures set out in these briefing notes, a series of outline construction method statements will be prepared to support this draft EMP once further information is available. For the purposes of this document an introduction to outline method statements is provided.

OUTLINE BRIEFING NOTE 1: GENERAL OBLIGATIONS

Contents:

1. Background and Context
2. Mandatory Actions
3. Monitoring Survey Requirements
4. Further Information

1. Background and Context

Any general obligations stated within a Section 36 consent (under the Electricity Act 1989 (as amended)) or Marine Licence (under the Marine (Scotland) Act 2010) that are not applicable to other briefing notes will be captured within this briefing note.

2. Mandatory Actions

Obligations listed within the European Offshore Wind Deployment Centre Environmental Statement 2011 are listed below

Table 1.1 Obligations out lined in the proposed EOWDC ES

Phase	Document	Chapter	Potential Impact	Obligation
Construction	Project Description	Chapter 3	Health and Safety/ Navigation	The wind farm would be designed and constructed to satisfy the requirements of the Civil Aviation Authority (CAA) and the Northern Lighthouse Board (NLB).
Construction	Project Description	Chapter 3	Health and Safety/ Navigation	The construction area will be depicted on Admiralty Charts by the UK Hydrographic Office. Information pertaining to construction will be disseminated through the Notice to Mariners procedure together with regular communication with local and regional stakeholders.

Construction	Project Description	Chapter 3		The construction area and incomplete structures would be lit and marked in accordance with the protocol recommended by Trinity House Lighthouse Service.
Construction	Project Description	Chapter 3	General obligation	Cables would be buried in the seabed to a sufficient depth, which will be determined by a burial protection study but would be to at least 0.6 m.
Construction	Project Description	Chapter 3	Safety	Advisory or applied for exclusion zones would be in place.
Operation	Project Description	Chapter 3	Visual Impact	Colour scheme of the wind turbine tower, nacelle and blades is likely to be light grey RAL 7035, white RAL 9010 or equivalent.
Operation	Project Description	Chapter 3	Health and Safety	All turbines would be designed to allow for the following safety features: a) yawing of the wind turbines shall be possible via the remote control b) remotely park the wind turbines in an oriented stop, to allow for heli-hoist operation

Any obligations outlined in the Section 36 Consent and Marine Licence would be listed below.

Table 1.2 Obligations outlined in Section 36 Consent and/ or Marine Licence

Phase	Document	Chapter	Potential Impact	Obligation

3. Monitoring / Survey Requirements

None at the time of writing.

4. Further Information

None at the time of writing.

OUTLINE BRIEFING NOTE 2: ORNITHOLOGY

Contents:

1. Background and Context

A total of 63 species of birds were recorded during ornithological surveys. Thirty seven of these species were either a qualifying species for a Special Protection Area or were recorded in numbers that could be of concern should there be an impact from the proposed EOWDC development.

For the majority of species the impact from the proposed EOWDC is deemed to be negligible. However, for some species the impact is deemed to be minor or moderate (on a scale of negligible, minor, moderate and major).

2. Mandatory Actions

Obligations listed within the European Offshore Wind Deployment Centre Environmental Statement 2010 are listed below.

Table 2.1 Obligations out lined in the proposed EOWDC ES

Phase	Document	Chapter	Potential Impact	Obligation
All Phases	Ornithology Baseline and EIA	Chapter 10	Numerous	Required mitigation and monitoring to be agreed.

Any obligations outlined in the Section 36 Consent and Marine Licence would be listed below.

Table 2.2 Obligations outlined in Section 36 Consent and/ or Marine Licence

Phase	Document	Chapter	Potential Impact	Obligation

3. Monitoring / Survey Requirements

A detailed monitoring programme aimed at specific issues or concerns would be developed with the Regulator and advisors should consent be granted.

4. Further Information

None at the time of writing.

OUTLINE BRIEFING NOTE 3: MARINE MAMMALS

Contents:

1. Background and Context

A number of marine mammals make use of Aberdeen Bay throughout the year; the more commonly sighted species are the harbour porpoise, bottlenose dolphin and grey and common seal. Potential impacts have been assessed as being of negligible to minor significance. However, in some instances behavioural disturbance and displacement during possible construction activities is considered to be of moderate to potentially major significance.

A number of mitigation strategies have been suggested in order to minimize any impacts upon marine mammals.

2. Mandatory Actions

Obligations listed within the European Offshore Wind Deployment Centre Environmental Statement 2010 are listed below.

Table 3.1 Obligations out lined in proposed EOWDC ES

Phase	Document	Chapter	Potential Impact	Obligation
All	Marine Mammals EIA	Chapter 12	Underwater noise causing physiological damage/ behavioural disturbance/ interference of sound produced by marine mammals	A Marine Mammal Protection Plan (MMPP) would be developed.

Any obligations outlined in the Section 36 Consent, Marine Licence or European Protected Species Licence would be listed below.

Table 3.2 Obligations outlined in Section 36 Consent and/ or Marine Licence

Phase	Document	Chapter	Potential Impact	Obligation

3. Monitoring / Survey Requirements

A detailed monitoring programme aimed at specific issues or concerns would be developed as part of the Marine Mammal Protection Plan.

4. Further Information

None at the time of writing.

OUTLINE BRIEFING NOTE 4: MARINE ECOLOGY

Contents:

1. Background and Context

An impact assessment has been undertaken for the European Offshore Wind Development Centre looking at the development's potential effects on the marine ecology within which the proposed EOWDC is located.

The majority of the site is covered by fine well sorted sands and fine muddy sands. The most common species at the site are worms and shellfish. On the sea bed brittle stars, brown shrimp and swimming crabs are common whilst fish species in the area are predominantly made up of plaice, dab, hooknose and whiting.

Impacts to marine ecology have been assessed as being negligible to minor with the exception of the worst case impact from construction noise upon fish which is considered to be of minor to possibly moderate significance.

2. Mandatory Actions

Obligations from the European Offshore Wind Deployment Centre Environmental Statement 2010 are listed below.

Table 4.1 Obligations out lined in ES

Phase	Document	Chapter	Potential Impact	Obligation
Construction	Marine Ecology EIA	Chapter 9	Habitat Loss	Good construction practices would be discussed with contractors and could include backfilling trenches (natural backfilling of the subsea trenches may take place) to just below the adjacent beach surface level to allow natural accretion to fill the upper surface.
Construction	Marine Ecology EIA	Chapter 9	Underwater Noise and Vibration on Fish and Shellfish	Soft-start procedure.

Operation	Marine Ecology EIA	Chapter 9	Impacts to fish and benthos resulting from Electromagnetic Fields.	Industry standards and best practice arising out of ongoing research work would be adopted for the EOWDC development where practicable.

Any obligations outlined in the Section 36 Consent and Marine Licence would be listed below.

Table 4.2 Obligations outlined in Section 36 Consent and/ or Marine Licence

Phase	**Document**	**Chapter**	**Potential Impact**	**Obligation**

3. Monitoring / Survey Requirements

Monitoring will be agreed with the relevant statutory authorities.

4. Further Information

None at the time of writing.

OUTLINE BRIEFING NOTE 5: IN-AIR NOISE

Contents:

1. Background and Context

Background noise measurements and wind speeds were measured on site over a period of 3 weeks. Consultation was carried out with the local authorities and key guidance documents were also used for the assessment.

The noise impact from the construction, operation and decommissioning of the proposed EOWDC on residential properties was assessed using suggested national limits (ETSU guidelines) as well as more stringent local noise limits.

The operational noise was assessed as being of negligible significance. For the noise associated with the construction of the proposed EOWDC it is anticipated that the impact during the day will be of minor significance. For night time hours mitigation suggests that certain construction activities are not carried out during this time, this resulting in a negligible significance.

2. Mandatory Actions

Obligations from the European Offshore Wind Deployment Centre Environmental Statement 2010 are listed below.

Table 5.1 Obligations out lined in proposed EOWDC ES

Phase	Document	Chapter	Potential Impact	Obligation
All	In-Air Noise EIA	Chapter 24	Noise impacts to local residents	Adherence to noise levels set by ETSU.
Construction	In-Air Noise EIA	Chapter 24	Sleep disturbance during piling night	No monopiles of 8.5 m diameter to be installed at night.
Construction	In-Air Noise EIA	Chapter 24	Stress, annoyance during piling daytime	Screens and good information policy.

Any obligations outlined in the Section 36 Consent and Marine Licence would be listed below.

Table 5.2 Obligations outlined in Section 36 Consent and/ or Marine Licence

Phase	Document	Chapter	Potential Impact	Obligation

3. Monitoring / Survey Requirements

Monitoring will be required to determine real sound levels and check efficiency of potential mitigation measures.

4. Further Information

None at the time of writing.

OUTLINE BRIEFING NOTE 6: OFFSHORE ARCHAEOLOGY

Contents:

1. Background and Context

The archaeological geophysical review identified several anomalies which may be man-made or natural features. Of these a potential impact has been predicted for one unidentified wreck which lies in close proximity to Wind Turbine 8.

2. Mandatory Actions

Obligations from the European Offshore Wind Deployment Centre Environmental Statement 2010 are listed below.

Table 6.1 Obligations out lined in proposed EOWDC ES

Phase	Document	Chapter	Potential Impact	Obligation
Construction	Offshore Archaeology EIA	Chapter 18	Damage to post-glacial submerged landscape features/ Known wreck sites	Avoidance, Reporting protocol.
Construction/ Operation/ Decommissioning	Offshore Archaeology EIA	Chapter 18	Damage to known wreck sites	Avoidance, Research, Reporting protocol.
Construction	Offshore Archaeology EIA	Chapter 18	Damage to prehistoric sites and finds	Reporting protocol.
Construction	Offshore Archaeology EIA	Chapter 18	Damage to unknown wreck sites	Reporting protocol.
Construction	Offshore Archaeology EIA	Chapter 18	Damage to unknown aircraft crash sites	Reporting protocol.

Any obligations outlined in the Section 36 Consent and Marine Licence would be listed below.

Table 6.2 Obligations outlined in Section 36 Consent and/ or Marine Licence

Phase	Document	Chapter	Potential Impact	Obligation

3. Monitoring / Survey Requirements

Monitoring could include:

Geophysical survey/ Remotely Operated Underwater Vehicle/ Finds Reporting Protocol

4. Further Information

None at the time of writing.

OUTLINE BRIEFING NOTE 7: COASTAL PROCESSES

Contents:

1. Background and Context

The coastal processes assessment included consideration of the potential changes to geology, waves, currents, sediment, seabed features and water quality.

It is shown that the majority of potential impacts can be considered of negligible significance. The exception is that of scour which, in the absence of scour protection measures, can be considered as minor significance.

2. Mandatory Actions

Obligations from the European Offshore Wind Deployment Centre Environmental Statement 2010 are listed below.

Table 7.1 Obligations out lined in proposed EOWDC ES

Phase	Document	Chapter	Potential Impact	Obligation
Operational	Coastal Processes EIA	Chapter 8	Scour around foundation base (and resulting habitat loss)	As a matter of good practice, the project's detailed design would consider whether scour protection can reasonably be provided to further reduce this impact.

Any obligations outlined in the Section 36 Consent and Marine Licence would be listed below.

Table 7.2 Obligations outlined in Section 36 Consent and/ or Marine Licence

Phase	Document	Chapter	Potential Impact	Obligation

3. Monitoring / Survey Requirements

It is not considered essential to include scour monitoring as an integral aspect of post-construction monitoring although it could be considered as an additional aspect.

Appropriate research studies will be implemented if novel techniques are used for cable installation where there is an absence of any previous research.

4. Further Information

None at the time of writing.

OUTLINE BRIEFING NOTE 8: COMMERCIAL FISHERIES

Contents:

1. Background and Context

Commercial fishing activities in the area surrounding the proposed EOWDC are considered to be at relatively low levels. Potting for crab and lobsters; trawling for whitefish; and dredging for scallops account for the majority of the activity.

Given the limited number of turbines proposed, the small area of the site and the low level of fishing activity within it, the overall impacts on commercial fishing are expected to be negligible, although for a small number of local vessels, the potential impacts may be of minor significance.

2. Mandatory Actions

Obligations from the European Offshore Wind Deployment Centre Environmental Statement 2010 are listed below.

Table 8.1 Obligations out lined in proposed EOWDC ES

Phase	Document	Chapter	Potential Impact	Obligation
Construction and decommissioning	Commercial Fisheries EIA	Chapter 21	Adverse impacts on commercially exploited species	Use of appropriate engineering techniques, eg soft start.
Construction and decommissioning	Commercial Fisheries EIA	Chapter 21	Complete loss of, or restricted access to traditional fishing grounds	Effective, on-going liaison.
Construction, operational and, decommissioning	Commercial Fisheries EIA	Chapter 21	Safety issues for fishing vessels	Implementation and adherence to standard offshore safety procedures. Involvement of the SFF for liaison and information distribution.
Construction, operational and decommissioning	Commercial Fisheries EIA	Chapter 21	Interference to fishing activities	Construction/ maintenance vessels using existing shipping routes. On-going liaison informing skippers of construction/

				maintenance vessels schedules and routes.
Construction and decommissioning	Commercial Fisheries EIA	Chapter 21	Increased steaming times to fishing grounds	Transitory, short term exclusion areas around construction activities within the site. Limited numbers of potentially impacted vessels.
Construction and decommissioning	Commercial Fisheries EIA	Chapter 21	Presence of seabed obstacles and obstructions	Contractors are required by contract to report and recover any accidentally dropped objects. Seabed obstructions and spoils identified during post-construction monitoring, which might represent a hazard to fishing, would be rectified. Any scour protection rock placement would be adjacent to wind turbine bases.
Operational	Commercial Fisheries EIA	Chapter 21	Damage to fishing gear/vessels from exposed cables	Cable burial to at least 0.6 m depth.
Operational	Commercial Fisheries EIA	Chapter 21	Damage to fishing gear/vessels from exposed cables	Implementation and adherence to standard offshore safety procedures.
Operational	Commercial Fisheries EIA	Chapter 21	Damage to fishing gear/vessels from exposed cables	Cable route surveys.
Operational	Commercial Fisheries EIA	Chapter 21	Damage to fishing gear/vessels from exposed cables	Temporary exclusion zones until issues are rectified.

Any obligations outlined in the Section 36 Consent and Marine Licence would be listed below.

Table 8.2 Obligations outlined in Section 36 Consent and/ or Marine Licence

Phase	Document	Chapter	Potential Impact	Obligation

3. Monitoring / Survey Requirements

None at the time of writing.

4. Further Information

None at the time of writing.

OUTLINE BRIEFING NOTE 9: SALMON AND SEA TROUT

Contents:

1. Background and Context

Scottish salmon populations are recognised as being of national and international importance. In addition to their ecological value, salmon and sea trout are species of importance from a socioeconomic perspective.

The majority of impacts have been assessed as having negligible impact although it is possible that construction activities could have a negligible to minor impact following mitigation. Mitigation is likely to include specific scheduling of construction periods so that peak times of salmon entering or exiting local rivers are not affected. Further consultation will be held with statutory consultees and salmon fisheries boards when construction methods and timing are considered further.

2. Mandatory Actions

Obligations from the European Offshore Wind Deployment Centre Environmental Statement 2010 are listed below.

Table 9.1 Obligations out lined in proposed EOWDC ES

Phase	Document	Chapter	Potential Impact	Obligation
Construction	Salmon and Sea Trout EIA	Chapter 22	Noise, Direct Impact	Soft-start piling.
Construction	Salmon and Sea Trout EIA	Chapter 22	Noise, Disturbance/ Delay/Barrier to Migration	Mitigation to be agreed if required.

Any obligations outlined in the Section 36 Consent and Marine Licence would be listed below.

Table 9.2 Obligations outlined in Section 36 Consent and/ or Marine Licence

Phase	Document	Chapter	Potential Impact	Obligation

3. Monitoring / Survey Requirements

Appropriate and relevant monitoring will be assessed through discussion with relevant stakeholders and regulators.

4. Further Information

None at the time of writing.

OUTLINE BRIEFING NOTE 10: COMMERCIAL SHIPPING AND NAVIGATION

Contents:

1. Background and Context

A Navigational Risk Assessment (NRA) has been carried out for the proposed EOWDC. A number of potential impacts were identified, the majority of these are considered to be negligible or to cause no impact. Compared to the marine accident risk levels in the UK, the increase in risk to both people and the environment caused by the proposed EOWDC is low.

Extensive consultation with Aberdeen Harbour Board (AHB) and key consultees has resulted in a number of changes being made to the site layout. Recent consultation has indicated that the current site is acceptable and all hazards are identified to be low.

2. Mandatory Actions

Obligations from the European Offshore Wind Deployment Centre Environmental Statement 2010 are listed below. Table 12.1 below summarises the main risk mitigation measures identified within the NRA, it should be noted that discussions on other measures will continue both pre- and post-construction and during the life of the project with the MCA, Aberdeen Harbour Board and other relevant stakeholders.

Table 10.1 Obligations out lined in proposed EOWDC ES

Phase	Document	Chapter	Potential Impact	Obligation
Construction	Project Description	Chapter 3	Health and Safety/ Navigation	The EOWDC would be designed and constructed to satisfy the requirements of the Civil Aviation Authority (CAA) and the Northern Lighthouse Board (NLB).
Construction	Project Description	Chapter 3	Safety and Navigation	The construction area will be depicted on Admiralty Charts by the UK Hydrographic Office. Information pertaining to construction would be disseminated through the Notice to Mariners procedure together with regular communication with local and regional stakeholders.

Construction	Project Description	Chapter 3		The construction area and incomplete structures would be lit and marked in accordance with the protocol recommended by THLS.
All	Navigational Risk Assessment	Appendix 15.1	Safety and Navigation	Marked on Admiralty Charts: The EOWDC would be charted by the UK Hydrographic Office using the magenta wind turbine tower chart symbol found in publication “NP 5011 - Symbols and Abbreviations used in Admiralty Charts”. Submarine cables associated with the project will also be charted on the appropriate scale charts.
All	Navigational Risk Assessment	Appendix 15.1		Information Circulation: Appropriate liaison to ensure information on the wind farm and special activitiesis circulated in Notices to Mariners, Navigation Information Broadcasts and other appropriate media.
All	Navigational Risk Assessment	Appendix 15.1		Marking and Lighting: Structures to be marked and lit in-line with NLB and IALA guidance.
All	Navigational Risk Assessment	Appendix 15.1		Wind Turbine Air Draught: Lowest point of rotor sweep at least 22 m above Mean High Water Springs as per RYA and MCA recommendations.
All	Navigational Risk Assessment	Appendix 15.1		Cable Protection: Cables to be buried to suitable depth based on cable protection study taking into account fishing and anchoring practices in Aberdeen Bay(but to at least 0.6 m). Periodic inspection of the cable to ensure it remains buried. Positions of cable routes notified to Kingfisher Information Services (KIS) for inclusion in cable awareness charts and plotters for the fishing industry.
All	Navigational Risk Assessment	Appendix 15.1		Compliance with MCA’s Marine Guidance Notice (MGN) 371 including Annex 5: Annex 5 specifies “Standards and procedures for generator shutdown and other operational requirements in the event of a

				search and rescue, counter pollution or salvage incident in or around an Offshore Renewable Energy Installation.”
All	Navigational Risk Assessment	Appendix 15.1		Formulation of an Emergency Response Cooperation Plan (ERCoP) as per MCA Template: AOWFL will use the draft template created by the MCA to formulate an emergency response plan and site Safety Management Systems, in consultation with the MCA.

Any obligations outlined in the Section 36 Consent and Marine Licence would be listed below.

Table 10.2 Obligations outlined in Section 36 Consent and/ or Marine Licence

Phase	Document	Chapter	Potential Impact	Obligation

3. Monitoring / Survey Requirements

The Navigational Risk Assessment will be reviewed as required. The health and safety plan will include an incident/accident reporting system which will allow incidents and near misses to be recorded and reviewed to monitor the effectiveness of the risk control measures in place at the site. In addition to this any information gleaned from near misses/accidents at other offshore wind farm sites will be considered with respect to the control measures applied at the proposed EOWDC.

Whilst no radar monitoring of vessel movements has been proposed for the site, Automatic Identification System monitoring is being considered which can be used to monitor and record the movements of vessels around the proposed EOWDC site and associated export cables to shore, as well as company vessels working at the site.

4. Further Information

None at the time of writing.

PART 3

8 OUTLINE CONSTRUCTION METHOD STATEMENTS

8.1 What are Construction Method Statements

Construction method statements are considered an important part of engineering best practice by making sure that safety, timetable, environmental conditions and commitments for mitigation are integrated into the construction process. Information on construction method statement procedures normally forms part of the tender process and often acts to distinguish competitive bids (that is, demonstration of an understanding of the environmental objectives becomes a criterion in tender evaluation). In this regard, it is normal practice for the environmental practitioner to set the objectives, but for the design and construction engineers/contractors to meet those objectives in the most efficient and cost-effective manner.

It is considered impracticable and contrary to the objectives of continuous improvement to produce detailed construction method statements prior to consent approval.

8.2 Outline Construction Method Statements

Outline construction method statements would be included in the tender package to inform construction contractors and their engineers as to the requirements of the tender, and to enable them to develop the construction method statements.

Accordingly, the method statements do not provide:

- detailed final design
- detailed site specific construction methodologies

The method statements will be produced to recognise that the different construction activities would require different construction methods, all of which may vary due to the relative site sensitivities. Examples of likely outline construction method statements are as follows:

- OCMS – Introduction
- OCMS 01 - Temporary Compound
- OCMS 02 - Cable Installation
- OCMS 03 - Waste Management
- OCMS 04 - Wind Turbine Construction
- OCMS 05 – Traffic (Vessel) Management
- OCMS 06 – Scour Protection
- OCMS 07 – Foundation Installation
- OCMS 08 – Commissioning
- OCMS 09 – Connection
- OCMS 10 – Pre-Installation Survey

- OCMS 11 – Post-Installation Survey
- OCMS 12 – Landfall Construction

8.3 Other Outline Method Statements

Other outline method statements would include:

- Decommissioning

It is unlikely that operations and maintenance would have specific method statements. An Operations and Maintenance Plan would be in place to ensure adherence to environmental, health and safety policies and legislation.

1 INTRODUCTION

The purpose of this document is to provide a summary of the information required to inform any possible Habitats Regulations Appraisal that may be required to be undertaken by the competent authority with respect to the proposed European Offshore Wind Deployment Centre (EOWDC) as required under the EU Habitats and Birds Directives.

The document aims to identify all qualifying species or habitats that, based on data collected at the proposed development site, have the potential to be impacted. A high level assessment on the risk of a possible adverse effect has been undertaken and a conclusion made on the level of risk to a qualifying species or habitat.

This assessment is based on site specific data collected from the surveys undertaken so far and, where appropriate, relevant data from other offshore wind farms. The aim of this assessment is to identify the species or habitats that may be required to be assessed by the competent authority as part of a Habitats Regulations Appraisal and potential future Appropriate Assessments and also consider the risk of a potential adverse effect occurring to the sites' qualifying species of habitats

This assessment takes into consideration comments received in response to the EOWDC Scoping Opinion request from SNH to Marine Scotland dated 29 September 2010 (SNH 2010) and further response from Marine Scotland to the *Assessment against the Habitats Regulations and cumulative impacts screening* (Genesis 2011; Marine Scotland 2011).

It is recognised that further bird and marine mammal data currently being collected may also be used to inform a future HRA. When the data become available it will be reviewed and used, if required, to update this document.

2 QUALIFYING SITES

Under Article 6 of the Habitats Directive and Regulation 45 of the Conservation (Natural Habitats etc) Regulations 1994 (as amended) the competent authority is required to assess whether or not a plan or programme will adversely affect the integrity of a Special Protection Area (SPA) or Special Area of Conservation (SAC).

There are a number of SPAs and SACs that have the potential to be impacted by the proposed offshore wind farm. The scope of this assessment is based on the Natura 2000 sites identified within the scoping document for which there is some evidence that the qualifying species could be present in the area of the proposed EOWDC and subsequent advice from SNH and Marine Scotland (SNH 2010; Marine Scotland 2011).

Special Protection Areas

Eleven SPAs have been identified as having qualifying species that have the potential to be impacted by the proposed offshore wind farm and an assessment has been made for each of the species cited against the site's Conservation Objectives (Appendix A). The assessment is based on whether the species is at risk of:

Collision – The risk of collision depends on a number of variables, in particular species specific near and far field avoidance rates, flight heights, speed of flight, frequency of movements in or near to the turbines as well as the size and location of the turbines themselves. Additional factors such as weather and species' behaviour can also affect the risk of collision.

Displacement – Evidence from existing offshore wind farms have identified that some species of seabird may avoid entering wind farms and therefore be displaced from areas that they would otherwise utilise. The level of displacement is very species specific and the duration of displacement may vary across species, with some species avoiding wind farms immediately post-construction and returning to the area after a period of time and other species showing little or no evidence of returning to the wind farm area post construction. Displacement from an area may cause reduced foraging areas, increasing inter and intra specific competition and consequently lowering survival rates. Secondary impacts such as reducing prey availability, i.e. less fish in an area during construction, may also cause displacement as birds forage elsewhere for food.

Barrier effects – In order to avoid flying through wind farms many species have been recorded flying around or over them and consequently may have to fly further than prior to the construction of the wind farm. This increase in flying distance may cause an increase in energy expenditure, which could have a detrimental effect on the fitness of the individual and reduce survival or fecundity rates. This is of particular concern should there be regular, daily, movements around a wind farm, i.e. to and from foraging or roosting areas.

In-combination impacts – in-combination impacts are assessed under the Conservation (Natural Habitats & c.) Regulations 1994 (as amended). Impacts include those arising from existing and reasonably foreseeable activities including:

- Shipping
- Fishing
- Aggregates
- Dredging
- Oil and gas installations
- Renewables

In-combination impacts relates specifically to those from other plans or projects on European Sites.

Special Areas of Conservation

Eight SACs have been identified that have qualifying species or habitats that may have the potential to be impacted by the proposed development. This assessment has considered each of the species or habitats cited for each site and their Conservation Objectives. The assessment is based on potential risks arising from:

Habitat disturbance – The qualifying habitats may be sensitive to physical impacts arising from the proposed offshore wind farm, in particular direct physical impacts caused by construction or less direct impacts caused by reduced or increased sediment loads.

Displacement – Species listed within the relevant SACs may be impacted by noise or other activities that may cause an increase in mortality, temporary injury, or displacement away from the area.

The following assessment attempts to assess the potential impacts arising from the proposed EOWDC against the qualifying species and habitats. For species or habitats where no potential for a likely significant effect has been identified no further assessment has been undertaken.

3 PROJECT DESCRIPTION

A detailed description of the proposed EOWDC project is presented in Chapter 3 of the Environmental Statement.

The proposed development is approximately 2 km from the coastline at its closest point in Aberdeen Bay (Figure 3-1). The total area of the turbine layout is 4.3 km^2 within the lease boundary area of 20 km^2. Water depth ranges from between 20 m and 30 m Lowest Astronomical Tide (LAT). The key project characteristic are presented in Table 3-1.

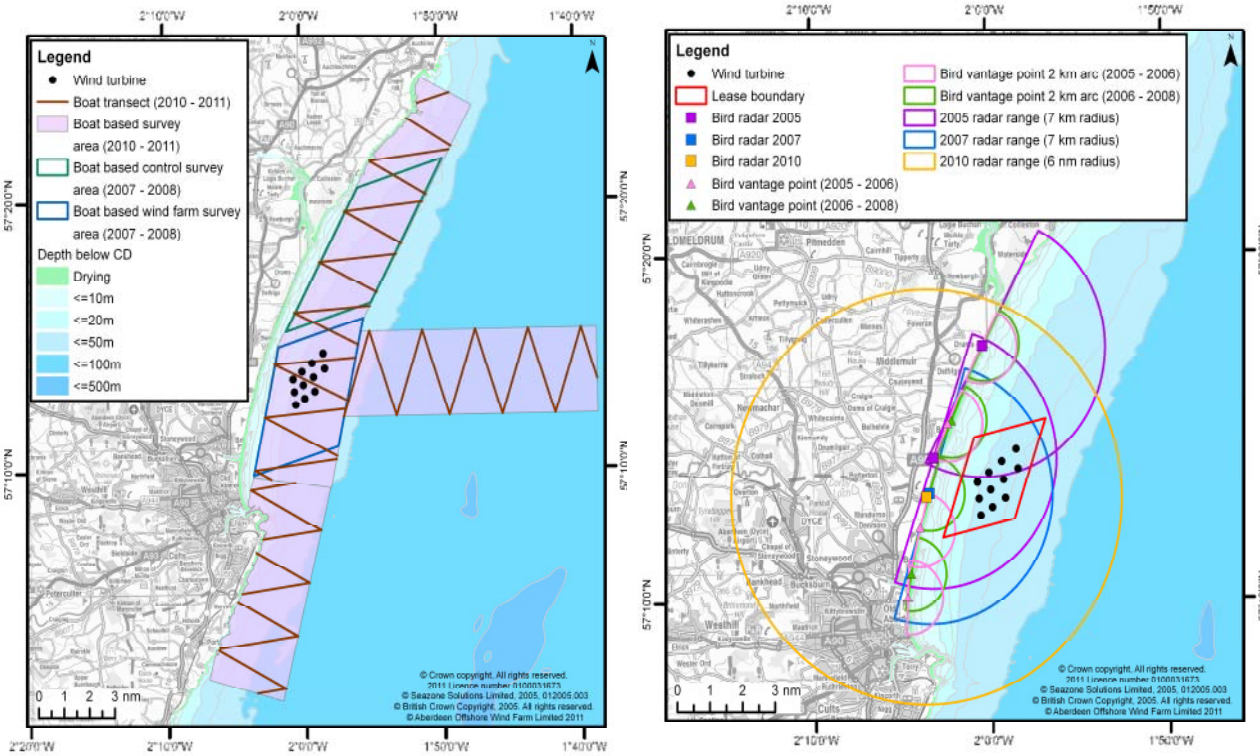

Figure 3-1: Location of proposed EOWDC and bird and marine mammal surveys undertaken

It is proposed that the project may be constructed in two phases. The actual deployment of wind turbines is at this stage not known and the numbers deployed in 2013 and 2014 are variable but for the purposes of the EOWDC assessment, the following has been assumed for the phasing

2013 - 4 wind turbines installed
2014 - 7 wind turbines installed

Table 3-1: key project characteristics

Key Project Characteristics	
Maximum Capacity	100 MW
Maximum Number of Wind Turbines	11
Lease Boundary Area	20 km^2
Distance to Shore	2 km
Water Depth Across Wind Turbine Locations	20 – 30 m
Individual Wind Turbine Capacity	4 to 10 MW
Maximum Rotor Diameter above LAT	150 m
Maximum Hub Height above LAT	120 m
Maximum Tip Height above LAT	195 m
Minimum Clearance Above Sea Level	22 m
Indicative Spacing between Wind Turbines	Between 790 m and 1,050 m
Foundation Types	Potential foundations include monopiles, jackets, tripods, gravity base structure, suction caisson/ buckets
Inter-array Cables	Maximum number of 12. Total length of 13 km.
Export Cables	Maximum number of 4 will run from the wind turbine array back to Mean High Water Spring (MHWS) Total length of 26 km

4 SCOPE OF ASSESSMENT

Likely species present

Which species of bird are known to occur or are likely to occur in the area of the proposed development?

In order to undertake this initial step a review has been undertaken of the site specific data collected at the proposed EOWDC location in Aberdeen Bay from both land and boat based surveys since 2005 and aerial surveys undertaken by the JNCC in 2005 and 2006.

Boat based survey data were used from surveys undertaken between January 2007 and July 2008 and reported in a number of reports:

- Monthly survey reports for February 2007 – April 2008
- 6-month interim report for February 2007 – July 2007
- 1st year survey report for February 2007 – January 2008
- Bird boat survey raw data for February 2007 – July 2008

Land based surveys from four vantage points across Aberdeen Bay were undertaken between April 2006 and March 2008. The surveys provided good coverage for the near-shore waters particularly areas inaccessible by boat due to shallow water depth. A number of reports presenting the results of the Vantage Point (VP) surveys have been produced:

- Monthly survey reports for April 2007 – March 2008.
- Six-month reports completed for
  - April –September 2006
  - October 2006 – March 2007
  - April – September 2007
  - October 2007 – March 2008
- VP data for March 2005 – October 2005.
- VP data for April 2006 – March 2008.

Radar Surveys have been undertaken on three occasions from two sites within Aberdeen Bay between 2005 and 2010. A total of ten days of radar surveys were undertaken in 2005 and fifteen in 2007 and further five days in 2010.

In April 2005 a study using both s-band and x-band radar was undertaken at two locations within Aberdeen Bay: Drums and East Hatton. A further fifteen day study in April 2007 was undertaken at Blackdog, just south of Drums. In 2010 a further survey was undertaken during April aimed to focus efforts on recording pink-footed goose migration. The study also recorded all other species observed during the study.

In addition to surveys undertaken specifically to obtain information relevant to the proposed project other ornithological surveys have been undertaken in Aberdeen Bay, the results from which have been used in this report. In particular, the results of three aerial bird surveys undertaken by the JNCC between December 2005 and May 2006. It is recognised that there are other potential sources of data including local bird reports or Wetland Bird Survey (WeBS) counts (Calbrade *et al.* 2010; NESBR). For the purposes of this assessment these data sources have been used for reference purposes. Species recorded in Aberdeen Bay from site specific surveys are presented in (Table 4-1).

For further detailed information on the species recorded within Aberdeen Bay the Ornithological Baseline and Impact Assessment should be referred to (Appendix 10.1 to the Environmental Statement).

Potential sensitivity to offshore wind farms

There are a number of publications presenting the likely sensitivity of bird species to offshore wind farms (e.g. Zucco *et al.* 2006; RSPB 2010) and there is general agreement between the various publications as to the main potential risks to birds and individual species sensitivities from wind farms. For the purposes of this assessment the report published by the RSPB in 2010 has been used to provide the relevant information on species' sensitivities. For species that were not included in the RSPB publication a score has been given based on existing data from offshore wind farms, e.g. Pettersson (2005); Petersen *et al*. (2006).

The potential sensitivities to wind farm developments based on the review by Langston (2010) and other offshore wind farm developments are presented in Table 4-1 for the species recorded in Aberdeen Bay from site specific surveys,.

Table 4-1: Species recorded in Aberdeen Bay from site specific surveys and their potential vulnerability

Little auk	*	**	**	**	N	W/P

Note – *** = high sensitivity, ** = moderate sensitivity, * = low sensitivity (Langston 2010).

High/mod/low designations have been made based on published data from offshore wind farms either for that particular species or similar 'sister' species.

5 SPAS

There is no clear guidance on how to define the extent and scope of a seabird population that could potentially be impacted by a proposed offshore wind farm. King *et al*. (2009) suggests that regional populations should be the Round 2 strategic areas (Renewable Energy Zones) or the Round 3 zones. However, as the proposed EOWDC is not in such an area there is no clear guidance as to how to identify the regional population for this assessment.

The scope of the review undertaken for this document was based on all coastal SPAs between Troup, Pennan and Lions Heads SPA, on the Moray Firth and the Forth Islands SPA to the south; covering approximately 300 km of coastline. This covers a greater length shoreline than any of the Round 2 Renewable Energy Zones and a significant proportion of eastern Scotland's coastline. Consequently, it covers an area greater than suggested as guidance within the COWRIE report (King *et al*. 2009); therefore ensuring that a representative area is covered.

All coastal or near coastal SPAs were identified using information from the SNH and JNCC websites (JNCC 2011, SNH 2011). A total of 11 SPAs have been identified as having qualifying species that are at potential risk of an adverse effect from the proposed project (Figure 5-1).

:

- Buchan Ness to Collieston SPA
- Fair Isle SPA
- Firth of Forth SPA
- Firth of Tay & Eden Estuary SPA
- Forth Islands SPA
- Fowlsheugh SPA
- Loch of Skene SPA
- Loch of Strathbeg SPA
- Montrose Basin SPA
- Troup, Pennan and Lion's Heads SPA
- Ythan Estuary, Sands of Forvie and Miekle Loch SPA

Further details on each of the SPAs including their qualifying species and Conservation Objectives are presented in Appendix A. Not all those species listed within the site designations have been recorded within the area of the proposed EOWDC and consequently not all qualifying species are at risk of a potential impact.

Table 5-1 links the species that have been recorded within the proposed EOWDC area (Table 4-1) with the relevant SPAs (Appendix A). In addition, the table presents the distance each SPA is from the proposed EOWDC and the population of each species at the time of designation and when available, more recent populations.

Potential for in-combination impacts

The consideration of potential in-combination impacts is of key importance when undertaking a Habitats Regulations Appraisal.

Having identified the species of seabird occurring within the proposed EOWDC area and the relevant SPAs for which the species may be a qualifying feature the next step is identify the potential for in-combination impacts.

EC Guidance (EC 2000) advises that '*when determining likely significant effects, the combination of other plans or projects should also be considered to take account of cumulative impacts. It would seem appropriate to restrict the combination provision to other plans or projects, which have been actually proposed*.

Guidance produced by COWRIE (King, *et al*. 2009) proposes that assessments should include:

- Projects that have been consented but which are yet to be constructed.
- Projects for which an application has been made,
- Projects that are reasonably foreseeable – i.e. those for which an application has yet to be made but where such application is known to be imminent.

Activities identified that may cause a potential in-combination impact include:

- Shipping
- Fishing
- Aggregates
- Dredging
- Oil and Gas
- Renewable Energy

Shipping and Fishing

Impacts from exisiting shipping and fishing activities are 'unregulated' activities, in that they do not require a specific permit before being undertaken. They are ongoing and impacts arising from them are reflected in the baseline environmental data. Currently, approximately 16,000 vessel movements take place in and out of Aberdeen harbour each year and there are no known planned increases in either shipping of fishing in the area. EC Guidance indicates that completed plans and projects are excluded from assessment requirements of Article 6(3) unless the continuing effects on the site point to a pattern of progressive loss of site integrity, which is not the case in the area of the proposed development with regards to either shipping or fishing activities. Consequently, they have not been considered as part of any in-combination impact assessment (EC 2000).

Aggregates

There are no aggregate activities in the vicinty of the proposed EOWDC.

Dredging

There are no dredging deposit sites within Aberdeen Bay. Dredging associated with Aberdeen Harbour can occasionally occur, although it is infrequent. There are currently plans to undertake dredging in Aberdeen Harbour during 2012. This will be completed prior to any proposed construction activites associated with the proposed EOWDC. Consequenlty, there will no in-combiantion impacts associated with dredging.

Oil and Gas

Aside from shipping activites associated with the oil and gas industry there are are no oil and gas acitivities in the wider Aberdeen Bay area.

Renewable Energy Projects

There are currently five proposed offshore wind farms in the Firth of Forth and Moray Firth. The Beatrice and Moray Firth Offshore Wind Farms are in the Moray Firth; approximately 150 km away and Neart na Gaiothe and Inch Cape and Firth of Forth are in the Firth of Forth, approximately 70 km to the south of the proposed EOWDC (Table 5-2 Figure 3-1). There is currenlty one operational demonstrator project in the Moary Firth, the Beatrice Demonstrator.

Table 5-2: Proposed offshore wind energy projects that may have potential in-combination impacts

Name of development	Developer	MW	Possible / Actual number of Turbines	Project timeframe construction
The Beatrice Demonstrator	Joint Venture Talisman and Scottish and Southern Energy	10	2	Installed operational
The Moray Firth Eastern Development	Moray Offshore Renewables Ltd	1,300	67	Construction starts 2015
The Moray Firth Western Development			Not yet known	Unknown >2015 (EIA commences 2013)
Beatrice	Sea Energy Renewables Ltd & Scottish and Southern Energy	920	184	2014
Firth of Forth: Phase 1	SeaGreen	1,075	215	2015
Firth of Forth: Phase 2		1,435	287	Unknown >2015
Firth of Forth: Phase 3		955	191	Unknown >2015
Neart na Gaoithe	Mainstream Renewable Power	420	130	2014
Inch Cape	SeaEnergy	905	181	2015

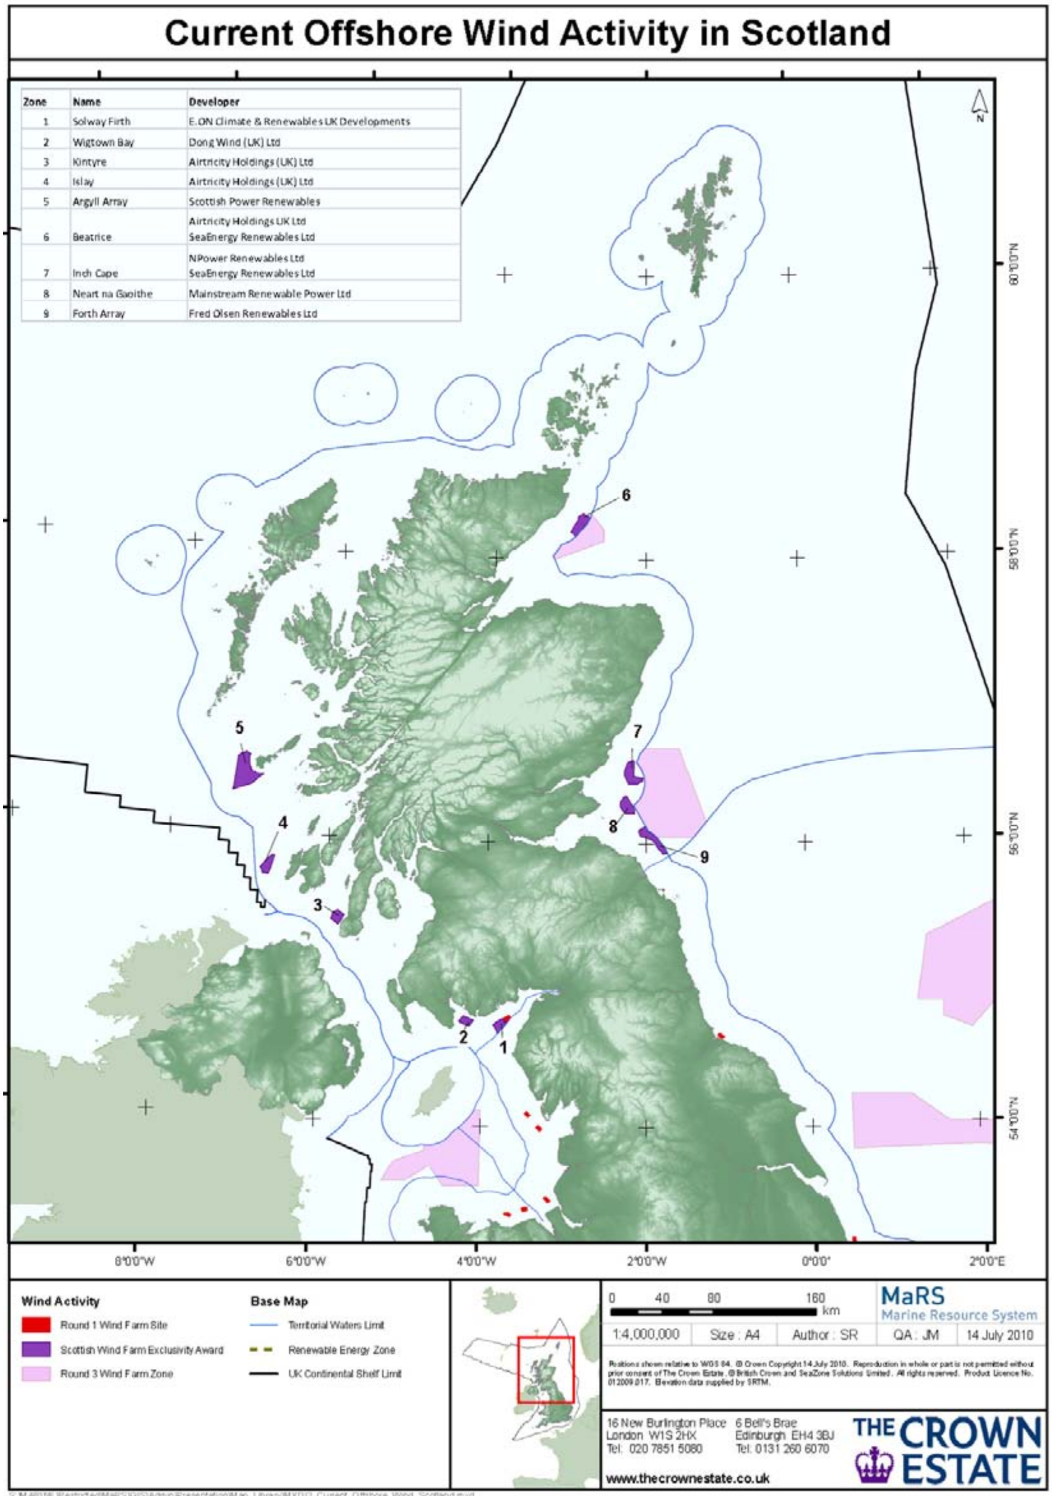

Figure 5-2: Map showing the nine initial proposed offshore wind farms in Scottish Territorial Waters

Based on the known foraging ranges of breeding seabirds occuring in the proposed EOWDC (Roos 2010, Thaxter *et al.* 2010) it has been identifed that there is the potential for an in-combination impact on the following plans or projects (Table 5-2):

- Beatrice Demonstrator Project (operational),
- The Beatrice Offshore Wind Farm (proposed),
- The Moray Firth Offshore Wind Farm (proposed),
- Inch Cape Offshore Wind farm (proposed),
- Firth of Forth Offshore Wind Farm (proposed),
- Neart na Gaoithe Offshore Wind Farm (proposed).

In order to undertake an in-combination impact assessment it is necessary to know details of the proposed plans. Currently, apart from an approximate number of turbines there is little information for any of the proposed developments and no data are available on the location or type of turbines planned to be installed nor, importantly, are there any survey data available to identify which species of bird may be present at each of the sites and in what numbers. Consequently, it is not possible to undertake a detailed in-combination impact assessment that includes the proposed renewable energy developments.

Identifying potential for interaction

Having identified the relevant SPAs and qualifying species an assessment has been undertaken to identify which species have the potential to interact with the proposed EOWDC either alone or in-combination with other plans or projects (Table 5-3). For breeding species the assessment is based on the maximum reported foraging ranges for each species and where more than one distance is available the greatest distance has been selected (Roos 2010, Thaxter *et al*. 2010). For non-breeding birds that are listed as qualifying species for an SPA they are all considered to be at potential risk but the level of significance is based on the number of birds recorded within the proposed development area and their behaviour.

Table 5-3: Breeding seabirds associated with a relevant SPA for which potential impacts could occur either alone or in-combination

Breeding bird species known to frequent area of development	Known foraging range from breeding colony (km)		Potential overlap with SPA colony	Distance from proposed EOWDC (km)	Potential overlap with proposed EOWDC (based on max foraging distance)	Potential overlap with other offshore wind farms and proposed EOWDC
	Max	Mean Max [-1]				
Common eider	100	38.33	Ythan Estuary	7.2	Y	No
			Montrose Basin	61	Y	Firth of Forth, Neart na Gaoithe, Inch Cape
			Firth of Tay & Eden Estuary	96	Y	Firth of Forth, Neart na Gaoithe, Inch Cape
			Firth of Forth SPA	134	N	No
Fulmar	664	311	Buchan Ness – Collieston,	9.5	Y	Moray Firth, Firth of Forth, Beatrice, Neart na Gaoithe, Inch Cape
			Fowlsheugh	31.1	Y	Moray Firth, Firth of Forth, Beatrice, Neart na Gaoithe, Inch Cape
			Forth Islands	124.4	Y	Moray Firth, Firth of Forth, Beatrice, Neart na Gaoithe, Inch Cape
			Troup, Pennan and Lions Head	74.3	Y	Moray Firth, Firth of Forth, Beatrice, Neart na Gaoithe, Inch Cape
			Orkney, Shetland, West coast of Scotland, North Sea	>260	Y	All UK offshore wind farms
Gannet	640	308	Forth Islands	124.4	Y	Moray Firth, Firth of Forth, Beatrice, Neart na Gaoithe, Inch Cape. All North Sea offshore wind farms

Breeding bird species known to frequent area of development	Known foraging range from breeding colony (km)		Potential overlap with SPA colony	Distance from proposed EOWDC (km)	Potential overlap with proposed EOWDC (based on max foraging distance)	Potential overlap with other offshore wind farms and proposed EOWDC
	Max	Mean Max [-1]				
			Fair Isle	260	Y	Moray Firth, Firth of Forth, Beatrice, Neart na Gaoithe, Inch Cape. All North Sea offshore wind farms North of the Wash
Cormorant	35	25	Forth Islands	124.4	N	No
European Shag	17	16	Buchan Ness to Collieston	9.5	Y	No
			Forth Islands	124.4	N	No
Lesser black-backed gull	180	132	Forth Islands	124.4	Y	Firth of Forth, Neart na Gaoithe, Inch Cape
Herring gull	92	61	Buchan Ness to Collieston	9.5	Y	No
			Fowlsheugh	31.1	Y	Firth of Forth, Neart na Gaoithe, Inch Cape
			Forth Islands	124.4	N	No
Kittiwake	83	66	Buchan Ness to Collieston	9.5	Y	No
			Fowlsheugh	31.1	Y	Firth of Forth
			Forth Islands	124.4	N	No
			Troup, Pennan and Lions Head	74.3	Y	Moray Firth, Beatrice

Breeding bird species known to frequent area of development	Known foraging range from breeding colony (km)		Potential overlap with SPA colony	Distance from proposed EOWDC (km)	Potential overlap with proposed EOWDC (based on max foraging distance)	Potential overlap with other offshore wind farms and proposed EOWDC
	Max	Mean Max [-1]				
Little tern	11	6	Ythan	7.2	Y	No
			Firth of Tay and Eden Estuary	96	N	No
Sandwich tern	70	42	Ythan	7.2	Y	No
			Loch of Strathbeg	47.6	Y	No
Common tern	37	34	Ythan	7.2	Y	No
			Forth Islands	124.4	N	No
Arctic tern	25	12	Forth Islands	124.4	N	No
Guillemot	135	71	Buchan Ness – Collieston	9.5	Y	Firth of Forth, Neart na Gaoithe, Inch Cape
			Forth Islands	124.4	Y	Firth of Forth, Neart na Gaoithe, Inch Cape
			Fowlsheugh	31.1	Y	Firth of Forth, Neart na Gaoithe, Inch Cape
			Troup, Pennan and Lions Head	74.3	Y	Moray Firth, Beatrice
Razorbill	150	31	Buchan Ness – Collieston	9.5	Y	Firth of Forth, Neart na Gaoithe, Inch Cape
			Fowlsheugh	31.1	Y	Firth of Forth, Neart na Gaoithe, Inch Cape

Breeding bird species known to frequent area of development	Known foraging range from breeding colony (km) Max	Mean Max [1]	Potential overlap with SPA colony	Distance from proposed EOWDC (km)	Potential overlap with proposed EOWDC (based on max foraging distance)	Potential overlap with other offshore wind farms and proposed EOWDC
			Forth Islands	124.4	Y	Firth of Forth, Neart na Gaoithe, Inch Cape
			Troup, Pennan and Lions Head	74.3	Y	Moray Firth, Beatrice
Puffin	200	86	Forth Islands	124.4	Y	Firth of Forth, Neart na Gaoithe, Inch Cape

[1] - Mean Max is the mean foraging distance based on the maximum foraging distances reported from various studies

Based on the above screening assessment, species identified as having a likely potential for an interaction with the proposed EOWDC are further considered in the high level screen assessment in Section **Error! Reference source not found.**. The information presented is a summary of that presented for each species in the Ornithological Baseline and Impact Assessment (Appendix 10.1 of the Environmental Statement) and this should be used in conjunction with the summarised information presented here to further inform any possible future Habitats Regulations Appraisal.

6 SCREENING ASSESSMENT

Whooper swan		Loch of Strathbeg
Population	SPA	203 individuals representing up to 3.7% of the wintering population in Great Britain (5 year peak mean 1991/2 - 1995/6)
	Recent population	333 individuals
Data	Aerial surveys	None
	Boat based (WF)	No sightings
	VP Surveys (Abdn Bay)	No sightings
	Radar	Five at Drums 28 October 2005.
Impact	Collision risk	One sighting of five birds below 20 m. Whooper swans are known to fly at turbine height.
	Displacement	No
	Barrier effect	Unknown
Evidence base	Site specific	Very few whooper swans recorded at proposed EOWDC
	Generic	Good data on flight height and direction from tagging studies (e.g. Griffen, Rees & Hughes 2010)
Evidence of potential impact	No	No evidence from existing wind farms of impacts but there is recognised to be potential risk of collisions.
Potential to assess	Yes	
Risk	Low	Very few recorded sightings at proposed location.
Further assessment	**No**	

Pink-footed goose		Ythan Estuary, Sands of Forvie and Meikle Loch	Montrose Basin	Loch of Strathbeg	Firth of Forth	Forth of Tay & Eden
Population	SPA	17,213 ind	31,622 ind	39,924 ind	12,400 ind	3,769
	Recent population	16,300 (07/08)	*c.*38,911 (08/09)	53,454 (08/09)	3,220 (08/09)	2,704 (08/09)
Data	Aerial surveys	No data				
	Boat based (WF)	No definite sightings				
	VP Surveys (Abdn Bay)	5.8 (birds per hour Oct – Mar 2006). A total of 646 were recorded from all sites Oct – Mar 08.				
	Radar	858 at Drums. Four sightings of 102 birds between 11 & 26th April 2007; 90 in April 2010.				
Impact	Collision risk	Flight height – of the 858 recorded at Drums, all were flying between 44 m and 60 m in October 2008. 90 birds in April 2007 were below 30 m.				
	Displacement	No				
	Barrier effect	Geese fly over or around wind farms.				
Evidence base	Site specific	Little evidence of significant usage of the site. Radar data has not recorded significant geese movements in April or October. Between half and 100% were recorded flying above 25 m.				
	Generic	Flight height data from R1 & R2 wind farms. Collision Risk Modelling, PVA by SNH and DECC				
Evidence of potential impact	No	No evidence of any impact on Geese species from either onshore or offshore wind farms. Barrow Offshore Wind Farm recorded avoidance behaviour (Petterson 2005; Petersen *et al.* 2006; Jensen 2006; BOW 2007)				
Potential to assess	Yes					
Risk	Low	Site specific data is limited but indicated high proportion at turbine height. Published data from other constructed wind farms indicating a very high avoidance rate and no impacts recorded.				
Further assessment	**Yes**					

Greylag goose		Loch of Skene	Montrose Basin	Firth of Tay & Eden Estuary	Loch of Strathbeg
Population	SPA	10,840 (5 year peak mean 1991/2 - 1995/6)	1,080	1,200	3,325
	Recent population	790 (2010). 5 year peak mean of 2,555 (03 – 08)	2,519 (Jan 2011)	2,640 08/09	580 (2007)
Data	Aerial surveys	No data			
	Boat based (WF)	No sightings			
	VP Surveys (Abdn Bay)	Peak average of 0.5 birds per hour (Oct 06 – Mar 07)			
	Radar	None reported			
Impact	Collision risk	Geese are very good at avoiding wind farms.			
	Displacement	No			
	Barrier effect	Geese fly either around or over wind farms. Minor barrier effect.			
Evidence base	Site specific	Few records with none from radar or boat based surveys.			
	Generic	Evidence that geese, including greylag geese, avoid wind turbines (e.g. Petterson 2005; Petersen *et al.* 2006; Jensen 2006; BOW 2007).			
Evidence of potential impact	No	No offshore wind farms have been shown to impact on geese.			
Potential to assess	Yes				
Risk	Low	Very few recorded sightings of greylag goose during either onshore or offshore surveys.			
Further assessment	**No**				

Barnacle goose		Loch of Strathbeg
Population	SPA	Article 4.2 - Waterfowl assemblage of at least 20,000 - Recorded as for all species as 95,000 individuals
	Recent population	121 (2008); 5 year peak mean 733 (03 – 08)
Data	Aerial surveys	No data
	Boat based (WF)	No sightings
	VP Surveys (Abdn Bay)	46 passed Balmedie (Oct 07 – Mar 08). 1,820 between April & September 2006
	Radar	281 observed at Easter Hatton. Mean flock size of 56.
Impact	Collision risk	All 281 observed barnacle geese were below 30 m in height.
	Displacement	No
	Barrier effect	Geese are known to fly around or over or between turbines.
Evidence base	Site specific	Evidence of passage occurring. Some data on flight heights.
	Generic	Data from Kalmar Sound and other offshore wind farms indicated high avoidance rates (e.g. Petterson 2005; Petersen *et al*. 2006; Jensen 2006; BOW 2007).
Evidence of potential impact	No	Geese have a very high avoidance rate. Relatively low numbers recorded at proposed EOWDC location.
Potential to assess	Yes	
Risk	Low	Published data from other constructed wind farms indicating a very high avoidance rate and no impacts recorded.
Further assessment	**No**	

Shelduck		**Montrose Basin**	**Firth of Forth**	**Firth of Tay & Eden estuary**
Population	SPA	Article 4.2 - Waterfowl assemblage of at least 20,000	3,586	Article 4.2 - Waterfowl assemblage of at least 20,000
	Recent population	988 (08/09)	3,166 (08/09)	1,114
Data	Aerial surveys	No data		
	Boat based (WF)	No Records		
	VP Surveys (Abdn Bay)	1 – 2 May 2007, Jan and March 2008,		
	Radar	No records		
Impact	Collision risk	Very low		
	Displacement	No		
	Barrier effect	No		
Evidence base	Site specific	Very few sightings		
	Generic	Wildfowl tend to fly around wind farms (Petterson 2005; Petersen *et al*. 2006).		
Evidence of potential impact	No	No evidence from existing wind farms of any impact on shelduck		
Potential to assess	Yes			
Risk	Low	Very low numbers recorded in proposed EWODC area. No evidence from other offshore wind farms of any impacts on shelduck.		
Further assessment	**No**			

Teal		Loch of Strathbeg
Population	SPA	Article 4.2 - Waterfowl assemblage of at least 20,000
	Recent population	504 (2007)
Data	Aerial surveys	No data
	Boat based (WF)	Two individuals
	VP Surveys (Abdn Bay)	27 pass Blackdog (Oct 07 – Mar 08)
	Radar	No records
Impact	Collision risk	One of the two teal recorded was between 25 – 200 metres
	Displacement	No
	Barrier effect	No
Evidence base	Site specific	Very few sightings
	Generic	Wildfowl tend to fly around wind farms (e.g. Petterson 2005; Petersen *et al*. 2006).
Evidence of potential impact	No	No evidence from existing wind farms of any impact on teal.
Potential to assess	Yes	
Risk	Low	Very low numbers recorded at proposed EOWDC area. No evidence from other offshore wind farms of any impacts on teal.
Further assessment	**No**	

Wigeon		Montrose Basin	Firth of Forth
Population	SPA	Article 4.2 - Waterfowl assemblage of at least 20,000	2,139
	Recent population	3,944 (08/09)	-
Data	Aerial surveys	No data	
	Boat based (WF)	1 April 2008	
	VP Surveys (Abdn Bay)	13 in March 2008	
	Radar	No data	
Impact	Collision risk	Very low	
	Displacement	No	
	Barrier effect	No	
Evidence base	Site specific	Very few sightings	
	Generic	Wildfowl tend to fly around wind farms (e.g. Petterson 2005; Petersen *et al.* 2006).	
Evidence of potential impact	No	No evidence from existing wind farms of any impact on wigeon.	
Potential to assess	Yes		
Risk	Low	Very low numbers recorded at proposed development area. No evidence from other offshore wind farms of any impacts on wigeon.	
Further assessment	**No**		

Common eider		Ythan Estuary, Sands of Forvie and Meikle Loch	Montrose Basin	Firth of Forth	Firth of Tay and Eden
Population	SPA	Article 4.2.	Article 4.2.	9,400	Article 4.2
	Recent population	3,688	1,983 (July 2010)	5,188	4,378
Data	Aerial surveys	JNCC data for Winter surveys in 2003, Dec 2005, Jan 2006 & May 2006 & summer surveys in 2006 both showed that extensive near-shore usage in waters <20 m. Peak count of 283 in May 2006.			
	Boat based (WF)	A total of 14 eider were recorded in the wind farm area from Feb 2007 – Mar 2008. With a max of 5 in April 2007. In the control area a total of 68 were recorded with a maximum of 26 in October 2007. Maximum counts of between 400 – 500 birds in August and September			
	VP Surveys (Abdn Bay)	877 recorded during VP surveys Oct 2007 to Mar 2008. An average of 8.1 per hour			
	Radar	Peak count of 680 common eider recorded October 2005, 0 – 4,000 m from shore.			
Impact	Collision risk	October 2005 – maximum flight height of 10 m from 680 sightings. All 835 in April 2007 were below 30 m. 98% of VP sightings were below 30 m.			
	Displacement	May be temporary displacement during construction but wind farm predominantly in waters > 20 m. Tuno Knob identified initial displacement followed by birds entering the wind farm.			
	Barrier effect	Evidence from Denmark and Sweden clearly indicate that common eider fly over or around wind turbines (e.g. Petterson 2005; Petersen *et al.* 2006).			
Evidence base	Site specific	The majority of common eider are within 500 m of the shore (>500 out 835 April 2007).			
	Generic	Flight height data from Denmark and Sweden shows common eiders fly predominantly below turbine height with very low collision risk. Evidence of barrier effect as common eider fly around turbines.			
Evidence of potential impact	Yes	Possible evidence of short-term displacement. No evidence of collision risk. Potential barrier effect.			
Potential to assess	Yes				
Risk	Low	Relatively few common eider recorded within proposed EOWDC area and evidence of very low collision risk. Possible displacement may occur.			
Further assessment	**Yes**	Due to significant numbers in wider area.			

Fulmar		**Buchan Ness to Collieston Coast**	**Fowlsheugh**	**Forth Islands**	**Troup Pennan and Lion Head**
Population	SPA	Article 4.2 - Waterfowl assemblage of at least 20,000	Article 4.2 - Waterfowl assemblage of at least 20,000.	Article 4.2 - Waterfowl assemblage of at least 20,000.	Article 4.2 - Waterfowl assemblage of at least 20,000.
	Recent population	1,370	246	Isle of May – 358 (2009 Bass Rock – 44 (2009)	636 (2007)
Data	Aerial surveys	No data			
	Boat based (WF)	In the wind farm peak count of 16 (Feb 2007). In the control area up to 45 peak count Dec 07.			
	VP Surveys (Aberdeen Bay)	Peak average of 9.5 birds per hour (Apr – Sep 2006).			
	Radar	Not reported.			
Impact	Collision risk	All 84 recorded sightings were below 15 m.			
	Displacement	No evidence of displacement.			
	Barrier effect	No data.			
Evidence base	Site specific	Eighteen months of boat data some flight height data available.			
	Generic	Few sightings from SNS wind farms showing no evidence of an effect.			
Evidence of potential impact	No	Relatively few records of fulmar at constructed offshore wind farms.			
Potential to assess	Yes				
Risk	Low	Low risk of collision due to low flight heights and relatively low numbers in the wind farm area.			
Further assessment	**No**				

Gannet		Forth Islands	Fair Isle
Population	SPA	34,400 pairs representing at least 13.1% of the breeding North Atlantic population (Count, as at 1994	1,166 nests
	Recent population	51,647 prs	3,582 (2009) nests
Data	Aerial surveys	No data	
	Boat based (WF)	In wind farm peak count 47 (August); 67 In the control area peak count was in August.	
	VP Surveys (Abdn Bay)	Peak of 120 birds per hour (July 2007).	
	Radar	110 recorded by radar in spring 2005. Peak numbers 3.0 km and 5 km from shore. 633 gannets were recorded in autumn 2007, most between 1.5 and 3.0 km from shore.	
Impact	Collision risk	17% of 347 recorded flights were between 25 m and 200 m; Up to 73% were >25 m at Drums (Oct 07 – Mar 08). Maximum height recorded using radar is 30 m.	
	Displacement	No	
	Barrier effect	Birds may fly around the wind farm.	
Evidence base	Site specific	Some boat based survey data.	
	Generic	Evidence of displacement from Horns Rev Offshore Wind Farm.	
Evidence of potential impact	Yes	Possible collision risk.	
Potential to assess	Yes	Based on flight height data and distribution.	
Risk	Medium	Frequently recorded and at rotor height.	
Further assessment	**Yes**		

Cormorant		Forth Islands
Population	SPA	200 prs - Article 4.2 - Waterfowl assemblage of at least 20,000
	Recent population	198 pairs
Data	Aerial surveys	No data
	Boat based (WF)	Peak of 17 in the wind farm area during October 2007; 20 in the control area during September 2007.
	VP Surveys (Abdn Bay)	Peak average of 4.2 birds per hour (Apr 06 – Sept 06)
	Radar	96 recorded during October 2005
Impact	Collision risk	All sightings from boat based surveys were below 25 m. 89 % of all flights at Nysted Offshore Wind Farm were below turbine height.
	Displacement	None reported
	Barrier effect	None reported
Evidence base	Site specific	Boat based data demonstrating birds are in water depths of <20 m.
	Generic	Evidence indicates very low collision risk and no displacement (Zucco *et al.* 2006).
Evidence of potential impact	No	None reported from offshore wind farms.
Potential to assess	Yes	
Risk	Low	Birds outwith wind farm area and low collision risk.
Further assessment	**No**	

European shag		Buchan Ness to Collieston Coast	Forth Islands
Population	SPA	Article 4.2 - Waterfowl assemblage of at least 20,000	2,887 pairs
	Recent population	331 (2007)	Isle of May – 465 (2009) Bass Rock – 15 (2009)
Data	Aerial surveys	No	
	Boat based (WF)	A total of 14 birds in total. *c* 5 within wind farm area	
	VP Surveys (Abdn Bay)	Peak of 3 birds per hour during April 2007 and an average peak of 0.9 birds per hour (Oct 06 – Mar 07).	
	Radar	14 records of 10 observations (spring 2007).	
Impact	Collision risk	No recorded flights above 25 m.	
	Displacement	Birds have been recorded near or in wind farms.	
	Barrier effect	Possible, due to regular flight movements. Not known if there is a barrier effect.	
Evidence base	Site specific	Few sightings, all near shore.	
	Generic	Uncommon at offshore wind farms. Little evidence available.	
Evidence of potential impact	No	Possible displacement or barrier.	
Potential to assess	Yes		
Risk	Low	Very low risk of collision and little or no evidence of displacement or barrier effects.	
Further assessment	**No**	Few sightings, nearshore low flying and no evidence of displacement.	

Oystercatcher		Montrose Basin
Population	SPA	Article 4.2 - Waterfowl assemblage of at least 20,000
	Recent population	1,766 (Feb 2010)
Data	Aerial surveys	No data
	Boat based (WF)	None recorded
	VP Surveys (Abdn Bay)	Up to 190 birds recorded during summer 2007. Peak movements along the coast of 3.1 birds/hr at the Don Mouth during the winter of 2006 & 2007.
	Radar	None
Impact	Collision risk	Few data available on flight heights. No evidence of concentrations or commuting routes across wind farm.
	Displacement	No
	Barrier effect	Waders have been recorded flying around wind farms.
Evidence base	Site specific	Little evidence of any usage of the site.
	Generic	Few nearshore wind farms have recorded oystercatcher behaviour and flight heights.
Evidence of potential impact	No	
Potential to assess	Yes	
Risk	Low	No evidence of any usage of the site or evidence of any regular passage.
Further assessment	**No**	

Lapwing		Ythan Estuary, Sands of Forvie and Meikle Loch
Population	SPA	Article 4.2 - Waterfowl assemblage of at least 20,000 - Recorded as a total of all species as 51,265
	Recent population	Peak numbers in Ythan in August with maximum of 6,269 in August 2006.
Data	Aerial surveys	No data
	Boat based (WF)	None recorded
	VP Surveys (Abdn Bay)	None recorded offshore.
	Radar	680 lapwing recorded October 2005. 835 birds in April 2007, 0 – 4.0 km from shore
Impact	Collision risk	Possible risk of collision. No evidence of any significant usage of the site.
	Displacement	No
	Barrier effect	May have barrier effect.
Evidence base	Site specific	Little evidence of any impacts to lapwing from offshore wind farms. Few records from Kalmar sound.
	Generic	Flight height data from Denmark and Sweden. Evidence of barrier effect.
Evidence of potential impact	No	Possible evidence of short-term displacement. No evidence of collision risk. Potential barrier effect. Few records from other offshore wind farms show majority fly below turbine height.
Potential to assess	Yes	
Risk	Low	Due to low numbers present offshore and those recorded from onshore being at Drums to the north of the proposed development and therefore at no risk of collision to and from the Ythan Estuary SPA.
Further assessment	**No**	

Redshank		Ythan Estuary, Sands of Forvie and Meikle Loch	Montrose Basin	Firth of Forth	Firth of Tay & Eden Estuary
Population	SPA	Article 4.2 - Waterfowl assemblage of at least 20,000 - Recorded as for all species as 51,265 individuals	Article 4.2 - Waterfowl assemblage of at least 20,000 ind.	Waterfowl assemblage	Waterfowl assemblage
	Recent population	1,497 in 2008; 5 year peak mean of 2,216 between 03 - 08	1,951 (Nov 2010)	5,111	1,162
Data	Aerial surveys	No data			
	Boat based (WF)	None recorded			
	VP Surveys (AbdnBay)	A total of 11 birds at the Donmouth (Oct 2007 – Mar 2008). Peak of 7 in Nov 2007.			
	Radar	None			
Impact	Collision risk	Few data available on flight heights. No evidence of concentrations or commuting routes across wind farm.			
	Displacement	No			
	Barrier effect	Waders have been recorded flying around wind farms.			
Evidence base	Site specific	Little evidence of any usage of the site.			
	Generic	Few nearshore wind farms have recorded redshank behaviour and flight heights.			
Evidence of potential impact	No				
Potential to assess	Yes				
Risk	Low	No evidence of any usage of the site or evidence of any regular passage. Very small numbers recorded.			
Further assessment	**No**				

Lesser black-backed gull		**Forth Islands**
Population	SPA	2,920 pairs representing at least 2.4% of the breeding Western Europe/Mediterranean/Western Africa population (Count, as at 1994)
	Recent population	2,779 apparently occupied nests
Data	Aerial surveys	No
	Boat based (WF)	Only two sightings in the wind farm area during June.
	VP Surveys (Abdn Bay)	Peak average of 2 birds per hour (Apr 06 – Sept 06).
	Radar	None reported.
Impact	Collision risk	Birds regularly fly at turbine height. Extensive data from other offshore wind farms.
	Displacement	No
	Barrier effect	No
Evidence base	Site specific	Small number of sightings.
	Generic	Data from other offshore wind farms.
Evidence of potential impact	Yes	Collision risk.
Potential to assess	Yes	
Risk	Low	Small numbers of gulls recorded in the area.
Further assessment	**No**

Data	Aerial surveys	No data			
	Boat based (WF)	43 birds between May & July 2007			
	VP Surveys (Abdn Bay)	Up to 300 birds per hour in August 2007			
Impact	Collision risk	Flight height –all recorded flights below 25 m, 16 were between 15 & 25 m.			
	Displacement	Little evidence that Sandwich terns avoid flying through wind farms (e.g. Evaraert & Stienen 2006).			
Evidence base	Site specific	Boat based data indicates low usage of the site compared to elsewhere. 4% of flights at rotor height from boat based surveys. Vantage Point surveys recorded 44% of flight heights at rotor height Nearly all sightings in waters of *c* 10 m and less than 20 m.			
	Generic	Flight height data available from Humber, Kentish Flats, Sheringham Shoal, London Array, Docking Shoal, Race Bank Offshore Wind Farms. Collision risk data from Zeebrugge Offshore Wind Farm. Overall 12% recorded at rotor height			
Evidence of potential impact	Yes	Although site specific data indicates predominantly low flight heights below probable turbine height, data from other wind farms identify potential collision risk.			
Potential to assess	Yes				
Risk	Medium	Based on site specific data the risk is low but data from elsewhere identify probable collision risk.			
Further assessment	**Yes**				

Common tern		**Ythan Estuary, Sands of Forvie and Meikle Loch**	**Forth Islands**
Population	SPA population	265 prs	800 prs
	Recent data	6 (2004), 0 (2005), 6 (2006),	378 AoN
Data	Aerial surveys	None	
	Boat based (WF)	55 peak monthly count (July 2007).	
	VP Surveys (Abdn Bay)	16.7 (birds per hr)	
	Radar surveys	14 common terns at Blackdog in April 2007.	
Impact source	Collision risk	Flight height – 14% above 25 m. Up to 23 % between 15 m and 25 m. Other wind farms reported 11% at rotor height.	
	Displacement	Common terns are not known to be displaced	
Evidence base	Site specific	All sightings within the wind farm footprint are in waters of <20 m. To the north they occur further offshore. 21 common terns were recorded 'on the sea' in the wind farm area during July 2007.	
	Generic	Flight heights available at Humber, Kentish Flats, Sheringham Shoal, London Array Offshore Wind Farms.	
Evidence of potential impact	Yes	Collision risk data from Zeebrugge indicates potential collision risk (e.g. Evaraert & Stienen 2006).	
Potential to assess	Yes		
Risk	Medium	Relatively high numbers recorded in wider wind farm area. However evidence shows that majority fly below turbine heights.	
Further assessment	**Yes**		

Arctic tern		Forth Islands
Population	SPA population	540 prs
	Recent data	908 prs
Data	Aerial surveys	None
	Boat based (WF)	3 Arctic terns in July 2007
	VP Surveys (Abdn Bay)	Peak of 150 birds per hour at Drums July 2008, In 2007 a peak of 10 birds per hour
	Radar surveys	None recorded
Impact source	Collision risk	Flight height – none above 25 m. Elsewhere 24% recorded at rotor height
	Displacement	Arctic terns are not known to be displaced
Evidence base	Site specific	Few sightings within proposed EOWDC area. The majority of sightings to the north.
	Generic	Flight heights available at Humber, Kentish Flats, Sheringham Shoal, London Array Offshore Wind Farms. 24% reported as being at rotor height.
Evidence of potential impact	Yes	Collision risk data from Zeebrugge indicates potential collision risk for Terns (e.g. Evaraert & Stienen 2006).
Potential to assess	Yes	
Risk	Low	Low numbers recorded and relevant SPA 124 km away
Further assessment	No

Data	Aerial surveys	No			
	Boat based (WF)	Peak count in wind farm area of 273 in August 2007; 112 in Nov 2007. Up to 378 in control area (August 2007)			
	VP Surveys (Abdn Bay)	Peak average of 1.5 birds per hour (Oct 06 – Mar 07); Peak of seven birds per hour in March 2006			
	Radar	Yes but data combined with guillemot.			
Impact	Collision risk	132 recorded flights all below 25 m.			
	Displacement	Possible			
	Barrier effect	Possible depending on flight line.			
Evidence base	Site specific	Boat based and VP data			
	Generic	Limited data from other offshore wind farms.			
Evidence of potential impact	Yes	No evidence of collision risk but possible displacement effect.			
Potential to assess	Yes				
Risk	Low	Relatively small numbers of birds widely distributed.			
Further assessment	**Yes**				

Puffin		Forth Islands
Population	SPA	21,000 pairs representing at least 2.3% of the breeding population (Count, as at 1992).
Data	Recent population	56,867 apparently occupied nests in 2009.
	Aerial surveys	None
Data	Boat based (WF)	In the wind farm area a peak count of 221 during August 2007 and 285 in the control area during September 2007. Most sightings were in water depths of greater than 20 metres.
	VP Surveys (Abdn Bay)	Peak average of 0.3 birds per hour (Apr 06 – Sept 06).
	Radar	One recorded in October 2005
Impact	Collision risk	Low
	Displacement	Possible – most sightings were in water depths of greater than 20 m.
	Barrier effect	Low
Evidence base	Site specific	One year of boat based data.
	Generic	None
Evidence of potential impact	No	Puffins have not been a species regularly recorded at offshore wind farms.
Potential to assess	Yes	
Risk	Low	Nearest SPA 124 km away. Relatively low numbers recorded and potential small area of displacement
Further assessment	No	

7 SPECIES ASSESSMENTS

Pink-footed goose

Pink-footed goose is a qualifying species for the Ythan Estuary, Sands of Forvie & Miekle Loch SPA, Loch of Strathbeg SPA and the Montrose Basin SPA. Further to the south it is also a qualifying species for Firth of Forth and Firth of Tay & Eden SPAs.

The Conservation Objectives for the SPAs are:

To avoid deterioration of the habitats of the qualifying species or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and

To ensure for the qualifying species that the following are maintained in the long term:

- *Population of the species as a viable component of the site.*
- *Distribution of the species within site.*
- *Distribution and extent of habitats supporting the species.*
- *Structure, function and supporting processes of habitats supporting the species.*
- *No significant disturbance of the species.*

Birds arrive from their breeding grounds in Iceland to North-east Scotland during September and October and the Loch of Strathbeg and the Miekle Loch are important roosting sites for the species. Pink-footed geese exhibit a high degree of site loyalty with up to 76 % of geese returning to the same roost between winters (Mitchell & Hearn 2004), although they can move in variable numbers to other wintering sites, e.g. in 2010 arriving autumn geese moved onwards to the Montrose Basin SPA where record numbers of approximately 65,000 were recorded. Following their arrival the majority of pink-footed geese continue south-west to Lancashire and then overland to Norfolk wintering in all three areas. Spring migration is more prolonged with peak numbers during the spring occurring during April.

The UK population of pink-footed geese has increased considerably since the 1950's with a UK wintering population of 302,774 in 2006 (WWT 2007). Peak numbers of pink-footed geese in North-east Scotland occur in October with a five year mean peak between 2003 and 2008 at the Loch of Strathbeg of 55,153 and a similar mean count of 15,515 on Meikle Loch (Holt *et al.* 2009).

7.1.1 Evidence of site usage

There have been no definite sightings of pink-footed geese within the proposed EOWDC area from boat based surveys, although a flock of 180 geese sp. were recorded from boat surveys in November 2007 may have been this species. Vantage Point (VP) surveys have recorded a total of 646 pink-footed geese and from radar studies a total of 858 individuals. Over half the geese were reported to be flying at rotor height, i.e. >25 m.

The coastal waters of Aberdeen Bay are therefore regularly used by pink-footed geese but in relatively lower numbers compared to onshore sites.

7.1.2 Evidence of potential impact

Evidence from data obtained for other offshore wind farms indicate that pink-footed geese regularly fly at rotor height. Observations from Walney Bird Observatory during 2005 and 2007 recorded between 33% and 58% of all sightings above 25 m. Further observations off

Lincolnshire recorded between 37% and 74% of pink-footed geese flying at rotor height. Consequently, pink footed geese could be at risk of collision.

Although studies undertaken in Sweden and Denmark do show Geese flying around wind turbines, there is no evidence that there will be any significant displacement or barrier effects (Petterson 2005).

7.1.3 Evidence of collision risk

Collision risk modelling has been undertaken based on a number of highly precautionary assumptions.

1. The total number of pink-footed geese passing through North-east Scotland each autumn is 340,000. This is based on the entire UK wintering population occurring in North-east Scotland, which is not thought to be the case, as some but an unknown number of geese will arrive directly into the north-west England from their breeding grounds in Iceland (WWT 2007).
2. All pink-footed geese migrate south across a front of up to 5 km offshore and 5 km inland and therefore over a 10 km wide front. The maximum width of the proposed development is 3.6 km and therefore intercepts 36% of the potential flight path. This is precautionary as site specific data indicates that the majority of geese fly within 1 km from shore and therefore do not interact with potential development. Furthermore ringing results indicate that a significant proportion of pink-footed geese fly south-west to north-west England which would lead them overland away from the proposed EOWDC. However, for the purposes of the collision risk modelling it assumed that 36% of the UK wintering population of pink-footed geese cross the proposed development area, i.e. 122,400 birds and that they pass through the site each autumn and spring, i.e. a total passage of 244,800 birds per year.
3. Those that do fly across the development area, 46% do so at turbine height and that there is no far field avoidance.
4. The same rate of passage occurs during the spring as it does during the autumn is also very precautionary as the numbers of pink-footed geese in the spring are always significantly lower than those in the autumn indicating that many pink-footed geese do not pass through the region during the spring migration.

Collision Risk Modelling has been undertaken on these precautionary assumptions using a range of avoidance rates: 98%, 99% and 99.5%.

Table 7-1: Number of pink-footed geese collisions at a range of avoidance rates

Collision probability	Avoidance rate (%)		
	98	99	99.5
8.4%	56	28	14

Based on the various very precautionary scenarios and using a precautionary avoidance rate of 99% as recommended by SNH, it is predicted that up to a 28 collisions per year may occur (Table 7-1).

The annual mortality rate for pink-footed goose is 13.7% (BTO 2011). Consequently, out of a population of 340,000 an annual mortality of 45,560 pink-footed geese may be predicted. Therefore, 1% of the baseline mortality is 4,556 birds per year.

Based on the results from the precautionary Collision Risk Modelling undertaken the number of pink-footed geese that may collide is lower than that which may cause concern of a potentially significant impact on pink-footed geese.

To assess whether there is the potential for an adverse effect on pink-footed geese as a qualifying species for the relevant regional SPAs the assessment is based on the 5 year peak mean counts as opposed to numbers published at the time of SPA citation as the populations of pink-footed geese have increased significantly since the SPA citations were originally made. It is also assumed that each SPA population is separate from each other and any collision impacts relate to birds only associated with that SPA.

This is unrealistic as the number of birds for which collision risk modelling has been undertaken is significantly greater than the numbers cited within site specific qualifying interests.

As the counts relate only to the autumn passage of geese the modelling is based on a similar rate of passage across each site in the spring.

Table 7-2: Predicted natural mortality rates of pink-footed geese at relevant SPAs

Site SPA	Population	Natural Mortality	1% of Natural Mortality
Ythan Estuary, Sands of Forvie and Meikle Loch	16,300	2,233	22
Loch of Strathbeg	53,454	7,323	73
Firth of Forth	3,220	441	4
Firth of Tay and Eden Estuary	2,704	370	4
Montrose Basin	38,911	5,330	53

Based on the above the results and the precautionary guidance threshold of a 1% increase in baseline mortality the results from the Collision Risk Modelling indicate that there is the potential for an adverse effect to occur should all potential collisions relate to geese associated with three of the SPAs.

Results from monitoring undertaken at constructed offshore wind farms indicate a very high level of avoidance of wind farms by Geese, including pink-footed geese. Monitoring undertaken at Barrow Offshore Wind Farm has demonstrated that the pink-footed geese flying at rotor height adjust their flight height and fly over the wind turbines. Less than 2 % remained at turbine height and those that did adjusted the flight lines to fly between the turbines. No collisions were observed (BOW 2007).

None of the 100,000 geese (brent, white-fronted and barnacle geese) recorded at Kalmar sound in Sweden collided with the Utrunden or Yttre Stengrund Wind Farms (Petterson 2005).

In total over 120,000 geese of eight species have been recorded from five constructed wind farms over a period of 12 years, during which time only one collision has been observed. The collision involved a brent goose recorded at Rønland Offshore Wind Farm in Denmark.

There is therefore strong evidence to suggest that geese, including pink-footed geese, have a very low collision risk. Furthermore the collision risk modelling is highly precautionary and the numbers predicted to collide are still relatively small compared to the population as a whole.

Further evidence to support the conclusions that the potential impacts from collision risk are minor come from Population Viability Analysis (PVA) undertaken on pink-footed geese which indicate that the pink-footed goose population may be able to withstand an increase in mortality (from whichever source) of 5,000 birds per year (Trinder *et al.* 2005). Further PVA commissioned by DECC to model the possible effects of additional mortality on the pink-footed goose population over a 25 year period indicated that there was a 2% chance of the pink-footed goose population decreasing to below 150,000 if, due to collisions, wind farms increase the annual mortality by more than 1,000 birds over and above current impacts, e.g. hunting. (Trinder 2008). Consequently, the possible additional increase in mortality of up to 28 birds per year will not cause an adverse effect..

Risk of an adverse collision effect - Low

7.1.4 Evidence of displacement

There is no evidence of any displacement effects on pink-footed geese from offshore wind farms.

Risk of an adverse displacement effect - Low

7.1.5 Evidence of barrier effect

Monitoring undertaken at Barrow Offshore Wind Farm identified pink-footed geese altering flight height to avoid the wind farm or flying between the turbines. Consequently, although pink-footed geese demonstrated avoidance behaviour there was no evidence of a significant barrier effect.

Risk of an adverse barrier effect – Low

7.1.6 Evidence of in-combination impact

There is the potential for an in-combination impact of pink-footed goose from other offshore developments that have previously been recognised as having a potential impact on pink-footed geese, particularly with respect to collision risk.

In-combination collision risk totals based on collision risk modelling are presented in Table 7-3. The collision risk modelling undertaken at the time was based on avoidance rates of 95, 99 and 99.5%. Based on an avoidance rate of 99%, a total of up to 167 pink-footed geese are predicted to be impacted from all the currently consented offshore wind farms.

Based on the total UK population of approximately 340,000 pink-footed geese and a 1% baseline mortality rate of 4,556 individuals per year the potential in-combination impacts are considered not to be adverse.

Further projects in the Firth of Forth and Moray Firth have the potential to cause an incremental increase in mortality rates. There are no data available on the likely numbers of pink-footed geese present within the proposed developments presented in Table 5-2. However, evidence from ringing indicate that the majority of pink-footed geese move south-west and are therefore unlikely to be recorded within the Firth of forth area in large numbers. However, the numbers likely to cross the Moray Firth are unknown. However, all evidence indicates that pink-footed geese avoid wind turbines and therefore it is believed that there is unlikely to be an adverse affect arising from collision risk.

Table 7-3: Predicted potential collision mortality for pink-footed geese.

Site	Avoidance rate		
	95%	**99 %**	**99.5 %**
Ormonde	77	15	8
Walney	6	1	<1
West of Duddon Sands	5	1	<1
Barrow	15	15	8
Docking Shoal		15	8
Humber Gateway		48	24
Lincs	171 - 262	34 – 52	17 – 26
Lynn & Inner Dowsing	100 - 165	20 – 33	10 – 17
Total	**374 - 530**	**149 – 167**	**69 – 85**

Risk of an adverse in-combination effect - Low

7.1.7 Conclusion

Taking into account data obtained from the proposed EOWDC and supported by published data from other sites it is concluded that the proposed EOWDC either alone or in-combination will not cause an adverse effect on the integrity of the relevant SPAs with regard to pink-footed goose.

Common eider

Common eider ducks are part of the qualifying assemblage under Article 4.2 of the Directive 2009/147/EC (codified 79/409/EEC) by regularly supporting at least 51,265 individual waterfowl (5 year peak mean 1991/2 - 1995/6) for the Ythan Estuary, Sands of Forvie and Meikle Loch SPA, Montrose Basin SPA, Firth of Tay & Eden Estuary SPA, Firth of Forth SPA.

The Conservation Objectives for the SPAs are:

To avoid deterioration of the habitats of the qualifying species or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and

To ensure for the qualifying species that the following are maintained in the long term:

- *Population of the species as a viable component of the site.*
- *Distribution of the species within site.*
- *Distribution and extent of habitats supporting the species.*
- *Structure, function and supporting processes of habitats supporting the species.*
- *No significant disturbance of the species.*

Common eiders occur in the area throughout the year but most adults winter in the Firth of Forth and Tay estuary. First winter birds remain near the estuary (Baillie & Milne 1988). Peak numbers occur in the Ythan during May with maximum counts of up to 4,212 in 2004 and a five year peak mean of 3,333 individuals. Within Aberdeen Bay, peak counts of common eider occur in late summer when up to 6,003 were recorded in 2005 and the peak mean between 2003 and 2008 in Aberdeen Bay was 4,833. In the Montrose Basin peak counts of common eider occur during July with 1,983 in July 2010.

7.1.8 Evidence of site usage

Aberdeen Bay has the fourth largest population of common eider in the UK (Holt *et al*. 2009).

Site specific boat based surveys undertaken between February 2007 and January 2008 recorded a total of 68 individuals across both the control area and the proposed development area with a maximum of five within the wind farm area in April 2007. All but one of the sightings occurred in waters of less than 20 m. In contrast to the boat based surveys, common eider were frequently recorded from the four land based vantage point survey locations with a total of 877 recorded in flight between October 2007 and March 2008 and an overall average of 8.1 birds per hour flying past each point. Thus, indicating extensive near-shore coastal usage.

Figure 7-1 presents the eider distribution from boat based data collected between September and May. Few sightings were obtained from boat based surveys between June and September. The results indicate that eider occur infrequently within the proposed development area.

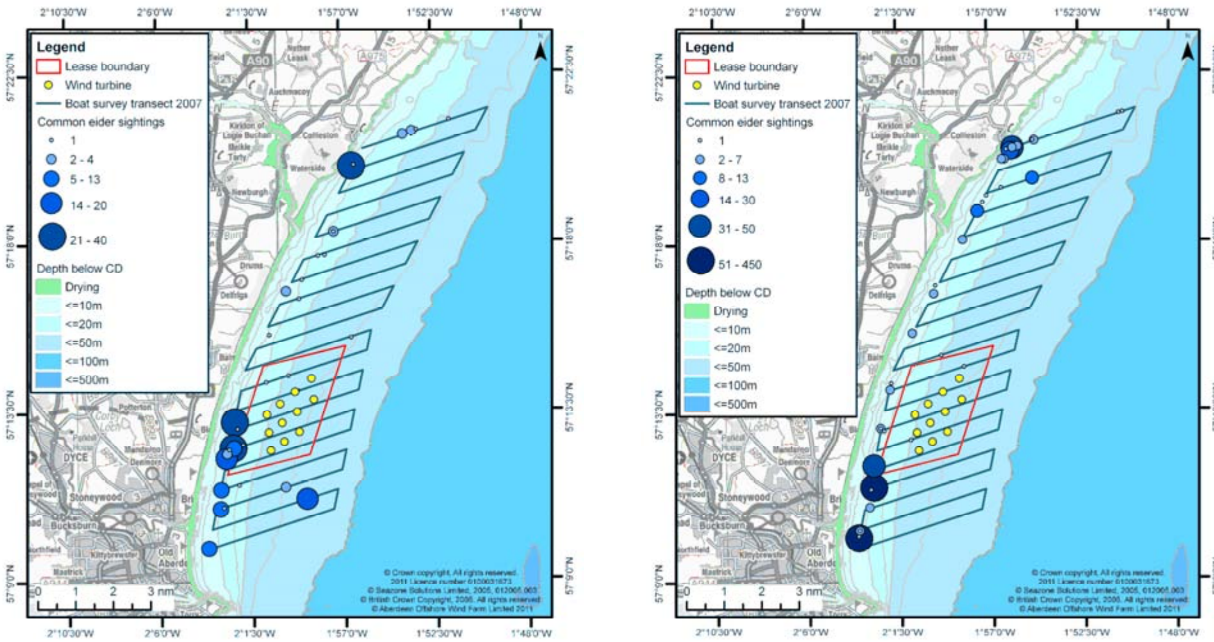

Figure 7-1: Common eider distribution in Aberdeen Bay September to May (all sightings).

Data from Denmark supports the evidence obtained from within Aberdeen Bay that common eider occur very infrequently in water depths of >20 m with less than 1 % of 36,700 records in the relatively deeper waters.

7.1.9 Evidence of collision risk

Evidence from data obtained for other offshore wind farms indicate that common eider fly predominantly below rotor height. Observations from Denmark indicate that more than 80 % of all common eider flights occur below 30 m (Kahlert *et al* 2000). Further evidence from Denmark and Sweden have demonstrated that Common eider duck have a very high avoidance rate with no collisions detected at Horns rev offshore wind farm that has an annual autumn passage of between 40,000 to 60,000 common eider per year (Petersen *et al* 2006). Similar avoidance rates were found at Kalmar Sound Offshore Wind Farm (Pettersson 2005). There is no evidence of a potential collision risk impact.

Risk of a significant effect - Low

7.1.10 Evidence of a displacement

Based on the results from the monitoring data, the worst-case scenario is that should displacement occur, that no eider will be within the proposed development area and there will be 80% displacement out to a distance of 1 km and a further 50% decrease in abundance out to 2 km from the wind farm.

Based on the peak density obtained from boat based surveys of 10.9 birds/km^2 during the winter period, should there be a total displacement of eider from within the proposed EOWDC area then it is predicted that up to 47 eider may be displaced during periods of peak density. Based on an 80% displacement out to 1 km (a total surface area of 12.3 km^2)

from the proposed development area then it is predicted that a total of 154 eider may be displaced with a further 44 out to 2 km should there be 20% displacement. Therefore, the maximum number of eider potentially displaced is up to 198 birds based on the highest densities recorded from any survey within Aberdeen Bay and at least some displacement out to 2 km.

Based on the estimated total of 198 potentially displaced eider out of a peak reported count of 3,500 eider at Blackdog, it is predicted that up to 6% of the eider within Aberdeen Bay may be displaced. However, the distribution of eider within Aberdeen Bay is clustered with peak numbers occurring at various sites across the bay during different seasons (Sohle *et al.* 2006). The area off Blackdog regularly records the peak counts of eider in Aberdeen Bay (NESBR) and should displacement occur a greater proportion of eider might be affected than is estimated using densities obtained from boat based surveys.

The Tuno Knob Offshore Wind Farm in Denmark is a relatively small wind farm of ten turbines in an area that holds up to 5,800 eider. Post-construction monitoring at Tuno Knob has indicated that the distribution of eider is closely related to their prey and although there may be some displacement immediately post-construction there is unlikely to be any significant displacement of eider from the proposed development area as long as their prey remain available (Guillemette *et al.* 1999). Evidence from studies undertaken at Nysted offshore wind farm have indicated that although there was an avoidance of the area during construction there was a subsequent increase of 48% within the wind farm area post-construction but a decrease in numbers out to 2 and 4 km (Zucco *et al.* 2006).

These two studies demonstrate that eiders do not avoid wind farms post-construction and their distribution is closely aligned to the availability of prey. The main prey items for eider are mussels (*mytilus edulus*). Evidence from constructed wind farms indicate that there is likely to be an increase in mussels around the base of turbines and that no significant impacts have been detected on mussels from the construction of wind farms. Consequently, there is unlikely to be a negative impact on prey availability for eiders within Aberdeen Bay.

Table 7-4: Calculations used to calculate potential displacement of eider

Calculations used for displacement	
Area	*Peak density of eider – 10.9 birds/km^2*
Area of EOWDC – 4.3 km^2	4.3 * 10.9 = 47
Area of EOWDC 1 km buffer – 12.3 km^2 @ 80%	(12.3 * 10.9)*0.8 = 107
Area of EOWDC 2 km buffer – 20.3 km^2 @ 20%	(20.3 * 10.9)*0.2 = 44
Total predicted displacement	47+107 + 44 = 198

7.1.11 Disturbance

Eiders may be disturbed by vessels both during the construction phase and during operations from maintenance vessels. Studies have indicated that there may be displacement from large vessels out to 1,000 m (Larsen & Laubek 2005).

During construction there may be a number of vessels operating within the area but they will likely be focussed around a single point where the turbine is being installed. Consequently, eider may be displaced from within 1 km radius of the installation; an area of 3 km^2. Based on the highest recorded density of 10.9 birds/km^2, it is therefore predicted that up to 33 eider may be displaced from the vicinity during construction. This equates to approximately 1% of the peak eider population within Aberdeen Bay based on the peak estimated figure of 3,500 individuals. The construction period will be of short duration and the impacts from construction vessels temporary. Displacement by service boats may diminish the re-population potential of the EOWDC. It is not known how many service vessels may be required but based on the scale of the proposed development there is unlikely to be frequently more than one vessel on any one occasion. The presence of the proposed development in the vicinity of the intensively used Aberdeen Harbour means that the potential increase of one vessel movement on a regular basis will not have any noticeable difference to the number of vessels already using Aberdeen Bay. Any specific displacement caused by the service or construction boats will be temporary as eiders will be able to move into the area once the vessels leave.

Risk of an adverse effect from displacement or disturbance - Low

7.1.12 Evidence of barrier effect

Evidence from Denmark and Sweden suggest that common eider fly around, rather than through, wind farms. Consequently, there will be an increase in energy expenditure. Research at the substantially larger Nysted Offshore Wind Farm comprising of 72 turbines calculated an increase of flight distance of 500 m caused by flying around the wind farm. The conclusions of the study were that such a flight would not have any adverse effect on migrating common eider.

There is no evidence of regular daily movements of eider within Aberdeen Bay to and from feeding or roosting areas. Should it occur with eider making daily movements from the Ythan Estuary to Aberdeen Bay to the south of the proposed development and the birds select to fly around the turbines up to 1 km away then they may incur an additional flight distance of up 3.2 km each way, or a total of 6.4 km. This may increase the daily energy expenditure to between 2.0 – 2.5% (Caldrow, Stillman & West 2007; Speakman, Gray & Furness 2009). This is a relatively small increase in daily energy expenditure and is unlikely to have an adverse effect on eiders in Aberdeen Bay.

The peak numbers of eider in Aberdeen Bay occur during July and August when the adult eider undergo a complete wing moult over a period of four weeks, during which time they become flightless. The daily energetic costs during this period increase but the birds remain within certain areas where they can forage and cannot undergo daily flight movements (Guillemette *et al.* 2007) Consequently, there is no incremental increase in daily energy expenditure due to the barrier effect during this period of higher energy expenditure.

Data obtained from two years of Vantage Point surveys did not detect any evidence to suggest that there are regular daily flights by eider across the proposed development area and so a regular barrier effect that may cause a long-term increase in daily energetic costs is not predicted. There is the potential for a relatively small *ad hoc* increase as birds move around the bay but as most movements are within 1 km of the coast regular barrier effects are unlikely.

Risk of a an adverse effect from barriers – Low

7.1.13 Evidence of in-combination impact

There is the potential for an in-combination effect with other shipping activities within Aberdeen Bay and the vessels associated with the proposed development. Currently there are up to 16,000 vessels per year using Aberdeen harbour and the incremental increase in vessel usage associated with the development, operation and decommissioning of the proposed EOWDC will be relatively small, particularly during the period of operation. Vessels associated with the proposed development will be no closer than 2 km from shore, the distance of the nearest turbine, and therefore unlikely to have an impact on the nearshore eider. There is no evidence of any potential in-combination effect from the proposed development and other offshore activities for common, particularly with respect to displacement/disturbance risk.

Risk of an adverse in-combination effect – Low

7.1.14 Conclusion

Taking into account data obtained from the proposed EOWDC and supported by published data from other sites it is concluded that the proposed development either alone or in-combination will not cause an adverse effect on the integrity of the relevant SPAs with regard to common eider.

Gannet

Gannets occur as a qualifying species for the Forth Islands SPA with a breeding population of 44,000 pairs (Mitchell *et al.,* 2004).

The Bass Rock is approximately 130 km from the proposed EOWDC location. Data from tagged gannets at Bass Rock have recorded breeding gannets foraging up to 540 km from the colony with a mean distance of 230 km and consequently could occur within the proposed EOWDC area.

Elsewhere the nearest SPA with gannet as a qualifying species is Fair Isle which is located 260 km to the north of the proposed development. The foraging ranges from gannets from their breeding colonies means that Fair Isle and all the other SPA colonies are within range of the proposed development.

Troup Head is the closest gannetry to the proposed development located approximately 73 km to the north. This gannetry has increased in size over the last twenty years and now contains 1,810 nests (NESBR 2009). Being considerably closer than other existing colonies the Troup Head colony is likely to be the main source of gannets in Aberdeen Bay during the breeding season but gannet is not a qualifying species for the SPA and therefore not considered as part of this assessment.

7.1.15 Evidence of site usage

Gannets were recorded throughout Aberdeen Bay from boat based surveys with no areas identified as being of particular importance but with the majority of sightings in water depths of between 20 m and 50 m. Numbers of gannets recorded were lowest between November and March and highest during the breeding season from April to August when gannets were widespread throughout the area.

Boat based survey data recorded a peak count of 47 birds in the original wind farm survey area and 67 in the control area. Vantage Point surveys recorded up to 43 birds per hour between April and September 2006. The majority of sightings were greater than 1.5 km from shore with peak numbers between 3.0 and 3.5 km from the coast.

There is no evidence to suggest that the gannets recorded in Aberdeen Bay are those from either the Bass Rock or Fair Isle SPAs. However, the area is within the known foraging range of the species and it is likely that at least some of the gannets recorded are associated with the Bass Rock and other SPAs elsewhere.

7.1.16 Evidence of collision risk

Data obtained from both boat and land based observations indicate that between 18 % and 73 % of gannets fly greater than 25 m above the sea surface. Data from other UK offshore wind farm indicate a lower percentage at rotor height with between 6 % and 14 % of gannets flying greater than 20 m above sea surface. There have been relatively few constructed wind farms where gannets have been regularly recorded. Data from Horns Rev Offshore Wind Farm suggest that gannets do not fly through wind farms and therefore avoid the area. Consequently, the risk of collision is low. Out of a total of 1,144 gannets recorded at Horns Rev, no collisions were observed. Gannets have been reported as occurring within North Hoyle Offshore Wind Farm and no collisions have been reported.

Collision risk modelling undertaken for the proposed development based on a range of potential avoidance rates from 98%, 99% and 99.5% indicate that between 0.41 and 1.6 gannets per year may collide with the proposed development.

Based on the various scenarios and using a precautionary avoidance rate of 98% it is predicted that a total of 1.6 collisions per year may occur. The current SPA population in the region is 51,647 pairs.

The annual mortality rate for gannet is 8.1 % (BTO 2011). Consequently, out of a population of 51,647 pairs (103,294 adults) an annual mortality of 8,367 gannets may be predicted. Therefore, 1% of the baseline mortality is 84 birds per year, i.e. an increase in mortality rate of more than 84 birds per year caused by collisions may be considered significant.

For the two individual SPAs the increase in mortality that could cause an adverse effect is lower:

- Fair Isle SPA has a current population of 3,582 AoN (5,164 adults); therefore an annual mortality rate of 418 adults. 1% of baseline mortality is therefore 4 individuals.
- Forth Islands SPA has a current population of 51,647 AoN (103,294); therefore an annual mortality rate of 8,367 adults. 1% of baseline mortality is therefore 84 individuals.

The results from the collision risk modelling indicate that between 1 and 2 gannets per year may collide with the proposed development. This is lower than either of the baseline mortality rates used to indicate whether the potential impact is will have an adverse effect.

There is no evidence that gannets from Fair Isle occur within the region during the breeding season. Foraging activity will likely remain within the waters around Shetland and therefore it is not predicted that there will be any impact on gannets associated with the Fair Isle SPA during the breeding season.

Tagging data of birds from the Bass Rock colony indicates that they forage widely and are potentially at collision risk with the proposed development (Hamer *et al.* 2000). Based on the collision risk modelling undertaken, should all the potential collisions be of birds arising from the Bass Rock colony in the Forth SPA, 124 km away, then there will be a very small increase in the baseline mortality rate and below the level that may be of concern.

Evidence from existing offshore wind farms indicates that gannets avoid flying through wind farms and may have a significant far field avoidance rate; this behaviour will further reduce the risk of potential collision.

Consequently, based on the evidence available it is unlikely that there will be an adverse effect on gannets from either of the SPAs due to collision mortality.

Risk of an adverse effect from collision - Low

7.1.17 Evidence of displacement

Evidence from Horns Rev Offshore Wind Farm indicates that gannets will avoid entering the wind farm. Data from boat based surveys and Vantage Point surveys indicate that there are no areas of Aberdeen Bay that are preferentially used by gannets and consequently any gannets displaced from the footprint of the wind farm will be able to forage elsewhere and there is no evidence to suggest that the displacement will cause an adverse effect on gannets using the area. Should avoidance occur, there will be a corresponding reduction in potential risk of collision.

There is the potential for displacement of prey species from the area during construction, should pile driving be undertaken. During this period it may be that gannets may be displaced from a wider area until such time their prey returns. Pile driving, should it occur, will be undertaken over a relatively short period of time and consequently the duration of potential displacement impact will also likely be relatively short and the area potentially impacted relatively small compared to the wider foraging ranges of Sandwich terns. Adult gannets are known to exhibit a great degree of flexibility in selection of prey, foraging locations and distances travelled. Consequently, they are adaptable to forage outwith the area during the period of potential impact (Hamer *et al.* 2007).

Risk of adverse effect from displacement – Low

7.1.18 Evidence of barrier effects

It is possible that the displacement of gannets from the proposed EOWDC area may cause a barrier effect. Evidence from Horns Rev Offshore Wind Farm indicates that gannets will fly around the wind farm area thus cause a potential increase in energetic costs. The predicted increase in distance travelled due to the presence of the wind farm is less than 500 m and consequently any additional increase in energetic expenditure will be negligible compared to the distance travelled to and from the breeding colonies.

Risk of an adverse effect from barrier – Low

7.1.19 Evidence of in-combination impact

The theoretical very large foraging range that gannets can fly suggest that any individual gannet may interact with a number of the proposed offshore wind farms in Scottish waters. Published data elsewhere indicates that gannets from colonies in Shetland or eastern England are unlikely to occur in Aberdeen Bay during the breeding season (Langston 2011), although they may occur during periods of passage.

Consequently, there is low potential for in-combination effects with respect to gannets from Fair Isle SPA or Bempton Cliffs SPA. However, there is evidence to suggest that the gannets from the Forth Island SPA may occur within the Aberdeen Bay area. Populations from this SPA may also interact with potential offshore wind farm developments currently proposed the Firth of Forth area, namely: Neart na Gaoithe, Inch Cape and Firth of Forth offshore wind farms. There is currently very limited information on the proposed developments as decisions on the location, scale and numbers of turbines are still to be decided. Based on the scoping reports it is currently predicted that there may be an additional 526 turbines within the Firth of Forth area (Table 7-5). Information on the use of these areas by gannets is limited with no published information currently available from on-going studies being undertaken for the proposed wind farms. It is therefore not possible to undertake an in-combination collision risk assessment based on collision risk modelling or an assessment on possible in-combination impacts arising from displacement or barrier effects.

Table 7-5: Predicted wind farms that may have an in-combination impact on gannets in the Firth of Forth

Project	Estimated no. of turbines	Area (km^2)	Predicted Application date
Inch Cape	181	151	2012
Neart Na Gaoithe	130	105	2012
Firth of Forth (phase I)	215	597	2013

There is a significant difference in scale between the proposed development and those planned elsewhere and it is a significantly greater distance from the Forth Islands SPA. Any potential incremental increase in mortality of between one and two birds per year arising from the proposed development will likely be very minor.

Collision Risk Modelling undertaken for Beatrice Offshore Wind Farm predicted a total of five gannets per year may collide with the Beatrice demonstrator project development based on a 98% avoidance rate (Talisman 2005). The additional mortality from the proposed development may increase this by one or two birds per year. There are two planned offshore wind farms within the Moray Firth that could potentially have an in-combination impact on the gannets at Troup head (Table 7-6). There is little information on the number or scale of turbines and there is no published information currently available from on-going studies being undertaken for the proposed wind farms. It is therefore not possible to undertake an in-combination collision risk assessment based on collision risk modelling or an assessment on possible in-combination effects from displacement or barrier impacts. The scale of the proposed development is significantly smaller than those proposed in the Moray Firth and consequently based on the current information on gannet distribution the scale of potential impact proportionally smaller.

Table 7-6: Predicted wind farms that may have an in-combination impact on gannets in the Moray Firth

Project	Estimated no. of turbines	Area (km^2)	Predicted Application date
Moray Firth (phase 1)	200	296	2012
Beatrice	184	131	2012

Risk of an adverse in-combination effect – Low

7.1.20 Conclusion

Taking into account data obtained from the proposed EOWDC and supported by published data from other sites it is concluded that the proposed development either alone or in-combination will not cause an adverse effect on the integrity of the relevant SPAs with regard to gannet.

Herring gull

Herring gull are a qualifying species for the Buchan Ness to Collieston Coast SPA, Fowlsheugh SPA and Forth Islands SPA (Mitchell *et al.* 2004). The UK breeding population has undergone a significant decline in recent years although the exact reasons for this decline are unknown.

During the breeding season herring gulls remain largely coastal with maximum foraging ranges from the breeding colony of 54 km.

7.1.21 Evidence of site usage

The known foraging range of breeding herring gulls indicates that herring gulls from the Forth Islands SPA will not occur in Aberdeen Bay during the breeding season. Birds from Buchan Ness to Collieston SPA and Fowlsheugh SPA may use the area.

Data from boat based surveys indicate significant seasonal variability in the usage of the site. Greatest numbers occurred in the wind farm study area during June and July with a peak count of 456 birds in July 2007. Most sightings were in the south-west of the study area with relatively few within the proposed development area. Further data from vantage point counts recorded a mean peak count of 54 birds per hour passing the observation points and no significant difference in the number of birds was detected across all four vantage point sites suggesting a relatively uniform usage of the coastline across Aberdeen Bay. Herring gulls were the most frequently recorded species from vantage point surveys from between October 2006 and March 2007.

7.1.22 Evidence of potential collision risk

Herring gulls are one of the most frequently recorded species in Aberdeen Bay. The species regularly flies at the height of the turbines and shows no avoidance of wind farms, nor any displacement.

Evidence from site specific monitoring using boat based and land-based surveys and other data sources indicate that herring gulls are widespread and frequent within Aberdeen Bay and with a distinct seasonal peak during the summer months.

Results from collision risk modelling assessed the potential impact across a range of avoidance rates of between 98 and 99.5%. The results indicate that between 1.8 and 7.2 herring gulls may collide with the proposed EOWDC each year.

Based on the regional SPA population of herring gulls of 19,562 individuals, the annual mortality rate will be 2,347 individuals and therefore the 1% baseline mortality rate will be 235 birds per year. The results from the Collision Risk Modelling predict a total of up to seven herring gulls per year may collide with the turbines.

The Buchan Ness to Collieston Coast SPA lies approximately 9.5 km away from the proposed development and holds approximately 6,158 breeding herring gulls (Based on counts undertaken in 2007). The colony will therefore have an annual mortality of 739 birds. It is likely that many of herring gulls recorded within Aberdeen Bay during the breeding period are associated with this colony. The results from the collision risk modelling predict an annual mortality of 7 herring gulls per year indicating that there will not likely be an adverse effect on the population of herring gulls associated with the SPA based on the precautionary assumption that an increase of 1% above baseline mortality could be adverse, i.e. more than 8 herring gulls a year collide with the turbines. However, the predicted mortality of 7 birds per year is close but it is based on a series of precautionary figures that assume the peak numbers recorded within the development area are constant throughout the year. It is therefore predicted that the number estimated to collide each year is precautionary as are the avoidance rates, which have been reported as being greater than 99% (Everaert & Kuijken 2007).

The Fowlsheugh SPA lies 31 km away from the proposed development and holds 122 breeding pairs of herring gull based on latest counts. Therefore, the annual mortality rate from this colony is 14 birds per year. Based on the results from the collision risk modelling it is concluded that if all the herring gulls at risk of collision are from Fowlsheugh then there is the potential for an adverse effect on the SPA population

The Forth Islands SPA is approximately 124 km away and holds 13,200 herring gulls. However, the SPA is too far away for breeding herring gulls from the SPA to occur regularly, if at all, within the proposed development area during the breeding season. Therefore, there will not be an adverse effect on the population of the Forth Islands SPA due to collision.

The collision risk modelling is based on the peak number of herring gulls recorded from any of the surveys. Whereas the number of birds present in the actual wind farm development area was lower. Consequently, the numbers used for the collision risk modelling are precautionary.

Risk of an adverse effect from collision – Low

7.1.23 Evidence of displacement

Evidence from existing offshore wind farms indicate that herring gulls may enter the wind farm. No evidence of any displacement has been recorded.

Risk of an adverse effect from displacement – Low

7.1.24 Evidence of barrier effects

There is no evidence of any barrier effect to herring gulls from offshore wind farms.

Risk of an adverse effect from barrier effects – Low

7.1.25 In-combination effects

There is a potential for an in-combination effect with herring gulls originating from the Fowlsheugh SPA with proposed plans for offshore wind farms in the Firth of Forth. There is limited information on the proposed projects and no information on the number of herring gulls present in the area. However, given the location of the proposed developments and the close proximity to coastlines that herring gulls frequent during the breeding season it is predicted that there will be relatively few herring gulls within the proposed Firth of Forth wind farm areas. Consequently, the risk of an adverse in-combination impact is predicted to be low.

7.1.26 Conclusion

Taking into account data obtained from the proposed EOWDC and supported by published data from other sites it is concluded that the proposed development either alone or in-combination will not cause an adverse effect on the integrity of the relevant SPAs with regard to herring gull.

Kittiwake

Kittiwake is a qualifying species for Buchan Ness to Collieston Coast SPA, Fowlsheugh SPA Forth Islands SPA and Troup Pennan and Lion's Heads SPA as part of the waterbird assemblages under Article 4.2 of the Directive. Populations of kittiwakes at these colonies have decreased over recent years. The colony at Fowlsheugh was the largest and held 35,000 breeding pairs in 1992 but has decreased to below 12,000 pairs in 2006. The largest colony is now at Troup Pennan and Lion's Heads SPA where 14,896 pairs nest, followed by Buchan Ness to Collieston SPA that has 12,542 apparently occupied nests, i.e. 25,000 individuals.

The foraging ranges of kittiwakes from breeding colonies have been studied at the Isle of May and have indicated a maximum foraging range of 83 km. Consequently, birds from the Forth Islands will be unlikely to be foraging within the proposed development area during the breeding season. Kittiwakes from Collieston, Fowlsheugh and Troup, Pennan & Lions Heads SPA may occur within the proposed development area.

7.1.27 Evidence of site usage

Kittiwakes were recorded throughout Aberdeen Bay in highly seasonally variable numbers. During the winter periods very few kittiwakes were recorded. However during the breeding season kittiwakes were frequently recorded with estimated populations within the control area during this period of 1,676 birds and 663 birds in the proposed EOWDC development area. Peak densities of 33 birds/km^2 were recorded to the north of the proposed development during the summer months. Land-based observations also recorded peak numbers during the summer months with a peak in July. Of those for which flight height was recorded, 22% were greater than 25 m above the sea surface. The majority of sightings were between 1 – 3 km of the coast.

7.1.28 Evidence of collision risk

Collision risk modelling undertaken for the proposed EOWDC over a range of avoidance rates between 98 and 99.5% indicated that between 0.9 and 3.6 kittiwakes per year may collide.

Based on the regional SPA population of kittiwakes of 83,156 individuals, the annual mortality rate will be 4,989 individuals and therefore the 1% baseline mortality rate is 50 birds per year. The results from the collision risk modelling predict a total of four kittiwakes per year may collide with the wind turbines and therefore the proposed development will not have an adverse effect on the regional SPA population of kittwakes

The Buchan Ness to Collieston Coast SPA lies approximately 9.5 km away from the proposed development and holds approximately 25,000 breeding kittiwakes, based on the latest available counts in 2007. The colony will therefore have an annual mortality of 1,505 birds. It is likely that many of kittiwakes recorded within Aberdeen Bay during the breeding period are associated with this colony. The results from the collision risk modelling, which predict a mortality of four kittiwakes per year, indicates that there will not be an adverse effect on the population of kittiwakes associated with the SPA. This is based on the precautionary assumption that an increase of 1% above baseline mortality could be adverse, i.e. more than 15 kittiwakes a year collide with the turbines.

The Fowlsheugh SPA lies 31 km away from the proposed development and holds 11,140 breeding pairs of kittiwake based on latest counts. Therefore, the annual mortality rate from this colony is 1,337 birds per year. Based on the results from the collision risk modelling it is concluded that if all the kittiwakes at risk of collision are from Fowlsheugh then there is unlikely to be an adverse effect on the SPA population.

The Troup Pennan & Lion's Head SPA lies 74.3 km to the north of the proposed development and holds 29,792 breeding kittiwakes. The annual mortality is estimated to be 1,787 birds per year and consequently, based on a 1% of annual mortality threshold, an adverse effect on kittiwakes from this colony is not predicted.

The Forth Islands SPA is approximately 124 km to the south and holds 4,632 breeding kittiwakes. However, the maximum foraging range for kittiwakes reported is 83 km (Roos 2010) and therefore the SPA is outwith the maximum foraging range for breeding kittiwakes and therefore there will not be an adverse effect on the population due to collision.

Based on the results of the Collision Risk Modelling and the current regional and SPA populations, it is predicted that that the potential population affect caused by collision impacts with the proposed development on kittiwakes is negligible.

Risk of an adverse effect from collision – Low

7.1.29 Evidence of barrier effects

There is no evidence of any barrier effect to kittiwake from offshore wind farms.

Risk of an adverse effect from barrier impacts – Low

7.1.30 Evidence of displacement

There is no evidence of any displacement effect of kittiwakes from other constructed offshore wind farms.

Risk of an adverse effect from displacement – Low

7.1.31 In-combination effects

There is a potential for an in-combination effect with kittiwakes originating from the Fowlsheugh SPA with proposed plans for offshore wind farms in the Firth of Forth and those from Troup, Pennan and Lions Heads with proposed plans in the Moray Firth. There is limited information on the proposed projects and no information on the number of kittiwakes present in the area. However, as the potential incremental increase in mortality from the proposed development is less than four birds per year it is predicted that this will not have add significantly to the potential in-combination effect on the population. Consequently, the risk of an adverse in-combination impact arising from this development is predicted to be low.

Risk of an adverse effect from in-combination effects – Low

7.1.32 Conclusion

Taking into account data obtained from the proposed EOWDC and supported by published data from other sites it is concluded that the proposed development either alone or in-combination will not cause an adverse effect on the integrity of the relevant SPAs with regard to kittiwake.

Little tern

Little tern is a qualifying species for the Ythan Estuary, Sands of Forvie and Meikle Loch SPA and held 36 breeding pairs in 2009 and Firth of Tay and Eden Estuary SPA.

Little terns no longer nest at the Firth of Tay and Eden Estuary SPA and therefore the site is not considered further in the assessment

They arrive from their West African wintering grounds from April onwards and depart in August and September. They feed on small fish, foraging in close in-shore waters.

The numbers nesting at Sands of Forvie varies considerably across years with many years having only a few pairs and others occasionally over 70 pairs nesting. The number of young fledged also varies considerably with most years producing only a few young due to predation and weather. During years where nests fail early on birds may leave the region by the end of June and early July but in years where nesting has been successful birds may remain in the area through to August or early September.

7.1.33 Evidence of site usage

Very few little terns were recorded from either the boat based or land-based surveys and none were recorded within the footprint of the proposed development area.

All sightings were within 2 km of the coast. Flight heights for those recorded were all below 30 m and typically little terns forage between 3 and 8 m above the sea surface.

7.1.34 Evidence of collision risk

No little terns were recorded within the proposed development area and flight heights of little terns are typically well below the turbine height (ECON 2006). Therefore, as little terns have not been recorded in the area and they fly predominantly below rotor height there is very little risk of collision

Risk of an adverse effect – Low

7.1.35 Evidence of displacement

Evidence from studies undertaken in Belgium and the UK has not shown any evidence of a displacement effect with some evidence of an increase in usage of a site following construction (ECON 2008). Consequently, it is predicted that there will be no displacement effects on little terns due to potential development.

Risk of an adverse effect – Low

7.1.36 Evidence Disturbance

Little terns forage on small fish often, young clupeids. Monitoring undertaken at Scroby Sands recorded a reduction in the availability of young herring following the construction of a wind farm by pile-driving and a subsequent breeding failure of little terns (ECON 2008). The little terns were able to compensate for the reduction in available prey by foraging further afield and changing prey items and there has not been any evidence of an overall population decline in the number of little terns in the area but the locations where the terns foraged and the sizes of colonies have varied.

The significance of any potential effect depends on the scale of displacement and its duration. It also depends on whether other suitable foraging areas can be located. Although these are difficult to predict any potential impacts upon prey are expected to be relatively short-term as they should affect only one or two breeding seasons depending on whether significant pile-driving takes place and whether construction is undertaken over one or two years. Following cessation of construction, it is predicted that new juvenile fish will be available the following season.

The numbers of little terns at the Sands of Forvie each year is highly variable as is their breeding success, with many years where they fail to produce many, if any, young consequently the integrity of the colony is unlikely to be effected by any reduction in breeding over a couple of years should it occur. Based on the available evidence, particularly the highly variable inter-annual breeding success and breeding population it is predicted that should pile-driving occur that there will not be any adverse effect on the integrity of the site with respect to breeding little terns.

Risk of adverse disturbance effect - Low

7.1.37 Evidence of barrier effects

As little terns forage predominantly within 2 km of the coast there will not be a barrier effect.

Risk of an adverse barrier effect – Low

7.1.38 In-combination effects

There are no other offshore developments that have the potential for an in-combination effect on little terns originating from the Ythan Estuary, Sands of Forvie and Miekle Loch SPA.

Risk of an adverse effect from in-combination effects – Low

7.1.39 Conclusion

Taking into account data obtained from the proposed EOWDC and supported by published data from other sites it is concluded that the proposed development either alone or in-combination will not cause an adverse effect on the integrity of the relevant SPAs with regard to little tern.

Sandwich tern

Sandwich tern is a qualifying species for the Ythan Estuary, Sands of Forvie and Meikle Loch SPA, Loch of Strathbeg SPA and Forth Islands SPA and Firth of Forth SPA.

The Ythan Estaury, Sands of Forvie and Meikle Loch SPA holds Scotland's largest breeding colony of Sandwich tern with a peak of 1,802 pairs in 1987 and an average of 517 pairs over the last 20 years. Recent counts of breeding birds at Sands of Forvie have been of 900 pairs in 2007, 670 in 2008 and 645 in 2009, indicating an ongoing and steady decline in the use of this site.

Sandwich terns have not bred at the Loch of Strathbeg SPA in recent years until 2010 when 1 pair nested.

The Firth of Forth SPA has a passage of Sandwich terns with up to 1,617 birds. It is not known which colonies these Sandwich terns originate from but are likely to be from a number of different colonies.

Birds return to their breeding grounds during April and remain in the area until the autumn. The number of terns breeding is highly variable and their success depends on the availability of suitable prey, predation and weather. Sandwich terns forage offshore for small fish species, particularly sandeels and clupeids. The distance that they forage varies depending on prey availability with distances of up to 67 km reported.

7.1.40 Evidence of site usage

The known foraging ranges of breeding Sandwich terns indicates that terns present within the wind farm study area may be associated with the Ythan Estuary, Sands of Forvie and Meikle Loch SPA.

Data from boat based surveys indicate very low usage of the wind farm study area with only five Sandwich terns recorded during May 2007. Elsewhere in Aberdeen Bay higher numbers were recorded particularly to the north, nearer to the Sands of Forvie breeding colony. Vantage point counts recorded relatively high numbers of Sandwich terns between April and September 2006 with an average of 25 birds per hour across all four vantage point sites. Evidence from boat based and vantage point surveys suggests that although there is extensive near shore usage of Aberdeen Bay there is relatively low usage of the proposed EOWDC location by Sandwich terns.

7.1.41 Evidence of collision risk

Collision risk modelling undertaken for Sandwich tern over a range of avoidance rates indicate a potential collision risk of between 0.1 and 0.4 birds per year.

Based on the regional SPA population of Sandwich tern of 645 breeding pairs the annual mortality rate will be 142 individuals and therefore the 1% baseline mortality rate is 1.4 birds per year. The results from the Collision Risk Modelling indicate less than 1 Sandwich tern will collide per year with the wind turbines.

Evidence from site specific monitoring using boat based and land-based surveys and other data sources indicate that relatively few Sandwich terns occur in area of the proposed development with nearly all sightings within 2 km of the coast and the majority within 1 km.

Data from existing offshore wind farms have reported relatively high number of collisions of sandwich tern with wind turbines (e.g. Everaert & Stienen 2006). However, they have also demonstrated high avoidance rates of greater than 99%. The number of collisions recorded has been largely due to the high number of transits made by the Sandwich terns at the sites. Site specific data indicates a low usage of the proposed development area and low numbers of transits across the site consequently a low risk of collision.

Based on the small numbers of sandwich terns recorded within the proposed development area and the relatively high avoidance rates reported for Sandwich terns, it is predicted that the risk of collision is low.

Risk of an adverse effect from collision – Low

7.1.42 Evidence of displacement

There is no evidence from offshore wind farms of any displacement effects on Sandwich terns.

Risk of an adverse effect from displacement - Low

7.1.43 Disturbance

Sandwich terns are not predicted to be impacted directly by disturbance from construction or operating vessels.

Sandwich terns feed predominantly on sandeels and clupeids (young herring) and should these prey species be impacted by construction activities in the vicinity of the proposed development then Sandwich terns may have to either forage more widely or find alternative prey. It is not possible to determine whether either possible impacts are potentially likely but Sandwich terns do forage widely in the coastal waters of Aberdeen Bay and appear not to occur in the EOWDC area so those that are effected may be able to relocate should there be a localised effect.

There is no evidence of an indirect impact on breeding Sandwich terns from other constructed offshore wind farms but there is the potential for a temporary effect on Sandwich terns should the construction of the proposed development cause a significant decline in the prey of Sandwich during the breeding season. If this effect occurs it is predicted that it would last no longer than the period of construction before fish numbers returns back to the population levels prior to construction.

Sandwich terns breeding success is highly variable across years with the population withstanding years with very low breeding success without having a significant effect on the colony size. Consequently should Sandwich terns be unsuccessful in breeding due to the potential displacement of prey then it is predicted that the effects will last no longer than the construction seasons and not have an adverse effect on the integrity of the site.

Risk of an adverse effect from disturbance impacts – Low

7.1.44 Evidence of barrier effects

There is no evidence of any barrier effect to Sandwich terns from offshore wind farms,

Risk of an adverse effect from barrier impacts – Low

7.1.45 In-combination effects

There are no other offshore developments that have the potential for an in-combination effect on Sandwich terns originating from the Ythan Estuary, Sands of Forvie and Miekle Loch SPA. Consequently, the risk of an adverse in-combination impact arising from the proposed EOWDC is predicted to be low.

Risk of an adverse effect from in-combination effects – Low

7.1.46 Conclusion

Taking into account data obtained from the proposed EOWDC and supported by published data from other sites it is concluded that the proposed development either alone or in-combination will not cause an adverse effect on the integrity of the relevant SPAs with regard to Sandwich tern.

Common tern

Common tern is a qualifying species for the Ythan Estuary, Sands of Forvie and Meikle Loch SPA. At the time of designation the SPA held 2.2 % of the UK breeding population with 265 pairs. Since then the population has decreased with no more than 6 pairs since 2006. They are also a qualifying species for the Forth Islands SPA where up to 378 pairs nest

Birds return to their breeding grounds during April and remain in the area until the autumn. The number of terns breeding is highly variable and their success depends on the availability of suitable prey, predation and weather. Common terns forage offshore for small fish species, particularly sandeels and clupeids. The distance that they forage varies depending on prey availability with distances of up to 34 km reported.

7.1.47 Evidence of site usage

The known foraging range of breeding common tern indicates that terns present within the wind farm study area may be associated with the Ythan Estuary, Sands of Forvie and Meikle Loch SPA but not the Forth Islands SPA.

Data from boat based surveys indicate regular usage of the wind farm study area during the breeding season with up to 55 birds recorded during a boat based survey undertaken in July 2007. Vantage point counts recorded an average of 16.7 birds per hour across all four vantage point sites.

7.1.48 Evidence of collision risk

Boat based surveys recorded 14% of flights at rotor height

Collision risk modelling based on a range of avoidance rates of 98% 99% and 99.5% predicted between 0.8 and 3.5 common terns per year may be at risk of collision.

Based on the regional SPA population of 768 breeding adults, the annual mortality rate will be 77 individuals and therefore the 1% baseline mortality rate is less than one bird per year. The results from the Collision Risk Modelling predict a total of 3.5 common terns per year may collide with the wind turbines.

Six pairs of common tern nest on the Sands of Forvie and consequently any increase in adult mortality could have an adverse effect. The Sands of Forvie lies approximately 7.2 km away from the proposed development and therefore may be within the potential foraging range of breeding common terns, which although have been estimated to forage less than 25 km away from their nests are more likely to be within 4 – 6 km (Roos 2010).

A total of 378 pairs of common tern nest at the Firth of Forth, which lies approximately 124 km away and therefore outwith the maximum foraging range recorded for common terns.

The data used in the collision risk model is based on the peak counts recorded from anywhere within Aberdeen Bay from boat based surveys which were significantly greater than those within the wind farm area itself. Consequently, the number of birds predicted to be at risk of collision is precautionary. As is the avoidance rate used of 98%.

Data obtained from Zeebrugge, where common terns frequently pass across an array of turbines, have reported relatively high collision mortalities although very low collision probabilities of 0.1% for birds flying at rotor height and 0.007% for birds at all altitudes (Everaert & Stienen 2006). Consequently, the use of a 99% avoidance rate may be more appropriate. Based on this, the number of potential collisions by common terns may be between one to two birds per year. Should one or more of the six breeding pairs from the Ythan Estuary, Forvie Sands and Meikle Loch SPA collide with the proposed EOWDC then the effect on the SPA population will be adverse. However, the relatively low usage of the site and the high avoidance rates makes this event unlikely and therefore the proposed development is not likely to have an adverse effect on the integrity of the site.

Risk of an adverse collision effect – Low

7.1.49 Evidence of displacement

Evidence from studies undertaken in Denmark where common terns were seen to enter operating wind farms indicates that there may be little or no displacement. Should displacement occur, site specific data indicates that common terns may forage elsewhere, particularly to the north where then numbers of common terns present were higher.

Risk of an adverse displacement effect – Low

7.1.50 Disturbance

Should the construction of the proposed development cause a reduction in the availability of prey to breeding terns then this may cause an adverse effect.

The location of nearest tern colonies and that more common terns were recorded to the north of the development area indicate that should there be a reduction of suitable prey in the vicinity of the proposed development than there are other areas where common terns may forage, e.g. in the Ythan Estuary. Any potential impact will likely last for no more than the one or two seasons as juvenile fish will be available as prey the following year.

The significance of any potential effect depends on the type of installation technique used the subsequent scale of disturbance and its duration. It also depends on whether other suitable foraging areas are available. Post construction monitoring undertaken at Kentish Flats did not record any reduction in the number of terns using the area and noted an increase in overall numbers (Gill *et al*. 2008).

Based on the results from site specific surveys indicating common terns can forage widely and evidence from studies undertaken at other constructed wind farms indicating that foraging with recently constructed wind farms can occur, it is predicted that there is unlikely to be an adverse effect from construction activities.

Risk of an adverse effect from disturbance - Low

7.1.51 Evidence of barrier effects

There is no evidence of any barrier effect to common terns from offshore wind farms.

Risk of an adverse barrier effect – Low

7.1.52 In-combination effects

There are no other offshore developments that have the potential for an in-combination effect on common terns originating from the Ythan Estuary, Sands of Forvie and Miekle Loch SPA. Consequently, the risk of an adverse in-combination impact arising from the proposed EOWDC is predicted to be low.

Risk of an adverse effect from in-combination impacts – Low

7.1.53 Conclusion

Taking into account data obtained from the proposed EOWDC and supported by published data from other sites it is concluded that the proposed development either alone or in-combination will not cause an adverse effect on the integrity of the relevant SPAs with regard to common tern.

Guillemot

There are three guillemot colonies as part of SPA assemblages along the coast of North-east Scotland. Colonies of nearly 20,000 birds to the north of the wind farm area in the Buchan Ness to Collieston Coast SPA and 16,000 at Troup, Pennan and Lion's Heads SPA and a further 51,000 guillemots to the south of the proposed development at the Fowlsheugh SPA. Further south the Forth Islands SPA holds 16,000 birds.

7.1.54 Evidence of site usage

Guillemots were recorded widely across Aberdeen Bay from all surveys. Data from boat based surveys indicate that peak counts in the bay occur during the post-breeding period, particularly in July with more birds recorded within the control site than within the proposed EOWDC development area. Relatively high numbers remain within the area until November after which numbers of guillemots in the area decrease. Land based observations recorded peak numbers during April. Data from boat based surveys recorded guillemots widely across the surveyed areas and land-based observations recorded most guillemots from between 1.5 km and 4.5 km from the coast.

7.1.55 Evidence of collision risk

Collision risk modelling has been undertaken using a range of potential avoidance rates of 98%, 99% and 99.5%. The results from the modelling based on the highest densities recorded from any of the boat based surveys indicates that between 0.01 and 0.04 birds per year may collide with the proposed development.

Out of a peak regional population of 5,447 individuals an annual mortality of 294 guillemot, may be predicted. Therefore, 1% of the baseline mortality is 3 birds per year.

Based on the results from collision risk modelling, which predicts a total of 0.04 collision per year at a 98% avoidance rate, there will not be an adverse effect on the guillemot due to collisions.

The assessment against the relevant SPA populations indicates a very low risk of an adverse effect arising from collisions.

Based on the results from the collision risk modelling it is concluded that the potential effect from collision risk is negligible.

Risk of an adverse collision effect – Low

7.1.56 Barrier effect

Studies undertaken in Sweden and Denmark indicate that there is some potential for a barrier effect to occur with a reduced number of birds crossing the constructed wind farms.

During the breeding season it is predicted that there may be regular flights to and from colonies some of which will intersect the proposed development area. Should a barrier effect occur with guillemots from either Fowlsheugh or Buchan Ness to Collieston Coast SPAs making daily movements from one location to another around the proposed development area then they may incur an additional flight distance of up 3.2 km each way, or a total of 6.4 km. This may increase the daily energy expenditure to between 2.0 – 2.5% (Speakman, Gray & Furness 2009). Multiple flights will increase this expenditure.

The location and size of the proposed development is such that it will only occupy a relatively small zone through which birds may avoid flying. Regular daily movements by individual birds that could cause an incremental increase in distance of foraging flights on a daily basis is not predicted to occur, i.e. birds from colonies will forage over a wider area and will not need to detour around the proposed development on a regular daily basis.

Based on the above it is concluded that the potential incremental increases in foraging distances are unlikely to cause an adverse effect on guillemots.

Risk of an adverse barrier effect – Low

7.1.57 Evidence of displacement effect

The maximum number of guillemot potentially displaced has been calculated to be up to 1,355 birds based on the highest densities recorded from any survey within Aberdeen Bay and displacement out to 2 km. Based on the regional SPA population estimate of 88,737 guillemots then approximately 1.5% of the regional SPA population may be displaced.

Should there be a displacement effect there is no evidence to suggest that the loss of the area of the proposed development will be significant and that individuals displaced will not be able to find suitable foraging areas elsewhere. Therefore, there is no evidence to suggest that any displacement will have a negative impact on guillemots.

Post-construction monitoring undertaken at Horns Rev offshore wind farm has indicated that displacement of guillemots can occur. However, results from other operating wind farms have not shown a total displacement of guillemots. Guillemots have been recorded at the constructed Kentish Flats Offshore Wind Farm but in reduced numbers (Gill *et al.* 2008).

Based on the evidence from existing offshore wind farms it is predicted that the potential impact from displacement may be moderate but unlikely to have an adverse effect on the integrity of the relevant SPAs as displaced birds will not all die and will be able to relocate to other suitable sites.

Risk of an adverse displacement effect – Low

7.1.58 In-combination effects

Birds from the relevant SPAs may also occur in either proposed developments in the Moray Firth or the Firth of Forth.

The only data available is that from the Beatrice Demonstrator Project which recorded 19 guillemots over a period of 12 months pre-construction surveys indicating a relative low usage of the site by guillemots (Talisman 2005). The size, scale and exact locations of the Round 3 and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of guillemots that may be present in the planned development areas. Consequently, it is not possible to determine whether there will be an in-combination impact arising from the proposed plans. However, although the developments are within the potential foraging ranges of guillemots from a number of SPAs the, relatively far, distance the proposed development is from the other planned offshore wind farms and its relatively small scale reduces the risk of a potentially significant in-combination effects. Furthermore, the effects from displacement are such that it is predicted that displaced guillemots will not die and therefore, although there may be a proportion of birds displaced it is predicted that the potential impacts will not be adverse.

Risk of an adverse effect from in-combination impacts – Low

7.1.59 Conclusion

Taking into account data obtained from the proposed EOWDC and supported by published data from other sites it is concluded that the proposed development either alone or in-combination will not cause an adverse effect on the integrity of the relevant SPAs with regard to guillemot.

Razorbill

There are four razorbill colonies as part of SPA assemblages that have the potential to be impacted by the proposed development. Buchan Ness to Collieston Coast SPA has 4,179 individuals, Fowlsheugh has 4,632 individuals, Forth Islands has 3,464 individuals and Troup, penan and Lion's Head has 3,216 razorbills.

7.1.60 Evidence of site usage

Razorbills were widely recorded across Aberdeen Bay from all surveys. Low numbers were present at the beginning of the year but increased from April onwards. Data from boat based surveys indicate peak counts in the bay between July and September but also a high count in October. Birds were recorded in relatively equal numbers across both the control site and the proposed EOWDC survey area. Land based observations recorded peak numbers during April and September.

Data from boat based surveys recorded razorbills widely across the surveyed areas and land based observations recorded most birds from between 2.0 km and 4.0 km from the coast.

All those recorded in flight were seen to be flying below 25 m.

7.1.61 Evidence of collision risk

No razorbills have been reported as flying at rotor height within Aberdeen Bay or from other wind farms and no reports of collisions by razorbills have been found. Consequently, it is concluded that the risk of a collision with a turbine is very small and that collision mortality will not cause an adverse effect to razorbills.

Risk of an adverse collision effect – Low

7.1.62 Barrier effect

During the breeding season it is predicted that there may be regular flights to and from colonies some of which will intersect the proposed development area. The distance razorbills forage varies depending upon the availability of suitable prey and at what stage during the breeding season they are. Should a barrier effect occur with razorbills from either Fowlsheugh or Buchan Ness to Collieston Coast SPAs making daily movements from one location to another around the proposed development area then they may incur an additional flight distance of up 3.2 km each way, or a total of 6.4 km. This may increase the daily energy expenditure to between 2.0 – 2.5% (Speakman, Gray & Furness 2009). More regular flights will increase energetic costs

The location and size of the proposed development is such that it will only occupy a relatively small zone through which birds may avoid flying. No significant concentrations of razorbills were recorded in the vicinity of the proposed development and therefore it is not considered to be a particularly favourable area for foraging. Regular daily movements by individual birds that could cause an incremental increase in distance of foraging flights on a daily basis is not predicted to occur, i.e. birds from colonies will forage over a wider area and will not need to detour around the proposed development on a regular daily basis.

Risk of an adverse barrier effect – Low

7.1.63 Evidence of displacement effect

Therefore, the maximum number of razorbill potentially displaced is up to 241 birds based on the highest densities recorded from any survey within Aberdeen Bay and displacement out to 2 km.

Based on the regional SPA population of 12,175 razorbills then approximately 1.9% of the regional population may be displaced.

Should there be a displacement effect there is no evidence to suggest that the loss of the area of the proposed development will be significant and that individuals displaced will not be able to find suitable foraging areas elsewhere.

Densities of razorbills within the area were not higher than elsewhere and consequently it is not thought that the proposed location is of particular importance, particularly as densities of razorbills tended to be higher to the north. There is no evidence to suggest that any displaced razorbills will not be able to relocate and no reason to suggest that those displaced will die. Consequently, it is predicted that there will not be an adverse effect on razorbills from displacement.

Risk of an adverse displacement effect – Low

7.1.64 In-combination effects

Birds from the relevant SPAs may also occur in either proposed developments in the Moray Firth or the Firth of Forth. There are no other additional activities within Aberdeen Bay that may cause in-combination impacts on razorbills.

The only data available is that from the Beatrice Demonstrator Project which recorded 1 razorbill over a period of 12 months pre-construction surveys (Talisman 2005). The size, scale and exact locations of the Round 3 and those in Scottish Territorial Waters are currently not known and there are no data available to determine the number of razorbills that may be present in the planned development areas. Consequently, it is not possible to determine whether there will be an in-combination impact arising from the proposed plans. However, although the developments are within the potential foraging ranges of razorbills from a number of SPAs the relatively far distance the proposed development is from the other planned offshore wind farms and it's relatively small scale reduces the risk of a potential in-combination effect.

Risk of an adverse effect from in-combination impacts – Low

7.1.65 Conclusion

Taking into account data obtained from the proposed EOWDC and supported by published data from other sites it is concluded that the proposed development either alone or in-combination will not cause an adverse effect on the integrity of the relevant SPAs with regard to razorbill.

8 SAC'S

The scope of the review undertaken for this document was based on all coastal SACs in the wider region and advice received from SNH.

All coastal or near coastal SACs were identified using information from the SNH and JNCC websites (JNCC 2011, SNH 2011). A total of eight SACs have been identified as having qualifying species or habitats that are at potential risk of an adverse effect from the proposed project:

- Berwickshire and North Northumberland Coast SAC
- Buchan Ness to Collieston SAC
- Firth of Tay & Eden Estuary SAC
- Isle of May SAC
- Moray Firth SAC
- River Dee SAC
- River South Esk SAC
- Sands of Forvie SAC

Further details on each of the SACs including their qualifying species and Conservation Objectives are presented in Appendix B.

Annex I habitats – Embryonic shifting sand dunes - *Ammophila arenaria, Empetrum nigrum*		**Sands of Forvie SAC**
SAC		Embryonic shifting dunes, shifting dunes along the shoreline with *Ammophila arenaria*, decalcified fixed dunes with *Empetrum nigrum*, humid dune slacks
Data	Site surveys	None
Impact	Physical impact	None
Evidence base	Site specific	There will be no direct or indirect impacts from the construction or presence of the wind farm on the site.
	Generic	There is no published evidence to indicate either a direct or indirect impact on sand dune habitats from offshore wind farms.
Evidence of potential impact	None	
Potential to assess	Yes	Sediment modelling would confirm lack of any potential impact.
Risk	Low	Proposed offshore wind farm too far to impact on coastal processes at Sands of Forvie SAC.
Further assessment	No	

Large shallow inlets and bays, mudflats and sandflats reefs and submerged or partially submerged caves Annex II species – grey seal		**Berwickshire and North Northumberland Coast SAC**
SAC		Large shallow inlets and bays Mudflats and sandflats not covered by seawater at low tide Reefs Submerged or partially submerged sea caves Grey seal
Data	Site surveys	Boat based survey
Impact	Physical impact	None on qualifying habitats. Potential for noise impacts on grey seals
Evidence base	Site specific	There will be no direct or indirect impacts from the construction or presence of the wind farm on the site's qualifying habitats. Grey seals were present throughout the survey area during all the boat based survey months.
	Generic	There is published evidence to indicate that there is potential for an impact on grey seals arising from noise generated during piling operations.
Evidence of potential impact	Yes	Seals may avoid areas with high levels of sound
Potential to assess	Yes	Noise modelling and site specific data.
Risk	Low	
Further assessment	**Yes**	For grey seal only

Vegetated sea cliffs of the Atlantic and Baltic Coasts		Buchan Ness to Collieston SAC
SAC		The vegetated cliff slopes support a wide range of coastal vegetation types with an abundance of such local species as Scots lovage (*Ligusticum scoticum*) and roseroot (*Sedum rosea*). Maritime heath, acid peatland and brackish flushes also occur.
Data	Site surveys	None
Impact	Physical impact	None
Evidence base	Site specific	There will be no direct or indirect impacts from the construction or presence of the wind farm on the site.
	Generic	There is no published evidence to indicate either a direct or indirect impact on vegetated cliff slopes from offshore wind farms.
Evidence of potential impact	None	
Potential to assess	Yes	
Risk	Low	
Further assessment	No	No evidence to indicate any impact.

Estuaries, Sandbanks, Mudflats and Sandflats Annex II species – Common seal		Forth of Tay & Eden Estuary SAC
SAC		Mudflats and Sandflats not covered by seawater at low tide. Sandbanks which are slightly covered by seawater all the time Estuaries Common seal
Data	Site surveys	Boat based surveys
Impact	Physical impact	None on qualifying habitats Potential for noise impact on common seal
Evidence base	Site specific	There will be no direct or indirect impacts from the construction or presence of the wind farm on the qualifying habitats: mudflats, sandflats, sandbanks and estuaries. No common (harbour) seals were observed during the boat based surveys carried out during 2007-2008. In the four months of boat based surveys carried out during 2010-2011 there were 27 harbour seals observed.
	Generic	There is published evidence to indicate that there is potential for an impact on common seal arising from noise generated during piling operations.
Evidence of potential impact	Yes	Seals may avoid areas with high levels of sound
Potential to assess	Yes	Noise modelling and site specific data.
Risk	Low	
Further assessment	**Yes**	For common seal only

Bottlenose dolphin		Moray Firth SAC	
SAC			
Data	Species	Bottlenose dolphin	Sandbank
	Recent population	193 – 237 individuals	Sandbanks are at least 105 km away
		Bottlenose dolphin – Marine mammal surveys have indicated that bottlenose dolphins occur within the proposed EOWDC area. Previous studies have concluded that they occur off Aberdeen throughout the year with a slight increase in occurrence between November and May. Aberdeen harbour has been identified as an important feeding area for bottlenose dolphins, especially during the winter and spring when dolphins are most abundant. Their presence at this site has been linked to salmon migration up the river.	
Impact	Physical impact	Dolphins present within close proximity to the turbines during pile driving may be physically impacted. No physical impacts on Sandbank habitats *c*105 km away	
	Displacement effect	Dolphins may be displaced away from the area during the construction phase.	
Evidence base	Generic	Bottlenose dolphins from the Moray Firth SAC are known to occur in the area of the proposed EOWDC and as far south as St Andrews Bay. Impacts from noise from pile driving on porpoises have indicated that there is some temporary displacement as far as 21 km away and studies from seismic surveys indicate avoidance behaviour for a range of dolphin species.	
Evidence of potential impact	Yes	Possible displacement or disturbance effect from noise during construction activities.	
Potential to assess	Yes	Noise modelling.	
Risk	Moderate		
Further assessment	**Yes**		

Presence of Annex II species, Freshwater Pearl Mussel, Atlantic Salmon, Otter		River Dee SAC		
SAC				
Data		Freshwater Pearl Mussel	Atlantic Salmon	Otter
	Recent population	1.5 million	-	The population of otter in the Dee catchment is estimated at 40-50 adults.
Impact	Physical	Freshwater Pearl mussel - there will be no direct impacts on fresh water pearl mussel. Potential secondary impact if significant impact on salmon occurs. Atlantic salmon – Possible displacement effect during construction period. Otter – possible disturbance effect on otters from construction noise.		
	Noise			
Evidence base	Site specific	none		
	Generic	Freshwater Pearl Mussel – use Atlantic salmon as a host species for a winter before maturing. No evidence of any impacts on freshwater pearl mussels from offshore wind farms or other offshore activities. Atlantic Salmon – No evidence of displacement effects on Atlantic salmon from noise impacts. Otter – No evidence of any impact from pile driving from offshore wind farms. Mouth of the River Dee is Aberdeen Harbour and Aberdeen City therefore very low usage of the site. Any displacement, should it occur, will only be for the duration of pile driving. No likely significant effect.		
Evidence of potential impact	Yes	Possible displacement of Atlantic salmon effect during construction.		
Potential to assess	Yes			
Risk	Low	Duration of activities will be of a relatively short duration.		
Further assessment	**Yes**			

Presence of Annex II species, Freshwater Pearl Mussel, Atlantic Salmon		River South Esk SAC	
SAC			
Data	Species	Freshwater Pearl Mussel	Atlantic Salmon
	Recent population	Abundant in the River South Esk. The pearl mussel population is most abundant in the middle reaches of the river where they attain densities > 20 m^2	The South Esk supports a large, high-quality salmon *Salmo salar* population in a river draining a moderate-sized catchment on the east coast of Scotland.
Impact	Physical impact	Freshwater Pearl mussel - there will be no direct impacts on fresh water pearl mussel. Potential secondary impact if significant impact on salmon occurs. Atlantic salmon – Possible displacement effect during construction period.	
	Displacement effect		
Evidence base	Generic	Freshwater Pearl Mussel – use Atlantic salmon as a host species for a winter before maturing. No evidence of any impacts on freshwater pearl mussels from offshore wind farms or other offshore activities. Atlantic Salmon – No evidence of displacement effects on Atlantic salmon from noise impacts. Impacts from noise on other fish species (including Salmonids) have indicated that any displacement, should it occur, will be temporary and only for the duration of the pile driving. Fish return to the area. Recovery from temporary threshold shift should it occur may be within 48 hrs. Salmon may avoid the area during the construction period.	
Evidence of potential impact	Yes	Possible displacement effect during construction	
Potential to assess	Yes		
Risk	Low	Duration of activities will be of a relatively short duration.	
Further assessment	**Yes**		

Reefs Annex II species – Common seal		**Isle of May SAC**
SAC		Reefs Grey seal
Data	Site surveys	Boat based survey
Impact	Physical impact	None on qualifying habitat. Potential for noise impacts on grey seals
Evidence base	Site specific	There will be no direct or indirect impacts from the construction or presence of the wind farm on the site's qualifying habitats. Grey seals were present throughout the survey area during all the boat based survey months.
	Generic	There is published evidence to indicate that there is potential for an impact on grey seals arising from noise generated during piling operations.
Evidence of potential impact	Yes	Seals may avoid areas with high levels of sound
Potential to assess	Yes	Noise modelling and site specific data.
Risk	Low	
Further assessment	**Yes**	For grey seal only

Bottlenose dolphin

Further information on the distribution of bottlenose dolphins is presented within the is presented within the *Marine Mammal Impact Environmental Baseline* and *EIA technical report on Marine Mammals* prepared for the proposed EWODC Environmental Statement (Appendices 12.1 and 12.2 of the Environmental Statement). Bottlenose dolphins are known to occur regularly in the Aberdeen Bay area. Observations indicate they are present in the area throughout the year, with a peak occurrence during the winter and spring months (November-May), when they can be observed almost daily feeding at Aberdeen Harbour (Canning 2007; Stockin *et al*. 2006).

Analysis of cetacean distribution and habitat use along the Aberdeenshire coast, indicate that the entrance to the River Dee (Aberdeen Harbour) is an important feeding area for bottlenose dolphins, especially during the winter and spring when dolphins are most abundant (Canning 2007). The majority of sightings away from Aberdeen were of groups travelling while those sighted at Aberdeen generally exhibited foraging behaviours (Canning, 2007).

There were 200 bottlenose dolphins recorded during 62 observations both on and off effort during the boat based surveys carried out 2007-2008 (Figure 8-1). There were 10 observations of 58 bottlenose dolphins collected on effort that would have been available for distance analysis (if statistically feasible). The mean group size of all sightings both on and off effort was 5.2 individuals. The majority of sightings occurred during the spring months with sightings occurring throughout the year. A higher number of individuals were observed in the wind farm survey area in comparison to the control site.

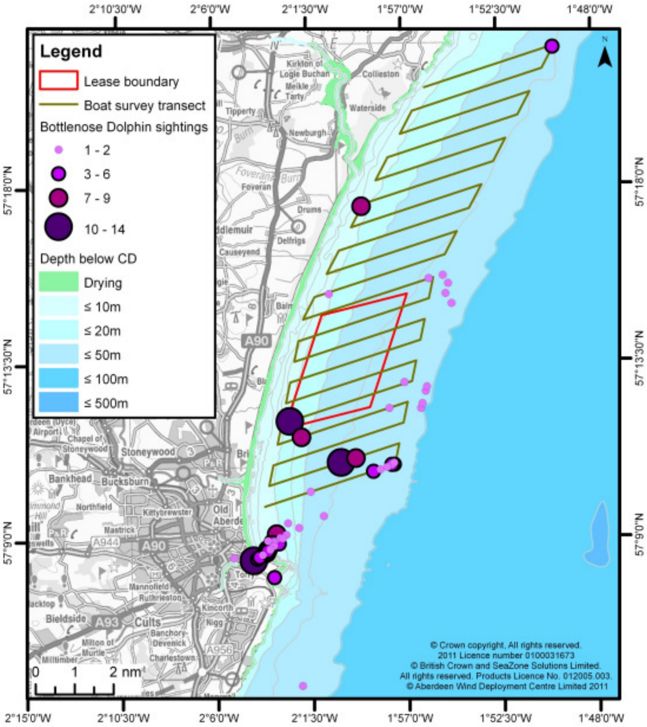

Figure 8-1: Bottlenose dolphins observed on and off effort during the 2007-2008 EOWDC boat surveys

8.1.1 Risk of physical impacts

Further detailed information on the potential impacts arising from the proposed development on bottlenose dolphins are presented in the EIA technical report on marine mammals (Appendix 12.2 of the Environmental Statement).

There is a risk of physical impacts on bottlenose dolphin from the proposed development, particularly during the construction phase when wind turbines may be pile driven into the seabed. Noise generated from pile driving has the potential to cause a range of effects ranging from mortality to permanent physical damage, temporary physical damage and disturbance or displacement.

Underwater sound modelling using the INSPIRE sound propagation model has been used to determine the potential range of underwater noise generated by installing a single 8.5 m diameter monopile. This is based on the worst-case scenario with respect to generation of underwater noise. The INSPIRE model uses a combination of loss caused by the spreading of the energy of the sound field (geometric loss) and loss caused by energy in the water column being absorbed in the underlying sea bed (absorption losses). This is used to estimate the likely transmission losses as the sound propagates away from the source; in this case impact piling. The model is therefore capable of estimating the effect of rapidly varying water depths that are commonly found in UK coastal waters.

For the assessment of physical injury to marine mammals the assessment applies a number of different impact criteria including those proposed by Parvin *et al*. (2007), and also the audiological impact criteria that have been developed by Southall *et al*. (2007).

Sound levels used in the assessment of physical impacts to determine potential adverse effect on Bottlenose dolphin are:

- lethal effect may occur in bottlenose dolphin where peak to peak levels exceed 240 dB re.1µPa
- physical injury may occur in bottlenose dolphin where peak to peak levels exceed 220 dB re.1µPa

The results from the underwater noise modelling undertaken at four wind turbines and the results from Turbine 11, the worst-case based on the piling of an 8.5 m diameter turbine are presented in Figure 8-2. The results from the modelling indicate that the lethal effect level (240 dB peak-peak) and the physical effect level (220 dB peak-peak) will be exceeded at 3 m and 60 m, respectively. As the environmental conditions are comparable for all the wind turbines; the modelling suggests that for physical impacts the anticipated ranges at which lethal effects and physical effects will be the same for all the wind turbine positions.

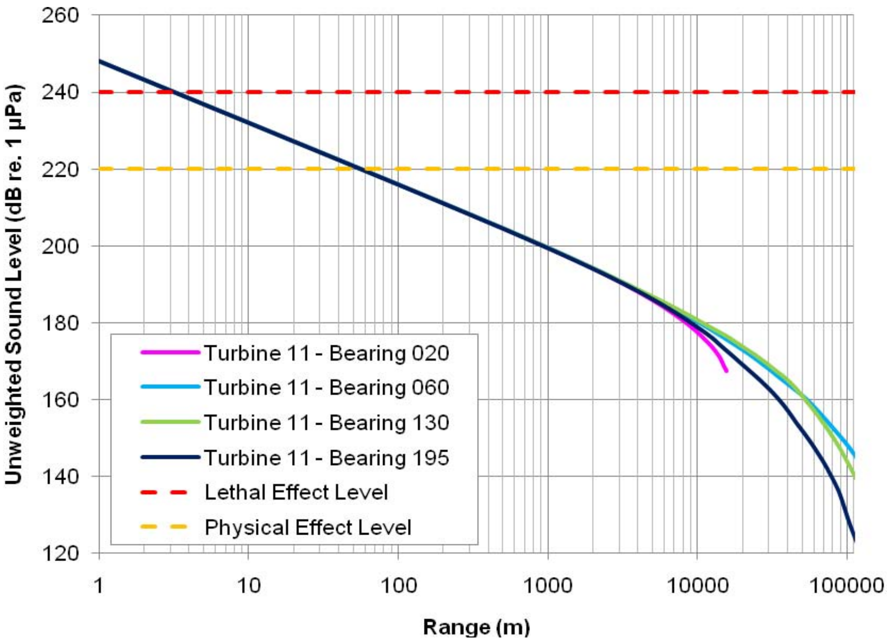

Figure 8-2: Graph showing the unweighted peak to peak noise level with range for the four transects extending from wind turbine 11

Although bottlenose dolphins frequently occur in Aberdeen Bay it is predicted that it is unlikely for a bottlenose dolphin to be within 3 m of the wind turbine during installation and therefore not at risk of mortality.

Hearing impairment in the form of a Temporary Threshold shift (TTS) in hearing may occur where a bottlenose dolphin is exposed to a levels of 130 dB_{ht} and Permanent Threshold Shift (PTS) may occur with repetitive exposure. M-weighted Sound Exposure Levels (dB re. 1 $\mu Pa^2 s$ (M)) have also been used and TTS is predicted to occur at sound levels of 198 dB re 1 $\mu Pa^2/s$ (M_{hf}) (Table 8-1).

Table 8-1: Proposed auditory exposure criteria for bottlenose dolphin frequency specific hearing

Marine mammal group	Sound type	
	Single pulses	Multiple Pulses
Mid Frequency Cetaceans (i.e. bottlenose dolphin)		
Sound Pressure Level	230 dB re 1 µPa (peak)	230 dB re 1 µPa (peak)
Sound Exposure Level	198 dB re 1 $\mu Pa^2/s$ (M_{hf})	198 dB re 1 $\mu Pa^2/s$ (M_{hf})

The 130 dB_{ht} perceived level is used to indicate traumatic hearing damage over a very short exposure time of only a few pile strikes at most (Nedwell *et al*. 2007). Based on this measure it is predicted that there is the potential for traumatic hearing damage out to 290 m from sound source. However, when applying the criteria used by Southall it is predicted that there is the potential for a permanent threshold shift out to 5 m from source or 7 m when based on the single pulse Sound Exposure Level (SEL) criteria which have taken consideration of the hearing capabilities of marine mammal function hearing groups (Southall *et al*. 2007).

Based on the above range of modelling results it is predicted that there is a potential for auditory injury, i.e. permanent threshold shift of between 5 m and 290 m from the sound source, depending on the criteria selected. For the purposes of this assessment the precautionary worst-case figure of 290 m has been used.

It is unlikely that bottlenose dolphin will be present in the vicinity of the proposed development during the period of construction at a range that could cause auditory injury.

As part of any potential future construction operations there will be a Marine Mammal Protection Plan developed in order to ensure that there is a minimal risk of potential impact on bottlenose dolphins arising from construction. As part of the Plan and likely industry standard Licence conditions there will be qualified and experienced marine mammal observers present during construction and the relevant JNCC guidelines will be followed. This will further minimise the potential risk of a bottlenose dolphin being present in the area during construction. Consequently, it is predicted that there will not be an adverse effect with respect to auditory injury on bottlenose dolphins arising from construction.

8.1.2 Risk of disturbance impacts

Similar modelling has been undertaken to assess the potential risk of disturbance to bottlenose dolphins from construction operations. Table 8-2 presents a comparison between the mean predicted dB_{ht} behavioural avoidance impact ranges and the mean M-weighted SEL behavioural avoidance impact ranges for bottlenose dolphin.

The impact ranges for dB_{ht} differ substantially from those predicted using the M-weighted SEL criteria. The ranges using the M-weighted SEL criteria are thought to be highly optimistic, and are in conflict with the limited amount of published information currently available. For instance, harbour porpoise have been found to avoid an area around similar pile driving operations out to a distance of 15 km (Tougaard *et al*. 2006). The most precautionary estimates for the extent of potential disturbance are that there is the potential for avoidance behaviour out to 8.5 km from the possible pile-driving operations.

The accumulated exposure to sound for marine mammals has also been assessed using the auditory injury criteria proposed by Southall *et al*. (2007). This has been done by calculating a standoff range for each marine mammal group, whereby it would safely be able to escape the affected area without receiving a damaging exposure to the sound. The results indicate that a bottlenose dolphin between 120 m and 820 m from the sound source may be impacted from a multiple sound source, i.e. repeated hammering of piles.

Table 8-2: Summary of impact ranges comparing the single pulse behavioural avoidance ranges predicted using the dB_{ht} criteria (Nedwell *et al.* 2007) and the M-weighted SEL approach (Southall *et al.* 2007)

dB_{ht} (Nedwell *et al*, 2007)		M-weighted SELs (Southall *et al*, 2007)	
Species	**Mean behavioural avoidance range (90 dB_{ht})**	**Equivalent M-weighting group**	**Mean behavioural avoidance range**
Bottlenose Dolphin	8.5 km	Mid Frequency Cetacean	120 m

The range at which potential adverse behavioural responses is up to 8.5 km for bottlenose dolphin. However, the behavioural effects are only expected to occur during the piling activities and as such are limited to a maximum time period of 24 hours per pile, although it is expected to take considerably less time than this. The piling of jacket structures is expected to require piles with smaller diameters and will take less time to install, although there will be a greater number of piles per platform. Any behavioural effects that occur to the bottlenose dolphin are expected to be reversible, in that their behaviour will no longer be changed when the piling activity has ceased. Furthermore, as bottlenose dolphins are present along the east coast of Scotland, it is predicted that the temporary displacement of animals from the Aberdeen Bay area will be mitigated by animals moving into other areas within their natural range albeit for a short period of time. Consequently, it is predicted that any potential behavioural responses will be of short duration and not significant.

Risk of an adverse effect– Low

8.1.3 In-combination effects

Bottlenose dolphins from the Moray Firth SAC also occur in the Tay and Firth of Forth area. And therefore there is a potential for an in-combination impact with developments in the Moray Firth and Firth of Forth.

Currently there are no known planned construction activities being undertaken at any of the Round 3 or Scottish Territorial Waters proposed offshore wind farms in 2013; the first year of potential construction planned for the EOWDC. However, there is potential for some construction to be undertaken in 2014 and this may overlap with construction of two other proposed developments in the Moray Firth and Firth of Forth (Table 5-2).

Should this occur then there may be a relatively short period of overlapping construction in 2014 during which time seven turbines may be installed at the proposed EOWDC. It is predicted that the installation of seven turbines will take place over a period of approximately seven days. Consequently, there will be a relatively short period when activities that could impact on bottlenose dolphins overlap. However, the two projects that have the potential to be constructing during the same period of seven days are both in excess of 100 km away and therefore the impacts arising from them, i.e. noise will not spatially overlap. There may be some displacement of bottlenose dolphins away from an area during the short period of time it will take to install up to seven turbines but this potential displacement is not considered to be significant either alone or in-combination with the possible two other projects 100 km away.

Risk of an adverse effect from in-combination impacts – Low

8.1.4 Conclusion

Taking into account data obtained from the proposed EOWDC area and supported by published data from other sites, along with industry standard mitigation measures, it is concluded that the proposed development either alone or in-combination will not cause an adverse effect on the integrity of the relevant SAC with regard to bottlenose dolphin.

The use of a soft start and marine mammal observers complying with the relevant JNCC guidance will reduce the risk of bottlenose dolphins being present within close proximity of the construction activities.

Grey and Common (harbour) seals

Further information on the distribution of both grey and common seals is presented within the *Marine Mammal Impact Environmental Baseline* and *EIA Technical Report on Marine Mammals* assessments prepared for the proposed EOWDC Environmental Statement (Appendices 12.1 and 12.2 of the Environmental Statement).

A total of 114 individual seals, of which a total of 44 were grey seals, 27 harbour seals and 37 were unidentified seals were observed during boat based surveys undertaken within Aberdeen Bay (Figure 8-3 and Figure 8-4).

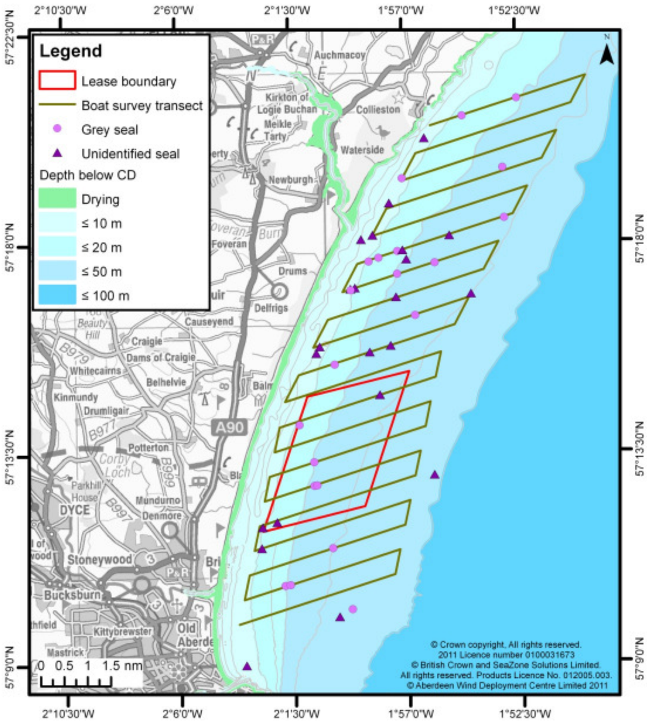

Figure 8-3: Grey and unidentified seals observed during the EOWDC boat based surveys during 2007-2008 (collected on and off-effort)

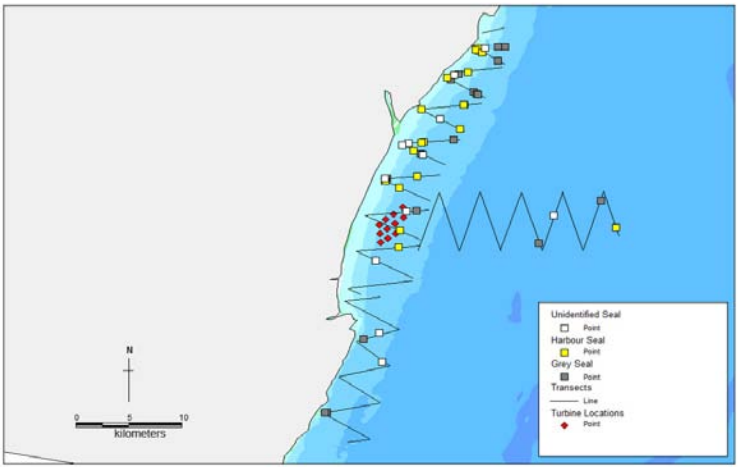

Figure 8-4: On-effort observations of seals along boat-based transects during August, September and November 2010, and January 2011.

Adult grey seals routinely move large distances. Grey seal movements have been studied in the North Sea using satellite-linked telemetry. In a study of animals at the Farne Islands and Abertay Sands, McConnell *et al.* (1999) found that movements were on two geographical scales: long and distant travel (up to 2,100 km away) to known haul-out sites; and local, repeated trips from haul-out sites to discrete offshore areas. Long-distance travel included visits to Orkney, Shetland, the Faroes, and far offshore into the Eastern Atlantic and the North Sea (Hammond *et al*. 2004). Recent telemetry studies have found that seals tagged as far south as the Farne Islands, Isle of May and Moray Firth have been found to enter the Pentland Firth area (SMRU 2011).

In 88% of trips to sea, individual grey seals returned to the same haul-out site from which they departed. The durations of these return trips were short (typically 2-3 days) and their destinations at sea were often localized areas characterized by a seabed of gravel/sand. This is the preferred burrowing habitat of sandeels, an important component of grey seal diet. The limited distance from a haul-out site of return trips (about 40 km) indicates that the seals were foraging within the coastal zone, rather than further offshore (Hammond *et al*., 2004).

The analysis of the seal telemetry data has shown that grey seals tagged in both the Isle of May SAC and Berwickshire and North Northumberland coast SAC appear to routinely travel past Aberdeen through the proposed location on the way to the Pentland Firth.

The radio-tracking of adult female common seals in the inner Moray Firth (1988, 1989, 1992) during the breeding season indicated that seals foraged up to 45 km from the haul-out site, but females with pups restricted their range markedly during the early part of the lactation period (Thompson *et al*. 1994).

Generally it has been thought that common seals forage relatively close inshore within a range of 60 km from their haul-out sites (Thompson *et al.* 1996). However, recent information on foraging movements and the distribution at sea of common seals has highlighted greater travel distances, ranging from 10 km to 120 km, with a mean of 46 km (Hammond *et al*. 2004).

Data from satellite relay data loggers (SRDLs) have highlighted different foraging behaviour of common seals off south-east Scotland and around Orkney and Shetland. Off south-east Scotland, animals were found to be very faithful in their use of haul-out sites on land, and moderately site-faithful in the areas individuals used to forage. Duration of trips ranged from less than one day to 23 days, with a mean of 4.5 days. Foraging in the Moray Firth was mostly closer to the shore. Around Orkney and Shetland there are indications that seals tend to move between haul-outs sites within a 40 km radius of where they were captured with one animal hauling out as far as 200 km from where it was initially tagged. Foraging behaviour is also much more variable both in distance travelled and in the duration of trips. Most foraging trips are within 40 km of haul-outs but there are also longer distance trips to areas more than 200 km from haul-out sites (Hammond *et al*. 2004).

8.1.5 Risk of physical impacts

Further detailed information on the potential impacts arising from the proposed development on grey and common seals are presented in the EIA technical report on marine mammals (Appendix 12.2 of the Environmental Statement).

There is a risk of physical impacts on grey and common seals from the proposed development, particularly during the construction phase when wind turbines may be pile driven into the seabed. Noise generated from pile driving has the potential to cause a range of effects ranging from mortality to permanent physical damage, temporary physical damage and disturbance or displacement.

Underwater sound modelling based on the installation of an 8.5 m diameter monopile

For the assessment of physical injury to marine mammals a number of different impact criteria including those proposed by Parvin *et al*. (2007), and also the audiological impact criteria that have been developed by Southall *et al*. (2007) have been used.

Sound levels used in the assessment of physical impacts to determine potential adverse effect on grey and common seal are:

- lethal effect may occur in seals where peak to peak levels exceed 240 dB re.1µPa
- physical injury may occur in seals where peak to peak levels exceed 220 dB re.1µPa

The results from the underwater noise modelling undertaken based on the worst-case scenario from piling an 8.5 m diameter turbine indicate that the lethal effect level (240 dB peak-peak) and the physical effect level (220 dB peak-peak) will be exceeded at 3 m and 60 m, respectively.

Although both grey and common seals frequently occur in Aberdeen Bay it is predicted that it is unlikely that they will be within 3 m of the wind turbine during installation and therefore not at risk of mortality. However, it is recognised that seals may be curious and therefore may approach the proposed construction activities closer than other marine mammals. The use of a soft start and marine mammal observers complying with the relevant JNCC guidance will reduce the risk of a seal being present within close proximity of the construction activities.

The nearest SAC for grey seal is the Isle of May SAC which is approximately 119 km to the south and the Berwick and Northumberland Coast SAC which is approximately 150 km from the proposed development. The nearest SAC for which common seal is a qualifying species is the Forth of Tay & Eden Estuary SAC which lies 96 Km to the south. Although there may be some passage of seals between this SAC and others in the Pentland Firth the number of either grey or common seals present in Aberdeen Bay from these sites during the relatively short period of construction is predicted to be low, particularly noting that grey seals return from foraging trips to the same haul out site on 88% of occasions and that common seals are not known to undertake regular foraging trips of greater than 60 km and are therefore unlikely to be regularly present in Aberdeen Bay.

Based on the modelling results it is predicted that there is a potential for auditory injury, i.e. permanent threshold shift of between 5 m and 130 m from the sound source, depending on the criteria selected. For the purposes of this assessment the precautionary worst-case figure of 130 m has been used.

The accumulated exposure to sound for marine mammals has been assessed using the auditory injury criteria proposed by Southall *et al*. (2007). This has been done by calculating a standoff range for each marine mammal group, whereby it would safely be able to escape the affected area without receiving a damaging exposure to the sound. The results indicate that a seal between 190 m and 3,600 m from the sound source may be impacted from a multiple sound source, i.e. repeated piling hammers.

It is expected that the perceived loudness of the piling activity will cause the marine mammal to exhibit an aversive behavioural reaction, with the animal moving from the area before the onset of any auditory injury can occur.

There is a risk to individual marine mammals that are exposed to high sound levels in the immediate vicinity of the piling operation, given that marine mammals may be subject to sound levels that are capable of causing physical impacts, including both auditory and non-auditory impacts. Animals would have to be present within the immediate area of the pile driver to be at risk of physical effects and it is considered the risk of marine mammals receiving sound levels capable of causing their death is remote.

8.1.6 Risk of disturbance impacts

Similar modelling has been undertaken to assess the potential risk of disturbance to grey and common seals from construction operations. Table 8-2 presents a comparison between the mean predicted dB_{ht} behavioural avoidance impact ranges and the mean M-weighted SEL behavioural avoidance impact ranges for bottlenose dolphin.

The impact ranges for dB_{ht} differ substantially from those predicted using the M-weighted SEL criteria. The ranges using the M-weighted SEL criteria are thought to be highly optimistic, and are in conflict with the limited amount of published information currently available. For instance, harbour porpoise have been found to avoid an area around similar pile driving operations out to a distance of 15 km (Tougaard *et al*. 2006). The most precautionary estimates for the extent of potential disturbance are that there is the potential for avoidance behaviour out to 8.5 km from the possible pile-driving operations.

The accumulated exposure to sound for marine mammals has also been assessed using the auditory injury criteria proposed by Southall *et al*. (2007). This has been done by calculating a standoff range for each marine mammal group, whereby it would safely be able to escape the affected area without receiving a damaging exposure to the sound. The results indicate that a bottlenose dolphin between 120 m and 820 m from the sound source may be impacted from a multiple sound source, i.e. repeated hammering of piles.

Table 8-3: Summary of impact ranges for common seals comparing the single pulse behavioural avoidance ranges predicted using the dB_{ht} criteria (Nedwell *et al*. 2007) and the M-weighted SEL approach (Southall *et al*. 2007)

dB_{ht} (Nedwell *et al*, 2007)		M-weighted SELs (Southall *et al*, 2007)	
Species	**Mean behavioural avoidance range (90 dB_{ht})**	**Equivalent M-weighting group**	**Mean behavioural avoidance range**
Common seal	9.6 km	Pinnipeds in water	1.6 km

The range at which potential adverse behavioural responses to common seals is up to 9.6 km and it is predicted that it will be the very similar for grey seals. The behavioural effects are only expected to occur during the piling activities and as such are limited to a maximum time period of 24 hours per pile; although it is expected to take considerably less time than this. Any behavioural effects that occur to the Seals are expected to be reversible, in that their behaviour will no longer be changed when the piling activity has ceased. Furthermore, as the seals that may be present are from SACs to the south of the proposed development area and any individuals present in Aberdeen Bay from the qualify sites are likely to be in transit and not resident, the potential displacement away from Aberdeen Bay will be temporary. It is therefore predicted that individuals in transit will not remain in the area of potential disturbance. Consequently, it is predicted that any potential behavioural responses will be of short duration and not significant.

Risk of an adverse effect– Low

8.1.7 In-combination effects

Grey seals from the Isle of May SAC and the Berwick and Northumberland SAC are likely to occur in areas of other potential offshore renewable projects, particularly in the Firth of Forth where there are currently three proposed offshore wind farms. Therefore, there is a potential for an in-combination impact with developments in the Moray Firth.

Based on results from tagging studies, common seals from the Firth of Tay and Eden Estuary are not predicted to occur regularly in the vicinity of the proposed EOWDC and therefore not at risk of an adverse in-combination effect in relation to the proposed development.

Currently there are no known planned construction activities being undertaken at any of the Round 3 or Scottish Territorial Waters proposed offshore wind farms in 2013; the first year of potential construction planned for the EOWDC. However, there is potential for some construction to be undertaken in 2014 and this may overlap with construction of one of the Firth of Forth development, Neart na Gaoithe (Table 5-2).

Should this occur then there may be a relatively short period of overlapping construction in 2014 during which time seven turbines may be installed over a period of approximately seven days at the proposed EOWDC. Consequently, there will be a relatively short period when activities that could impact on seals overlap. However, the proposed Neart Na Gaoithe development is in excess of 100 km from the proposed EOWDC site and therefore the impacts arising from them, i.e. noise will not spatially overlap. There may be some displacement of grey and common seals away from the area during the short period of time it will take to install up to seven turbines but this potential displacement is not considered to be significant either alone or in-combination with a possible other project 100 km away.

Risk of an adverse effect from in-combination impacts – Low

8.1.8 Conclusion

Taking into account data obtained from the proposed EOWDC and supported by published data from other sites along with industry standard mitigation measures it is concluded that the proposed development either alone or in-combination will not cause an adverse effect on the integrity of the relevant SACs with regard to grey seal or common seal.

Atlantic Salmon

The Atlantic salmon is a qualifying species for the River Dee SAC and River South Esk SAC.

Further information on the Atlantic salmon is presented within the *Salmon and Sea Trout Ecology and Fisheries Baseline Assessment* and the *Salmon and Sea trout Impact Assessment* sections of the EIA (Appendices 22.1 and 22.2 of the Environmental Statement).

Atlantic salmon have complex lifecycles during which they spend a proportion of their lives in both freshwater and saltwater.

Young salmon remain in the rivers where they hatched for up to four or five years, although in Scottish rivers two or three years is more usual. Approximately 75% of smolt (young salmon) caught in the River Dee are 2 years old with the rest being mainly 3 years old. They migrate down river to the sea between April and June where they remain for at least one year but usually two or three, before returning back up river, usually in the spring, to spawn, after which the majority of adult salmon die.

When salmon leave the rivers they do so together in shoals leaving the rivers rapidly. The exact migration routes of Salmon from Scottish rivers are not precisely known but they are known to occur in the north-west Atlantic and around West Greenland and the Faroes. The fish swim rapidly at a rate of between 7 – 30 km per day near to the sea surface and can rapidly travel over long distances.

Although salmon may return to the rivers throughout the year with no specific migration period, Multi Sea Winter (MSW) salmon start returning to the rivers in late winter and early spring and continue through to end of May or early June. All the salmon caught in the River Dee during this period are MSW salmon. Summer salmon occur from May onwards and have spent two winters at sea. They, along with grilse (one year old salmon), occur in highest numbers from between July and October. Returning salmon do not delay entry into the rivers and move into them as long as the river conditions are suitable. It is thought that returning salmon migrate along the coasts before entering their rivers.

A review paper by Malcolm *et al.* (2010), suggests a range of potential migratory routes for salmon in Scottish coastal waters, primarily using the results of adult fish tagging studies and the spatial distribution of tag returns from adult fish tagged as smolts as they left Scottish rivers.

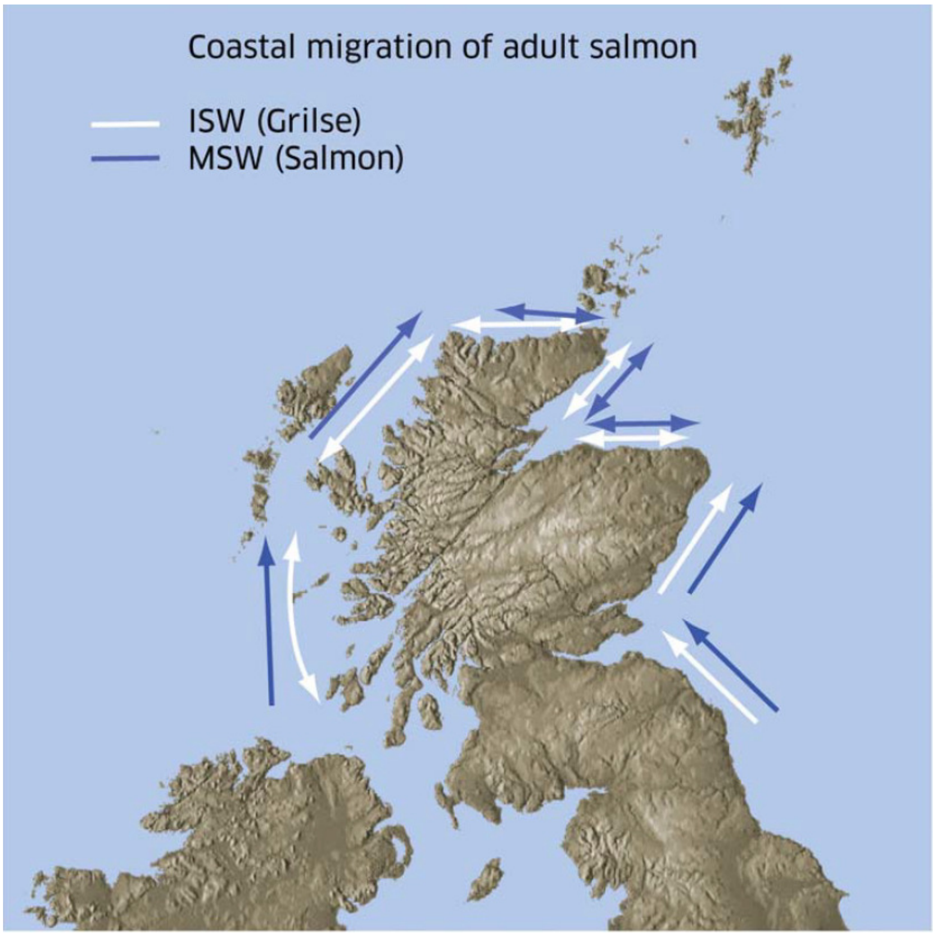

Figure 8-5: Predicted routes of Scottish Atlantic salmon (Malcolm *et al.* 2010)

Salmon entering the River South Esk SAC and River Dee SAC do so from a southerly direction and leave the rivers moving north.

8.1.9 Risk of physical impacts from noise

Potential adverse effects could arise from noise generated during the construction, operation and decommissioning phases of the proposed development. In particular, during the construction period where, should piling occur, the highest noise levels will arise.

Noise modelling undertaken for the proposed EOWDC predict that should piling of 8.5 m diameter piles take place, there is the potential for traumatic hearing damage to Atlantic salmon (based on 130 dB_{ht}) at distances of 20 m or less from the piling operations.

The results from noise modelling undertaken indicate that lethal effects on Atlantic salmon from pile driving associated with the proposed development will only occur out to 3 m from the source. Physical hearing damage may occur out to 20 m or less. Based on the very close range at which salmon are predicted to be required to be in order for there to be a risk of a physical impact and the low numbers of salmon that would occur within the small spatial area along with the relatively short duration possible pile-driving may occur, it is predicted that there will not be any adverse effect on the Atlantic salmon associated with either the River Dee SAC or River South Esk SAC.

8.1.10 Risk of behavioural impacts from noise

Modelling undertaken based on the piling of 8.5 m diameter piles indicates that there is the potential for a strong behavioural reaction out to between 3.6 km and 4.7 km from the construction activities based on a threshold of 90 dB_{ht} and that at levels of 75 dBht up to 85% of salmon may react to noise. The results from the noise modelling undertaken are presented in Figure 8-6.

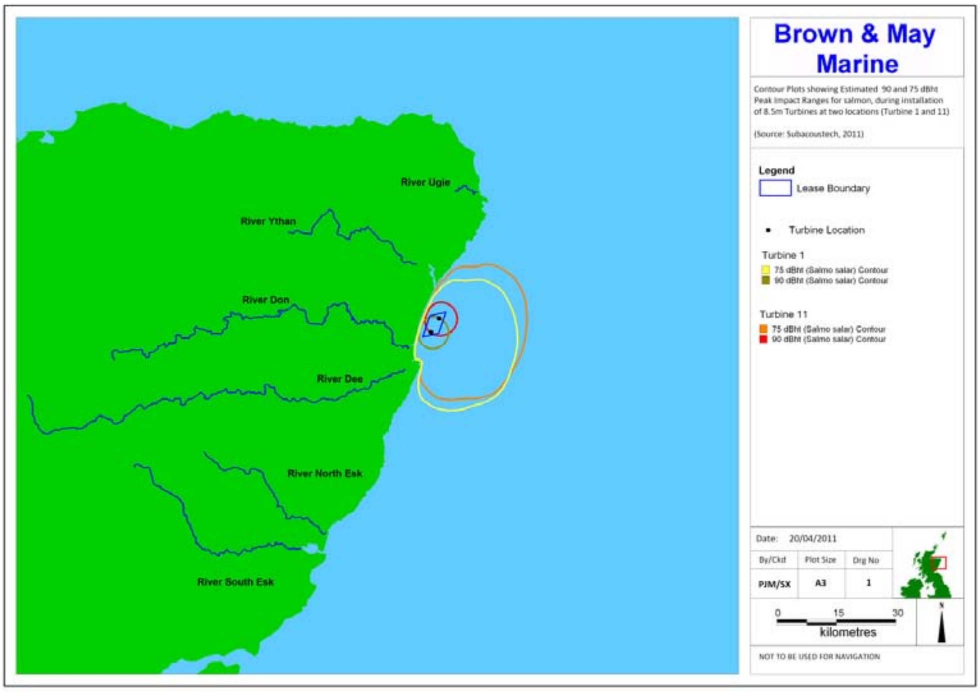

Figure 8-6: Contour Plots showing Estimated 90 and 75dB_{ht} *(Salmo salar)* peak impact ranges during installation of 8.5 m diameter wind turbines at two locations (Turbine 1 and 11)

Salmon are considered to be poor at detecting sounds within the water column although they may be able to detect substrate borne sounds (Gill and Bartlett, 2010).

Salmon smolts and post smolts leaving the SACs do so rapidly, leaving the rivers between April and June and most likely move northwards towards north-west Atlantic, Greenland and the Faroes and unlike returning adults do not necessarily follow the coastlines. Therefore, there is the potential for salmon leaving the relevant SACs to occur within the vicinity of the proposed development. However, the number of salmon smolts and post smolts likely to be in the area of potential impact at any one time is predicted to be low as they depart the rivers over a period of months. The consequences to those that could be affected may mean that either they delay their departure from the rivers for the relatively short period of time during construction, or they may detour around the sound source during the period of migration. The scale of any detour is very small compared to the distances travelled during migration. It is therefore predicted that any behavioural responses arising from construction of the proposed development will not have an adverse effect.

Adult salmon returning to the River South Esk will be unlikely to be impacted by construction activities associated with the proposed development as they return to the river from the south and therefore outwith any zone of potential effect. Salmon returning to the River Dee SAC may be impacted as there is a potential overlap with sound sources that could cause behavioural responses and the River Dee SAC. There are predicted to be potentially two behavioural responses that may occur. Returning Atlantic salmon may delay their entry into the river during piling activities or they may ignore the sound source and enter the river without delay. Should they delay their entry into the River Dee SAC then it will for the duration of piling operations which are predicted to last no longer than 24 hrs per wind turbine and therefore of relatively short duration. Atlantic salmon are known to naturally delay entry into rivers until suitable conditions occur so a delay would not likely have an impact on the salmon.

There is no evidence from other offshore wind farms that operational noise has any adverse effect on fish species, with no decreases in the numbers of fish present within turbine arrays during the operational period of a wind farm. Studies undertaken on Atlantic salmon indicate that although salmon can detect operational turbines at a distance of 0.4 km and 0.5 km behavioural responses only occurred 4 m and then only at high wind speeds (above 30 m/s) (Walhberg & Westerberg 2005).

Based on the above it is predicted that the potential noise impacts arising from the proposed project will not have an adverse effect on the Atlantic salmon associated with the River Dee SAC or River South Esk SAC

Risk of an adverse effect– Low

8.1.11 Risk of impacts from increased sediments

Construction activities such as cable laying, piling and rock placement have potential to result in temporary sediment re-suspension increasing turbidity.

Suspended sediment concentrations within Aberdeen Bay range from 0.1 to 43.1 mg/l with an average of 20.7 mg/l. Sediment modelling has indicated that following construction there is the potential for a sediment plume to occur with a maximum concentration of 35mg/l extending from Aberdeen Harbour to approximately 3 km south of the River Ythan.

Salmon can be affected by high sediment loads, which if high enough can be lethal or at lower levels cause behavioural changes. Lethal sediment loads typically range from between hundreds and thousands mg/l, whilst sub-lethal effects may occur at lower levels, ranging from tens to hundreds mg/l depending on species specific tolerance. Salmon are considered tolerant of relatively high sediment loads with behavioural changes occurring at between 60 to 180 mg/l and therefore unlikely to be affected by the potentially increased loads arising during construction period. The duration of any impact will be short and, should it occur, only arise during the period of construction, which is predicted to be less than 24 hours per turbine. It is therefore predicted that there is unlikely to be an adverse effect arising from the proposed development on Atlantic salmon due to possible short-term increased in turbidity.

8.1.12 Risk of impacts from Electromagnetic Fields

The magnetic fields anticipated to be produced by the AC cables associated with the proposed EOWDC are small (1.5 µT) in comparison to the Earth's magnetic field (approximately 50 µT). Atlantic salmon are expected to perceive these magnetic fields as new localised additions to the heterogeneous pattern of geomagnetic anomalies already occurring naturally and anthropogenically in the sea (MS 2011).

The location of the proposed development, to the north of the River Dee SAC and River South Esk SAC means that returning salmon from the south will not be impacted by any potential EMF arising from the proposed development.

Salmon leaving the SACs may pass across the cables and therefore detect an electromagnetic field. However, studies undertaken on chum salmon and other fish species have not been able to detect any effects from magnetic fields on them (OSPAR 2008). Consequently, it is predicted that there will not be an adverse effect on Atlantic salmon from electromagnetic fields.

Risk of an adverse effect– Low

8.1.13 In-combination effects

Atlantic salmon from the relevant SACs may also occur in either the proposed developments in the Moray Firth or the Firth of Forth.

Currently, there are no known planned construction activities being undertaken at any of the Round 3 or Scottish Territorial Waters proposed offshore wind farms in 2013, the first year of potential construction planned for the proposed EOWDC. There is potential for some construction to be undertaken in 2014 and this may overlap with construction of two other proposed developments (Table 5-2).

Should this occur then there may be a relatively short period of overlapping construction in 2014 during which seven turbines may be installed at the proposed EOWDC. The relatively short duration of any overlapping activities and that the projects are both in excess of 100 km away, it is predicted that should there be any in-combination effects they will not cause an adverse effect on the Atlantic salmon associated with the River Dee and River South Esk SACs.

Risk of an adverse effect from in-combination impacts – Low

8.1.14 Conclusion

Taking into account data obtained from the proposed EOWDC area and supported by published data from other sites it is concluded that the proposed development either alone or in-combination will not cause an adverse effect on the integrity of the relevant SACs with regard to Atlantic Salmon. Consultation with the Regulator, statutory advisors and relevant stakeholders will take place once detailed construction information is available to identify any practical, robust and appropriate mitigation measures that may further reduce any risk.

.

Freshwater Pearl Mussel

The Freshwater Pearl Mussel is a qualifying species for the River Dee SAC and the River South Esk SAC.

The freshwater pearl mussel is dependent on salmonid fish during the larval stage of their life cycle, during which time they attach themselves onto the gills of salmon or sea trout until the following summer when they drop off onto the river bed. There is therefore a theoretical possibility that, should there be any significant displacement of salmon or sea trout from their spawning rivers, there could be an adverse effect on the freshwater pearl mussel. As indicated above, it is concluded that any potential effect, either alone or in-combination on Atlantic salmon would, should one occur, be localised, of short duration and only likely to affect a small number of individuals. The same conclusions are made with respect to sea trout.

It is therefore predicted that there will not be any adverse effects on the host species from the proposed development. Consequently, it is anticipated that there will not be any impact on the freshwater pearl mussel.

Risk of an adverse effect – Low

9 CONCLUSIONS

Based on data obtained from the proposed EOWDC area and supported by published data from other sites, it is considered that sufficient information is available to enable a Habitats Regulations Appraisal to be undertaken should it be required. It is concluded that the proposed EOWDC will not cause, on its own or in-combination, an adverse effect on the integrity of the relevant European Sites. Agreed mitigation measures will further reduce the risk of any potential impact. An agreed monitoring programme to be prepared in consultation with the Regulator and advisors will further ensure that the conclusions made are valid.

11 APPENDIX A

Site	**Buchan Ness to Collieston Coast (including marine extension) SPA**
Area	Area: 5,400.94 ha
Site description	Buchan Ness to Collieston Coast SPA is a stretch of south-east facing cliff in Aberdeenshire, Scotland. The 15 km stretch of cliffs, formed of granite, quartzite and other rocks, runs south of Peterhead, broken only by the sandy beach of Cruden Bay. The varied coastal vegetation on the ledges and the cliff tops includes maritime heath, grassland and brackish flushes. The boundary of the SPA follows the boundaries of Bullers of Buchan Coast SSSI and Collieston to Whinnyfold Coast SSSI, and the seaward extension extends approximately 2 km into the marine environment to include the seabed, water column and surface.
Qualifying Interest	Article 4.2 by regularly supporting in excess of 20,000 individual seabirds. It regularly supports 95,000 seabirds including nationally important populations of the following species: Black-legged kittiwake *Rissa tridactyla* (30,452 pairs, 6.2% of the GB population), Common guillemot *Uria aalge* (8,640 pairs, 1.2% of GB population), Herring gull *Larus argentatus* (4,292 pairs, 2.7% of the GB population), European shag *Phalacrocorax aristotelis* (1,045 pairs, 2.7% of the GB population) Northern fulmar *Fulmarus glacialis* (1,765 pairs, 0.3% of the GB population).
Conservation Objectives	To avoid deterioration of the habitats of the qualifying species (listed below) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and To ensure for the qualifying species that the following are maintained in the long term: • Population of the species as a viable component of the site. • Distribution of the species within site. • Distribution and extent of habitats supporting the species. • Structure, function and supporting processes of habitats supporting the species. • No significant disturbance of the species. Qualifying Species: Fulmar (*Fulmarus glacialis*) Guillemot (*Uria aalge*) Herring gull (*Larus argentatus*) Kittiwake (*Rissa tridactyla*) Shag (*Phalacrocorax aristotelis*)* Seabird assemblage

Site	Fair Isle SPA
Area	6,824.40 ha
Site description	Fair Isle is an Old Red Sandstone island, the most southerly of the Shetland group, lying halfway between Mainland and Orkney. It has a rocky, cliff coastline with adjacent coastal waters, heather moorland, acidic grassland, maritime grassland and crofting in-bye. The boundary of Fair Isle SPA is coincident with Fair Isle SSSI. The seaward extension extends approximately 2 km into the marine environment to include the seabed, water column and surface.
Qualifying Interest	Fair Isle SPA qualifies under Article 4.1 by regularly supporting populations of European importance of the Annex 1 species: Fair Isle wren *Troglodytes troglodytes fridariensis* (33 territorial males, 100% of the GB population) Arctic tern *Sterna paradisaea* (1100 pairs, 1% of the GB population). Fair Isle SPA further qualifies under Article 4.2 by regularly supporting populations of European importance of the migratory species: Common guillemot *Uria aalge* (32,300 individuals, 1.4% of the north Atlantic biogeographic population). Fair Isle SPA also qualifies under Article 4.2 by regularly supporting in excess of 20,000 individual seabirds. It regularly supports 180,000 seabirds including nationally important populations of the following species: Atlantic puffin *Fratercula arctica* (23,000 individuals, 2% of the GB population) Razorbill *Alca torda* (3,400 individuals, 2% of the GB population), Black-legged kittiwake *Rissa tridactyla* (18,160 pairs, 4% of the GB population), Great skua *Stercorarius skua* (110 pairs, 1% of the GB population), Arctic skua *Stercorarius parasiticus* (110 pairs, 3% of the GB population) European shag *Phalocrocorax aristotelis* (1,100 pairs, 3% of the GB population) Northern gannet *Morus bassanus* (1,166 pairs, 0.6% of the GB population), Northern fulmar *Fulmaris glacialis* (35,210 pairs, 7% of the GB population) Common guillemot *Uria aalge* (32,300 individuals, 3% of the GB population) Arctic tern *Sterna paradisaea* (1,100 pairs).
Conservation Objectives	To avoid deterioration of the habitats of the qualifying species (listed below) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and To ensure for the qualifying species that the following are maintained in the long term: • Population of the species as a viable component of the site. • Distribution of the species within site. • Distribution and extent of habitats supporting the species. • Structure, function and supporting processes of habitats supporting the species. • No significant disturbance of the species. Qualifying Species:

	Arctic skua (*Stercorarius parasiticus)* Arctic tern (*Sterna paradisaea)* Fair Isle wren (*Troglodytes troglodytes fridariensis)* Fulmar (*Fulmarus glacialis)* Gannet (*Morus bassanus*) Great skua (*Stercorarius skua*) Guillemot (*Uria aalge)* Kittiwake (*Rissa tridactyla)* Puffin (*Fratercula arctica)* Razorbill (*Alca torda)* Shag (*Phalocrocorax aristotelis)** Seabird assemblage
Note – Relevant qualifying interests are for gannet only as advised by SNH (SNH 2010).	

Site	Firth of Forth SPA and Ramsar
Area	6,313.72 ha
Site description	The Firth of Forth SPA is a complex of estuarine and coastal habitats in south-east Scotland stretching east from Alloa to the coasts of Fife and East Lothian. The site includes extensive invertebrate-rich intertidal flats and rocky shores, areas of saltmarsh, lagoons and sand dune. The site is underpinned by the Firth of Forth SSSI.
Qualifying Interest	The Firth of Forth SPA qualifies under Article 4.1 by regularly supporting wintering populations (1993/94-97/98 winter peak means) of European importance of the Annex 1 species: Red-throated diver *Gavia stellata* (90 individuals; 2% of GB) Slavonian grebe *Podiceps auritus* (84; 2% of NW Europe, 21% of GB) Golden plover *Pluvialis apricaria* (2,949; 1% of GB) Bar-tailed godwit *Limosa lapponica* (1,974; 2% of Western Europe, 4% of GB). The site further qualifies under Article 4.1 by regularly supporting a post-breeding (passage) population of European importance of the Annex 1 species: Sandwich tern *Sterna sandvicensis* (1,617, 6% of GB, 1% of East Atlantic). The Firth of Forth SPA qualifies under Article 4.2 by regularly supporting wintering populations (1993/94-97/98 winter peak means) of both European and international importance of the migratory species: Pink-footed goose *Anser brachyrhynchus* (10,852; 6% of Icelandic/Greenlandic), Shelduck *Tadorna tadorna* (moulting flock of 4,509; 2% of NW European), Knot *Calidris canutus* (9,258; 3% of western European/Canadian), Redshank *Tringa totanus* (4,341; 3% of European/West African) Turnstone *Arenaria interpres* (860 individuals; 1% of European). The Firth of Forth SPA further qualifies under Article 4.2 by regularly supporting a wintering waterfowl assemblage of European importance: a 1992/93-96/97 winter peak mean of 95,000 waterfowl, comprising 45,000 wildfowl and 50,000 waders. This assemblage includes nationally important numbers of 15 migratory species: Great crested grebe *Podiceps cristatus* (720; 7% of GB), Cormorant *Phalacrocorax carbo* (682; 5% of GB), Scaup *Aythya marila* (437; 4% of GB), Eider *Somateria mollissima* (9,400; 13% of GB), Long-tailed duck *Clangula hyemalis* (1,045; 4% of GB), Common scoter *Melanitta nigra* (2,880; 8% of GB), Velvet scoter *M. fusca* (635; 21% of GB), Goldeneye *Bucephala clangula* (3,004; 18% of GB population), Red-breasted merganser *Mergus serrator* (670; 7% of GB), Oystercatcher *Haematopus ostralegus* (7,846; 2% of GB), Ringed plover *Charadrius hiaticula* (328; 1% of GB), Grey plover *Pluvialis squatarola* (724; 2% of GB), Dunlin *Calidris 122enelo* (9,514; 2% of GB), Curlew *Numenius arquata* (1,928; 2% of GB). The assemblage also includes large numbers of the following species:

	Wigeon *Anas penelope* (2,139 [1991/2-95/96]), Mallard *A. platyrhnchos* (2,564 [1991/2-95/96]) Lapwing *Vanellus vanellus* (4,148 [1991/2-95/96]).
Conservation Objectives	To avoid deterioration of the habitats of the qualifying species (listed below) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and To ensure for the qualifying species that the following are maintained in the long term: • Population of the species as a viable component of the site. • Distribution of the species within site. • Distribution and extent of habitats supporting the species. • Structure, function and supporting processes of habitats supporting the species. • No significant disturbance of the species. Qualifying Species: Bar-tailed godwit (*Limosa lapponica)* Common scoter *(Melanitta nigra)* Cormorant (*Phalacrocorax carbo)* Curlew (*Numenius arquata)** Dunlin (*Calidris alpina alpina)* Eider (*Somateria mollissima)* Golden plover (*Pluvialis apricaria)* Goldeneye (*Bucephala clangula)* Great crested grebe (*Podiceps cristatus)* Grey plover (*Pluvialis squatarola*) Knot (*Calidris canutus)* Lapwing (*Vanellus vanellus)* Long-tailed duck (*Clangula hyemalis)* Mallard (*Anas platyrhnchos)* Oystercatcher (*Haematopus ostralegus)* Pink-footed goose (*Anser brachyrhynchus)* Red-breasted merganser (*Mergus serrator)* Redshank (*Tringa totanus)* Red-throated diver (*Gavia stellata)* Ringed plover (*Charadrius hiaticula)* Sandwich tern (*Sterna sandvicensis)* Scaup (*Aythya marila)* Shelduck (*Tadorna tadorna)* Slavonian grebe (*Podiceps auritus)* Turnstone (*Arenaria interpres)* Velvet scoter (*Melanitta fusca)* Wigeon (*Anas penelope)** Waterfowl assemblage

Site	Firth of Tay & Eden Estuary SPA & Ramsar
Area	6,923.29 ha
Site description	The Firth of Tay & Eden Estuary SPA is a complex of estuarine and coastal habitats in eastern Scotland stretching from the mouth of the River Earn in the inner Firth of Tay east to Barry Sands on the Angus coast and St Andrews on the Fife Coast. The site includes extensive invertebrate-rich intertidal flats and areas of reedbed, saltmarsh and sand dune. The SPA is contained within the following SSSIs: Inner Tay Estuary, Monifieth Bay, Barry Links, Tayport-Tentsmuir Coast and Eden Estuary
Qualifying Interest	The Firth of Tay & Eden Estuary SPA qualifies under Article 4.1 of the Birds Directive by regularly supporting nationally important breeding populations of the Annex I species: Marsh harrier *Circus aeruginosus* (average of 4 females in 1992-96, 3% of British population) Little tern *Sterna albifrons* (average of 25 pairs between 1993 and 1997, 1% of British) Bar-tailed godwit *Limosa lapponica* (2,400, 5% of GB and 2% of Western European). The SPA qualifies under Article 4.2 by regularly supporting an internationally important wintering population of redshank *Tringa totanus* (1,800 individuals; 2% of GB and 1% of northwest European populations). The SPA qualifies under Article 4.2 by regularly supporting in winter over 20,000 waterfowl with a 1990/91-94/95 winter peak mean of 48,000 waterfowl, comprising 28,000 wildfowl and 20,000 waders. This assemblage includes internationally important wintering populations (1990/91-94/95 winter peak means) of: Pink-footed goose *Anser brachyrhynchus* (2,800; 1% of GB and Icelandic/Greenlandic populations) Greylag goose *A. anser* (1,200; 1% of GB and Icelandic populations) Nationally important wintering populations of: Cormorant *Phalacrocorax carbo* (230, 2% of GB) Shelduck *Tadorna tadorna* (1,200, 2% of GB) Eider *Somateria mollissima* (13,800, 18% of GB) Long-tailed duck *Clangula hyemalis* (560, 2% of GB) Common scoter *Melanitta nigra* (3,100; 9% of GB) Velvet scoter *Melanitta fusca* (730, 24% of GB), Goldeneye *Bucephala clangula* (230, 1% of GB) Red-breasted merganser *Mergus serrator* (470, 5% of GB) Goosander *Mergus merganser* (220, 2% of GB), Oystercatcher *Haematopus ostralegus* (5,100, 1% of GB), Grey plover *Pluvialis squatarola* (920, 2% of GB), Sanderling *Calidris alba* (220, 1% of GB), Dunlin *Calidris alpina* (5,200, 1% of GB) Black-tailed godwit *Limosa limosa* (150, 2% of GB)
Conservation Objectives	To avoid deterioration of the habitats of the qualifying species (listed below) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and To ensure for the qualifying species that the following are maintained in the long term:

	Population of the species as a viable component of the site. Distribution of the species within site. Distribution and extent of habitats supporting the species. Structure, function and supporting processes of habitats supporting the species. No significant disturbance of the species. Qualifying Species: Bar-tailed godwit (*Limosa lapponica*) Black-tailed godwit (*Limosa limosa islandica)* Common scoter (*Melanitta nigra*) Cormorant (*Phalacrocorax carbo*) Dunlin (*Calidris alpina alpina)* Eider *(Somateria mollissima)* Goldeneye (*Bucephala clangula)* Goosander (*Mergus merganser*) Grey plover (*Pluvialis squatarola*) Greylag goose (*Anser anser*) Little tern (*Sterna albifrons*) Long-tailed duck (*Clangula hyemalis*) Marsh harrier (*Circus aeruginosus*) Oystercatcher (*Haematopus ostralegus*) Pink-footed goose (*Anser brachyrhynchus*) Red-breasted merganser (*Mergus serrator*) Redshank (*Tringa totanus*) Sanderling (*Calidris alba*) Shelduck (*Tadorna tadorna*) Velvet scoter (*Melanitta fusca*) Waterfowl assemblage

Site	Forth Islands SPA
Area	9,796.98 ha
Site description	Forth Islands SPA consists of a series of islands supporting the main seabird colonies in the Firth of Forth. The islands of Inchmickery, Isle of May, Fidra, The Lamb, Craigleith and Bass Rock were classified on 25 April 1990. The extension to the site, classified on the 13th February 2004 consists of the island of Long Craig, which supports the largest colony of roseate tern in Scotland. It is the most northerly of only six regular British colonies. The boundary of the Special Protection Area overlaps with the boundaries of the following SSSIs: Long Craig, Inchmickery, Forth Islands, Bass Rock and the Isle of May, and the seaward extension extends approximately 2 km into the marine environment to include the seabed, water column and surface
Qualifying Interest	Forth Islands SPA qualifies under Article 4.1 by regularly supporting populations of European importance of the Annex 1 species: Arctic tern *Sterna paradisaea* (mean between 1992 and 1996 of 540 pairs, 1.2% of the GB population), Roseate tern *Sterna dougallii* (an average of 8 pairs, 1997 - 2001; 13% of GB population), Common tern *Sterna hirundo* (an average of 334 pairs, 1997-2001; 3% of GB population) Sandwich tern *Sterna sandvicensis* (an average of 440 pairs, 3% of GB). Forth Islands SPA further qualifies under Article 4.2 by regularly supporting populations of European importance of the migratory species; Northern gannet *Morus bassanus* (21,600 pairs, 8.2% of world biogeographic population), European shag *Phalacrocorax aristotelis* (2,400 pairs, 1.9% of N Europe biogeographic population), Lesser black-backed gull *Larus fuscus* (1,500 pairs, 1.2% of total *L.f. graellsii* biogeographic population) Atlantic puffin *Fratercula arctica* (14,000 pairs, 1.5% of total *F.a.grabae* biogeographic population). Forth Islands SPA also qualifies under Article 4.2 by regularly supporting in excess of 20,000 individual seabirds. The site regularly supports 90,000 seabirds (three year mean, 1986 – 1988) including nationally important populations of the following species: Razorbill *Alca torda* (1,400 pairs, 1.4% of GB population) Common guillemot *Uria aalge* (16,000 pairs, 2.2% of GB population), Black-legged kittiwake *Rissa tridactyla* (8,400 pairs, 1.7% of GB population), Herring gull *Larus argentatus* (6,600 pairs, 4.1% of GB population), Great cormorant *Phalacrocorax carbo* (200 pairs, 2.8% of GB population), Northern gannet (21,600 pairs), Lesser black-backed gull (1,500 pairs), European shag (2,400 pairs), Atlantic puffin (14,000 pairs), Northern fulmar (798 pairs), Arctic tern (540 pairs), Common tern (334 pairs),

	Roseate tern (8 pairs) Sandwich tern (440 pairs)
Conservation Objectives	To avoid deterioration of the habitats of the qualifying species (listed below) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and To ensure for the qualifying species that the following are maintained in the long term: • Population of the species as a viable component of the site. • Distribution of the species within site. • Distribution and extent of habitats supporting the species. • Structure, function and supporting processes of habitats supporting the species. • No significant disturbance of the species. Qualifying Species: Arctic tern (Sterna paradisaea) Common tern (Sterna hirundo) Cormorant (Phalacrocorax carbo) Fulmar (Fulmarus glacialis) Gannet (Morus bassanus) Guillemot (Uria aalge) Herring gull (Larus argentatus) Kittiwake (Rissa tridactyla) Lesser black-backed gull (Larus fuscus) Puffin (Fratercula arctica) Razorbill (Alca torda) Roseate tern (Sterna dougallii) Sandwich tern (Sterna sandvicensis) Shag (Phalacrocorax aristotelis) Seabird assemblage

Site	Fowlsheugh (including marine extension) SPA
Area	Area: 1,303.54 Ha National Grid References: NO 879836 to NO 869782
Site description	Fowlsheugh SPA, located 4 km south of Stonehaven on the east coast of Aberdeenshire in north-east Scotland, is a 10.15 ha stretch of sheer cliffs, between 30 m and 60 m high, cut mostly from basalt and conglomerate rocks of Old Red Sandstone age. The boundary of the SPA overlaps with the boundaries of Fowlsheugh SSSI. The seaward extension extends 2 km into the marine environment and includes the seabed, water column and surface.
Qualifying Interest	Fowlsheugh SPA qualifies under Article 4.2 by regularly supporting in excess of 20,000 individual seabirds. The colony regularly supports 145,000 seabirds. The colony further qualifies under Article 4.2 by regularly supporting populations of European importance of the migratory species: Common guillemot *Uria aalge* (56,450 individuals, 5% of GB population, 1.7% of Western European population), Black-legged kittiwake *Rissa tridactyla* (36,650 pairs, 7.5% of the GB population, 1.2 % of World population). The colony also regularly supports nationally important populations of: Razorbill *Alca torda* (5,800 individuals, 3.9% of the GB population). Northern fulmar *Fulmarus glacialis* (1,170 pairs, 0.2% of the GB population), Herring gull *Larus argentatus* (3,190 pairs, 2% of the GB population).
Conservation Objectives	To avoid deterioration of the habitats of the qualifying species (listed below) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and To ensure for the qualifying species that the following are maintained in the long term: • Population of the species as a viable component of the site • Distribution of the species within site • Distribution and extent of habitats supporting the species □ • Structure, function and supporting processes of habitats supporting the species □ • No significant disturbance of the species Qualifying Species: Fulmar (*Fulmarus glacialis*) Guillemot (*Uria aalge)* Herring gull (*Larus argentatus*) Kittiwake (*Rissa tridactyla)* Razorbill (*Alca torda*) Seabird assemblage

Site	Loch of Skene SPA & Ramsar
Area	120.89 ha
Site description	Loch of Skene is located about 15 km west of Aberdeen in Scotland. It is a shallow (<2 m deep) eutrophic lowland loch surrounded by fringing reedbeds and birch-willow carr. The loch supports an internationally important roost of: • Icelandic Greylag Goose *Anser anser*, • Icelandic Whooper Swan *Cygnus cygnus*. Both swans and geese feed away from the SPA on surrounding agricultural land during the day.
Qualifying Interest	This site qualifies under Article 4.1 of the Directive (79/409/EEC) by supporting populations of European importance of the following species listed on Annex I of the Directive: Over winter: Whooper Swan *Cygnus cygnus,* 203 individuals representing up to 3.7% of the wintering population in Great Britain (5 year peak mean 1991/2 - 1995/6). This site also qualifies under Article 4.2 of the Directive (79/409/EEC) by supporting populations of European importance of the following migratory species: Over winter: Greylag Goose *Anser anser*, 10,840 individuals representing up to 10.8% of the wintering Iceland/UK/Ireland population (5 year peak mean 1991/2 - 1995/6).
Conservation Objectives	To avoid deterioration of the habitats of the qualifying species (listed below) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and To ensure for the qualifying species that the following are maintained in the long term: • Population of the species as a viable component of the site. • Distribution of the species within site. • Distribution and extent of habitats supporting the species. • Structure, function and supporting processes of habitats supporting the species. • No significant disturbance of the species. Qualifying Species: Greylag goose (*Anser anser*)

Site	Loch of Strathbeg SPA & Ramsar
Area	615.94 ha
Site description	The Loch of Strathbeg is located in north-eastern Scotland, in Aberdeenshire, inland from Rattray Head. It is a shallow, naturally eutrophic loch with adjoining reedbeds, freshwater marshes, and Alder *Alnus glutinosa* and willow *Salix* spp. carr. The calcareous dunes and dune slacks within the site are relatively undisturbed and contain a rich flora. The loch constitutes the largest dune slack pool in the UK (200 ha) and the largest waterbody in the north-east Scottish lowlands. It is separated from the sea by a 0.5-1 km wide dune system. The SPA provides wintering habitat for a number of important wetland bird species, particularly wildfowl (swans, geese and ducks), and is also an important staging area for migratory wildfowl from Scandinavia and Iceland/Greenland. In summer, coastal parts of the site are an important breeding area for Sandwich Tern *Sterna sandvicensis*, which feed outside the SPA in adjacent marine areas.
Qualifying Interest	This site qualifies under Article 4.1 of the Directive (79/409/EEC) by supporting populations of European importance of the following species listed on Annex I of the Directive: During the breeding season: Sandwich Tern *Sterna sandvicensis*, 530 pairs representing up to 3.8% of the breeding population in Great Britain (5 year mean, 1993-1997). Over winter: Barnacle Goose *Branta leucopsis*, 226 individuals representing up to 1.9% of the wintering population in Great Britain (5 year peak mean 1991/2 - 1995/6). Whooper Swan *Cygnus cygnus,* 183 individuals representing up to 3.3% of the wintering population in Great Britain (5 year peak mean 1991/2 - 1995/6). This site also qualifies under Article 4.2 of the Directive (79/409/EEC) by supporting populations of European importance of the following migratory species: Over winter: Greylag Goose *Anser anser*, 3,325 individuals representing up to 3.3% of the wintering Iceland/UK/Ireland population (winter peak means). Pink-footed Goose *Anser brachyrhynchus*, 39,924 individuals representing up to 17.7% of the wintering Eastern Greenland/Iceland/UK population (5 year peak mean 1991/2 - 1995/6). Assemblage qualification: A wetland of international importance. The area qualifies under Article 4.2 of the Directive (79/409/EEC) by regularly supporting at least 20,000 waterfowl. Over winter: the area regularly supports 49,452 individual waterfowl (5 year peak mean 1991/2 - 1995/6) including: Teal *Anas crecca*, Greylag Goose *Anser anser,* Pink-footed Goose *Anser brachyrhynchus*, Barnacle Goose *Branta leucopsis,* Whooper Swan *Cygnus cygnus*.
Conservation Objectives	To avoid deterioration of the habitats of the qualifying species (listed below) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and To ensure for the qualifying species that the following are maintained in the long term: • Population of the species as a viable component of the site. • Distribution of the species within site. • Distribution and extent of habitats supporting the species. • Structure, function and supporting processes of habitats supporting the species. • No significant disturbance of the species. Qualifying Species: Barnacle goose (*Branta leucopsis*)

	Greylag goose (*Anser anser)* Pink-footed goose (*Anser brachyrhynchus*) Sandwich tern (*Sterna sandvicensis)* Teal (*Anas crecca)* Whooper swan (*Cygnus cygnus)* Waterfowl assemblage

Site	**Montrose Basin SPA & Ramsar**
Area	984.61 ha
Site description	The Montrose Basin is located on the east coast of Scotland in Angus. It is an enclosed tidal basin fed by the River South Esk and contains areas of mud-flat, marsh and agricultural land, and Dun's Dish, a small eutrophic loch. It is a good natural example of an estuary, relatively unaffected by development, with high species diversity in the intertidal zone and supporting a large population of wintering waterbirds. The site is important for wintering populations of Iceland/Greenland Pink-footed Goose *Anser brachyrhynchus* and Icelandic Greylag Goose *Anser anser,* along with ducks and waders. The geese feed away from the SPA on surrounding agricultural land during the day.
Qualifying Interest	This site qualifies under Article 4.2 of the Directive (79/409/EEC) by supporting populations of European importance of the following migratory species: Over winter: Greylag Goose *Anser anser,* 1,080 individuals representing at least 1.1% of the wintering Iceland/UK/Ireland population (5 year peak mean, 1987/8-1991/2). Knot *Calidris canutus*, 4,500 individuals representing at least 1.3% of the wintering Northeastern Canada/Greenland/Iceland/Northwestern Europe population (5 year peak mean 1991/2 - 1995/6). Pink-footed Goose *Anser brachyrhynchus*, 31,622 individuals representing at least 14.1% of the wintering Eastern Greenland/Iceland/UK population (5 year peak mean 1991/2 - 1995/6). Redshank *Tringa totanus*, 2,259 individuals representing at least 1.5% of the wintering Eastern Atlantic - wintering population (5 year peak mean 1991/2 - 1995/6) The area qualifies under Article 4.2 of the Directive (79/409/EEC) by regularly supporting at least 20,000 waterfowl: Over winter, the area regularly supports 54,917 individual waterfowl (5 year peak mean 1991/2 - 1995/6) including: Dunlin *Calidris alpina alpina*, Oystercatcher *Haematopus ostralegus*, Eider *Somateria mollissima*, Wigeon *Anas penelope*, Shelduck *Tadorna tadorna*, Redshank *Tringa totanus*, Knot *Calidris canutus*, Greylag Goose *Anser anser,* Pink-footed Goose *Anser brachyrhynchus*.
Conservation Objectives	To avoid deterioration of the habitats of the qualifying species (listed below) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and To ensure for the qualifying species that the following are maintained in the long term: • Population of the species as a viable component of the site. • Distribution of the species within site. • Distribution and extent of habitats supporting the species. • Structure, function and supporting processes of habitats supporting the species.

	• No significant disturbance of the species. Qualifying species: Dunlin (*Calidris alpina alpina*) Eider (*Somateria mollissima*) Greylag goose (*Anser anser*) Knot (*Calidris canutus*) Oystercatcher (*Haematopus ostralegus*) Pink-footed goose (*Anser brachyrhynchus*) Redshank (*Tringa totanus*) Shelduck (*Tadorna tadorna*) Wigeon (*Anas penelope*) Waterfowl assemblage

Site	**Troup, Pennan and Lion's Heads SPA**
Area	3,367 ha
Site description	The Troup, Pennan and Lion's Heads Special Protection Area is a 9 km stretch of sea cliffs along the Aberdeenshire coast. The cliffs support large colonies of breeding seabirds. The boundary of the Special Protection Area overlaps with the boundary of Gamrie and Pennan coast SSSI and the seaward extension extends approximately 2 km into the marine environment to include the seabed, water column and surface.
Qualifying Interest	The site qualifies under Article 4.2 by regularly supporting over 20,000 individual breeding seabirds. In 1995 the site supported about 150,000 individual seabirds of 9 species. The site qualifies further under Article 4.2 by regularly supporting internationally important breeding populations of the migratory species: Black-legged kittiwake *Rissa tridactyla* (31,600 pairs in 1995; 6% of the British population and 1% of the total population of the sub-species *R. t. tridactyla*). Common guillemot *Uria aalge* (44,600 individuals in 1995; 4% of the British and 1% of total population of the sub-species *U. a. aalge* and *U. a. albionis*). In addition to the species mentioned above, the assemblage of breeding seabirds includes the regularly occurring migratory species Northern fulmar *Fulmarus glacialis* (4,400 pairs), Herring gull *Larus argentatus* (4,200 pairs; 2% of the British breeding population). Razorbill *Alca torda* (4,800 individuals). All figures in brackets are estimates for 1995.
Conservation Objectives	To avoid deterioration of the habitats of the qualifying species (listed below) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and To ensure for the qualifying species that the following are maintained in the long term: • Population of the species as a viable component of the site. • Distribution of the species within site. • Distribution and extent of habitats supporting the species. • Structure, function and supporting processes of habitats supporting the species. • No significant disturbance of the species. Qualifying Species: Fulmar (*Fulmarus glacialis)* Guillemot (*Uria aalge*) Herring gull (*Larus argentatus)* Kittiwake (*Rissa tridactyla*) Razorbill (*Alca torda)** Seabird assemblage

<table>
<tr><th>Site</th><th>Ythan Estuary, Sands of Forvie and Meikle Loch SPA & Ramsar</th></tr>
<tr><td>Area</td><td>1016.24 ha</td></tr>
<tr><td>Site description</td><td>Ythan Estuary, Sands of Forvie and Meikle Loch are located north of Aberdeen on the east coast of Scotland. The site comprises the long, narrow estuary of the River Ythan and Meikle Loch. At its mouth, the river splits an extensive area of sand dunes with the Forveran Links on the west bank and the Sands of Forvie dune system on the east bank. Extensive mud-flats in the upper reaches of the estuary are replaced by coarser gravels with Mussel Mytilus edulis beds closer to the sea. The margins of the estuary are varied, with areas of saltmarsh, reedbed and poor fen. Meikle Loch is an important roost site for geese, which feed away from the SPA on surrounding farmland in winter. It is a eutrophic loch supporting limited aquatic vegetation. In summer the coastal habitats of the dunes and estuary provide an important breeding site for three species of tern, whilst in winter the estuary holds large numbers of waders, ducks and geese.</td></tr>
<tr><td>Qualifying Interest</td><td>This site qualifies under Article 4.1 of the Directive (79/409/EEC) by supporting populations of European importance of the following species listed on Annex I of the Directive:
During the breeding season:
Common Tern Sterna hirundo, 265 pairs representing up to 2.2% of the breeding population in Great Britain (Count, as at early 1990s).
Little Tern Sterna albifrons, 41 pairs representing up to 1.7% of the breeding population in Great Britain (Count, as at early 1990s).
Sandwich Tern Sterna sandvicensis, 600 pairs representing up to 4.3% of the breeding population in Great Britain (Seabird Census Register).
This site also qualifies under Article 4.2 of the Directive (79/409/EEC) by supporting populations of European importance of the following migratory species:
Over winter;
Pink-footed Goose Anser brachyrhynchus, 17,213 individuals representing up to 7.7% of the wintering Eastern Greenland/Iceland/UK population (winter peak means).
The area qualifies under Article 4.2 of the Directive (79/409/EEC) by regularly supporting at least 20,000 waterfowl.
Over winter, the area regularly supports 51,265 individual waterfowl (5 year peak mean 1991/2 – 1995/6) including:
Redshank Tringa totanus,
Lapwing Vanellus vanellus,
Eider Somateria mollissima,
Pink-footed Goose Anser brachyrhynchus.</td></tr>
<tr><td>Conservation Objectives</td><td>To avoid deterioration of the habitats of the qualifying species (listed below) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and
To ensure for the qualifying species that the following are maintained in the long term:
• Population of the species as a viable component of the site.
• Distribution of the species within site.
• Distribution and extent of habitats supporting the species.
• Structure, function and supporting processes of habitats supporting the species.
• No significant disturbance of the species.
