Aberdeen Renewable Energy Group

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

Introduction

This document is a Non-Technical Summary (NTS) of the Environmental Statement for the proposed European Offshore Wind Deployment Centre (EOWDC).

The purpose of this document is to provide an overview of the key findings of the offshore Environmental Impact Assessment undertaken by Aberdeen Offshore Wind Farm Limited (AOWFL).

This NTS provides the project details, including information relating to the scientific studies that have been undertaken and the key findings of these studies. For a more in depth evaluation of the information provided here please refer to the main Environmental Statement.

Aberdeen Offshore Wind Farm Limited (AOWFL)

This application is being made by Aberdeen Wind Offshore Wind Farm Limited (AOWFL). AOWFL is an established legal entity owned by Vattenfall Wind Power Ltd (VWPL) (75 %) and Aberdeen Renewable Energy Group (AREG) (25 %).

The project is being part-funded by a grant under the EU [Economic Recovery Programme in the field of Energy]. Consortium members in this grant action are AOWFL, VWPL, AREG and Technip UK Ltd.

Vattenfall

VWPL's ultimate holding company is Vattenfall AB (Vattenfall). Vattenfall is owned by the Swedish state. Vattenfall is Europe's fifth largest generator of electricity and the continent's largest producer of heat.

Vattenfall currently operates over 500 Mega Watts of onshore wind and almost 700 Mega Watts of offshore wind across northern Europe. This portfolio includes Kentish Flats Offshore Wind Farm and Thanet Offshore Wind Farm, both located off the UK's Kent coast.

Vattenfall is currently constructing Ormonde Offshore Wind Farm off Barrow-in-Furness which will be completed during 2011. An application to build Kentish Flats Offshore Wind Farm Extension is planned for August 2011. Vattenfall is also in partnership with ScottishPower Renewables to develop the Round 3 East Anglia Offshore Wind Farm. This project is expected to deliver around 7,200 MW of wind capacity which would provide clean electricity for the equivalent annual demand of around 4 million UK homes.

The north east of Scotland is an important region for VWPL with the planned EOWDC, the Clashindarroch onshore scheme, approved for consent in December 2010, and the planned Aultmore onshore scheme.

Aberdeen Renewable Energy Group (AREG)

AREG is an incorporated company representing the interests of over170 member organisations. Established in 2001, AREG aims to ensure that Aberdeen City and Shire and its businesses play a major role in the energy revolution. AREG has been supported by the Energising Aberdeen Fund of Aberdeen City Council. The Fund represents a £22.25 million investment in the future of Aberdeen over five years by the Scottish Government.

Technip

Technip is a world leader in the fields of project management, engineering and construction, offering innovative solutions to the global oil and gas industry.

With 23,000 employees, integrated capabilities and proven expertise in underwater infrastructures, offshore facilities and large processing units and plants on land, Technip is a key contributor to the development of sustainable solutions for the energy challenges of the 21st century.

Through its Aberdeen based operating centre, Technip provides best-in-class subsea products and services to oil and gas companies operating offshore in the UK, Denmark, the Netherlands and West Coast of Ireland. Further to its established subsea business, Technip is rapidly developing capability to support the growing offshore wind sector.

Project Details

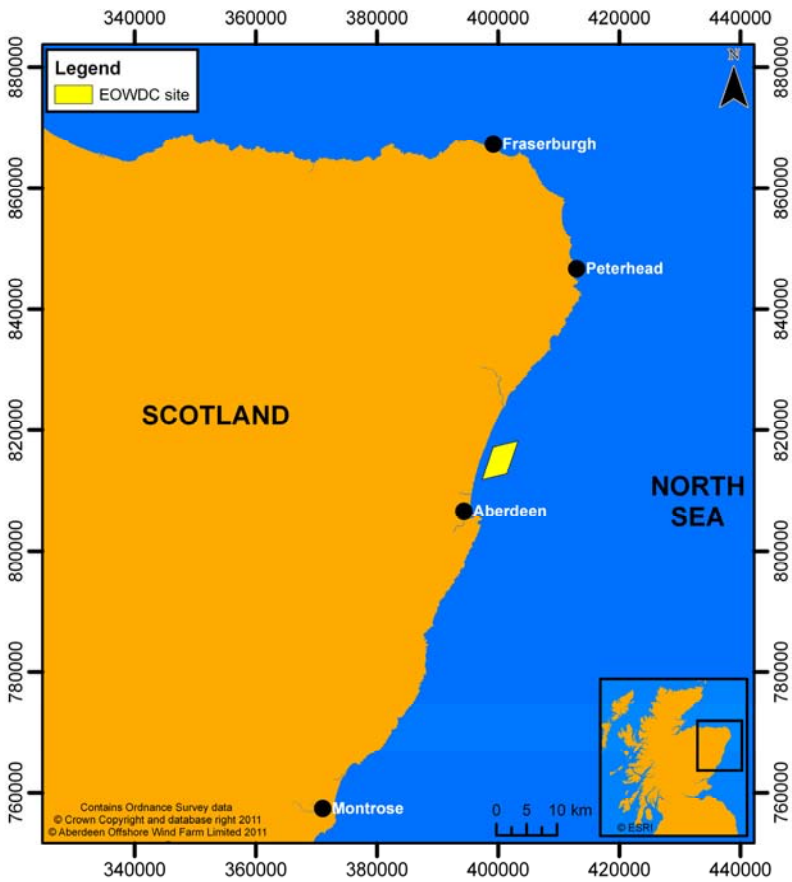
The proposed EOWDC is an innovative offshore wind turbine deployment facility proposed off the Aberdeenshire coast.

The project is part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy. In December 2010 a grant of up to 40 million Euros was awarded to the EOWDC project by the European Union (EU) as part of wider proposals to invest in key energy projects throughout Europe. The vision of this project is:

"To deploy new equipment, systems, processes, and initiate R&D to improve the competitiveness of offshore wind energy production, whilst generating environmentally sound, marketable electricity and to increase the supply chain capabilities in Scotland, the wider UK and Europe."

The Applicant was awarded a lease for the seabed from The Crown Estate earlier this year. The project consists of up to 11 wind turbines with a maximum power generation of up to 100 Mega Watts. The wind turbines would export the electricity onshore to a new substation and then to the National Grid. Additional onshore facilities may include a deployment centre with a research and development centre.

Location of the Proposed European Offshore Wind Deployment Centre



The onshore works associated with the proposed EOWDC would be subject to a separate planning application later in 2011 but are likely to be:

- a small substation
- underground cables connecting the wind turbines to the substation
- possible research and development facilities next to the substation

Key Project Characteristics	
Maximum EOWDC capacity	100 Mega Watts
Maximum Number of Wind Turbines	11
Approximate Distance from EOWDC to Shore	2.4 kilometres
Water Depth across the Wind Turbine Locations	20 metres to 30 metres below Lowest Astronomical Tide
Maximum Rotor Diameter	150 metres
Maximum Hub Height	120 metres
Maximum Tip Height	195 metres
Minimum Clearance Above Sea Level	22 metres above Mean High Water Spring level (MHWS)
Indicative Spacing between Wind Turbines	Between 790 metres and 1,050 metres
Foundation type	There are currently five options: Monopile Gravity Base Tripod Steel Jacket Suction Caisson / Bucket
Inter array Cables	Maximum number of 12 Total length of 13 kilometres
Export Cables	Maximum number of four would run from the wind turbine array back to Mean High Water Spring (MHWS) Total length of 26 kilometres

Regulatory Consents and the Purpose of the Environmental Statement

A number of regulatory consents are required for the construction and operation of the proposed EOWDC.

The following consents will be applied for:

- consent under Section 36 of the Electricity Act 1989 (as amended), for the installation of any offshore generating station with a permitted capacity of 1 Mega Watt or above
- a Marine Licence, established via the Marine (Scotland) Act 2010

Marine Scotland and Scottish Ministers will be responsible for determining the outcome of the application process.

In addition consents will be required for onshore work associated with the EOWDC development. This will be a separate application due later in 2011.

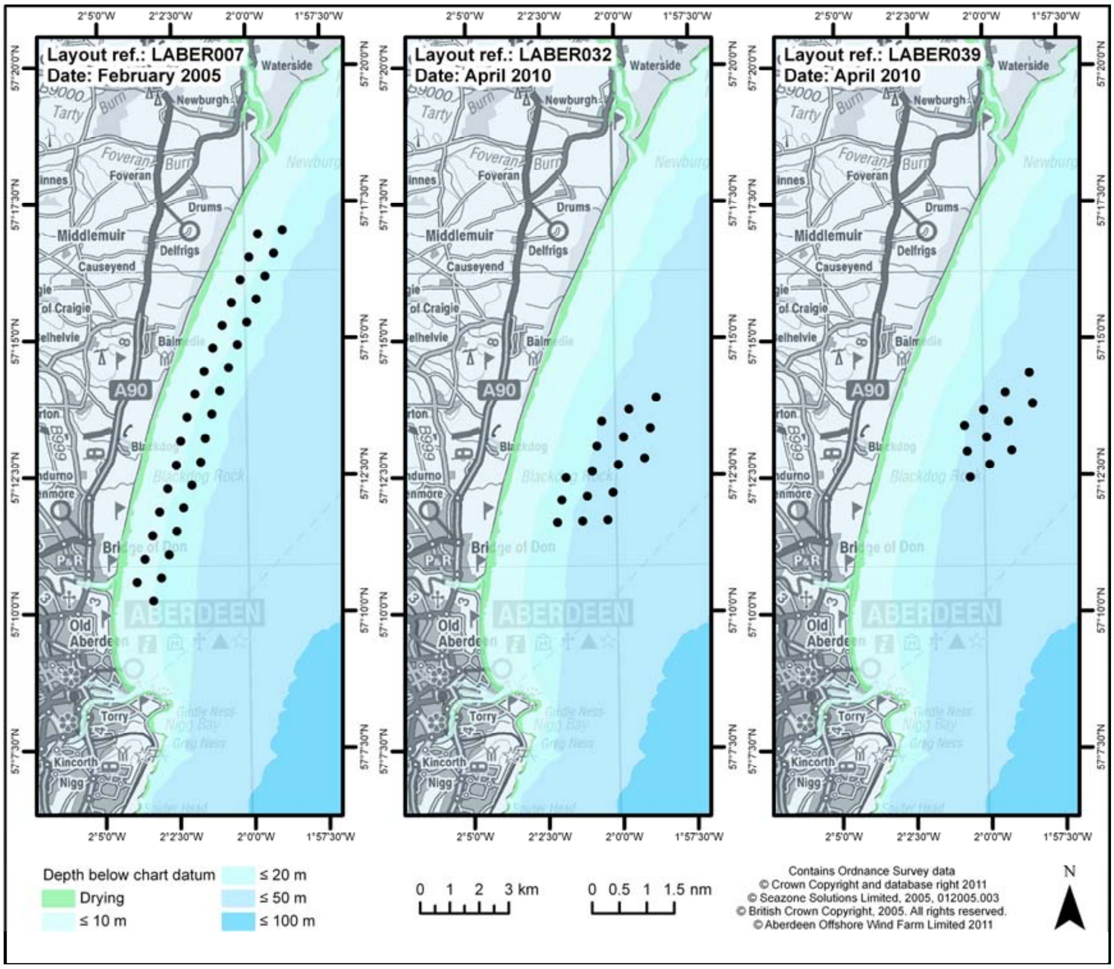
Site Selection and Alternatives

The proposed EOWDC site location has undergone a number of changes that have been determined through a long process of examining the constraints, undertaking consultations, and conducting surveys, studies and assessments.

These changes have primarily been a result of consultation with Aberdeen Harbour Board, the aviation industry, the Ministry of Defence and key environmental stakeholders.

Examples of the numerous site iterations can be found below. Further details are described within the Environmental Statement.

Three Site Iterations from 2005 and 2010 Including the Final Iteration from April 2010



Environmental Impact Assessment

Environmental Impact Assessments were undertaken in order to assess the possible impacts that the proposed EOWDC might have upon the local physical, biological and human environment.

To account for all possible scenarios a worst case impact has been assessed for each study. This ensures that any possible negative impacts upon the environment resulting from the development of the EOWDC would never be more than, and are likely to be less than, the findings of the Environmental Impact Assessment.

Where it is possible that there would be a negative impact upon the environment appropriate mitigation is suggested. The purpose of mitigation is to reduce the level of impact, for example this could be by following specific guidelines or not constructing at certain times of the day.

The key findings of the Environmental Impact Assessment are presented within this Environmental Statement.

Wind Turbines Awaiting Installation at the Ormonde Offshore Wind Farm (Copyright Tony West Photography)

Scoping, Consultation and Public Exhibitions

Public exhibitions have played an important role in informing and communicating with the population of Aberdeen and the wider area. A number of exhibitions have taken place since 2005, most recently in November 2010.

In 2010 public exhibitions were held between 22 and 26 November in:

- The Palace Hotel, Peterhead
- Udny Arms Hotel, Newburgh
- Kirk Centre, Ellon
- Beach Ballroom, Aberdeen
- White Horse Inn, Balmedie

Shortly after the Section 36 and Marine Licence applications are submitted for the proposed EOWDC further exhibitions will be held to give members of the public and interested organisations an opportunity to ask questions about the project and review the outcome of the various environmental studies.

Physical Environment

Coastal Processes

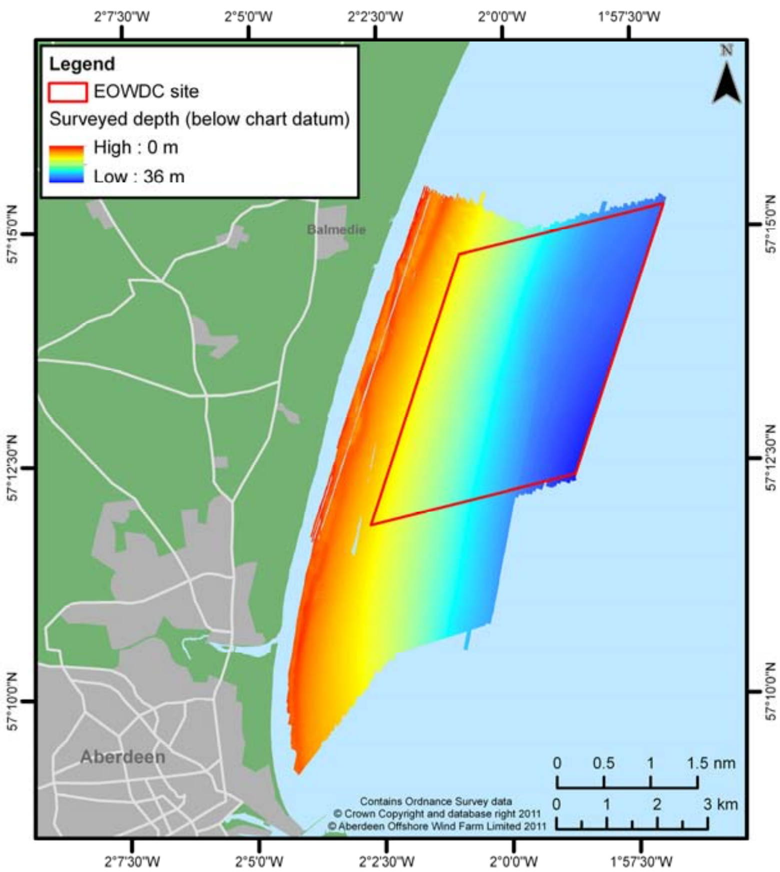
The assessment includes consideration of the potential changes to geology, waves, currents, sediment, seabed features and water quality.

Studies have provided an assessment of the potential impacts of the proposed EOWDC development within Aberdeen Bay upon the existing coastal processes. To assess the potential impacts relative to the baseline (existing) coastal environment, qualitative assessment of site data, empirical evaluation and detailed numerical modelling have been used.

It is shown that the majority of potential impacts can be considered of negligible significance. The impacts that have been assessed as minor are scour (natural removal of sediment around wind turbine foundations), increase in suspended sediment as a result of foundation and cable installation and removal activities, and changes to processes maintaining the Aberdeen Bay coastline as a result of the presence of turbine foundations.

Mitigation is not considered necessary except for the case of scour where scour protection measures are advised (this could include material being placed in the sea bed surrounding the wind turbine).

Geophysical Assessment Results Showing Depth of Aberdeen Bay



Biological Environment

Designated Sites

There are no designated sites of local, regional or national importance within the lease boundary for the proposed EOWDC.

Potential impacts upon designated sites within close proximity to the proposed EOWDC have been assessed within the Environmental Impact Assessments.

Ornithology

Three different types of ornithological surveys have been undertaken since 2005. The results from these surveys along with additional information have been used to help inform the Environmental Impact Assessment.

A total of 79 species of birds were recorded during ornithological surveys. Thirty seven of these species were either a qualifying species for a Special Protection Area (protected sites for rare or vulnerable birds) or were recorded in numbers that could be of concern should there be an impact from the proposed EOWDC development. These 37 species were assessed in detail.

Possible impacts to birds could include displacement and disturbance effects throughout the construction, operation and decommissioning stages.

For the majority of species the impact from the proposed EOWDC is deemed to be negligible. However, for some species, such as the red throated diver, the impact is deemed to be minor or moderate.

Possible mitigation for these impacts could include minimising vessel movements by using existing shipping lanes, avoiding significant piling operations during periods of high seabird sensitivity and minimising use of lights.

Razorbills Were Frequently Spotted Throughout the Survey Area

Marine Ecology

Desk top review and survey work have been undertaken in order to assess the possible environmental impacts of the proposed EOWDC on the marine ecology of the area.

The majority of the site is covered by fine well sorted sands and fine muddy sands. The most common species at the site are worms and shellfish. On the seabed brittle stars, brown shrimp and swimming crabs are common whilst fish species in the area are predominantly made up of plaice, dab, hooknose and whiting.

Possible impacts to species in the area include temporary loss of and disturbance to the seabed, resuspension of sediment and effects generated from electromagnetic fields from subsea cables.

Overall the impacts have been assessed as being negligible to minor with the exception of the worst case impact from construction noise upon fish which is considered to be of minor to possibly moderate significance. Possible mitigation could include a ‘soft start’ procedure. During this procedure noise from construction begins quietly, allowing for fish (or marine mammals) to leave the area before the noise becomes too loud.

Marine Mammals

Boat based surveys, land based vantage point surveys and desk top review were used to inform the marine mammal Environmental Impact Assessment.

A number of marine mammals make use of Aberdeen Bay throughout the year; the more commonly sighted species are the harbour porpoise, bottlenose dolphin and grey and common seal.

Marine mammals can be affected by impacts such as physiological damage from construction noise, exclusion of the site during construction and suspended sediment levels. These impacts have been assessed as being of negligible to minor significance.

In some instances behavioural disturbance and displacement during possible construction activities is considered to be of moderate to potentially major significance.

A number of mitigation strategies have been suggested in order to minimize any impacts upon marine mammals. A Marine Mammal Protection Plan (MMPP) would be developed to address and mitigate any of the impacts identified as being of concern. The final MMPP would be developed in consultation with advice from statutory consultees. The applicant would follow any advice provided by Marine Scotland on the European Protected Species licences to apply for, if these are required.

Grey Seal Swimming in Aberdeen Bay

Human Environment

Commercial Fisheries

Desk based review and thorough consultation with the Scottish Fishermen's Federation (SFF), local fishermen and the District Fishery Officer provided information to inform the Environmental Impact Assessment.

Commercial fishing activities in the area surrounding the proposed EOWDC are considered to be at relatively low levels. Potting for crab and lobsters; trawling for whitefish; and dredging for scallops account for the majority of the activity.

It is understood that at the time of writing only four, 11 metre and under trawlers actively fish in the area of the site. Whilst larger trawlers operating out of Aberdeen may transit through the site, the area is not sufficiently productive to justify such vessels actually fishing within it.

Given the limited number of wind turbines proposed, the small area of the site and the low level of fishing activity within it, the overall impacts on commercial fishing are expected to be negligible, although for a small number of local vessels, the potential impacts may be of moderate significance. It is expected that fishing would be able to continue within the proposed EOWDC during operation which should help to mitigate this impact.

24 metre Vessel fishing in Barrow Offshore Wind Farm (Copyright Brown and May Marine)

Salmon and Sea Trout

Extensive consultation was undertaken to inform this assessment. Meetings were held with all the salmon fishery boards located within the north-east region of Scotland and with representatives of the netting fishery.

Scottish salmon populations are recognised as being of national and international importance. In addition to their ecological value, salmon and sea trout are species of importance from a socioeconomic perspective.

Potential impacts upon local salmon and sea trout populations arise from the noise and vibration associated with the development of the site, increased suspended sediments, electromagnetic fields generated from subsea cables and the physical presence of the wind turbines.

The majority of impacts have been assessed as having negligible impact although it is possible that construction activities could have a negligible to minor impact following mitigation. Mitigation could include specific scheduling of construction periods so that peak times of salmon entering or exiting local rivers are not affected. Further consultation will be held with statutory consultees and salmon fisheries boards when construction methods and timing are considered further.

Seascape, Landscape and Visual Character

Site specific desk studies, field work and consultation with local Councils and statutory consultees have helped to inform the Environmental Impact Assessment process. The area within a 40 kilometres radius of the development was used for assessment.

Many possible receptors were identified including residential communities, road, rail and ferry users, sailing and boating users and National Trails and National Cycle route users. Numerous potential impacts were identified but only a limited number were considered to be significant.

The visual impact on Aberdeen is limited by the densely built up nature of the city. The significant number and diversity of built elements along the coastline would also help to absorb the visual profile of the proposed wind turbines.

The overall visual effect is therefore considered to be moderate to major with only localised and isolated areas of more significant effect. These significant effects are described in further detail within the Environmental Statement.

The proposed European Offshore Wind Deployment Centre as seen from Aberdeen Beach (image is for illustrative purposes only as not to scale). A full size representation of this photomontage is available in Volume 4 of the Full Environmental Statement found on the DVD at the back of this document.

The proposed European Offshore Wind Deployment Centre as seen from Balmedie Beach (image is for illustrative purposes only as not to scale). A full size representation of this photomontage is available in Volume 4 of the Full Environmental Statement found on the DVD at the back of this document.

Shipping and Navigation

Site surveys, desk based review and consultation have helped to inform a full Navigational Risk Assessment (NRA) for the proposed EOWDC. The NRA provides background information on local commercial and recreational navigational issues and then assesses the potential impact that the proposed EOWDC development could have upon local navigation.

A number of potential impacts were identified, the majority of these are considered to be negligible or cause no impact. Compared to the marine accident risk levels in the UK, the increase in risk to both people and the environment caused by the proposed EOWDC is low.

Extensive consultation with Aberdeen Harbour Board (AHB) and key consultees has resulted in a number of changes being made to the site layout. Recent consultation has indicated that the current site is acceptable and all hazards were identified to be low.

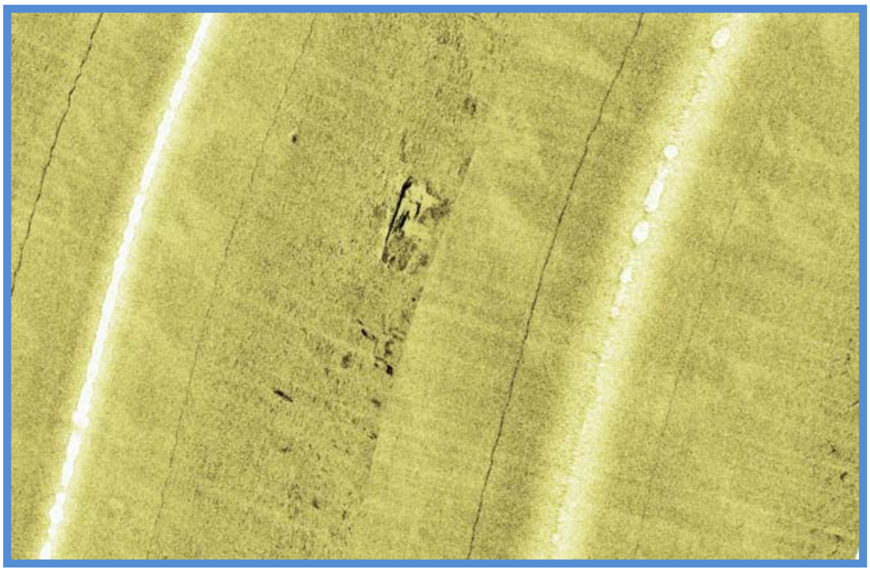
The Passenger Ferry Hjaltland Passes by the Proposed European Offshore Wind Deployment Centre Site during One of the Five Marine Traffic Surveys Undertaken

Maritime Archaeology

A maritime archaeological assessment was carried out via consultation with relevant bodies, a full desk top review, and a thorough examination of geophysical information collected for the site.

The geophysical survey has identified several anomalies which may be man-made or natural features. Of these a potential impact has been predicted for one unidentified wreck which lies in close proximity to Wind Turbine 8. The proposed mitigation for this wreck is an exclusion zone to ensure there are no impacts upon this potentially valuable site. After mitigation the impact has been assessed as of minor significance.

Geophyscial Evidence of the Unidentified Wreck by Wind Turbine Location 8 (Copyright Wessex Archaeology (2011), Data Supplied by Osiris Projects, 2010)



Cultural Heritage

Site survey and desk based review have been used to assess the potential impact that the proposed EOWDC could have upon the setting of all nationally important designated cultural heritage assets within 10 kilometres of the wind turbines and selected assets beyond this limit.

Potential impacts have been identified in five cases: Torry Battery (Scheduled Monument), Peterseat Cairns (Scheduled Monument), Hare Cairn (Scheduled Monument), Orrok House and Girdle Ness Lighthouse (Grade A-listed buildings). The impacts have been assessed as being of minor significance with the exception of Girdle Ness Lighthouse for which the impact is considered of Minor to Moderate. No mitigation is proposed in relation to these impacts, they would persist throughout the lifetime of the EOWDC and end upon decommissioning.

Aviation Radar

In order to address any potential aviation issues that could arise from the proposed development an Aviation Working Group was established in 2005.

Possible impacts to aviation included changes to helicopter routeing and impacts upon local radar facilities.

Early and ongoing consultation has helped all parties to move forward together with these issues. The Applicant has entered a contract with National Air Traffic Services Limited in order to apply for an Air Space Change. This would be implemented by NATS, in consultation with the Aviation Working Group. The Applicant is also currently negotiating a contract with NATS to determine the most efficient and effective technical solution to overcoming any primary and/or secondary radar issues.

Ministry of Defence

Consultation with the Ministry of Defence has been ongoing since 2005. Two possible impacts have been highlighted, these are the effect of the wind farm on the operability of the defence radar installation at Peterhead and the possible effect to the Black Dog Firing Range – a small-arms firing range on the coast nearby.

The project has had a long-term relationship with the MoD during its development, through the MoD Defence Estates department in Birmingham. The Applicant understands that plans for the area of the Black Dog Firing Range are acceptable, although further discussions will be needed on operational aspects. There will now need to be an intensive period of work to address recent MoD concerns regarding the Peterhead radar issue.

Unexploded Ordnance (UXO)

Although not a statutory requirement, given the history of Aberdeen during World Wars One and Two and the presence of local MoD facilities the risk of encountering unexploded ordnance has been assessed.

Between 2007 and 2010 three studies were undertaken to inform the project on the risk of UXO across the site. The conclusion of the latest assessment in 2010 was that the main ordnance threat was due to the Black Dog Firing Range. Outside this area there is a low UXO risk to the development of the proposed EOWDC.

Other Marine Users

The proposed EOWDC has the potential to impact a variety of other marine users such as surfers and recreational sailors. Most impacts are anticipated to be negligible.

Through consultation with the Royal Yachting Association two potential impacts on recreational sailing have been identified: impacts to navigational safety and loss of routes and sailing and racing areas. Such impacts can occur during construction, operation and decommissioning of the development. After mitigation such as the enforcement of safety zones it is anticipated that these impacts would be of negligible significance.

Surfers Enjoying the Scottish Coast

Socioeconomics, Recreation and Tourism

Through a process of thorough consultation and desk based assessment the potential socioeconomic, tourism and recreational impacts of the proposed EOWDC were assessed.

Consultees felt that the project would play a significant role in supporting the development of the offshore renewables industry including research and development. Impacts resulting from the project were for the majority moderate (positive), with no impact falling below negligible.

The impact of the proposed development on tourism and recreation is considered to be of negligible significance.

In Air Noise

Background noise measurements and wind speeds were measured on site over a period of 3 weeks. Consultation was carried out with the local authorities and key guidance documents were also used for the assessment.

The noise impact from the construction, operation and decommissioning of the proposed EOWDC on residential properties was assessed using suggested national limits as well as more stringent local noise limits.

The operational noise was assessed as being of negligible significance. For the noise associated with the construction of the proposed EOWDC it is anticipated that the impact during the day would be of minor significance. For night time hours mitigation suggests that certain construction activities are not carried out during this time, this resulting in a negligible significance.

PREFACE

Aberdeen Offshore Wind Farm Limited (AOWFL) is applying to the Scottish Ministers under Section 36 of the Electricity Act 1989 (as amended) and a Marine Licence in terms of the Marine (Scotland) Act 2010 to construct, operate and decommission an offshore wind farm and deployment centre off the coast of Aberdeen, known as the European Offshore Wind Deployment Centre (EOWDC).

The planning application comprises an Environmental Statement (ES), prepared in accordance with the Electricity Works (Environmental Impact Assessment) (Scotland) Regulations 2000 (as amended) and Marine Works (Environmental Impact Assessment) Regulations 2007 (as amended) and follows current best practice.

The complete submission comprises the following volumes:

- Volume 1 – Non-Technical Summary
- Volume 2 – Environmental Statement
- Volume 3 – Figures
- Volume 4 – Technical Appendices

Where to View the Consent Application
The complete submission may be viewed at the following locations during normal office hours:

Vattenfall Wind Power Ltd 3rd Floor The Tun Holyrood Edinburgh EH8 8AE	Balmedie Library Eigie Rd Balmedie AB23 8YF
Aberdeen Central Library Rosemount Viaduct Aberdeen AB25 1GW	Peterhead Library 51 St Peter Street Peterhead AB42 1QD
Ellon Library Station Road Ellon AB41 9AE	Bridge Of Don Library Scotstown Road Bridge Of Don Aberdeen AB22 8HH

The Environmental Statement can also be viewed at the Scottish Government Library at Victoria Quay, Edinburgh, EH6 6QQ.

OBTAINING YOUR OWN COPY OF THE PLANNING APPLICATION

Volumes 1, 2 and 3 of the ES are available on the Vattenfall website. Volume 4 is not available on the Vattenfall website however the complete set of submitted documents may be obtained (free of charge for a data DVD or £350 for a hard copy) by contacting Vattenfall at the Hexham address:

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 1: Introduction

VATTENFALL Technip areg Aberdeen Renewable Energy Group

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

1 INTRODUCTION

1.1 The European Offshore Wind Deployment Centre (EOWDC)

1 Aberdeen Offshore Wind Farm Limited (AOWFL) is proposing to develop an offshore wind farm and deployment centre off the coast of Aberdeen, known as the European Offshore Wind Deployment Centre (EOWDC) (see Figure 1.1).

2 The proposed project would combine a small commercially operated wind farm with a test and research centre, allowing manufacturers to test “first of run” wind turbines and innovative foundation solutions along with related operation and maintenance access logistics.

1.2 The Applicant

3 This application is being made by Aberdeen Wind Offshore Wind Farm Limited (AOWFL). AOWFL is an established legal entity owned by Vattenfall Wind Power Ltd (VWPL) (75 %) and Aberdeen Renewable Energy Group (AREG) (25 %).

4 The project is being part-funded by a grant under the European Union [Economic Recovery Programme in the field of Energy]. Consortium members in this grant action are AOWFL, VWPL, AREG and Technip UK Ltd.

1.2.1 Vattenfall

5 VWPL’s ultimate holding company is Vattenfall AB (Vattenfall). Vattenfall is owned by the Swedish state. Vattenfall is Europe’s fifth largest generator of electricity and the continent’s largest producer of heat.

6 Vattenfall currently operates over 500 mega watts (MW) of onshore wind and almost 700 MW of offshore wind across northern Europe. This portfolio includes Kentish Flats Offshore Wind Farm and Thanet Offshore Wind Farm, both located off the UK’s Kent coast.

7 Vattenfall is currently constructing Ormonde Offshore Wind Farm off Barrow-in- Furness which will be completed during 2011. An application to build Kentish Flats Offshore Wind Farm Extension is planned for August 2011. Vattenfall is also in partnership with ScottishPower Renewables to develop the Round 3 East Anglia Offshore Wind Farm. This project is expected to deliver around 7,200 MW of wind capacity which would provide clean electricity for the equivalent annual demand of around 4 million UK homes.

8 The north-east of Scotland is an important region for VWPL with the planned EOWDC, the Clashindarroch onshore scheme approved for consent in December 2010, and the proposed Aultmore onshore scheme.

1.2.2 Aberdeen Renewable Energy Group (AREG)

9 AREG is an incorporated company representing the interests of over 170 member organisations. Established in 2001, AREG aims to ensure that Aberdeen City and Shire and its businesses play a major role in the energy

revolution. AREG has been supported by the Energising Aberdeen Fund of Aberdeen City Council. The Fund represents a £22.25 million investment in the future of Aberdeen over five years by the Scottish Government.

1.2.3 Technip

10 Technip is a world leader in the fields of project management, engineering and construction offering innovative solutions to the global oil and gas industry.

11 With 23,000 employees, integrated capabilities and proven expertise in underwater infrastructure, offshore facilities and large processing units and plants on land, Technip is a key contributor to the development of sustainable solutions for the energy challenges of the 21st century.

12 Through its Aberdeen based operating centre, Technip provides best-in-class subsea products and services to oil and gas companies operating offshore UK, Denmark, the Netherlands and West Coast of Ireland. Further to its established subsea business, Technip is rapidly developing capability to support the growing offshore wind sector.

1.3 External Consultants

13 A number of external consultants have supported this Environmental Statement (ES). Table 1.1 summarises the consultants' participation and a summary of their qualifications and experience can be found in Appendix 1.1 (Volume 4).

1.4 Introduction of the Project

1.4.1 Background to the Proposal

14 In 2005 there was an intention to develop a project comprising 33 commercially operating wind turbines off the coast of Aberdeen. Due to constraints on the layout which became apparent at an early stage, the size

of the project was reduced considerably. Recent rapid developments in technology and the need for further research in key areas led, in 2008, to the development of the project to its current form. The project is now known as the European Offshore Wind Deployment Centre (EOWDC), which is both a small (11 wind turbine) commercially operated wind farm and a test and research facility.

15 As well as delivering renewable electricity to the National Grid, the Deployment Centre would allow supply chain companies to test a variety of products and applications in a real time offshore environment before commercial deployment, with the aim of reducing large scale development risks and capital costs to industry. The Deployment Centre also provides a platform for environmental research and development.

1.4.2 Support under the European Economic Plan for Recovery in the field of Energy

16 The project is part-funded by the European Union (EU) under the European Economic Plan for Recovery in the field of Energy.

17 The origin of the European Energy Programme for Recovery (EEPR) is the global €200 billion European Economic Recovery Plan presented by the Commission on 26 November 2008. The focus of the Plan is on containing the impact of the global financial crisis: protecting jobs and purchasing power, boosting infrastructure and creating jobs in the low carbon sectors of the future. The Recovery Plan sets out how Member States and the European Union could coordinate their policies in order to provide new stimulus to the European economy and increase Union spending in strategic sectors. Investments in energy projects were considered an important tool to support the economic recovery.

18 The EEPR helps to speed up and secure investments in the energy sector, which will have a direct impact on the EU economy and employment. It will also help to improve the security of supply of the most vulnerable Member States and link ‘energy islands’ to the rest of the EU energy market.

19 The EEPR Regulation created the basis for providing substantial co-financing from the Union budget to key energy projects. Never before has the EU agreed to dedicate such a significant amount to energy infrastructures. The €3.98 billion budget for the implementation of the Regulation is allocated as follows:

- gas and electricity infrastructure projects: €2.365 billion (60 % of budget)
- offshore wind energy projects (OWE): €0.565 billion (14 % of budget)
- carbon capture and storage projects (CCS): €1.05 billion (26 % of budget)

1.4.3 The Project Vision

20 Thanks to financial support from the European Union, the EOWDC would provide a platform to deploy and demonstrate new concepts, products and services in offshore wind whilst enabling research in this new sector – ideal for a partnership with Europe’s renewables industry, academia and research community.

21 The vision is:

"To deploy new equipment, systems, processes and initiate R&D to improve the competitiveness of Offshore Wind Energy production, whilst generating environmentally sound marketable electricity and to increase the supply chain capabilities in Scotland, the wider UK and Europe."

22 This project is targeted at both enabling and encouraging increased competition into the European wind turbine supply chain by providing sites for manufacturers both to prove new and innovative solutions and also to allow the acquisition of offshore "hands-on" design, build and operational and maintenance experience, in advance of Round 3.

23 This project would allow "first of run" production wind turbine systems to be operated in the marine environment so that developers, owners and financiers can gain confidence in wind turbine manufacturer's new machine designs, allowing the development of the supply chain in this area. The intention is to highly instrument the equipment to provide maximum learning opportunity.

24 The EOWDC has the potential to promote and enable the deployment of pre-production innovative foundations, or foundation production methods. It may also be available as a platform to test energy storage and/or Flexible Alternating Current Transmission Systems (FACTS) devices.

25 In addition and as indicated, the Applicant will also look at increased monitoring which would improve understanding of wind farm design and operation to ensure increased efficiency and operation.

26 There is potential for an Ocean Laboratory that could hold meteorological masts, environmental monitoring equipment and be used for access training. The inclusion of an Ocean Laboratory would allow environmental monitoring during and after deployments but would be subject to a separate application. Environmental data may also be collected through a series of planned surveys. The environmental effects of the deployment centre could be closely monitored and data collected prior to Round 3 offshore wind farms being installed.

27 Environmental monitoring would provide stakeholders with information on associated environmental impacts prior to large scale deployments ie Scottish Territorial Waters or Round 3. Via the EU grant, a proposal has been made to allocate in excess of £2.7 million, funded jointly by the Applicant and the EU to environmental studies over the project lifetime including the development of environmental research with external partners. Details of exact activities, and confirmation of EU matched funding, will be achieved as research proposals and requirements are received and selected.

1.4.4 Environmental Research and Development Opportunities

28 A key aspect of the proposed EOWDC is to encourage and enable environmental monitoring through ongoing research and development in advance of the larger build and operational experience of Scottish Territorial Water Developments and Round 3.

29 The agreed environmental monitoring programme would be in excess of the industry norm and would seek to answer outstanding questions on environmental impacts of offshore wind, which will be of benefit to all stakeholders. The programme would provide stakeholders with information on the environmental impacts of new technologies, processes and operations, and the Applicant hopes to encourage University level research especially that from nearby Aberdeen and Robert Gordon Universities.

30 As part of the Environmental Impact Assessment (EIA) for the EOWDC, advice has been sought from the relevant consultants as to future research and monitoring opportunities for the site. These opportunities are provided in the Environmental Statement in addition to any monitoring put forward for the purposes of consent.

31 The Applicant will shortly embark on an exercise to scope out the potential environmental research opportunities for the site and will encourage input from interested parties including statutory nature conservation agencies and research organisations and external Consultants working in the offshore wind sector.

1.4.5 Supply Chain Participation

32 The proposed EOWDC is keen to attract pre-commercial deployment of offshore wind turbines and other associated technologies. The proposed EOWDC could provide the opportunity to deploy technologies, goods and services ahead of the major development of the Round 3 offshore wind farms.

33 The Applicant is therefore keen to speak to wind turbine manufacturers, component manufacturers, installation contractors, other supply chain companies, universities and research establishments about their participation.

34 The Applicant is engaging with the supply chain to identify how the project could add value. This will be carried out via number of events and other methods of consultation. Interested parties are likely to include:

- wind turbine manufacturers
- foundation manufacturers
- cable manufacturers
- cable installers
- offshore construction companies
- vessel suppliers
- offshore wind turbine access solution providers
- universities and research establishments

1.4.6 The Proposed Development

35 The Applicant is proposing to construct 11 wind turbines off Aberdeen Bay each with a nominal output of up to 10 MW and a maximum output for the wind farm of up to 100 MW. A summary of the key project characteristics associated with the proposal is provided in Table 1.2.

TABLE 1.2 **Key Project Characteristics**	
Maximum Capacity	100 MW
Maximum Number of Wind Turbines	11
Lease Boundary Area	20 km^2
Approximate Distance to Shore	2.4 km
Water Depth across the Wind Turbine Locations	20 – 30 m below Lowest Astronomical Tide
Individual Wind Turbine Capacity	4 to 10 MW
Maximum Rotor Diameter	150 m
Maximum Hub Height	120 m
Maximum Tip Height	195 m
Minimum Clearance Above Sea Level	22 m above mean high water springs level (MHWS)
Indicative Spacing between Wind Turbines	Between 790 m and 1050 m
Foundation Types	Potential foundations include monopiles, jackets, tripods, gravity base structure, suction caisson/ buckets
Inter-array Cables	Maximum number of 12. Total length of 13 km.
Export Cables	Maximum number of 4 would run from the wind turbine array back to Mean High Water Spring (MHWS) Total length of 26 km

36 The proposed EOWDC site can be seen on Figure 1.2. The onshore works for the project are currently unknown but they are likely to comprise the following:

- onshore cables
- miscellaneous cable joints/ cable protection and cable/pipeline crossings
- temporary pre-assembly construction facilities onshore (location currently unknown)
- Onshore substation and deployment centre

37 The onshore works will be applied for separately under the Town and Country Planning (Scotland) Act 1997 as amended. The Local Planning Authorities in proximity to the site are Aberdeenshire Council and Aberdeen City Council. The boundaries of the two jurisdictions are shown on Figure 1.3. Once the onshore works are defined a planning application will be made to the relevant authority. Both of the two councils will be consultees in the Section 36 and Marine Licence process.

Plate 1.1 A 5 MW Installed Wind Turbine at the Ormonde Offshore Wind Farm

38 A full description of the proposed construction, operation and decommissioning of the development is given in Chapter 3 Description of the Proposed Project.

1.5 The Purpose of this Environmental Statement

39 This ES presents the findings of the EIA of the proposed EOWDC. The document is in 4 volumes as outlined in Table 1.3.

1.5.1 Data Gaps and Uncertainties

1.5.1.1 Data Gaps

40 The Applicant acknowledges that there is still a requirement from statutory bodies for further bird and marine mammal boat-based survey data. AOWFL contracted further monthly boat-based surveys which started in August 2010 and which will run until July 2011. Four months of this survey data has been analysed and is included in the bird and marine mammal impact assessments within this ES. The remaining eight months of data will be analysed and

submitted to Marine Scotland as an Addendum to this Environmental Statement as soon as practicable.

1.5.1.2 Uncertainties

41 As the project is a deployment centre there is still a need to obtain a certain degree of flexibility when applying for consents as there is still uncertainty as to the size and type of foundations to be installed. It should be noted that, in defining the project that has been assessed during the EIA, the "Rochdale Envelope" approach (see Chapter 4) has been adopted. By adopting this approach, it will be possible to conclude that the environmental impact of the proposed development will be no greater than set out in this ES.

42 The Applicant has undertaken an EIA, which is based on the optimum design and layout information available to the project when making the application, involving an assessment allowing for different types of wind turbines and foundations.

43 As not all the details of the proposed development are known at this time, a worst case approach has been undertaken, according to the principles described as the "Rochdale Envelope". What is considered to be the worst case is different depending on the receiving environment affected (eg birds, shipping & navigation etc) and the activity undertaken (construction/de-commissioning or operation). It should be noted that when carrying out the assessment the possibility of mixed foundation types within the development has been considered, however, in each case a single foundation type at each location has been identified as the worst case ie for the coastal processes assessment 11 gravity bases structures are considered.

1.6 Development Context

1.6.1 The Need for Offshore Wind Energy

44 Climate change represents one of the greatest environmental threats faced by the world today with far reaching implications for the global environment and economy. Renewable electricity generation is vital for decarbonising the global energy system and hence global climate change mitigation. Wind energy is one of the most competitive technologies in renewable energy. However, large scale implementation offshore, whilst offering potential for significant opportunity to develop vast wind resource capacity, also poses huge challenges, requiring technological innovation, industrial & market development and, in parallel, significant cost reduction to become cost competitive with other forms of energy sources.

45 The UK, and specifically Scotland, has some of the best wind resource in Europe.

46 The Scottish Government aims to achieve a target of 100 % of Scottish demand for electricity from renewable sources by 2020. The Scottish Parliament passed the Scottish Climate Change Act in 2009. It demanded a 42 % cut in greenhouse gas emissions by 2020 and 80 % cuts by 2050, based on a 1990 baseline. The development of Scotland's offshore wind

potential will be crucial to the delivery of Scotland's legal obligations on climate change.

47 The rapid development of offshore wind capacity is central to the delivery of the UK's share of the EU target of 20 % renewable energy by 2020. The Crown Estate, as the seabed owner, has announced proposals to deliver up to 25 Giga Watts (GW) of new offshore wind farm sites by 2020 through the Round 3 licensing. This is intended to provide a stimulus throughout the EU and to provide an important contribution to both reducing CO_2 emissions and improve security of energy supply to the wider EU. This builds on the 8 GW of offshore wind farm projects currently under development and to be delivered by Rounds 1 and 2. If successful, the addition of the capacity from Round 3 and the Scottish Territorial Waters Round together with any additional smaller sites, could lead to a potential total of 39.5 GW of offshore wind energy.

48 The scale of the challenge in delivering such a large programme means that the equipment and services supply chains need to be dramatically enhanced in a very short timescale. The central requirement of the industry is for live operational experience of the various wind farm components with validated data. This requires an area to deploy novel technologies to gain data during actual operational hours in a controlled offshore environment.

49 The EOWDC's focus is on proving new technology, processes and operations, and improving existing technology, processes and operations with the key objectives of increasing reliability, efficiency and reducing cost. As such, the EOWDC would directly contribute to the delivery of not only the UK Round 3 and Scottish Territorial Water Rounds, but also the wider European programme of offshore development.

50 The maximum output of the EOWDC, as governed by The Crown Estate lease conditions, is 100 MW. Assuming a 35 % capacity factor, the EOWDC could provide enough capacity to meet the demand of over 68,400 homes, equating to a supply large enough to meet over 65 % of the domestic need of the Aberdeen City population[1]. The 2013 household estimate for Aberdeen is 108,150 (See Appendix 1.2).

1.6.2 Creation of Employment from Wind Energy

51 Estimates vary as to the global job creation potential for wind power (on and offshore). However a middle case scenario suggests 462,000 by 2010 and 1.3 million by 2020 with a potential maximum recognised as 572,000 by 2010 and 2.2 million by 2020 (GWEA, 2008). As Europe is a particularly intensive area for wind development, it is to be expected that the proportion of global employment secured could be significantly higher than implied by the population or land mass and sea area. The European Wind Energy Association estimates that European employment in wind power will increase to almost 330,000 in 2020 and to 375,000 by 2030, 57 % of the latter figure being accounted for by offshore wind (EWEA, 2008).

[1] This assumes number of households in Aberdeen was 102,900 in 2008. This is based on the "Household Projections for Scotland 2008-based" from the General Register Office for Scotland (2010).

1.7 Statutory and Regulatory Framework

52 The construction and operation of the EOWDC will require a consent under Section 36 of the Electricity Act 1989 (as amended). The Electricity Act 1989 (Requirement of Consent for Offshore Generating Stations) (Scotland) Order 2002 requires Section 36 consent for the installation of any offshore generating station with a permitted capacity of 1 MW or above.

53 Section 57(2) of the Town and Country Planning (Scotland) Act 1997 provides that the Scottish Ministers can direct that planning permission for development of the Section 36 application or ancillary development can be deemed to be granted. The requirement for planning permission may apply to only a small portion of the export cable.

54 In formulating an application for a Section 36 consent the Applicant is obliged to have regard to the desirability of preserving natural beauty, of conserving flora, fauna and geological or physiographical features of special interest and in protecting sites, buildings and objects or architectural, historic or archaeological interest. Furthermore the Applicant is obliged to do what he reasonably can to mitigate any effects which the proposal would have on such matters. In considering any proposals the Scottish Ministers are obliged to have regard to the desirability of preserving the list of assets and also the extent to which the Applicant has complied with their duty reasonably to mitigate any effects. The applicant is also obliged to avoid so far as possible causing injury to fisheries or to the stock of fish in any waters. These matters have been addressed in this ES.

55 In addition to a Section 36 Consent the EOWDC will also require a marine licence in terms of the Marine (Scotland) Act 2010. This Act imposes a number of duties upon the Scottish Ministers in respect of the grant of any marine licence. It includes obligations under Section 3 to act in a way which is best calculated to further the achievement of sustainable development, including the protection or where appropriate the enhancement of the health of that area, and under Section 4 to act in a way best calculated to mitigate, and adapt to, climate change so far as consistent with the purpose of the function concerned. In terms of Section 15 all public authorities are obliged to take authorisation decisions in accordance with appropriate marine plans unless relevant considerations indicate otherwise. Furthermore, in the determination of a marine licence application, Section 27 implies certain statutory requirements on the determination process. The Scottish Ministers must have regard to the need to protect the environment, human health and prevent interference with legitimate uses of the sea and such other matters as the Scottish Ministers consider relevant. These are all matters which have been considered and assessed within the ES.

56 The Applicant has determined that the development is an EIA development and this Environmental Statement has been produced to comply with the requirements contained in the Electricity Works (Environmental Impact Assessment) (Scotland) Regulations 2000 (as amended) and the relevant marine regulations, The Marine Works (Environmental Impact Assessment) Regulations 2007 (as amended).

57 The Conservation (Natural Habitats, & c.) Regulations 1994 (as amended) provide the requirement to consider the potential effects of the project on European sites and species. The Scottish Ministers will be the appropriate

authority in determining the extent to which an appropriate assessment will be required, or issuing any European Protected Species licences. These matters have been considered in terms of the relevant chapters of the ES. The regulations also regulate activities which could potentially disturb European protected species.

58 More information on the applicable statutory and regulatory framework may be found in the Appendix 1.3 to this ES.

1.8 Legislative Policy

59 The determination of both a Section 36 Consent and a marine licence potentially involve a wide range of material considerations. This is likely to include Energy Policy, published and emerging Marine Policy, relevant Development Plans and National Planning Policy. Where the policies are relevant to a particular assessment they have been referred to as the relevant material in the ES. It should be noted that the planning policies would only directly be applicable to support a small portion of the onshore export cables from the mean low water mark up until the mean high water spring tide level. In addition a number of the effects of the offshore elements of the EOWDC will potentially have impacts onshore. Planning policy may assist in carrying out an assessment of the potential affects on such onshore receptors. Where relevant to a particular assessment these have been referred to.

60 The overall determinations will have to have regard to a wide range of policy and they will be important in evaluating the consenting balance having regard to both the positive, neutral and negative aspects arising from the EOWDC.

1.8.1 Energy Policy

61 There are three levels of applicable renewable energy legislation and policy: (1) European, (2) UK, and (3) Scottish. Common to each level is a presumption that offshore wind can make a significant and meaningful contribution to environmentally friendly electricity production, which is a key priority for the European Community and the UK and Scottish Governments. More information on renewable energy legislation and policies may be found in Appendix 1.3 to this ES.

1.8.2 Marine Policy

62 In Scotland, the legislation allows for three levels of planning – a UK wide Marine Policy Statement, a Scottish National Marine Plan and regional plans. Consistent throughout each is a presumption in favour of sustainable marine development. Underlying this presumption is a key marine planning policy objective to maximise sustainable economic and social growth, which the Scottish Government believe to be intrinsically linked to such development. The North East Region is highlighted as having favourable conditions for marine development, particularly in the offshore wind context, which is noted as being critical to the future security of energy supply in Scotland. More information on the relevant legislation and guidance may be found in the Appendix 1.3 to this ES.

1.8.3 Planning Policy

63 In terms of the offshore elements of the EOWDC project only a small section of the proposal will directly engage the onshore planning system. That relates to the area between the low water mark and the mean high water spring tide. This represents the overlap between the Marine and Onshore Licensing Regimes. More information on the relevant planning policy may be found in Appendix 1.3 to this ES. It is not the subject matter of the Annex to assess the development proposals against development plan policy but to identify the relevant policy elements. Some of the impacts of the EOWDC will affect land based receptors and where relevant these have been referred to within the technical appendices and assessment chapters.

European Offshore Wind Deployment Centre
Environmental Statement

Chapter 10: Ornithology

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

10 ORNITHOLOGY

10.1 Introduction

1 The Ornithological Baseline and Impact Assessment report provides a detailed assessment of the potential impacts and possible effects on the birds present within the proposed European Offshore Wind Deployment Centre (EOWDC) area. The assessment is based on the findings from site specific bird surveys undertaken to help inform the impact assessment along with desk-based studies using published data from existing offshore wind farms.

2 This chapter provides a condensed summary of the findings presented in the Ornithological Baseline Impact Assessment report, which should be referred to for further information. Genesis Oil and Gas Consultants carried out the ornithological assessment.

10.2 Data Information and Sources

3 Three different types of surveys have been undertaken since 2005 in order to obtain a representative sample of bird data to inform the EIA and, if required, a Habitats Regulations Appraisal.

4 Monthly boat-based surveys were undertaken between February 2007 and April 2008 and an additional 12 months of surveys commenced in August 2010. In addition to the boat-based surveys, two years of Vantage Point surveys were undertaken from March and October 2005 and from April 2006 to March 2008 and three radar surveys were carried out in October 2005, April 2006 and April 2010.

5 The data obtained from these surveys along with additional information from other offshore wind farms have been used to help inform the Environmental Impact Assessment (EIA).

10.2.1 Boat-based Surveys

6 There have been two periods of boat-based bird surveys undertaken in support of the proposed development.

7 Between February 2007 and April 2008 boat-based surveys were undertaken on a monthly basis. Each survey covered an area of 101.6 km^2, which included the then proposed development site plus a buffer zone and a control survey area located immediately to the north (Figure 10.1). The control survey area of 50.8 km^2 was the same size as the then proposed development site (including the buffer zone). The site proposed at the time the surveys were being undertaken represented 12 % of the total area surveyed, and 24 % of the proposed EOWDC survey area. The distance of the shoreline to the proposed EOWDC survey area varied between 0.6 km to 7 km and the control survey area between 0.5 km to 6 km. The control survey area was positioned in an area exhibiting similar physical attributes (bathymetry and seabed type) to that of the then development site (IECS 2008).

8 Following the completion of the Year 1 bird surveys (February 2007 – April 2008), the location and size of the proposed development was revised. Although the original boat-based surveys did cover the revised location, the potential for future monitoring was improved by using an alternative survey strategy designed for the surveys undertaken since August 2010 (Figure 10.1). Three blocks have been surveyed each month out to 25 km from the shoreline, allowing a gradient approach of potential impact areas to be used (SMRU 2011). The total area surveyed each month was 339 km^2, comprising of three strata: 150.8 km^2 (north), 82.8 km^2 (south) and 105.2 km^2 (offshore).

10.2.2 Vantage Point Surveys

9 Vantage Point (VP) surveys have been undertaken from a total of six sites (four in any one year) within Aberdeen Bay over a period of three years between March 2005 and October 2005 and April 2006 and March 2008 (Figure 10.2) (EnviroCentre 2007; Alba Ecology 2008).

10 Watches were conducted by a single observer with binoculars and telescope for one to two hours from each VP site. Observations were carried out during daylight hours and in conditions of good visibility. Up to four surveys per month were undertaken.

11 A total of 294 VP surveys and 582 hours of surveys have been undertaken over a period of three years across six different areas of Aberdeen Bay (Table 10.1).

TABLE 10.1
Vantage Point Survey Summary

Site	No. of VP surveys	No. of Hours
Drums	55	114
Balmedie	52	102
Blackdog	84	167
Murcar *	10	16
Donmouth	83	163
Promenade *	10	20
Total	294	582

* = Data collected between March and October 2005 only

10.2.3 Bird Detection Radar Surveys

12 Bird Detection radar has been used on three occasions during periods predicted to be of high migration in Aberdeen Bay: October 2005, April 2006 and April 2010. Original surveys were undertaken at Easter Hatton and Drums, but later moved to Blackdog, closer to the proposed development area. The survey areas of the radar surveys are shown on Figure 10.2

13 Bird movements were tracked continuously up to a range of 11 km, including during periods of darkness or poor weather conditions. The radar could detect bird movements, their flight trajectory, flight speed and altitude to a height of 1.4 km.

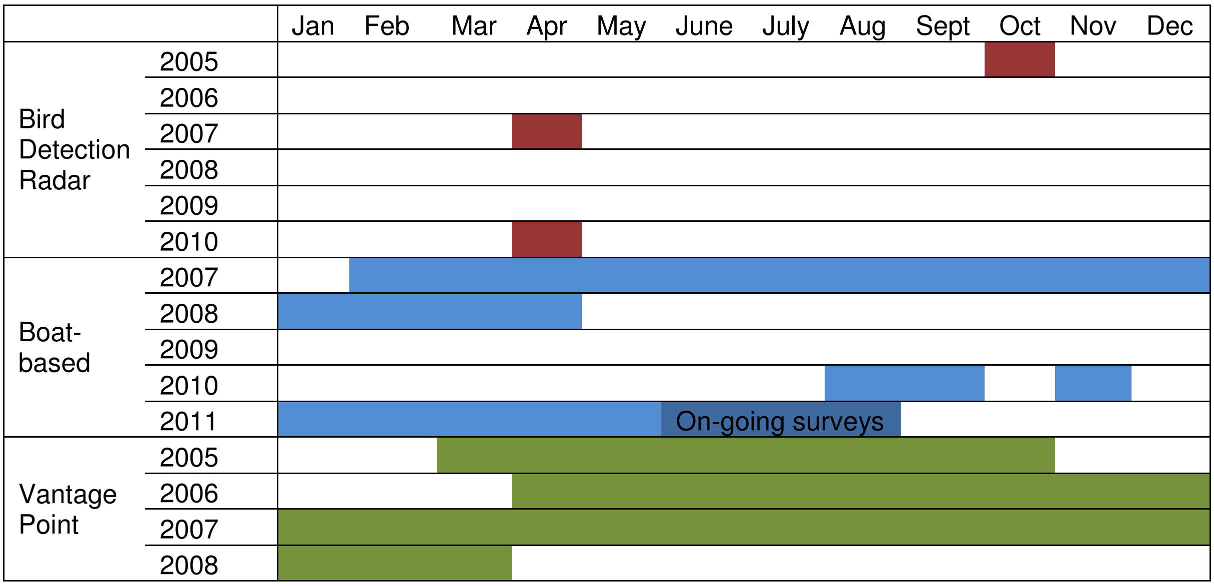

Diagram 10.1 Ornithological surveys undertaken in Aberdeen Bay 2005 – 2011

14 Diagram 10.1 outlines the survey coverage to date.

15 A summary of the main survey reports and studies used in the EIA for birds is presented below:

10.2.4 Consultation

16 Consultation with key stakeholders, specifically SNH, JNCC and Marine Scotland occurred at an early stage of the project in 2006 and continued throughout the scoping stage of the EOWDC. Key issues raised were the potential impacts upon birds, specifically red-throated diver and common scoter and also the potential adverse effects to birds from Special Protection Areas (SPAs).

10.3 Impact Assessment Methodology

17 Potential impacts on birds arising from the proposed development have been identified based on site specific data from Aberdeen Bay. Other published information on the birds likely to be present in the area has also been drawn upon.

18 Whenever possible, additional information from existing offshore wind farms

19 Three potentially significant impacts on birds have been identified:

- Collision risk: Birds are at risk of colliding with wind turbines. The level of collision depends on the location and size of the development and the species present. Species such as Auks, Divers and Scoter, fly predominantly below rotor height, whereas other species such as Gulls may fly more frequently at rotor height and therefore be at a greater risk.

- Displacement: Birds that would otherwise use an area may avoid entering the wind farm and therefore be displaced. Birds may be also be displaced if the availability of their prey is reduced or if they are disturbed by vessels associated with the proposed development. The significance of any displacement is largely dependent on the scale and duration of the impact and whether other suitable sites are available to which the birds may go should they be displaced
- Barrier effects: Birds may avoid flying through the proposed EOWDC and select to fly either over or around it. Should this occur then this might entail the birds flying further than would otherwise have been the case. Many species of bird have been recorded avoiding offshore wind farms, often by altering course at a distance of 1 km or more, eg wildfowl and gannets

20 The impact assessment has been based on the above potential effects.

21 There are four main phases in the development of the proposed programme that have been considered whilst undertaking the impact assessment.

- pre-construction
- construction
- operation
- decommissioning

22 For the purposes of this EIA an evidence based approach has been used to determine potential impacts as well as expert judgement based on the baseline information and results from other offshore wind farms. Impact specific matrices have been used to provide a structure and consistency of approach and also as tool to help inform the impact assessment. The structure and content of the tables are based on those originally developed by Percival et al. (1999) and developed further by Maclean et al. (2009). However, the results from the impact matrices have not been considered to be definitive, nor in isolation. The assessment is ultimately based on the latest published data available on potential impacts, ie wherever possible an evidence based approach has been adopted.

23 A species specific sensitivity assessment has been undertaken in line with recommendations made in Maclean et al. (2009). Sensitivities of species groups to particular impacts are ranked and combined with the non-impact sensitivities to give an overall sensitivity.

24 By combining the overall sensitivity of a species with the potential magnitude of the impact, an indicative overall sensitivity of the species to the potential impact is obtained (Table 10.2). However, it is recognised that this is only an indicative sensitivity and evidence from existing wind farms and consequently expert judgement is used to determine whether the potential impact is likely to be significant or adverse.

Table 10.2 Potential Significance of Impact				
Magnitude	**Overall Sensitivity of Receptor**			
	Very High	**High**	**Medium**	**Low**
Very High	Major	Major	Major	Moderate
High	Major	Major	Moderate	Minor
Medium	Major	Moderate	Minor	Minor
Low	Moderate	Minor	Minor	Negligible
Negligible	Minor	Negligible	Negligible	Negligible

10.3.1 Initial Screening Results

25 The results from the initial impact indicated that the following species were at a potentially moderate or major risk of:

- collision mortality: gannet , kittiwake, herring gull, lesser black-backed gull, great black-backed gull, common tern and Arctic tern
- barrier effects: pink-footed goose, barnacle goose, common eider, common scoter, velvet scoter and red-throated diver
- displacement and disturbance: common eider, long-tailed duck, common scoter, velvet scoter, red-breasted merganser, red-throated diver, cormorant and shag

10.3.2 Designated Sites

26 Although the proposed site does not lie within a designated area, there are a number of SPAs along the east coast of Scotland that have the potential to be impacted by the proposed development. For the purposes of the EIA, qualifying species from SPAs 74 km to the north between Troup, Pennan and Lion's Head and the Forth Islands SPA approximately 134 km to the south, have been considered and assessed against the relevant Conservation Objectives. The selection of sites is based largely on the potential foraging areas or known passage routes of the species recorded during surveys undertaken within the proposed development area (Roos 2010).

10.3.3 Implications of Significance

27 Where the potential significance is identified as being negligible or minor this is considered to be of limited or no concern. Moderate significance is of concern but may be tolerable depending on the causes that give rise to the potential impact. Major concerns are considered to be a potentially significant effect.

10.3.4 Determining Potential Adverse Effects

28 To determine potential adverse effects the assessment is based on the Conservation Objectives and qualifying species of the site.

29 To identify whether an impact is potentially adverse with respect to potential impacts on population levels a measure based upon the 1 % of baseline mortality rate has been used as a guide. It is not considered to be a definitive

'cut-off' but a tool to indicate whether the potential impact could cause an adverse effect.

10.3.5 Assessment of Cumulative Impacts

30 The cumulative impact assessment considers all other industries which have the potential to impact on the birds that may be present at the proposed development location, these include:

- offshore wind farms
- shipping
- aggregates
- dredging
- oil & gas

31 Offshore renewable projects that have been identified as having the potential for a cumulative effect include two developments in the Moray Firth and three in the Firth of Forth. The sites in the Moray Firth are approximately 150 km to the north and those in the Firth of Forth approximately 120 km to the south of the proposed development.

32 The construction of the proposed EOWDC may overlap with construction activities being undertaken at other planned developments. However, given the stage of development of the renewable projects yet to be constructed and the uncertainty as to the types of foundations and wind turbines that will be used, there is sparse information available to incorporate into any impact assessment, which limits the effectiveness of cumulative assessments considering conceptual projects yet to be subject to a formal consent application and for which no environmental or design data are currently available.

33 Therefore, the cumulative impact assessment can only be undertaken with data available from the currently operating Beatrice demonstrator project in the Moray Firth. Although, the assessment does wherever possible consider potential cumulative impacts from other yet unconsented renewable projects.

34 Shipping associated with the harbour which has been undertaken in Aberdeen Bay over many centuries with currently approximately 16,000 vessel movements per year. There are no known plans that are likely to cause a significant increase in the level of shipping currently being undertaken in Aberdeen Bay and any impacts shipping may currently be having on the birds within Aberdeen Bay will be part of the baseline.

35 There are no aggregates activities within Aberdeen Bay. There are no licensed dredging sites within Aberdeen Bay but occasional dredging of the harbour may occur, with the next dredging scheduled for 2012.

36 Aside from shipping there are no oil and gas related activities within Aberdeen Bay.

10.3.6 Assessment of In-combination Impacts

37 The Conservation (Natural Habitats, & c.) Regulations 1994 (as amended) require that a Habitats Regulations Appraisal (HRA) must be conducted by a competent authority. The HRA considers the implications for European sites in view of the European sites conservation objectives, in respect of any plan or project which is not directly connected with or necessary to the management of the European site for conservation purposes and which is likely to have a significant effect on the European site either alone or in-combination with other plans or projects.

38 Therefore the term 'in-combination' will be used when considering the impacts of the proposals with other plans or projects on European sites.

39 The main industries considered for potential in-combination impacts are proposed offshore wind farms, aggregate industry, dredging, oil and gas and shipping. Of these, proposed offshore wind farms and shipping are the only activities identified for which there is a potential for an in-combination impact.

10.4 Baseline Assessment

40 The ornithological environmental baseline draws upon results from project specific surveys undertaken to inform the EIA and existing published information on the birds present in the wider area.

41 A total of 79 species of bird have been recorded from site specific surveys, of which 37 species are either a qualifying species for a SPA or were recorded in numbers that could be of concern should there be an impact and were therefore further assessed.

42 *Wildfowl*: The most frequently recorded wildfowl were common eider and common scoter, both of which were recorded in relatively large numbers particularly during the winter and summer months. Peak counts of eider from boat-based surveys were obtained during the winter months with up to 556 birds being recorded. For common scoter the peak recorded was 1,157 birds counts during the spring and summer months. Evidence from other sources indicated that up to approximately 3,000 of each species may occur in Aberdeen Bay during the summer months. Other species of potential concern included pink-footed goose and barnacle goose, both of which were recorded flying through the area during the spring and autumn.

43 *Divers*: The red-throated diver was the only species of diver frequently recorded during the surveys. They were recorded throughout the survey area in water depths of less than 20 m. Peak numbers occurred during the winter and spring with up to 25 birds recorded within the EOWDC area during May.

44 *Seabirds*: A total of 20 species of seabird were recorded during the surveys undertaken in Aberdeen Bay.

- **Fulmars** were widespread throughout the area during most of the year. Highest densities were recorded during September and December
- **Gannets** were recorded throughout the area and throughout the year with peak numbers during August and September. The majority of

sightings were between 2-3 km offshore and most were recorded flying below turbine height

- **Cormorant and shags** were recorded regularly during site specific surveys predominantly within 2 km of the coast. All those recorded in flight were below turbine height
- **Skuas**. Both great skua and Arctic skua were recorded in low numbers between April and November with the majority of sightings during the autumn
- **Gulls.** Kittiwakes were the most frequently recorded gull. Birds were present throughout the year but peak numbers occurred in June and July when over 2,000 kittiwakes were in the whole of the surveyed areas. Of those recorded in flight, 22 % were at rotor height and therefore at risk of potential collision. Other species of Gull recorded included black-headed, common, lesser black-backed, herring and great black-backed
- **Terns.** Four species of Tern were recorded during surveys. The most frequently recorded species was Sandwich tern with peak numbers between May and August with up to 43 birds recorded. The majority of sightings were of birds within 2 km from shore but 44 % were at rotor height. There were fewer records of little, common and Arctic terns with the majority of sightings within 2 km of the coast and relatively few within the proposed development area
- **Auks.** Puffins, guillemots and razorbills were frequently recorded throughout the surveyed area. Peak numbers occurred during the summer and early autumn when up to 80 birds/km^2 and an estimated abundance of approximately 4,000 birds present to the north of the proposed development area
- **Other species.** A total of 43 other species of bird were recorded in low numbers from all the surveys undertaken. Due to the low numbers recorded they were not considered to be at risk of a likely significant impact or an adverse effect

10.5 Impact Assessment

TABLE 10.3
Summary of Impact Assessments

Impact	Environmental effect	Probability of effect occurring	Magnitude	Duration	Spatial extent	Significance level	Mitigation	Residual impacts	Monitoring
Construction									
Disturbance	Displacement away from the area by presence of construction vessels	High	Negligible to Medium for more sensitive species, e.g. red-throated diver.	Temporary	Species dependent. Potentially up to 2 km for some species such as red-throated diver and common scoter	Negligible to Moderate for red-throated diver	Minimise vessel movements and use existing shipping routes as far as practicable.	Localised temporary displacement	Reporting protocol
Sound (piling)	Reduction in availability of prey species due to displacement away from sound source or increased mortality	High	Negligible to Medium for Terns and Divers	Temporary	Species dependent. Local.	Negligible to Moderate	Minimise as far as practicable significant piling operations during periods of high seabird sensitivity	Displacement away from construction area.	Tern breeding colony monitoring and boat-based bird surveys.
Operation									
Collision with turbines	Increased mortality	Negligible to Low	Negligible to minor for some Gulls,	Long-term	Local	Minor	None	Possible collision mortality	If practicable, possible

TABLE 10.3
Summary of Impact Assessments

Impact	**Environmental effect**	**Probability of effect occurring**	**Magnitude**	**Duration**	**Spatial extent**	**Significance level**	**Mitigation**	**Residual impacts**	**Monitoring**
			Terns and barnacle geese						land-based surveys.
Lighting of turbines	Passerines and other birds may be attracted to the turbines.	Negligible	Negligible	Long-term	Local	Negligible	Minimise use of lights as far as practicable	Possible collision mortality	None
Barrier effect	Increased distances flown causes increased energetic expenditure	High	Negligible to minor for some seaduck and cormorants	Long-term	Local	Minor	None	Potential increase in energetic expenditure	If practicable possible land based surveys.
Disturbance	Displacement away from the area by presence of maintenance vessels	High	Negligible to Medium	Long-term	Local	Negligible to Minor	Minimise vessel movements and use existing shipping routes as far as practicable.	Localised temporary displacemen t	Reporting protocol
Decommissioning									
Disturbance	Displacement away from the area by presence of decommissioning vessels	High	Negligible to Medium	Long-term	Local	Negligible to Minor	Minimise vessel movements and use existing shipping routes as far as practicable.	Localised temporary displacemen t	Reporting protocol

10.5.1 Mitigation and Monitoring

45 Detailed mitigation and monitoring measures would be further developed to avoid, remove or reduce any potentially significant impacts during consultation with the Regulator and their statutory advisors and other stakeholders.

46 The main potential impacts arising from the proposed development relate primarily to direct or indirect displacement effects on Divers and Terns. Mitigation measures that may be considered as measures to help avoid, remove or reduce them include:

47 *Minimising the proposed development area:* By reducing as far as practicable the overall area of the proposed development at the earier design stage of the proposed EOWDC, the total area and consequently the total number of red-throated divers or other species that may be displaced has been minimised.

48 *Vessel management plans:* The potential disturbance of seaduck and Divers and other seabirds from the proposed development area by vessels may be reduced by minimising the number vessels used and by ensuring that all vessels, as far as practicable, use the existing shipping lanes.

49 *Foundation types*: The use of monopiles may require the use of pile-driving to install them. By selecting alternative foundation types, there is the potential to reduce the risk of an impact on the prey species and therefore reduce the possibility of a displacement effect being caused by construction activities.

50 *Timing and duration of installation*: The timing and duration of installation have still to be determined. Although it may not be possible to select a period for construction activities to take place that is of lower sensitivity. It would be taken into consideration when developing potential project schedules.

51 *Minimising aviation and navigation lighting:* Birds can be attracted to bright lights, e.g. lighthouses, particularly during poor weather conditions. In order to reduce the risk of birds being attracted to the proposed development all lighting would be kept as far as practicable to a minimum but still kept within the requirements to ensure safety.

52 It is essential that any monitoring undertaken is designed to address specific concerns or potential impacts identified during the EIA process. Poorly designed ad hoc monitoring is likely to be inefficient and not provide useful or meaningful results. It is therefore important that any monitoring programme is developed in collaboration with the Regulator and statutory advisors and takes note of key stakeholders comments arising from the consultation period.

53 A detailed monitoring programme aimed at specific issues or concerns would be developed with the Regulator and advisors should consent be granted.

10.6 Summary

54 Site specific boat-based and land based surveys undertaken in Aberdeen Bay identified a total of 80 species of bird, of which 36 species were considered as being at potential risk of being impacted by the proposed development. Three

possible impacts were identified: collision, displacement and barrier effects. A detailed impact assessment undertaken indicated that for most species the proposed EOWDC is only likely to have a negligible or at worse a minor effect on the species present. However, for red-throated diver and three species of tern (Sandwich, little and common terns), the possible effect was considered to be of potentially moderate significance due to displacement effects arising from disturbance or reduced prey availability, however this displacement effect is likely be of a very temporary nature.

55 Further assessment based on evidence from other offshore wind farms indicates that potential effects are unlikely. A detailed monitoring programme would be developed in conjunction with the Regulator and statutory advisors.

56 Information to Inform a Habitats Regulations Appraisal (HRA) with respect to birds can be found in Appendix 29.1.

European Offshore Wind Deployment Centre
Environmental Statement

Chapter 11: Bats

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

11 BATS

11.1 Introduction

1 This section has been prepared by Genesis Oil and Gas Consultants and reviews the information available for bats that are present in the Aberdeen Bay area with the focus being on bats that could be present in the offshore area beyond the high water mark. All bat species found in Scotland are classified as European Protected Species and are fully protected under the Conservation (Natural Habitats) Regulations 1994 as amended. This lists a number of offences in relation to bats and the places which they live.

2 Surveys for any bat roosts and feeding areas will be carried out to inform the onshore environmental impact assessment. These surveys will be conducted using qualified surveyors at the proposed substation and cable landfall and the results will be presented in the Onshore Environmental Statement.

3 The impacts considered in this report are all related to the operational phase and are listed as:

- physical impacts from direct collision or flying close proximity to wind turbine blades
- indirect impacts, changing foraging behaviour of bats by attraction to lights and increased risk of physical impacts from collision

3 The following technical reports support this chapter:

- Bat Environmental Impact Assessment (EIA)Technical Report (Appendix 11.1)

11.2 Summary

4 Six species of bats are thought to occur in north-east Scotland, although only three of them are common species. The bats are not expected to use the waters of Aberdeen Bay for feeding and there are no known flyways or migration corridors in the area. Once the proposed EOWDC is operational there is the small possibility that the EOWDC could attract insects and bats offshore due to the small lights required for safety reasons on the wind turbines. The evidence suggests a lack of bats in the offshore waters of Aberdeen Bay. Impacts from the construction, operation and subsequent decommissioning of the EOWDC on bat species are considered to be negligible.

5 A thorough survey for bat species and their associated roosts will be undertaken as part of the environmental surveys carried out for the onshore Environmental Impact Assessment to look at the impact of the onshore works.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 12: Marine Mammals

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

12 MARINE MAMMALS

1 This Environmental Statement (ES) chapter provides a condensed summary of the marine mammal baseline and presents the findings of the EIA technical report. Genesis Oil and Gas Consultants carried out the marine mammal assessment.

2 The structure of the marine mammal assessment can be summarised as follows:

- Marine Mammal Baseline Report (Appendix 12.1): this provides a summary of the existing information relating to the distribution and abundance of marine mammals in Scotland with a focus on Aberdeen Bay. This report draws on the findings of a desk based study, marine mammal research studies and also dedicated marine mammal surveys carried out for the purpose of supplementing the baseline for the EOWDC
- Marine Mammal EIA Technical Report (Appendix 12.2): provides an assessment of the impact of the project on marine mammals in the study area

12.1 Introduction

12.1.1 Methodology Consultation

3 Consultation with key stakeholders, specifically Scottish Natural Heritage (SNH), Joint Nature Conservation Committee (JNCC) and Marine Scotland occurred at an early stage of the originally proposed development and has continued throughout the scoping stage of the EOWDC. Key issues raised were potential impacts upon marine mammals from underwater sound and potential impacts to marine mammal species from nearby Special Areas of Conservation (SACs).

12.1.2 Data Information and Sources

12.1.2.1 <u>Boat-based Surveys</u>

4 Boat-based surveys were carried out during to collect species-specific data on marine mammals within the proposed EOWDC area and its immediate surroundings from 2007- 2008 by IECS and 2010-2011 by SMRU Ltd (Figure 10.1). Surveys were conducted once every month during daylight hours and efforts were made to undertake the survey over two consecutive days. All surveys utilised at least two trained marine mammal observers, an additional two marine mammal observers were utilised in the surveys conducted between 2010 and 2011. Details of the methodology and survey areas are covered are provided in Appendix 12.1.

5 A towed Passive Acoustic Monitoring (PAM) system was used on during both the IECS and SMRU Ltd boat surveys to collect information on vocalising marine mammals.

12.1.2.2 Vantage Point Surveys

6 Shore-based vantage point bird surveys were conducted for two hours weekly at Blackdog and Donmouth and fortnightly at Drums and Balmedie covering a distance of up to 2 km from shore (Figure 10.2). These surveys were designed primarily for bird observations, but collected information on marine mammals observed. Vantage point surveys were conducted from August 2005 until March 2008 (Alba Ecology and Envirocentre 2008).

12.1.2.3 Desk-based Study

7 In order to establish and better understand the marine mammal species present in the Aberdeen Bay and wider area an in-house desk based study was completed to form the basis of the baseline marine mammal report.

12.1.2.4 Underwater Sound Modelling

8 During the scoping stage of the project the potential impacts of sound from construction activities was identified as an issue requiring detailed investigation. The Applicant commissioned Subacoustech Ltd to carry out predictive noise modelling and an impact assessment of the piling sound on the marine mammal receptors (Appendix 3.1)

12.1.3 Key Guidance Documents

9 A summary of the main survey reports and studies used in the EIA for marine mammals is presented below:

- Envirocentre and Alba Ecology (2008). Shore based Vantage Point counts of marine mammals 2005 – 2008 in Aberdeen Bay
- IECS (2008). Aberdeen Offshore Wind Farm – ship-based Marine Mammal Survey Results (February 07- January 08). The Institute of Estuarine & Coastal Studies (IECS)
- Gordon, J (2008). Analysis of acoustic detections of porpoise from AMEC surveys off Aberdeen. Ecologic UK Ltd Report. 11pp
- RPS (2008). Review of Bird and Marine Mammal Data, RPS
- SMRU Ltd (2010) Marine Mammal Data Review. Sea Mammal Research Limited
- SMRU Ltd (2011) 4 month boat based survey report. Sea Mammal Research Limited
- Travers, S., Thomson, S. and Mander, L. (2008). Institute of Estuarine & Coastal Studies, University of Hull. 68pp. Monthly boat based marine mammal survey reports February-April 2008. The Institute of Estuarine & Coastal Studies (IECS)

12.2 Baseline Assessment

10 The marine mammal environmental baseline drew upon existing research surveys conducted on marine mammals in the wider area as well as several years of land based and boat surveys of the wider EOWDC development area. Several marine mammal species have been recorded (sighting and/or stranding) in Aberdeen Bay and the surrounding area; including 12

odontocete species, three mysticete species and three pinniped species. Of these, bottlenose dolphins, harbour porpoises, white-beaked dolphins, minke whales, Risso's dolphins, harbour seals and grey seals occur regularly in the area, with other species only being recorded occasionally or rarely.

11 Bottlenose dolphins in the Aberdeen area are part of the resident population from the Moray Firth Special Area of Conservation (SAC) and Aberdeen is recognised as an important area for bottlenose dolphins. Bottlenose dolphin were the second most frequently sighted cetacean species during the surveys carried out as part of the EOWDC, with a total of 200 individuals being detected.

12 Harbour porpoises are the most common species of cetacean in the North Sea and have a wide range and distribution in both coastal and offshore areas. Harbour porpoises were the most recorded cetacean species during the EOWDC boat surveys with over 420 individuals detected visually and was also the species detected most frequently during acoustic surveys. The harbour porpoise was the only species that was detected in sufficient numbers to enable density estimates to be generated.

13 White-beaked dolphins are present in the central and northern North Sea throughout most of the year. Sightings data suggests their presence in the coastal waters off Aberdeenshire is seasonal, with sightings recorded between June and August. White beaked dolphins were detected during the EOWDC surveys over the course of several years during the month of August.

14 Minke whales occur throughout the central and northern North Sea, particularly during summer months. The seasonal movement of minke whales into coastal waters during the summer is thought to be related to prey availability. Six minke whales have been observed as part of the EOWDC surveys.

15 In the northern and central North Sea, Risso's dolphins are primarily observed around Shetland and Orkney. Risso's dolphins have been recorded off Aberdeenshire since 2005 at various times of the year. Risso's dolphins were observed during vantage point surveys, but not during any of the EOWDC boat surveys. The increase in sightings of Risso's dolphins may point towards an increase in the use of the Aberdeen area in comparison to historic levels.

16 Both grey and harbour seals are regularly present and frequently sighted in Aberdeen bay, especially at the entrances to the rivers Dee and the Don. Grey seals were the most frequently observed seal species recorded during the boat surveys carried out in 2007-2008. Almost equal proportions of grey and common seals were recorded during boat surveys carried out during 2010-2011.

17 Designated coastal SACs for harbour seals are present along the east coast of mainland Scotland, these are situated in the Dornoch Firth and Morrich Moore in the Moray Firth and Firth of Tay and Eden estuary.

18 Designated SAC's for grey seals along the east coast of Scotland include the Isle of May at the entrance of the Firth of Forth, and it can be expected that individual seals from these colonies may be passing through and the EOWDC development area.

19 Other marine mammal species including white-sided dolphins, killer whales, common dolphins, striped dolphins, long-finned pilot whales, sperm whales, humpback whales, fin whales, beaked whales and other seal species, although present in the area off north-east Scotland this is only a marginal part of their habitat, and is likely to be inhabited only during a restricted part of the year by relatively few individuals.

12.3 Impact Assessment

12.3.1 Impact Assessment Methodology

20 All cetacean species and seals that are likely to be found in Aberdeen Bay are of either national or international importance due to their conservation status. All cetacean species and seals are considered to be receptors of high importance due to the national and international protection measures afforded to them.

21 The Habitats Directive outlines a number of protection measures for marine mammals and has been implemented in Scotland through the Conservation (Natural Habitats, &c.) Regulations 1994 (as amended in Scotland) termed the 'Habitat Regulations'. The Habitat Regulations provide the protection afforded to European Protected Species (EPS) animals listed on Annex IV of the Habitats Directive which includes all species of cetacean whose natural range occurs in Great Britain.

22 The European Protected Species (EPS) provisions create a number of offences that relate to causing injury or disturbance to EPS species as defined in regulation 39 of the Conservation (Natural Habitats, &c.) Regulations 1994 (as amended). Before an EPS licence can be issued there are three tests which must be met by the appropriate licensing authority, which in the case of a renewable energy development would be issued by the Scottish Government. The EPS licence process and other protection measures for marine mammals are explained in more detail in Appendix 12.2.

23 The harbour seal, common seal, the harbour porpoise and bottlenose dolphin are listed on Annex II of the Habitats Directive and require member countries to consider the designation of Special SACs for these animals. The cetacean species which require the designation of SACs are the bottlenose dolphin and the harbour porpoise.

24 The Marine (Scotland) Act 2010 introduces a number of measures for seal protection to update and replace the earlier Conservation of Seals Act 1970. It is now an offence to kill or take any seal at any time (with exceptions only under specific licence or for animal welfare) and it is also now an offence to harass seals at their haul-out sites.

25 For each impact, the assessment aims to describe the magnitude of effect (i.e the change created by an activity in terms of its spatial extent, duration and scale) and the sensitivity of each receptor, that is, the resources that would be affected (based on the importance of the receptor and its recoverability). The combination of the effect and the sensitivity of the receptor were used to derive the significance of the impact.

26 Whilst the matrix approach was used in the impact assessment as a way to categorise and assess the significance of any potential impacts to marine mammals, discussions with SNH have reiterated the importance of also applying rigorous professional judgement in determining the significance of any potential impacts.

27 Impact significance is then given as major, moderate, minor or negligible guided by the following matrix.

TABLE 12.1
Matrix for significance of impact (based on importance and recoverability

	Sensitivity of Receptor				
Magnitude of Effect (based on spatial, duration and scale of effect)		**Very High**	**High**	**Medium**	**Low**
	Very High	Major	Major	Major	Moderate
	High	Major	Major	Moderate	Minor
	Medium	Major	Moderate	Moderate	Minor
	Low	Moderate	Minor	Minor	Negligible
	Negligible	Minor	Negligible	Negligible	Negligible

28 All marine mammal species are protected species, as such their sensitivity within the impact assessment is considered to be 'Very high', and therefore even when the magnitude of effect has been assessed as being of negligible significance, this still results in a 'minor' significant impact.

12.3.2 Impact Assessment

12.3.2.1 Construction Phase

Impact of Noise: Physiological Damage

29 The impact assessment has considered the risks and impacts to marine mammals from the construction, operation and decommissioning of the EOWDC.

30 The significance of potentially killing a marine mammal during the piling of the EOWDC was assessed as being of major significance, however, with the successful adoption of the mitigation measures for piling, there are not anticipated to be any residual risks given that a marine mammal would have to be present in such close proximity to the pile driver (3 m) to be at any risk. It is considered the risk of marine mammals receiving sound levels capable of causing their death appears to be remote.

31 Other forms of physical injury (non-auditory) are estimated to occur out to a greater range (60 m), and the risk of piling causing other forms of physical impacts cannot be ruled out, and has been assessed as being of major significance for all marine mammal species. The natural curiosity of seals may increase the risk of exposing both grey and common seals to sound levels capable of causing adverse physical effects.

Impact of Noise: Cumulative Exposure Impacts

32 The cumulative noise dose modelling indicate that unless a cetacean is within the immediate vicinity of piling operations (<1.35 km) or a seal is situated within 3.6 km, the only possibility for an auditory injury to occur is during the initial piling period. It is expected that the perceived loudness of the piling activity would cause the marine mammal to exhibit an aversive behavioural

reaction, with the animal moving from the area before the onset of any auditory injury can occur.

33 The marine mammals which are most likely to be exposed are the more commonly sighted species within Aberdeen Bay, with the harbour porpoise, bottlenose dolphins and grey and common seals being the species most at risk from physical impacts. Given that the relatively small Moray Firth bottlenose dolphin population has been increasing its range expansion in a southerly direction, and that Aberdeen Bay frequently has bottlenose dolphins, especially during the winter and spring months, the potential impact both to the individual and population is considered to be of high magnitude and potentially of major significance. It should be considered that the majority of bottlenose dolphins sightings have been observed frequenting the harbour mouth area and that the mitigation measures mentioned below they should be sufficient to ensure that no bottlenose dolphins are situated within 820 m prior to piling activities. If such measures are put in place the anticipated magnitude of the effects is expected to be negligible and thus be of minor significance to the bottlenose dolphin populations.

Impact of Noise: Behaviour Disturbance and Displacement

34 The range at which behavioural responses are considered potential adverse is up to 22 km for harbour porpoise and 16 km for common and grey seals. For harbour porpoises the results of post-monitoring studies suggest that after piling stops the animals have been found to return to the area within a few hours. The haul out locations of seals could be affected by the piling operations, which could cause temporary displacement of seals from such areas. Therefore, behavioural disturbance, which would lead to displacement of marine mammals from the piling activities, is only expected to occur for the duration of piling activities.

35 The potential exclusion of bottlenose dolphins through behavioural displacement for the duration of the piling activity and out to an extent of 16 km has been assessed as being of high magnitude, and therefore of potentially of major significance to the bottlenose dolphin. As bottlenose dolphins are present along the east coast of Scotland, it has been predicted that the temporary displacement of animals from the Aberdeen Bay area would be mitigated by animals moving into other areas within their natural range. This is a hypothetical assessment and is based on the available habitat range for bottlenose dolphins being extensive and covering the coastal waters along the Scottish east coast.

36 The other species of cetacean present in Aberdeen Bay are not restricted to coastal areas and are present throughout a far wider area. Aberdeen Bay has not been recognised as being of particular importance for breeding or calving purposes for other cetacean species. The possible exception is that in that shallower coastal water of the east coast of Scotland other cetacean species have been speculated to have a role in breeding or calving for the white beaked dolphin during the summer period.

37 If piling occurs during summer months (July/August) the significance of the behavioural disturbance could be major for the white beaked dolphins and the bottlenose dolphin, but of minor significance impact for all other cetacean species. Any temporary exclusion of the cetacean species (except bottlenose) from Aberdeen Bay is considered to be of moderate significance, given that there is likely to be adequate areas for foraging relatively nearby.

38 The vessels used in the construction of Aberdeen Bay may locally increase the ambient sound levels, cause disturbance and may temporarily contribute to the displacement marine mammal from the vicinity of construction activities. However, the significance of this local displacement of marine mammals is minor.

Impact of Noise: Interference with the use of Sound

39 During the pile driving construction activities there is the potential for the sound to mask any seal vocalisations, potentially out to a distance of 80 km. The spatial scale of the potential masking would be dependent upon prevailing ambient sound levels and 80 km is a theoretical maximum. The actual significance of this potential impact is expected to be low given that there are no notable haul out locations in close proximity to Aberdeen Bay and that any potential masking would be temporary.

40 Masking of biologically relevant sounds produced by high frequency cetaceans, such as the harbour porpoise, and possibly mid-frequency cetaceans, such as the bottlenose dolphin, is unlikely as the piling pulses have little high frequency energy (Thomsen et al., 2006). Pile driving pulses are of short duration, and are therefore likely to be below the time where full detection of signals is possible in cetaceans (Thomsen et al., 2006). The magnitude of the impact on marine mammal vocalisations is considered to be low for seal and negligible for other cetacean species. The overall significance is considered to be moderate for seals and minor for cetaceans. After completion of the construction works there are not anticipated to be any residual impacts.

41 Vessel sounds are likely to be audible to marine mammals, they are not considered to be capable of permanently masking the sounds produced by cetacean species that are most commonly present in Aberdeen Bay.

Impact of Elevated Suspended Sediments

42 No impacts to marine mammals are anticipated from an increase in suspended sediments levels as the increases are still within the ranges of naturally occurring levels.

Impact of Displacement of Prey Species

43 Marine mammals are highly mobile and are expected to follow their prey should they be displaced from the area during construction activities. Piling would be infrequent and temporary so that any disturbance to prey species would be intermittent and not consecutive. Therefore any foraging impacts are unlikely to be of sufficient magnitude or duration to adversely affect any life history traits of marine mammals. The marine mammals present in Aberdeen have been known to feed on varied prey species and should be adaptable if one of the more sensitive species to sound is temporarily displaced from the local area.

Impact of Increased Vessel Activity

44 Increased shipping levels could be considered to increase the risk of collisions with marine mammals. Construction vessels would be transiting at slow speeds within Aberdeen Bay and are typically slow moving and generate low frequencies. It is considered that any marine mammals would be able to avoid approaching vessels. There have never been any reports of ship strikes from stranding records along the Grampian coast, which suggests the magnitude of the effect to marine mammals is negligible.

12.3.2.2 Operation Phase

Impact of Underwater Sound

45 The noise from the operational wind farm is not considered to be capable of causing disturbance or displacement to marine mammals. There has been considerable variation in the reported underwater noise measurement from operational wind farms, yet all the sound levels reported thus far are relatively low.

46 Aberdeen Bay is already very busy with a wide range of human activities and the small increase in vessel activity associated with the maintenance of the EOWDC proposed wind farm is unlikely to cause any notable increase disturbance to marine mammals.

Impact of Loss of Habitat

47 The worst case scenario in terms of seabed habitat lost would be through the use of gravity based structures for all 11 wind turbines, this would result in the loss of 0.03 km^2 of seabed habitat. As the turbines are separated by a considerable distance, the movement of marine mammals should not be restricted through the EOWDC. This loss of seabed habitat, in terms of similar available habitat within Aberdeen Bay is of negligible magnitude, with the significance of the impact being minor.

Impact of Electromagnetic Fields generated from cables

48 From the monitoring studies of constructed wind farms there is no evidence of any increases or decreases in marine mammal activity that would suggest attraction or avoidance related to magnetic fields. The information on the potential effects of EMF on marine mammals is largely unknown and further research is required to determine the potential risks this may pose to these species. The ecological significance of EMFs is an area of research which requires further study and is discussed further in Chapter 13.

TABLE 12.2
Summary of Impact Assessment

Impact	Environmental effect	Probability of effect occurring	Magnitude	Duration	Spatial extent	Significance level*	Mitigation	Residual impacts	Monitoring
Construction

Cutting of foundations	Disturbance to marine mammals	Low / Medium	Moderate	Temporary	Local	Moderate / Major	Decommissioning Plan recommended mitigation	None	None

12.3.2.3 Mitigation and Monitoring

49 The Marine Mammal Protection Plan would be developed to address and mitigate any of the impacts identified as being of concern to marine mammals. The MMPP would outline the mitigation procedures to be used during construction activities to minimise the risk of impacts to marine mammals, the final MMPP would be developed in consultation with advice from statutory consultees.

50 The programme of boat based surveys and acoustic monitoring using both towed and stationary devices (C-Pods) would continue throughout the development and construction of the EOWDC to enable the identification of marine mammals in the lead up to construction and also to identify potential impacts upon marine mammals

12.4 Summary

51 The environmental baseline identified the distribution and abundances of the marine mammal species in the developmental area that could be potentially impacted. The impacts assessment process considered the worst case developmental scenario and applied this to potential impacts during the construction, operation and subsequent decommissioning of the EOWDC.

52 Underwater sound, principally generated during the piling activities, was assessed as being of potential concern with a number of potentially significant impacts identified (physical damage, behavioural disturbance and in-direct impacts on prey species). The underwater sound generated from the operation and the losses of seabed habitat from the placement of the foundations were both assessed as being impacts of moderate significance. The removal of the foundation by cutting techniques could be an activity that is of major / moderate significance of causing disturbance to marine mammals. Providing the appropriate mitigation measures are followed during construction, operation and decommissioning activities there are not anticipated to be any long lasting residual impacts upon marine mammals.

53 Information to Inform a Habitats Regulations Appraisal (HRA) with respect to marine mammals can be found in Appendix 29.1.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 13: Electromagnetic Fields

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

13 ELECTROMAGNETIC FIELDS

13.1 Background Introduction

1 The transportation of electricity within cables can cause electric and magnetic fields (EMF) to be generated. This has been a cause of concern amongst stakeholders regarding potential impacts upon marine life. These concerns relate to the behaviour of animals found near the source of the EMFs, specifically whether the fields result in the attraction or repulsion of animals from areas around cables and whether the fields influence migration behaviour of certain commercially important or protected fish species.

2 The purpose of this section is to explain the types of EMF that can be generated within subsea cables associated with offshore wind farms and to summarise the potential environmental impacts of EMFs. This section is not an impact assessment, the impacts of EMFs are considered in more detail in the impact assessments for Marine Ecology (Chapter 9) and Marine Mammals (Chapter 12) and Salmon and Sea Trout (Chapter 22). This section has been prepared by Genesis Oil and Gas Consultants.

13.2 Data information and Sources

3 The subject of EMFs has received much attention from the renewable energy industry and Collaborative Offshore Wind Research in the Environment (COWRIE) has commissioned several reports on the subject. The first of these reports provided a review of the potential for electromagnetic fields generated by the offshore wind energy industry (CMACS, 2003; Gill et al., 2005). A second COWRIE report tested fish responses to EMFs from the sub-sea cables (Gill et al., 2009). Both reports are discussed within this chapter.

4 Additional information considered in this report includes an internal report produced by Vattenfall on the impact of EMF from submarine cables on marine organisms (Olsson and Larsson 2010) and a literature review produced by Scottish Natural Heritage (SNH) on the potential effects of electromagnetic fields on protected species (Gill et al., 2010).

13.3 Introduction to EMF Fields

5 EMFs are generated every time electricity is produced, transported or used, with all electric equipment including power cables having the potential to produce EMFs.

6 The principal source of EMFs in offshore wind farm developments are the subsea cables. There are three components to the EMFs from the Alternating Current (AC) submarine power cables considered for the proposed EOWDC (Gill *et al*., 2010). These are:

- an electric field that is contained within an insulated conductor and earthed metallic screen
- a magnetic field which radiates into the surrounding medium
- an induced electric field (iE). This can be generated by water and/or fish movement through the magnetic field. Induced iE fields have also been

shown to arise from the fluctuating magnetic fields produced by AC cables (Gill et al., 2010)

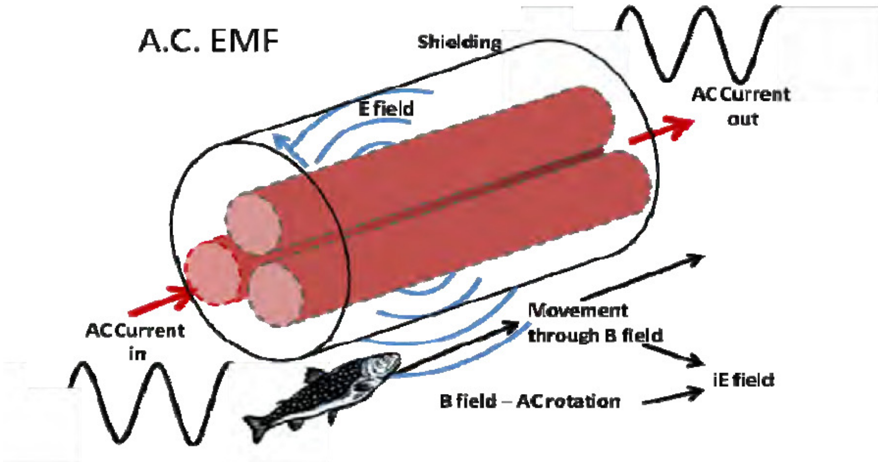

Figure 13.1 Subsea AC cable showing the three cores with the alternating current following a typical oscillating sine wave pattern through each core. (Reproduced from Gill et al., 2010)

7 Electric field strength is measured in volts per meter (V/m). The magnetic filed can be described in terms of the the B-field or the H-field. ‘B’ fields describe the magnetic flux density (T), whilst ‘H’ fields describe the magnetic field strength in amperes per metre (A/m), referenced to a particular point (Table 13.1). B fields are generally used to describe the magnetic field generated within a medium as they are more easily measured than H fields.

TABLE 13.1 Components of the electric and magnetic field			
Field	**Denotation**	**Unit**	**Proportional to**
Electric	E-field	Volt / meter (V/m)	Voltage (V)
Magnetic	Flux density (B-field)	Telsa (T)	Current (I)
Magnetic	Intensity (H-field)	Ampere / meter (A/m)	Current (I)

8 The coating of electric subsea cables ensures that electric fields are contained within the cable, however magnetic fields can radiate from the cable. Whilst it is theoretically possible to contain the magnetic fields through cable burial, it is likely that burial to depths realistically achievable offshore makes no significant difference to the resultant magnetic fields or the distance over which they propagate (CMACS, 2008). The decay in the resultant magnetic fields occurs over a very short scale, at a distance of 10 m they will be undetectable.

13.4 Cable Configuration and Potential for EMFs at the Proposed EOWDC

9 The final cable design and route corridors for the proposed EOWDC have yet to be determined, however it is expected that there would be a maximum of 4 export power cables required, with a total maximum length of 26 km. The precise power requirements of the cables have yet to be established, although it is expected that they would be 33 kV AC cables.

10 The AC cables are three-phase such that there would be three separate cores each of which would be shielded by an insulation screen. As mentioned previously, the use of insulation screens confines any electric fields produced within the cable and reduces the risk of causing electric shocks.

11 There would also be inter-array cables connecting the wind turbines which would have the same power requirements as the export cables. It is expected the inter-array cabling arrangements and associated electrical infrastructure would be comparable to other existing wind farms.

12 A study employing modelling of EMFs from cables with contrasting conductor sizes and current loads at the Kentish Flats Offshore Wind Farm site was undertaken by the University of Liverpool, the results of which are applicable to the proposed EOWDC (Gill et al., 2002). Table 13.2 provides the estimated output parameters for industry standard cables buried 1.5 m in the seabed. These models predicted that the B field on both the surface of a 33 kV cable (millimetres from the source) and the seabed directly above the cable was of the order of 40 µA m-2 or 1.5 µT. Assuming the seabed has a conductivity of 1 S m-1 the resultant electric field would have a probable strength of 40 µVm-1. The electric field within the seabed was modelled to dissipate rapidly to only 1 or 2 µV m-1 within a distance of approximately 10 m from the cable.

13 The magnetic fields produced by the cables would be 1.5 µT which is the equivalent of less than 15 % of the Earth's magnetic field (ie 10 µT).

TABLE 13.1
EMF Output Parameters for Industry Standard Cables Buried 1.5 m in the Seabed (Gill *et al.*, 2002)

Conductor size (mm2)	500
Maximum voltage (kV)	33
Maximum current (A)	530
Maximum B field in seabed (µT)	1.5
Maximum B field in sea (µT)	0.03
Maximum current density in seabed above cable (µA m-2)	40
Maximum current density in sea at seabed surface (µA m-2)	10
Maximum iE field in seabed (µVm-1)	40
Maximum iE field in sea (µVm-1)	2.5
Estimated normal iE field in seabed (µV m-1)	20
Estimated normal B field in sea (µT)	0.015

14 The magnetic and induced electric fields generated by the cables are expected to naturally decay to the extent that electrical fields above 0.5 μVm^{-1} will not be detectable beyond 10 m in any direction from the cable (ie in the water column or the seabed).

15 Each cable is expected to generate similar magnetic and electric fields. Modelling of magnetic and induced electrical fields undertaken for other windfarm developments has identified that broadly comparable fields would be generated by a range of cabling scenarios. The effects of the electric and magnetic fields are expected to become additive when the separation distance between the cables is less than 10 m.

16 The export and inter-array cables would be buried. The burial of the cables increases the separation distance between the cable and any swimming

animals and thereby reduces the magnitude of potential EMF effects. The cable would need to be buried approximately 10 m to avoid the potential for any magnetic fields to be detectable on the surface, which as mentioned previously is uneconomical for an offshore cable installations.

13.5 Existing Anthropogenic Sources of EMF in the Vicinity of the Proposed EOWDC

17 A review of Kingfisher cable awareness charts, SeaZone and Admiralty chart data, shows that there are no other cables in Aberdeen Bay that may produce EMFs. Two telecommunications cables near to The Crown Estate EOWDC lease area were identified however these do not generate EMFs.

18 Gas pipelines can be heated electrically in order to minimise the potentially of hydrates forming, and this can produce EMFs. The St. Fergus gas terminal situated 35 km north of Aberdeen processes 20 % of the UK's gas supply from 8 main pipelines delivering gas from fields across the North Sea. None of the gas pipelines are known to be electrically heated and hence are not expected to act as EMF sources.

19 For the purposes of the environmental assessment of the proposed EOWDC, the effects of EMFs have been considered in isolation from any potential effects from other planned offshore wind farms in the Moray Firth or the Firth of Forth area.

13.6 Use of EMFs by Marine Biological Receptors and Potential Sensitivity of These Receptors to EMFs

20 Naturally occurring EMFs in the form of geomagnetic fields are the predominant EMF that occurs in the marine environment. In addition electric fields are also naturally emitted as a result of biochemical, physiological and/or neurological processes that can occur within an organism, these are known as bioelectric fields. Induced Electric fields can also occur as a result of the animal itself or oceanic waters interacting with the geomagnetic field.

21 A number of biological mechanisms are known by which marine organisms are able to detect an electric and/or magnetic field. Species can be broadly separated into those that are either electroreceptive and / or those that are magneotoreceptive.

22 Electroreception is believed to be closely linked to the mechanisms involved in finding prey, locating conspecifics (other individuals), finding mates and in some instance for navigation, while magnetoreception is believed to primarily be linked to navigation and homing behaviours.

23 The available information on animals detection mechanisms for EMFs is limited, however three possibilities have been proposed:

- electromagnetic induction
- magnetic field dependent chemical reactions, and
- magnetite based magnetoreception

24 Magnetite is a magnetically sensitive material that occurs within the skeletal structure of a large variety of marine organisms and is commonly considered

to have a role in the direction finding using the Earth's geomagnetic field (Kirshvink, 1997).

25 Behavioural experiments have demonstrated that diverse animals, including representatives from all five vertebrate classes, can sense the Earth's magnetic field and use it as an orientation cue (Lohman and Johnsen 2000). The list of animals that is known to possess magnetic compasses includes isopods, sea turtles, spiny lobsters, rays, eel and salmon (Lomann et al., 2008; Westerberg and Lagenfelt, 2008).

26 An unproven hypothesis that some animals possess an additional mapping sense that allows them to determine their position relative to their destination has been proposed. The use of magnetic positional information has been demonstrated in several diverse animals which suggest that such systems are widespread amongst the animal kingdom and have functional abilities across a range of scales (Lohmann, 2007).

27 Responses to induced electric (iE) fields are generally assumed to aid navigation and may either be passive or active on the part of the animal. In active navigation the organism generates its own EMF to interact with the horizontal component of the Earth's magnetic field, whereas passive detection is derived from the interaction of the tide or wind driven currents and the vertical component of the Earth's geomagnetic field (Von der Emde, 1998). Species such as eels and salmonids are able to detect voltage gradients associated with water movement through the geomagnetic field. This mechanism is not fully understood but it is believed that species can detect fields in the range of 8-25 µV/m associated with peak tidal flows.

28 Cartilaginous fish are the major group of organisms that are known to be electroreceptive, this group includes the sharks, skates and rays, collectively known as elasmobranchs. Elasmobranchs register electric fields through a series of pores in the surface skin connected to electroreceptors which enable them to detect small voltage gradients in the environment (CMACS, 2003). The paddlefish, bichirs, lungfish and catfish are also electroreceptive but are not known to be present in the developmental area. There are a number of mostly tropical species that are electrogenic in that they can actively produce electricity, an example being the electric eel.

29 In terms of other groups of marine mammals being electroreceptive, there has been no evidence of any marine mammals species or of any invertebrates using electroreception, but this could be attributed to a lack of research targeting this area as noted for the invertebrates by Bullock (1999).

30 For most magnetoreceptive or electroreceptive species there is little or no information present on how, or if, submarine AC cables affect their behaviour. To date, research has focused on effects of submarine cables on migrating eels and elasmobranchs.

31 In the UK, research has been conducted on elasmobranchs in various controlled environments. The fish are exposed to EMFs which replicate EMFs from subsea cables. Results show that the emitted EMFs may be detectable by the fish, although the response is categorised as a behavioural change that varied between species and between individuals within the same species. No conclusions as to whether the behavioural changes of the elasmobranchs are positive, negative, or have no environmental impact have been drawn (Gill *et al.*, 2009).

13.7 Potential Impact of EMFs Generated from Anthropogenic Sources

32 Any potential impacts of EMFs are restricted to the operational phase when the cables would be transporting electricity, with no impacts being anticipated during either the construction or decommissioning phases. The impacts can be summarised as follows:

- animals may confuse EMF signals with those of potential prey species and may hence waste energy hunting in areas containing prey, or be attracted to areas where they believe conspecifics are present
- repulsion of animals would result in the reduction of available habitat or disrupt the movement or migration of animals throughout Aberdeen Bay creating barrier effects to the natural movement of animals
- disruption to the navigation or orientation may arise for those species using the Earth's geomagnetic field to orientate or time behavioural movements in response to daily events such as tidal cycles. Depending on the magnitude and persistence of the magnetic field, the impact could be a relatively minor temporary change in swimming direction or a more serious impact on migration
- the potential physiological effects on marine organisms may include impacts on cellular development

13.8 Summary

33 The potential EMF generated from the proposed EOWDC submarine cables has been presented, with the marine groups sensitive to the electric and magnetic fields being identified. The detailed impact assessments of the marine species potentially sensitive to EMF has been provided in the impact assessments for Chapter 9 Marine Ecology, Intertidal Ecology, Sediment and Water Quality and Chapter 12 Marine Mammals and Chapter 22 Salmon and Sea Trout.

34 The ecological significance of EMFs is the subject of ongoing research. To date, studies have shown that there is potential for impacts on marine species, however field tests have been inconclusive and both the offshore wind industry and regulators recognise the need for improved understanding in this area.

Environmental Statement

Chapter 14: Statutory Designations and Conservation

14 STATUTORY DESIGNATIONS AND CONSERVATION

1 This section of the ES is for information and is not an assessment chapter. Although the proposed site does not lie within a designated area, the north-east coast of Scotland does support many sites of national and international importance for wildlife. Table 14.1 presents the designated sites that may be affected by the proposed EOWDC. These sites are identified on Figure 14.1. Any effects on designations have been considered in the individual impact assessments.

TABLE 14.1 Designated Sites Potentially Impacted By the Proposed EOWDC		
Designation	**Approximate distance from proposed EOWDC (km)**	**Citation Information**
Special Areas of Conservation (SACs)	*Convention of Natural Habitats and of Wild Fauna and Flora Directive (92/43/EEC) transposed in the UK through the Conservation (Natural Habitats) Regulations 1994.*	
River Dee SAC	7.5	Annex II species, Freshwater Pearl Mussel, Atlantic Salmon, Otter
Sands of Forvie SAC	7.2	Annex I habitats, Embryonic shifting dunes, shifting dunes along the shoreline with *Ammophila arenaria*, decalcified fixed dunes with *Empetrum nigrum*, humid dune slacks
Buchan Ness to Collieston SAC	12.2	Annex 1 habitats, vegetated sea cliffs
River South Esk SAC	63	Annex II species: Atlantic salmon, Freshwater pearl mussel
Firth of Tay and Eden Estuary SAC	96	Annex II species: Common seal Annex I habitats: Estuaries, Intertidal mudflats and sandflats, Subtidal sandbanks
Isle of May SAC	119	Annex II species: Grey seal Annex I habitats: Reefs
Moray Firth SAC	150	Annex II species: Bottlenose dolphin Annex I habitats: Sandbanks which at all times are covered by seawater
Berwickshire and North Northumberland Coast SAC	150	Annex II species: Grey seal Annex I habitats: Large shallow inlets and bays' Mudflats and sandflats not covered by seawater at low tide, Reefs, Submerged or partially submerged sea caves
Special Protection Areas (SPAs) and Ramsar Sites	*Council Directive 79/409/EEC on the Conservation of Wild Birds*	
Ythan Estuary, Sands of Forvie and Meikle Loch SPA & Ramsar	7.2	Qualifying species, Article 4.2 pink-footed goose, Article 4.1 Sandwich tern, common tern, little tern Article 4.2 eider, redshank and lapwing, pink-footed goose

Forvie Biogenetic Reserve	7.2	Heathland Interest.

2 There are no other national or local landscape designations such as national scenic areas within the vicinity of the proposal that have the potential to be affected by the proposed project.

3 In pre-scoping consultation, SNH highlighted, in conjunction with the JNCC that they are in the process of identifying possible marine SPAs. Currently, there have been no sites identified within Aberdeen Bay.

14.1 Conservation Designations

4 A number of protected sites and species in the vicinity of the proposed EOWDC site are designated both internationally and nationally (Table 14.1). The following section provides details of these designations and sites identified of relevance to the proposed project.

14.1.1 Requirement for a Habitats Regulation Appraisal (HRA)

5 Under the Conservation (Natural Habitats, & c.) Regulations (as amended), the relevant Competent Authority (in this case the Scottish Government) must consider the effect of a development on the integrity of a European site. If the development is considered likely to have a significant effect on that site, the competent authority would undertake a Habitats Regulation Appraisal using information supplied as part of the EIA process to accurately determine risk to site integrity. Special Areas of Conservation (SACs) or Special Protection Areas (SPAs) constitute a European site.

6 Initial consultation with statutory bodies has indicated that the interaction between the proposed EOWDC and European sites in the wider area would need to be considered as part of the EIA process and that Habitats Regulation Appraisal may be required.

14.1.1.1 International Sites

Ramsar Sites

7 These sites are internationally important wetland sites protecting wildfowl habitat. Ramsar sites are designated under the Convention of Wetlands of International Importance. The Convention was adopted in Ramsar, Iran, in 1971 and ratified by the UK Government in 1976.

Natura 2000 Sites

8 The two most influential pieces of European legislation relating to nature conservation are the “Habitats” Directive and the “Birds” Directive. The ‘Council Directive 92/43/EEC on the conservation of natural habitats and of wild fauna and flora’, commonly known as the Habitats Directive, adopted in 1992, complements and amends the 1979 ‘Council Directive 79/409/EEC on the conservation of wild birds’, commonly known as the Birds Directive. A further Directive *On The Conservation of Wild Birds* (Directive 2009/147/EC) is a codified version of the 1979 Directive.

9 The Birds Directive protects all wild birds, their nests, eggs and habitats within the European Community. It gives EU member states the power and responsibility to classify Special Protection Areas (SPAs) to protect birds, which are rare or vulnerable in Europe as well as all migratory birds that are regular visitors.

10 The Habitats Directive builds on the Birds Directive by protecting natural habitats and other species of wild plants and animals. Together with the Birds Directive, it underpins a European network of protected areas known as Natura 2000. This network includes SPAs classified under the Birds Directive and Special Areas of Conservation (SAC) under the Habitats Directive.

11 Annexes I and II of the Habitats Directive identify a set of habitats (Annex I) and species (Annex II), which require special conservation measures to be taken by Member States. These lists of habitats and species have been used to define the ‘features’ of a site which form the basis for designating the site as a SAC. Marine SACs may be put forward for habitats of conservation importance (listed in Annex I to the Habitats Directive) or for species of conservation importance (listed in Annex II) (Table 14.2).

TABLE 14.2 Marine Habitats on Annex I and Species on Annex II of the Habitats Directive Found in UK waters	
Annex I Habitats Considered for SAC Selection in UK Offshore Waters	**Species Listed in Annex II Know to Occur in UK Offshore Waters**
Sandbanks which are slightly covered by seawater all the time Reefs (bedrock, biogenic and stony) – Bedrock reefs – made from continuous outcroppings of bedrock which may be of various topographical shape (eeg pinnacles, offshore banks) – Stony reefs – these consist of aggregations of boulders and cobbles which may have some finer sediments in interstitial spaces (eg cobble and boulder reefs, iceberg ploughmarks) – Biogenic reefs – formed by cold water corals (eg *Lophelia pertusa*) and the polychaete worm *Sabellaria spinulosa* Submarine structure made by leaking gases Submerged or partially submerged sea caves	Grey seal (*Halichoerus grypus*) Harbour or common seal (*Phoca vitulina*) Bottlenose dolphin (*Tursiops truncatus*) Harbour porpoise (*Phocoena phocoena*) Salmon (*Salmo salar*) Otter (*Lutra lutra*) Freshwater pearl mussel (*Margaritifera margaritifera*)

Source: JNCC (2002, 2010)

Special Protection Areas (SPAs)

Buchan Ness to Collieston SPA

12 Buchan Ness to Collieston Coast SPA is located on the coast of Aberdeenshire in North-east Scotland, approximately 9.5 km from the EOWDC site. It is a 15 km stretch of south-east facing cliff formed of granite, quartzite and other rocks running to the south of Peterhead, interrupted only by the sandy beach of Cruden Bay. The low, broken cliffs (generally less than 50 m high) show many erosion features such as stacks, arches, caves and blowholes. The varied coastal vegetation on the ledges and cliff tops includes maritime heath, grassland and brackish flushes.

13 The site is of importance as a nesting area for a number of seabird species (Gulls and Auks). These birds feed outside the SPA in the nearby waters as well as more distantly. It is the sea bird assemblage of international importance that qualifies Buchan Ness to Collieston as a SPA. The area qualifies under Article 4.2 of the Habitats Directive (79/409/EEC) by regularly supporting at least 20,000 seabirds.

14 During the breeding season, the area regularly supports 95,000 individual seabirds (Count, as at mid-1980s) including: Guillemot (*Uria aalge*), Kittiwake (*Rissa tridactyla*), Herring Gull (*Larus argentatus*), Shag (*Phalacrocorax aristotelis*), Fulmar (*Fulmarus glacialis*).

Ythan Estuary, Sands of Forvie and Meikle Loch SPA

15 The Ythan Estuary, Sands of Forvie and Meikle Loch make up an area of 1016.24 ha. The site comprises the long, narrow estuary of the River Ythan and eutrophic Meikle Loch. At its mouth, the river splits an extensive area of sand dunes with the Forveran Links on the west bank and the Sands of Forvie dune system on the east bank. Extensive mud-flats in the upper reaches of the estuary are replaced by coarser gravels with mussel (*Mytilus edulis*) beds closer to the sea (JNCC, 2010).

16 These varying habitats give rise to a varied substrate including clay, sands and gravel, extensive areas of bare mud, small areas of salt marsh with representative northern salt marsh flora. Small areas of club-rush swamp are associated with the salt marsh. In the upper parts of the estuary there is a reed bed and near the mouth of the estuary there are shifting sand dunes and areas of bare shingle. To the west of the estuary there is a large area of improved grassland.

17 The margins of the estuary are varied with areas of salt marsh, reed bed and poor fen, heath and scrub, coniferous woodland and grassland. Meikle Loch is an important roost site for geese, which feed away from the SPA on surrounding farmland in winter. It is a eutrophic loch supporting limited aquatic vegetation. In summer, the coastal habitats of the dunes and estuary provide an important breeding site for three species of tern, whilst in winter the estuary holds large numbers of waders, ducks and geese.

18 The site qualifies under a number of articles of the European Directive. Firstly, the site qualifies under Article 4.1 of the Habitats Directive (79/409/EEC) by supporting populations of European importance of the following species listed on Annex I of the Directive. During the breeding season it supports common tern (*Sterna hirundo),* 265 pairs representing up to 2.2 % of the breeding population in Great Britain, little tern (*Sterna albifrons*), 41 pairs representing up to 1.7 % of the breeding population in Great Britain and Sandwich tern (*Sterna sandvicensis*), 600 pairs representing up to 4.3 % of the breeding population in Great Britain (Seabird Census Register).

19 This site also qualifies under Article 4.2 of the Directive (79/409/EEC) by supporting populations of European importance of migratory species. Over-winter pink-footed goose (*Anser brachyrhynchus*), 17,213 individuals representing up to 7.7 % of the wintering Eastern Greenland/Iceland/UK population (winter peak means).

20 The site also qualifies under Article 4.2 of the Directive by regularly supporting at least 20,000 waterfowl. Over winter, the area regularly supports 51,265 individual waterfowl including: redshank *Tringa totanus*, lapwing *Vanellus vanellus*, eider *Somateria mollissima*, and pink-footed goose *Anser brachyrhynchus*.

21 The Ythan Estuary and Meikle Loch sites are also designated as a Ramsar wetland site. The justification for this designation is the assemblages of internationally important waterfowl and the species/populations occurring at levels of international importance.

Loch of Strathbeg SPA

22 The Loch of Strathbeg is located in north-eastern lowland coats of Scotland, in Aberdeenshire, inland from Rattray Head and covers an area of 615.93 ha.

23 The SPA provides wintering habitat for a number of important wetland bird species, particularly wildfowl (swans, geese and ducks), and is also an important staging area for migratory wildfowl from Scandinavia and Iceland/Greenland. In summer, coastal parts of the site are an important breeding area for Sandwich tern (*Sterna sandvicensis*), which feed outside the SPA in adjacent marine areas.

24 The site qualifies under Article 4.1 of the Habitats Directive (79/409/EEC) by supporting populations of European importance of species listed on Annex I of the Directive. During the breeding season it supports Sandwich tern (*Sterna sandvicensis*), 530 pairs representing up to 3.8 % of the breeding population in Great Britain. Over winter it supports barnacle goose (*Branta leucopsis*), 226 individuals representing up to 1.9 % of the wintering population in Great Britain and whooper swan (*Cygnus cygnus*), 183 individuals representing up to 3.3 % of the wintering population in Great Britain.

25 This site also qualifies under Article 4.2 of the Directive (79/409/EEC) by supporting populations of European importance of migratory species. Over winter it supports greylag goose (*Anser anser*), 3,325 individuals representing up to 3.3 % of the wintering Iceland/UK/Ireland population, pink-footed goose, (*Anser brachyrhynchus*), 39,924 individuals representing up to 17.7 % of the wintering Eastern Greenland/Iceland/UK population.

26 In addition area qualifies under Article 4.2 of the Directive (79/409/EEC) by regularly supporting at least 20,000 waterfowl and being a wetland of international importance. Over winter, the area regularly supports 49,452 individual waterfowl including: teal (*Anas crecca*), greylag goose, (*Anser anser*), pink-footed goose, (*Anser brachyrhynchus*), barnacle goose, (*Branta leucopsis*), and whooper swan, (*Cygnus Cygnus*).

27 The majority of the site is managed by the Royal Society for the Protection of Birds (RSPB) for conservation and primarily for the SPA interest. Scottish Natural Heritage (SNH) has piloted a Strathbeg Goose Management Scheme to alleviate the conflict between the geese, which roost on the loch, and the surrounding farms where they feed.

28 The Loch of Strathbeg site is also a designated Ramsar site as the loch constitutes the largest dune slack pool in the UK and the largest water body in the north-east Scottish lowlands, one of the very few naturally eutrophic lochs of the size in the region. The site also qualifies under criterion 5 and 6 with assemblages of international importance, especially peaks in winter, and species/populations occurring at levels of international importance.

Loch of Skene SPA

29 Loch of Skene lies approximately 21 km from the proposed EOWDC location.

30 The qualifying species is greylag goose, which roost on the loch during the winter. The population of wintering greylag geese on the Loch has declined in recent years as increasing numbers of greylag geese now winter in Orkney.

31 In addition to greylag geese the loch also holds nationally important numbers of goldeneye (*Bucephala clangula*) and goosander (*Mergus merganser*) during the winter and a large roost of common gulls occurs during the winter. During the summer the loch holds 50 to 100 pairs of tufted duck.

Fowlsheugh SPA

32 Fowlsheugh is a 10.15 ha stretch of cliffs to approximately 31.1 km south of the proposed EOWDC location. It is an important site for breeding seabirds with up to 145,000 birds present including guillemot, razorbill, kittiwake, fulmar and herring gull. The site is also part of an RSPB reserve.

Troup, Pennan and Lion's Heads SPA

33 The sea cliffs along Troup, Pennan and Lion's Head SPA hold internationally and nationally important numbers of seabirds, notably kittiwake, guillemot, fulmar, herring gull and razorbill. There is a seaward extension out to 2 km from the cliffs, which are approximately 74.3 km from the project location.

Montrose Basin SPA

34 The Montrose Basin lies approximately 63 km to the south of the proposed EWODC and comprises of a large tidal basin containing mud flats and marsh.

35 The area is important for wintering and migrating wildfowl and waders, particularly pink-footed and graylag geese. Other species of importance include: eider, wigeon, shelduck and waders such as knot, oystercatcher and dunlin.

Fair Isle SPA

36 Fair Isle lies halfway between Mainland Shetland and Orkney. It has a rocky, cliff coastline with adjacent coastal waters, heather moorland, acidic grassland, maritime grassland and crofting in-bye. There is a seaward extension out to 2 km from the island.

37 The island lies nearly 300 km from the proposed EWODC site and contains a large assemblage of breeding seabirds the most relevant of which is the gannet that has a foraging range during the breeding season in excess of 300 km. Other species present includes Auks, Skua and Terns as well as fulmars and shags.

Firth of Tay and Eden Estuary SPA

38 The Firth of Tay & Eden Estuary SPA is a complex of estuarine and coastal site in eastern Scotland stretching from the mouth of the River Earn in the inner Firth of Tay east to Barry Sands on the Angus coast and St Andrews on the Fife Coast. The site lies approximately 96 km to the south of the proposed development.

39 It holds a nationally important breeding population of marsh harrier and little tern. It also holds nationally important wintering and migrating populations of a variety of wildfowl and waders including pink-footed goose, graylag goose, eider, scoters and waders such as bar-tailed godwit and oystercatcher.

Firth of Forth SPA

40 The Firth of Forth SPA is a complex of estuarine and coastal habitats in south-east Scotland stretching east from Alloa to the coasts of Fife and East Lothian. The site lies approximately 134 km to the south of the proposed EOWDC. It contains nationally important wintering populations of wildfowl and waders including pink-footed goose, red-throated diver, Slavonian grebe, golden plover and bar-tailed godwit and ducks including goldeneye, eider and long-tailed duck.

Forth Islands SPA

41 The Forth Islands SPA comprises a series of islands situated in the Firth Forth and includes the Bass Rock and the Isle of May. It is a site holding internationally and nationally important seabirds including gannet, fulmar, shag, cormorant, common tern, Sandwich tern, Arctic tern and roseate tern. Three species of auk: puffin, razorbill and guillemot, and three species of gull: herring, lesser black-backed and kittiwake are found there.

Special Ares of Conservation (SACs)

Buchan Ness to Collieston Coast SAC

42 Buchan Ness to Collieston Coast, an area of 207.52 ha, is a designated special area of conservation (SAC). The site includes shingle sea cliffs and islets, bogs marshes, water fringed vegetation and fens as well as heath, scrub, maquis, garrigue, phygrana, humid grassland, and mesophile grassland. Such habitat qualifies the site as an Annex I Habitat, 1230 Vegetated Sea Cliff of the Atlantic and Baltic Coasts.

43 The vegetated cliff slopes support a wide range of coastal vegetation types with an abundance of such local species as Scots lovage (*Ligusticum scoticum*) and roseroot (*Sedum rosea*). In several places the cliff edge retains semi-natural plant communities such as maritime heath, acid peatland and brackish flushes. All these are now rare on the coast of North-east Scotland and this section of coastline contains some of the best remaining examples. Possibly due to the local microclimate and the presence of lime-rich soils, these communities contain several plants, which are associated with dry, calcareous grassland, including carline thistle (*Carlina vulgaris*) and cowslip (*Primula veris*). Sea wormwood (*Seriphidium maritimum*) also occurs. The cliffs and offshore stacks support a scattered but considerable colony of cliff-nesting seabirds with bird-influenced vegetation.

Sands of Forvie SAC

44 The Sands of Forvie SAC includes an area of coastal sand dunes, beaches, machair, inland water bodies, sea cliffs, bogs, marshes, water fringed vegetation, fens, heath, scrub, marquis and garrigue, phygrana, humid grassland and mesophile grassland covering an area of approximately 734.05 ha. There are three primary reasons for selecting Sands of Forvie as an SAC. These include the embryonic shifting dunes, shifting dunes along the shoreline with *Ammophila arenaria* (white dunes), decalcified fixed dunes with *Empetrum nigrum* and humid dune slacks.

45 Sands of Forvie is one of only three sites on the east coat of Scotland which represent the northern part of the UK range of embryonic shifting dunes. Sands of Forvie is one of the most geomorphically active dune systems in the UK and as a result the site contains significant representation of dune types associated with shifting sands. Present throughout the site are identifiable zones of lyme-grass (*Leymus arenarius*) and sand couch (*Elytrigia juncea*).

46 In recent years, Terns have bred in much lower numbers owing to predation and the periodic overtopping of the favoured shingle beds by sand. There is growing concern about the effects of eutrophication on the estuary and its flora and fauna. The continuing build up of algal mats has apparently led to a reduction in the populations of invertebrates, which are the prey of waterfowl such as redshank and shelduck.

47 The site forms the Forvie National Nature Reserve, which is managed for its nature conservation interest under an agreed management plan. The site is also 100 % covered by SSSI designation.

Moray Firth Marine SAC

48 The Moray Firth was designated by Scottish Ministers as a Special Area of Conservation (SAC) on 17 March 2005. The Moray Firth marine SAC has been designated for the species bottlenose dolphin (*Tursiops truncatu*), which is, listed on Annex II of the Habitats Directive, as well as for the Annex I habitat 'Sandbanks which are slightly covered by sea water all the time'.

49 The conservation objectives for the Moray Firth marine SAC with regards to bottlenose dolphins are:

- to avoid deterioration of the habitats of the qualifying species (bottlenose dolphin *Tursiops truncatus*) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained and the site makes an appropriate contribution to achieving favourable conservation status for the qualifying interest
- to ensure for the qualifying species that the following are established then maintained in the long-term:
  - population of the species as a viable component of the site
  - distribution of the species within the site
  - distribution and extent of habitats supporting the species
  - structure, function and supporting processes of habitats supporting the species
- no significant disturbance of the species.

50 The conservation objectives ensure that the obligations of the Habitats Directive are met; that is, there should not be deterioration or significant disturbance of the qualifying interest. This will also ensure that the integrity of the site is maintained and that it makes a full contribution to achieving favourable conservation status for its qualifying interests (SNH, 2006).

River Dee SAC

51 The River Dee SAC lies inland from the proposed project and enters the sea at Aberdeen. The river contains three qualifying species otter (*Lutra lutra*), freshwater pearl mussel (*Margaritifera margaritifera*) and Atlantic salmon (*Salmo salar*). The salmon enter the river throughout the year and the freshwater pearl mussel relies upon the salmon for part of its life cycle when it uses the salmon as a host species. Otters are infrequent on the coast and the majority of the otter population found along the Dee is upstream from the river mouth.

River South Esk SAC

52 The River South Esk SAC is adjacent to the Montrose Basin SAC as the river runs into the basin. The river is nationally important for salmon and freshwater pearl mussel.

Firth of Tay and Eden Estuary SAC

53 The Firth of Tay and Eden Estuary SAC lies approximately 96 km to the south of the proposed EOWDC. The sites comprise of coastal habitats including, estuaries, sand banks, sand flats and mud flats and holds a population of common seal.

Isle of May SAC

54 The Isle of May SAC covers an area of 357 ha and lies 119 km to the south of the proposed development. Grey seal is a qualifying species present and the population has increased significantly since the 1980's when approximately 500 pups were born each year to 2,100 pups in 2,000. The population has since levelled off.

Berwickshire and North Northumberland Coast SAC

55 This large SAC comprising of large variety of habitats including large shallow inlets and bays, mudflats, reefs and sea caves covers an area of 60,545 ha. The site holds a population of grey seals. The site lies approximately 150 km to the south of the proposed development.

14.1.1.2 National Sites

Sites of Special Scientific Interest (SSSI)

Corby, Lilly and Bishops Lochs SSSI

56 Corby, Lilly and Bishops Lochs are designated as Sights of Special Scientific Interest under the Wildlife & Countryside Act (1981). The Lochs lie approximately 6.7 km inland from the proposed EOWDC location. The lochs contain locally important vegetation and invertebrate populations. The Lochs also use to hold roosting greylag geese but the numbers roosting on the Lochs has reduced in recent years.

Foveran Links SSSI

57 Extensive sand dune systems lie to the north of the proposed development. Up to the Ythan Estuary. The 205 ha Foveran Links SSSI contains plant communities not found elsewhere along the coast and a variety of habitats including, fixed dunes, dune pastures, marshes and heaths.

Sands of Forvie and Ythan Estuary SSSI

58 The Sands of Forvie lie approximately 7.2 km to the north of the proposed EOWDC location. The site is also covered by the SAC.

59 It is an extensive area of sand dunes containing a wide range of typical dune habitats and very diverse range of flora. The site holds the UKs largest breeding colony of eider ducks and nationally and internationally important populations of pink-footed geese and other wildfowl and waders.

Meikle Loch and Kippet Hills SSSI

60 Meikle Loch and Kippet Hills SSSI lies approximately 11 km to the north-west of the proposed development. The Loch is freshwater Loch and holds internationally important number so f geese, particularly pink-footed geese

which roost on the Loch and feed in the neighboring area. Other wildfowl species present include graylag goose and teal, wigeon and tufted duck

Collieston to Whinnyfold SSSI

61 This coastal SSSI holds nationally important populations of breeding seabirds including kittiwake, guillemot, razorbill and shag. The site lies approximately 15 km to the north of the proposed development.

Bullers of Buchan SSSI

62 The rocky maritime cliffs at the Bullers of Buchan contain breeding seabirds including guillemots, razorbills, puffins, fulmars and shags.

Fowlsheugh SSSI

63 The cliffs at Fowlsheugh hold the largest breeding seabird colony in the North-east with national important numbers of kittiwakes, guillemots, razorbills as well as puffins, fulmar and shag.

Loch of Skene SSSI

64 The Loch of Skene is approximately 21 km inland from the proposed EOWDC. The site holds nationally important numbers of breeding tufted duck and during the winter goldeneye, goosander, pochard, teal and wigeon. The Loch use to hold nationally important numbers of geese and swans but numbers present on the loch have decreased in recent years. During the winter there is a large common gull roost on the loch.

Loch of Strathbeg SSSI

65 The Loch of Strathbeg is a large shallow freshwater loch on the coast to the north of the proposed development. It is of international importance for its wildfowl, particularly passage and wintering pink-footed geese. It also holds nationally important numbers of whooper swan, graylag goose and important concentrations of pochard, tufted duck, wigeon, goldeneye, goosander and mute swans.

St Cyrus and Kinnaber Links SSSI

66 St Cyrus and Kinnaber Links SSSI is a coastal SSSI located approximately 53 km to the south of the proposed development. It comprises of a wide range of habitats including sand dunes, shingle, slat marsh and grassland. It has diverse range of breeding birds including waders: curlew, redshank, ringed plover and oystercatcher. Breeding passerines include sedge warbler, grasshopper warbler and whinchat and stonechat.

14.1.1.3 <u>Local Sites</u>

Biodiversity

67 Following the 1992 Rio Earth Summit, the UK Biodiversity Action Plan was published in 1994. At the local level, this is implemented through the North East Scotland Local Biodiversity Action Plan (LBAP). LBAP is a partnership of local authorities, environmental, forestry, farming, land and education agencies, businesses and many individuals involved in biodiversity across North East Scotland (Aberdeen, Aberdeenshire and Moray)

68 Most of the North East action for biodiversity is addressed through Habitat Action Plans (HAPs), which incorporate action for associated priority species. These HAPs are grouped under the broader habitat headings of Coastal & Marine; Farmland & Grassland; Woodland; Montane, Heath & Bog; Wetland & Freshwater; and Urban (NESBiodiversity, 2007).

69 The Coastal and Marine Habitat Action Plans (HAPs) are the most relevant for the proposed development. The protection of these coastal and marine habitats is a top priority for North East LBAP and several specific action plans have been developed, including:

- Coastal Sand Dunes and Shingle
- Coastal Cliffs and Heaths [action plan development in progress]
- Marine Habitats [action plan development in progress]
- Estuarine and Intertidal Habitats

70 A number of species has been identified with dedicated North East Action Plans (NESBiodiversity, 2007).

14.1.2 Marine (Scotland) Act 2010

71 The Marine (Scotland) Act (which applies to Scottish territorial waters) introduces new powers relating to functions and activities in the Scottish marine area, including provisions concerning marine plans, licensing of marine activities, the protection of the area and its wildlife including seals, and regulation of sea fisheries. The Act comprises six key elements: the formation of Marine Scotland, a strategic marine planning system, a streamlined marine licensing system, improved marine nature conservation measures, improved measures for the protection of seals and improved enforcement measures (JNCC, 2010).

72 Marine Scotland will deliver integrated marine management functions relating to marine science and data, planning, policy development and delivery, compliance, monitoring and enforcement, whether fully or executively devolved to Scottish Ministers out to 200 nautical miles; and will work closely with the UK Marine Management Organisation (MMO) established under the UK Marine and Coastal Access Act 2009 (JNCC, 2010).

73 Scottish Marine Protection Areas (MPAs) are a new national designation under the **Marine (Scotland) Act** for inshore waters and the **Marine and Coastal Access Act 2009** for offshore waters. Scottish Ministers have executive devolution of authority for the designation of MPAs for the conservation of important marine biodiversity and geodiversity out to 200 nm.

74 Within the Marine Nature Conservation element, powers in the **Marine (Scotland) Act** enable Scottish Ministers to designate three types of Marine Protected Area (MPA) across Scottish territorial waters: Nature Conservation MPAs; Historic MPAs; and Research/Demonstration MPAs (JNCC, 2010).

75 The Scottish MPA project has been established by Marine Scotland (Scottish Government), Scottish Natural Heritage and the Joint Nature Conservation Committee (JNCC) to identify and recommend MPAs for the conservation of nationally important features of marine biodiversity and geodiversity to Government. Scottish MPAs will be identified using science-based selection criteria, but socio-economic information may be taken into account when

selecting between sites of equal scientific merit and to identify likely management issues (Natural England, 2010).

76 The new MPA powers allow Scotland to contribute to the UK's European and International marine conservation commitments, such as those laid out under the Marine Strategy Framework Directive, the OSPAR Convention and the Convention on Biological Diversity (JNCC, 2010) and the government is required by European law to introduce a network of MPAs by the end of 2012 (Natural England, 2010).

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 15: Shipping and Navigation

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

15 SHIPPING AND NAVIGATION

15.1 Introduction

1 This section summarises the work undertaken as part of the Navigation Risk Assessment (NRA) by Anatec UK Ltd to identify the baseline vessel activity and navigational features in the vicinity of the proposed European Offshore Wind Deployment Centre (EOWDC) and to assess the potential impacts associated with the different phases of the development. Planned mitigation measures to manage the impacts, which have been identified in consultation with maritime stakeholders, are also documented.

2 The following technical reports support this chapter and can be found as:

- Navigational Risk Assessment (Appendix 15.1)

15.1.1 Methodology Consultation

3 The methodology applied was based on the DECC Guidelines "Methodology for Assessing the Marine Navigational Safety Risks of Offshore Windfarms, Version Date: 7th September 2005".

4 Extensive consultation on navigational issues has been carried out with stakeholders during the evolution of the proposed development. This following list section briefly summarises the key consultees:

- Aberdeen Harbour
- Marine Safety Forum
- NorthLink ferries
- Craig Group
- Gulf Offshore
- Trico
- Shell Marine
- Scottish Fishermen's Federation
- Other Marine Stakeholders

5 A hazard review workshop was held in Aberdeen on the 25 August 2010, hosted by Aberdeen Harbour. The purpose of the workshop was to identify and review the potential navigational hazards associated with the proposed development of the EOWDC.

6 Various consultation exercises have also been carried out by the project over a number of years including several public events which allowed all stakeholders to contribute opinions on the proposals.

15.1.2 Key Guidance Documents

7 The following key guidance documents have been referred to:

- MCA Marine Guidance Notice 371, Offshore Renewable Energy Installations (OREIs) - Guidance on UK Navigational Practice, Safety and Emergency Response Issues MCA Wind Farm: "Shipping Route" Template

- DECC, U.K. Government, Methodology for Assessing the Marine Navigational Safety Risks of Offshore Windfarms, Version Date: 7th September 2005
- IMO, Guidelines for Formal Safety Assessment (FSA) for use in the IMO rule Making Process, 5th April 2002
- MCA Marine Guidance Notice 372 (M+F), Guidance to Mariners Operating in the Vicinity of UK OREIs, August 2008
- IALA Recommendation O-139 On The Marking of Man-Made Offshore Structures, Edition 1, Dec 2008

15.1.3 Data Information and Sources

8 The following data sources have been used within this assessment:

- AIS and Radar Survey 1 (Anatec, 24 March – 7 April 2009)
- AIS and Radar Survey 2 (Anatec, 21 September – 5 October 2009)
- AIS and Radar Survey 3 (Anatec, 9 April – 23 April 2010)
- AIS and Radar Survey 4 (Anatec, 1 November – 15 November 2010)
- AIS and Radar Survey 5 (Anatec, 18 February – 4 March 2011)
- RYA, UK Coastal Atlas
- EOWDC Commercial Fisheries Assessment (Chapter 21 of this ES)

15.2 Baseline Assessment

9 A baseline assessment gives account to:

- shipping and navigational practices
- Aberdeen Harbour
- oil and gas infrastructure
- MoD Exercise Areas
- metocean data
- hydrographic data

10 Due to the proximity of the site to Aberdeen Harbour particular attention was placed on detailing information on this port.

11 Aberdeen Harbour is the principal commercial port serving the northeast of Scotland with approximately 16,000 ship movements in 2009 handling approximately 4.5 million tonnes of import and export goods. The port is the main marine support centre for the North Sea oil and gas industry. In addition to the oil and gas support services there are regular shipping services to Orkney, Shetland and Scandinavia via Ro-Ro services for passengers and cargo, with 142,468 passengers passing through the port in 2009.

12 The port also has a large modern fish market and although there are no commercial fisheries within the area of jurisdiction of Aberdeen Harbour or proximity, deep-sea fishing vessels and a number of locally registered potters land their catches at the Aberdeen fish market.

13 The nearest proposed turbine within the EOWDC site would be located over 2 nautical miles (nm) from the northern limits of Aberdeen Harbour.

14 There is a designated anchorage area just to the north of the Aberdeen Harbour boundary, which was established in 2010 (see Figure 2.2).

15 Figure 15.1 presents details on shipping as gathered in the AIS and radar during a two week survey in November 2010.

15.3 Impact Assessment

15.3.1 Impact Assessment Methodology

16 The AIS and radar survey data were analysed and further consultation was carried out to assess the potential impacts of the proposed development on shipping and navigation. Through this process, the main shipping and navigation hazard scenarios identified were as follows:

- commercial shipping impact within EOWDC site
- not under command vessel collision
- dragging anchor event
- ship-to-ship collisions
- recreational vessel collisions
- fishing vessel collisions
- fishing vessel gear snagging

17 Further assessment of these scenarios was carried out using qualitative and quantitative techniques. A number of consultation meetings were held with key stakeholders and a Hazard Workshop was carried out in August 2010 in-line with the DECC Guidelines.

18 In addition to the above scenarios, the NRA also assessed the potential impact of the development on a number of factors as outlined in the DECC Guidelines, including:

- visual navigation
- marine radar systems
- communications and position fixing
- search and rescue
- aids to navigation
- anchoring (sea room availability and the potential of cable interaction)

19 The main conclusions of this work are as follows:

- the proposed EOWDC site has been relocated and reduced in size such that it would not affect the main navigation routes in the area, including the bulk of shipping heading to/from Aberdeen Harbour
- moving the site to the north has provided a 0.25 nm separation between the nearest wind turbine and the designated anchorage area in Aberdeen Bay
- consultation with Aberdeen Harbour Board and other users of the area, such as NorthLink Ferries, indicated the site is acceptable in terms of navigational safety
- there is limited fishing and recreational vessel activity in the area
- in the hazard review workshop involving local navigational stakeholders, all hazards were identified to be low

- following identification of the key navigational hazards, risk analyses were carried out to investigate selected hazards in more detail. The overall annual level of risk due to the presence of the proposed EOWDC was estimated to increase by approximately 1 in 404 years (base case) and 1 in 367 years (future case based on traffic growth estimates over the life of the development). The majority of this risk is from passing powered ship collisions with the wind turbines, followed by fishing vessel collisions
- the risks associated with recreational craft interaction with the proposed EOWDC structures (blade/mast and vessel/structure collisions) were qualitatively assessed and concluded to be as low as reasonably practicable given the mitigation measures planned
- a quantitative assessment estimated that, compared to the background marine accident risk levels in the UK, the increase in risk to both people and the environment caused by the proposed EOWDC is low

20 It was concluded that with the correct mitigation measures in place (see Table 15.1) the shipping and navigational impact of the EOWDC development is Low.

21 This outcome was found to be the same for all phases of the development; during construction, operation and decommissioning, although it was noted that the mitigation measures may vary for each phase.

22 No cumulative and in-combination effects were identified throughout the process.

23 The following table summarises the main mitigation measures identified during the NRA.

TABLE 15.1 Mitigation Measures Identified during the NRA	
Mitigation	**Description**
Site selection	Site selected to avoid significant navigational impacts, eg, located away from main anchorage area and navigation lanes to/from Aberdeen following consultation with Aberdeen Harbour, etc.
Marked on Admiralty Charts	EOWDC would be charted by the UK Hydrographic Office using the magenta turbine tower chart symbol found in publication “NP 5011 - Symbols and Abbreviations used in Admiralty Charts”. Submarine cables associated with the project would also be charted on the appropriate scale charts.
Information Circulation	Appropriate liaison to ensure information on the wind farm and special activities is circulated in Notices to Mariners, Navigation Information Broadcasts and other appropriate media.
Marking and Lighting	Structures to be marked and lit in-line with Northern Lighthouse Board and International Association of Marine Aids to Navigation and Lighthouses (IALA) guidance.
Turbine Air Draught	Lowest point of rotor sweep at least 22 m above Mean High Water Springs as per RYA and MCA recommendations.
Cable Protection	Cables to be buried to suitable depth based on cable protection study taking into account fishing and anchoring practices in Aberdeen Bay. Periodic inspection of the cable to ensure it remains buried. Positions of cable routes notified to Kingfisher Information Services (KIS) for inclusion in cable awareness charts and plotters for the fishing industry.
Compliance with MCA’s Marine Guidance Notice (MGN) 371 including Annex 5	Annex 5 specifies “Standards and procedures for generator shutdown and other operational requirements in the event of a search and rescue, counter pollution or salvage incident in or around an OREI.”
Formulation of an Emergency Response Cooperation Plan (ERCoP) as per MCA template	The Applicant would use the draft template created by the MCA to formulate an emergency response plan and site Safety Management Systems, in consultation with the MCA.

15.4 Summary

24 The Shipping and Navigation Assessment was carried out in accordance with the regulations and guidance.

25 Throughout the project marine navigational marking would be provided in accordance and consultation with the NLB requirements, which would comply with IALA and the additional requirements of MCA. It is also noted that there is a requirement to mark selected structures with lights for aviation as per Civil Aviation Authority (CAA) requirements.

26 One of the main elements of the process has been extensive consultation with the key navigation stakeholders to ensure the site design is optimised. Having achieved this, it was identified that the shipping and navigation impacts associated with the development would be Low, provided the correct mitigation measures are implemented.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 16: Aviation

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

16 AVIATION

16.1 Introduction

1 This chapter considers the potential implications of the European Offshore Wind Deployment Centre (EOWDC) in relation to potential aviation issues.

2 Aberdeen airport serves more than three million travellers a year and is the world's busiest commercial heliport, transporting more than 500,000 passengers in support of the North Sea oil and gas industry.

3 The presence of helicopter traffic is the most significant aviation issue for the site. Following early consultation with the relevant authorities it was identified that in certain weather conditions the helicopters may descend to 1,000 feet (or lower), while the tip height of the wind turbines could be in the region of 640feet. This would breach the minimum clearance limit required for helicopter safety and consequently the wind farm layout has been amended to account for the helicopter corridors. This was a major revision to earlier wind farm layouts, and has dominated all subsequent layout considerations.

16.1.1 Methodology Consultation

4 In order to address any potential aviation issues that could arise from the proposed development an Aviation Working Group was established as early as 2005.

5 Although there have been periods of lesser activity the group were active during 2010, with over four meetings discussing a range of issues.

6 The Civil Aviation Authority (CAA) was an early attendee at these meetings, but in recent years they have been content to allow aviation issues – largely operational in nature – to be discussed by National Air Traffic Services (NATS) (Aberdeen) and BAA (Aberdeen). These meetings have also been attended by the three helicopter companies operating out of Aberdeen airport – Bond, Bristows and CHC Scotia. Also in attendance has been Oil and Gas UK, the main client for their helicopter operations.

16.1.2 Key Guidance Documents

7 NATS studies have taken due account of all relevant aviation guidance documents.

16.1.3 Data Information

8 The data used for these studies has come from existing NATS operational data. The following reports have been prepared/ are underway:

- Aberdeen Wind Farm Analysis, April 2011, produced by NATS Procedure Design Group at Heathrow House, Bath Road, Cranford, TW5 9AT
- Aberdeen Wind Farm Radar study - report in preparation by NATS technical specialists
- Assessing the Impact of the Proposed Vattenfall/AREG Wind Farm on Perwinnes MSSR, QinetiQ, March 2010

16.2 Baseline Assessment

16.2.1 Helicopter Routeing

9 As part of the agreement on the final layout of the wind farm, it has been agreed that the northern helicopter route into Aberdeen could be moved to the north, thereby allowing greater clearance between the wind farm and Aberdeen Harbour entrance. The change would be brought about by applying for an Air Space Change, the project has entered into a contract with NATS to bring this into effect.

10 The presence of the EOWDC would also require some minor changes to helicopter procedures in the event of encountering problems during take-off and landing phases at Aberdeen which may be exacerbated in icy conditions.

16.2.2 Primary and Secondary Radar Facilities

11 The proposed layout is within 10 km of the secondary radar facility at Aberdeen airport and as such it has been necessary to assess the potential impacts of the project on this function. The Applicant has commissioned a study from QinetiQ and the report has been passed to NATS. The report shows that although there may be potentially significant effects there are a number of technical solutions available to solve them. The project is currently negotiating a contract with NATS to determine the most efficient and effective technical solution to this issue. The project has also requested that this work include a confirmation that the project does not cause difficulties for the primary radar at Aberdeen airport.

16.3 Impact Assessment

16.3.1 Change to Air Route Maps

12 The project has entered a contract with NATS in order to apply for an Air Space Change. This would be implemented by NATS, in consultation with the Aviation Working Group.

16.3.2 Primary and Secondary Radar Facilities

13 The project is currently negotiating a contract with NATS to determine the most efficient and effective technical solution to this issue.

16.3.3 Mitigation and Monitoring

14 Through the creation of the Aviation Working Group early consultation has ensured that mitigation has been built in to the development process. As a result it is not anticipated that any further mitigation would be required.

15 The implementation of these measures would be the subject of ongoing monitoring by the Aviation Working Group, thereby ensuring that the objectives of minimal impact are sustained.

16 Details of the development would be provided to the Defence Geographic Agency as required.

16.4 Summary

17 Close liaison with key consultees and the formulation of the Aviation Working Group has ensured that there are not likely to be any detrimental effects upon aviation as a result of the EOWDC proposal. Ongoing monitoring during construction, operation and decommissioning would ensure that if any unforeseen issues arise they can be dealt with promptly.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 17: Ministry of Defence

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

17 MINISTRY OF DEFENCE

17.1 Introduction

1 This chapter considers the potential implications of the European Offshore Wind Deployment Centre (EOWDC) in relation to any impacts upon the Ministry of Defence (MoD).

2 The proposed EOWDC is in close proximity to military facilities such as the Black Dog firing range, therefore the MoD interests and potential conflicts with other activities has been a key consideration for the project.

17.1.1 Methodology Consultation

3 Consultation with the MoD has been ongoing since 2005. Liaison with MoD has been constructive, with several meetings being held at Defence Estates, and one at a Royal Air Force (RAF) base in the north of England to discuss the radar interference issue.

17.1.2 Key Guidance Documents

4 Development of any issues will comply with all relevant MoD guidance documents in this area.

17.1.3 Data Information and Sources

5 In matters of national security, the MoD is the sole holder of the relevant detail to make the assessment of the impact of the project upon their activities

17.2 Baseline Assessment

6 Consultation with the MoD has raised two key issues relating to the proposed EOWDC, these are:

- any effect of the project on the operability of the defence radar installation at Buchan (Peterhead)
- any effect of the project on the Black Dog firing range – a small-arms firing range on the coast nearby, but with an associated exclusion zone at sea during firing

17.3 Impact Assessment

17.3.1 Effect of the EOWDC on the Operability of the Defence Radar Installation at Buchan (Peterhead)

7 The MoD undertook an assessment on the current layout 39 (LABER039) in September 2010 as a response to a Request for Scoping Opinion (see Appendix 4.2). They responded that 'the wind turbines will be 26 km from; in line of sight to; and will cause unacceptable interference to the Air Defence (AD) radar at Buchan'.

8 Further correspondence revealed that the MoD was of the opinion that the current 11 wind turbine layout was additional to a 10 wind turbine layout (Layout 12, LABER 012, see Site Selection Chapter 2) assessed in 2008 by the MoD and confirmed by the MoD as raising no concerns. This misunderstanding was recently clarified with the MoD, however, the MoD has maintained their objection to the current 11 wind turbine layout.

9 Given the response to the assessment of layout 12 (LABER012) the Applicant did not anticipate the change in the outcome of the assessment between layouts 12 and 39 leading to a change in position of the MoD from no concern to now a concern of unacceptable interference.

10 At a meeting in June 2011 the MoD confirmed that their advice in response to Scoping 2010 and their current position to a single project of 11 wind turbines remained only if no suitable mitigation could be agreed.

11 The Applicant working in conjunction with the MoD therefore needs to develop technical mitigation measures to accommodate these concerns, and plan to do so during the period of consultation on the project.

17.3.2 Effect of the EOWDC on the Black Dog Firing Range

12 Regarding the Black Dog Firing range, the MoD has consistently stated that no wind turbines should be placed within the safety exclusion zone at sea.

13 While there would be no wind turbines within the firing range exclusion zone, there would be a need for project vessels to enter the area for the purposes of surveying, construction, operations and maintenance. It would therefore be necessary to agree access provisions with the MoD.

14 Operational procedures would be agreed with MoD to allow vessel access to the firing range exclusion zone for project activities during the lifetime of the project.

15 Once operational procedures have been established with the MoD it is not envisaged that there would be any further impact, therefore any potential impacts upon the firing range are considered to be negligible.

17.4 Summary

16 The project has had a long-term relationship with the MoD during its development, through the MoD Defence Estates department in Birmingham. The Applicant understands that plans for the area of the Black Dog Firing Range are acceptable, although further discussions will be needed on operational aspects. There will now need to be an intensive period of work to address MoD concerns regarding the Buchan (Peterhead) radar issue.

European Offshore Wind Deployment Centre
Environmental Statement

Chapter 18: Marine and Maritime Archaeology

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

18 MARINE AND MARITIME ARCHAEOLOGY

18.1 Introduction

1 An Environmental Impact Assessment (EIA) has been undertaken for the proposed European Offshore Wind Deployment Centre (EOWDC) by Wessex Archaeology, to support this Environmental Statement (ES). The impact of eleven wind turbines with inter-array cabling and export cabling to the coast (to the mean high-water mark) upon cultural heritage receptors in marine contexts was assessed. The EIA is underpinned by a baseline technical report which incorporates information from documentary sources and from a geophysical assessment of the seabed and sub-seabed sediments to identify cultural heritage assets within the marine study area (MSA).

2 The following technical reports support this chapter and can be found as:

- Marine and Maritime Archaeology Baseline Technical Report (Appendix 18.1)
- Marine and Maritime Archaeology Environmental Impact Assessment Technical Report (Appendix 18.2)

18.1.1 Methodology Consultation

3 During the preparation of this baseline report organisations were consulted. These are listed below:

- UK Hydrographic Office (UKHO) (101201), documentary sources of wrecks and seabed obstructions
- Royal Commission on the Ancient and Historic Monuments of Scotland (RCAHMS) (101201), documentary sources of wrecks, recorded losses
- Ministry of Defence, Third Sector Heritage (110128), supplementary background source for protected places and control sites

18.1.2 Key Guidance Documents

4 The following guidance documents have been utilised:

- The Code of Practice for Seabed Developers, Joint Nautical Archaeology Policy Committee 2006 (JNAPC 2006)
- Historic Environment Guidance for the Offshore Renewable Energy Sector, COWRIE 2007 (Wessex Archaeology 2007)
- Guidance for Assessment of Cumulative Impacts on the Historic Environment; from Offshore Renewable Energy, COWRIE 2008 (Oxford Archaeology & George Lambrick Archaeology and Heritage, 2008)
- Protocol for Archaeological Discoveries: Offshore Renewables Projects, The Crown Estate, 2010 (Wessex Archaeology, 2010)
- Offshore Geotechnical Investigations and Historic Environment Analysis: Guidance for the Renewable Energy Sector (Gribble & Leather/COWRIE 2011)

18.1.3 Data Information and Sources

- Archaeological records for the MSA available in the maritime section of the CANMORE database held by the RCAHMS which constitute the National Monuments Record for Scotland (NMRS), also interrogated via a map interface, CANMAP
- Archaeological records for the MSA held locally in the Aberdeenshire, Moray and Angus Sites and Monuments Record (SMR)
- Records of wrecks and obstructions collated by the UK Hydrographic Office (UKHO)
- Records of Protected Places and Controlled Sites provided by the Ministry of Defence
- SeaZone datasets including basemapping and wreck information (derived from UKHO records)
- British Geological Service (BGS) mapping and UKHO charts
- Various secondary sources relating to the palaeo-environment of the area and to the Palaeolithic and Mesolithic archaeology of Northern Europe
- Secondary sources relating to wrecks and the maritime environment and the history and archaeology of Aberdeen and its surrounding area

5 Geophysical data that have been archaeologically assessed as part of this report is associated with the following reports:

- Emu Ltd (2008) Geophysical and Seabed Habitat Assessment of the Proposed Aberdeen Offshore Wind Farm for Aberdeen Offshore Wind Farm Ltd. Report No. 07/J/1/02/1136/0716
- Osiris Projects (2010) Aberdeen Offshore Wind farm Geophysical Survey. Volume 1: Operations Report. No. C10023

18.2 Baseline Assessment

18.2.1 Maritime Cultural Heritage Assets

6 A total of two sites designated as of anthropogenic origin and of archaeological interest (WA 7071 and WA 7072) have been identified during the assessment of geophysical survey data within the MSA, located approximately 40 m apart. Of these, one is a previously uncharted wreck site (WA 7071) and the other is possibly a large piece of debris relating to a wreck (WA 7072).

7 It is not currently possible to define the type, identity and archaeological importance of the unidentified wreck (WA 7071). The sonar dimensions of the vessel are 25 m long by 6.5 m wide and it is partially buried by seabed sediment from the east. The wreck is associated with a small magnetic anomaly suggesting it could be of partly metal construction.

8 Both cultural heritage assets are in close proximity to the proposed location of Wind Turbine 8 (maximum distance around 60 m not including foundation dimensions) and the possible inter-array cable routes between Wind Turbines 8 - 9, 8 – 11 and 8 – 5 (around 30 m at nearest points not including trenching dimensions).

9 No other specific wreck sites have been identified in the MSA through geophysical survey interpretation. A magnetic anomaly WA 7070 (potentially an unknown wreck/aircraft crash site) is situated close to the proposed location of Wind Turbine 3 (maximum distance around 40 m not including foundation dimensions).

18.2.2 Submerged Prehistory & Palaeo-landscape Potential

10 The shallow geological sequence underlying much of the survey area represents a prograding shoreline sequence and records changes in sea level in the area since the Last Glacial Maximum. This, makes it a potentially important palaeogeographical and palaeoenvironmental sequence in relation to local and regional patterns of early prehistoric coastal activity and now-submerged archaeological landscapes.

11 The sandy sediment type suggests that potentially important organic palaeoenvironmental indicators may not have been preserved and that prehistoric archaeological material if present and preserved could mainly be lithic in nature.

12 The nature of the local Mesolithic records of lithic scatters associated with coastal sand dunes directly adjacent to the MSA suggests there may be potential for encountering early prehistoric lithic finds in offshore sediments of Holocene age.

18.3 Impact Assessment

18.3.1 Impact Assessment Methodology

13 Cultural heritage receptors are a finite resource, they cannot recover following physical impacts upon them and the security of the context in which they are found is critical to their value and importance. A summary of the nature and type of impacts is given in Table 18.1.

14 The adverse and beneficial impacts affecting cultural heritage receptors can be seen to derive from three main activities during the lifetime of the proposed project. Primary impacts are products of the main activities occurring within the project and would derive from:

- installation of inter-array and export cabling and
- installation of wind turbine foundations

15 Secondary impacts are produced as a consequence of other impacts such as primary impacts and would derive from:

- the seabed footprint of attending vessels which may also cause impacts during construction, operation and decommissioning of the project

16 Both primary and secondary impacts can be direct or indirect. Direct impacts, as the name suggests, directly affect cultural heritage assets, eg excavation or compression of the seabed.. Indirect impacts, via an additional process or processes, affect cultural heritage assets, eg erosion of the seabed by turbulence induced by a seabed structure..

18.3.1.1 Impacts

TABLE 18.1 Summary of the Nature and Type of Impacts		
Impact	**Nature of Impact**	**Type of Impact**
Direct damage to both *in situ* cultural heritage assets and assets in secondary contexts	Adverse	Direct
Disturbance of relationships between structures, artefacts and their surroundings or contexts	Adverse	Direct
Destabilisation and erosion of sites through changes to seabed characteristics	Adverse	Indirect
Burial of sites due to re-deposited sediment, potentially protecting and promoting the favourable preservation of cultural heritage receptors	Positive	Indirect

18.3.1.2 Cultural Heritage Receptors

17 The Cultural Heritage Receptors examined in this study are presented in Table 18.2. Baseline conditions highlight the presence or potential of prehistoric, maritime and aviation archaeology

TABLE 18.2 Cultural Heritage Receptors defined for MSA by Theme		
Prehistoric Archaeology	**Maritime Archaeology**	**Aviation Archaeology**
Post-glacial submerged landscape features & fills	Known wreck sites	Unknown aircraft crash sites
Isolated prehistoric finds	Unknown wreck sites	

18.3.1.3 Sensitivity of the Receptor

18 The security of the context in which cultural heritage receptors are found is a key factor in assessing their value and importance. Generally impacts have adverse effects upon archaeological materials but some effects can be positive.

19 The sensitivity of the cultural heritage receptors is based on the definitions in Table 18.3. Cultural heritage receptors may be important for other reasons such as wartime significance (eg protected under the Protection of Military Remains Act 1986).

20 The terms used in the impact assessment are defined in Table 18.3. Where the importance or significance is unknown or cannot be clearly defined (eg for unknown distributions of prehistoric archaeological materials or unidentified wrecks), a precautionary approach is taken and receptors' archaeological potential, if adversely directly impacted, is assessed.

TABLE 18.3 Definition of Terms Associated with the 'Sensitivity of Receptor'	
Sensitivity	**Definition**
Very High	Feature of International Importance OR best known example and/or significant potential to contribute to knowledge and understanding and/or outreach.
High	Feature of National Importance OR above average example and/or high potential to contribute to knowledge and understanding and/or outreach.
Medium	Feature of Regional Importance OR average example and/or moderate potential to contribute to knowledge and understanding and/or outreach.
Low	Feature of Local Importance OR below average example and/or low potential to contribute to knowledge and understanding and/or outreach.

21 For some cases, a negligible significance of impact may be surmised in association with Table 18.5. In relation to cultural heritage assets this would be defined as a "poor example and/or little or no potential to contribute to knowledge and understanding and/or outreach".

18.3.1.4 Magnitude of Effect

22 The magnitude of effect is assessed relative to the worst realistic case and the impact of development upon specific or regional cultural heritage assets relative to baseline conditions. The terms are defined as shown in Table 18.4:

TABLE 18.4 Definition of Terms Associated with the 'Magnitude of Effect'	
Magnitude	**Definition**
Very High	Total loss or very major alteration to key elements/features of the baseline conditions such that post development character/composition/attributes would be fundamentally changed and may be lost from the site altogether.
High	Major alteration to key elements/features of the baseline (pre-development) conditions such that post development character/composition/attributes would be fundamentally changed.
Medium	Loss or alteration to one of more key elements/features of the baseline conditions such that post development character/composition/attributes of baseline would be partially changed.
Low	Minor shift away from baseline conditions. Change arising from the loss/alteration would be discernible but underlying character/composition/attributes of baseline condition would be similar to pre-development circumstances/patterns.
Negligible	Very slight change from baseline condition. Change barely distinguishable, approximating to the 'no change' situation.

18.3.1.5 Assessment of Significance

23 Based upon these criteria a judgement on receptor's sensitivity and the magnitude of effect is made. The significance of impact is then derived from Table 18.3 and Table 18.4 and guided by the matrix shown in Table 18.5.

TABLE 18.5 Matrix for Significance of Impact					
	Sensitivity of Receptor				
Magnitude of Effect based on spatial, duration and scale of effect		**Very High**	**High**	**Medium**	**Low**
	Very High	Major	Major	Major	Moderate
	High	Major	Major	Moderate	Minor
	Medium	Major	Moderate	Moderate	Minor
	Low	Moderate	Minor	Minor	Negligible
	Negligible	Minor	Negligible	Negligible	Negligible

18.4 Impact Assessment

24 During construction, without mitigation there may be adverse impacts of moderate significance to currently unknown/unidentified prehistoric cultural heritage receptors - submerged landscape features and fills, and potentially to isolated prehistoric finds within the MSA from development activities associated with cable trenching and wind turbine foundations.

25 Without mitigation there may be impacts of major significance to maritime archaeology receptors, in particular known wreck sites.

26 In addition, secondary impacts to known wreck sites of potentially major significance may also occur during operation and decommissioning phases of the project. This is due to the close proximity of known wreck site WA 7071 to the proposed position of Wind Turbine 8 and inter-array cable routes.

27 Using a worst case approach there may be several direct effects upon cultural heritage assets WA 7071 (unidentified wreck) and WA 7072 (possible debris) of anthropogenic origin of archaeological interest by a gravity base structure, skirting and scour protection at the Wind Turbine 8 position and cable trenching between Wind Turbines 8 and 9 (maximum 10.38 m width x 3 m deep).

28 There may be several direct effects in particular locations within the MSA from multiple export cable routes (up to a maximum of four 10.38 m width x 3 m deep trenches). The exact location of these is currently not fixed within the indicative export cable corridor. In the seabed area between the MCA designated anchorage abutting the south of the MSA and the exclusion zone around the Black Dog rifle range to the north, the concentration of trenching would be greater, increasing the spatial extent of adverse effects upon cultural heritage receptors that may be present in a localised area.

29 As a precautionary mitigation strategy, 50 m exclusion zones (buffered around the visible extents of each cultural heritage asset) have been recommended for WA 7071 and WA 7072 (see Appendix 18.2 Figure 1). WA 7070 cannot currently be identified as an anthropogenic feature and therefore has not been given a precautionary exclusion zone. Avoidance, or further site examination to identify the archaeological importance of WA 7070, 7071 and 7072, is proposed.

18.4.1 Cumulative and In-combination Effects

30 There may also be cumulative effects upon cultural heritage assets within the MSA in association with the following activities:

- a potential Ocean Laboratory to the south of Wind Turbine 1
- Maritime and Coastguard Agency (MCA) designated anchorage area
- commercial fisheries activity
- subsea cables within the Blackdog Rifle Range exclusion zone
- port/harbour dredging operations

31 In-combination effects, in this case, are not applicable to cultural heritage assets only to European sites associated with the EU Habitats Directive.

32 Recent and future developments are subject to EIA and mitigation strategies derived during this process should effectively manage impacts to cultural heritage receptors.

33 Table 18.6 presents a summary of the assessment for adverse impacts and positive impacts, as outlined in Table 18.1.

TABLE 18.6 Impact Assessment				
Potential Impact / Receptors	**Significance Level**	**Mitigation**	**Residual Significance**	**Monitoring**
Construction – Cable Trenching, Wind Turbine Foundations & Secondary Impacts from Vessel Seabed Footprints – ADVERSE IMPACTS				
Post-glacial submerged landscape features & fills	Moderate	Avoidance, Reporting protocol	Minor	Geophysical survey, ROV, finds reporting protocol
Isolated prehistoric finds	Moderate	Reporting protocol	Minor	Geophysical survey, ROV, finds reporting protocol
Known wreck sites	Major	Avoidance, Research, reporting protocol	Minor / Negligible	Geophysical survey, ROV, finds reporting protocol
Unknown wreck sites	Minor	Reporting protocol	Minor	Geophysical survey, ROV, finds reporting protocol
Unknown aircraft crash sites	Minor	Reporting protocol	Minor	Geophysical survey, ROV, finds reporting protocol
Operation – Secondary Impacts from Vessel Seabed Footprints – ADVERSE IMPACTS				
Known wreck sites	Major	Avoidance, Research, reporting protocol	Minor	Geophysical survey, ROV, finds reporting protocol
Decommissioning – Secondary Impacts from Vessel Seabed Footprints – ADVERSE IMPACTS				
Known wreck sites	Major	Avoidance, Research, reporting protocol	Minor	Geophysical survey, ROV, finds reporting protocol
Construction – Cable Trenching & Wind Turbine Foundations – POSITIVE IMPACTS				
All receptors	Negligible	-	-	Geophysical survey, ROV, finds reporting protocol

18.5 Summary

34 Impacts to cultural heritage receptors have been assessed for the proposed EOWDC. The significance of adverse impacts to potential prehistoric archaeology receptors, isolated prehistoric sites and finds and submerged landscape features, are assessed to be moderate. Following mitigation the significance of impacts is likely to be minor.

35 Adverse impacts relating to the damage and disturbance of known cultural heritage assets have been identified primarily with respect to the unidentified wreck (WA 7071) in close proximity to Wind Turbine 8 and associated inter-array cable routes between Wind Turbines 8 and 9, 8 and 11 and 8 and 5 (Figure 18.1). Without mitigation adverse impacts to this heritage asset are likely to be major. With mitigation, impacts may be avoided or significantly reduced.

36 Further research and site inspection of this feature may be an effective method for ascertaining the archaeological importance of this unidentified wreck and ultimately the most appropriate methods for impact mitigation.

37 The significance of adverse impacts to potential maritime archaeology and aviation archaeology receptors – unknown wreck sites and unknown aircraft

crash sites – are assessed to be moderate. Following mitigation the significance of impacts is likely to be minor.

38 Avoidance, where practicable, is the preferred mitigation strategy for known cultural heritage assets. Minor amendments to the position of cable trenching and the configuration or placement of the foundation of Wind Turbine 8 have been outlined.

39 There is potential for encountering previously unknown archaeology in the. Strategies have been proposed to mitigate adverse impacts to these receptors.

40 Research, particularly the geoarchaeological examination of vibrocores and grab samples from sub-seabed sediments, taken for engineering or other development purposes provides a cost-effective mitigation strategy to directly investigate the age and archaeological potential of sub-seabed sediments of potential prehistoric archaeological importance. The integration of this kind of geoarchaeological analysis early in the sequence of development activities is advisable to provide the most effective mitigation strategy (Gribble and Leather 2011).

41 Monitoring may be achieved through remote means such as geophysical or ROV survey. In addition, The Crown Estate has recently published a reporting protocol for finds from offshore developments (The Crown Estate/Wessex Archaeology 2010). Best-practice and effective monitoring may be partly achieved by implementing this protocol. Added value would also be provided to the National Monuments Record.

European Offshore Wind Deployment Centre
Environmental Statement

Chapter 19: Seascape, Landscape and Visual

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

19 SEASCAPE, LANDSCAPE AND VISUAL

19.1 Introduction

1 The Seascape, Landscape and Visual Impact Assessment (SLVIA) considered the potential effects that the European Offshore Wind Deployment Centre (EOWDC) would have on the existing seascape, landscape, and visual environment. This assessment was conducted by LDA Design. The purpose of the assessment was to determine the sensitivity, magnitude, and therefore significance of any change to the character of the regional seascape, landscape, and any areas of designated landscapes. The potential effect upon views, visual amenity and receptor groups within the overall Zone of Theoretical Visibility (ZTV) was also assessed. The cumulative seascape, landscape, and visual effects of the proposed development with the existing, consented and in-planning wind farms were also assessed for the study area.

2 The following technical reports support this chapter and can be found as:

- SLVIA Baseline Technical Report (Appendix 19.1)
- SLVIA Environmental Impact Assessment Technical Report (Appendix 19.2)
- SLVIA Figures and Visualisations (Appendix 19.3)

19.1.1 Methodology Consultation

3 Consultation to agree upon the assessment methodology and a number of other important parameters regarding the scope of the SLVIA took place with Scottish Natural Heritage, Aberdeen City Council, and Aberdeenshire Council. The Baseline Report (Appendix 19.1) provides a summary of the key stages of consultation and also provides a detailed record of all consultation which took place on the SLVIA throughout the project.

19.1.2 Key Guidance Documents

4 Key guidance documents that have informed the SLVIA include:

- Maritime Ireland/Wales Interreg 1994 – 1999 Guidance ‘Guide to Best Practice in Seascape Assessment’ (GSA), published in March 2001
- ‘An assessment of the sensitivity and capacity of the Scottish Seascape in relation to wind farms’, (SNH commissioned Report 103, 2005)
- Guidance on the Assessment of Effect of Offshore Wind Farms: Seascape and Visual Effect Report (DTI – November 2005)
- Guidelines for Landscape and Visual Effect Assessment (Institute of Environmental Management and Assessment (IEMA) and the Landscape Institute’s (LI), second edition 2002)
- Visual Representation of Windfarms Best Practice Guidance (SNH 2006, albeit published in 2007)
- Cumulative Effects on Windfarms, (SNH, 2005)
- Siting and Designing Windfarms in the Landscape (SNH, December 2009)

19.1.3 Data Information and Sources

5 The list below records the main survey information that was used in this assessment. Site visits in April 2010 and October 2010 were also undertaken to establish the baseline and assessment work was carried out on site in February 2011.

- SNH (1977) Beaches of Northeast Scotland
- SNH (1994) Banff and Buchan Landscape Assessment
- SNH (1996) Landscape Character Assessment of Aberdeen
- SNH (1998) South and Central Aberdeenshire Landscape Character Assessment

19.2 Baseline Assessment

6 A 40 km radius study area was agreed with the consultees. This area includes a large part of Aberdeenshire which extends along the coast from Kinneff, south of Stonehaven to Crimond, near Peterhead in the north, and inland to the Grampian Mountains (see Figure 19.1). The city of Aberdeen is the main settlement within the study area on the North Sea coast approximately 5 km south-west at its closest point to the proposed EOWDC wind turbines. Stonehaven and Peterhead are the main coastal towns within the study area and Ellon, Inverurie and Banchory are the main inland towns.

7 The baseline landscape, seascape and visual environments within the 40 km radius study area have been defined and sensitivity to the type of development proposed assessed. Sensitivity to change is assessed for seascape/landscape receptors such as regional seascape units, designated areas and landscape character areas, and for visual receptors (people) at agreed viewpoints. It provides an indication of the sensitivity of those receptors to the development proposed.

8 Sensitivity is assessed for each receptor type on the following scale. A full description of the sensitivity methodology can be found in the Baseline Technical Report (Appendix 19.1).

- high – material effects are likely to arise from a development of this nature
- medium – material effects may arise from a development of this nature
- low - material effects are unlikely to arise from a development of this nature

9 Within the study area there are no national designated landscapes except for a number of Gardens and Designed Landscapes (GDLs). Please refer to the Chapter 20 Cultural Heritage for discussion on these and other historical landscape features. Local landscape designations include Areas of Landscape Significance (ALS) which cover a large proportion of the coast line and inland areas adjacent to the Cairngorms (see Figure 19.2). The closest of these to the EOWDC lies between Balmedie and Longhaven and has a high sensitivity to the type of proposed development.

10 Six seascape units were defined from Inverbervie to Fraserburgh with varying sensitivities towards the proposed development (see Figure 19.3). The north part of Aberdeen Bay at Forvie Sands has the highest sensitivity, assessed at

High to Medium, due principally to the remote and unspoilt dune landscape. This sensitivity is reduced to some degree by the presence of nearby existing wind turbines, and views of the developed seafront at Aberdeen.

11 The sensitivity of the landscape character areas within the 40 km radius study area was also assessed. The landscape character types and areas are identified on Figures 19.4 and 19.5. Those character areas from which views out to the sea and coastline are a key characteristic have the highest sensitivity. This includes the higher Moorland Plateau character types at the furthermost extents of the study area, Hills surrounding Aberdeen, and the Open Farmland and Agricultural Heartlands adjacent to the coastline.

12 The visual baseline identified key receptors of residents, travelling public (including sea travel), and visitors and tourists. Twenty representative viewpoints were selected through the consultation process from which the effects upon visual receptors was assessed (please see Figure 19.6 for viewpoint locations). The sensitivity to the proposed development of the main identified visual receptor group at each viewpoint is described in the Baseline Report (Appendix 19.1). Fifteen of the viewpoints are located within 15 km of the site, with seven of these in and around Aberdeen. Those with highest sensitivity to the proposed development are those viewpoints where residents or visitors are the key visual receptors. This includes viewpoints at Balmedie Beach, Aberdeen Beach, Forvie Nature Reserve, Udny Station, near Netherley, and near Slains Castle. Photographic panoramas of each viewpoint are presented in Appendix 19.3.

19.3 Impact Assessment

19.3.1 Impact Assessment Methodology

13 The full assessment methodology is set out in the Baseline Technical Report (Appendix 19.1) and a brief summary of the methodology used to assess impacts is discussed below.

14 The magnitude of effect is assessed for all seascape, landscape and visual receptors and identifies the degree of change arising as a result of the proposed development. It is rated on the following scale:

- high – total or major alteration to key elements, features or characteristics, such that post development the baseline situation would be fundamentally changed
- medium - partial alteration to key elements, features or characteristics, such that post development the baseline situation would be noticeably changed
- low – minor alteration to key elements, features or characteristics, such that post development the baseline situation would be largely unchanged despite discernable differences; and
- negligible – very minor alteration to key elements, features or characteristics, such that post development the baseline situation would be fundamentally unchanged with barely perceptible differences

15 The process of forming a judgment regarding the significance of any potential effect is based upon the site assessment of magnitude of effect which is then correlated with the sensitivity of the receptor to come to a professional

judgment as to how important this effect is in enabling others to come to a decision as to whether consent should be granted. This judgment is illustrated in Table 19.1:

Table 19.1 Matrix for Significance of Impact				
	Magnitude of Effect			
Sensitivity of Receptor	Negligible	Low	Medium	High
High	Negligible	Moderate	Major-Moderate	Major
Medium	Negligible	Moderate-Minor	Moderate	Major-Moderate
Low	Negligible	Minor	Moderate-Minor	Moderate

19.3.2 Seascape and Landscape Effects

16 The scale and extent of the proposed EOWDC, located just over 2 km east off the Aberdeenshire coast, would inevitably affect the surrounding seascape and landscape environments. The primary source point of the effects would be the 11 wind turbines. Whilst the assessment also considered construction and decommissioning effects, the SLVIA is primarily concerned with the operational effects as these have the most potentially significant effects due to the duration of this stage.

17 The proposed EOWDC site would be located within the Aberdeen Bay regional seascape unit which would thus carry the greatest effect arising from the EOWDC development. The EOWDC would be a prominent feature within the seascape unit and would become a defining characteristic. However, the scale of the seascape unit and the presence of existing prominent man made elements would assist to some extent with containing the overall extent of the effect locally to major to major-moderate in the north to major-moderate in the south of the seascape unit.

18 Given the distance between the proposed site and the coastline, the wind turbines would also be theoretically visible from five other regional seascape units and would thus have a degree of effect upon the visual attributes of their character. A combination of distance, the nature and scale of these units; and the fact that effects are confined to visual influence only, will, however, assist with limiting the overall extent of effect to major-moderate to moderate at Aberdeen Beach and no more than moderate in the remaining seascape units.

19 Whilst there would be no direct effects upon their physical character, the landscape character areas defined for the study area would also experience a range of effects on their visual characteristics. The most significant effects of major-moderate to moderate would be upon the Perwinnes Open Farmland and major-moderate to moderate to moderate-minor on the Formartine Lowlands which both lie adjacent to the coastline where views across the sea are a key characteristic. The more elevated inland character areas encompass far ranging and expansive views within which the EOWDC would be a noticeable, but not dominant, element and therefore would not result in any significant effects.

20 The EOWDC would have a major to negligible indirect effect on the Area of Landscape Significance which lies along the coast from Balmedie to Longhaven due to its proximity to the proposed wind turbines, which at its closest is 3 km. However, significant effects would reduce to negligible further north within this ALS.

19.3.3 Visual Effects

21 The proposed 11 wind turbines have a maximum nacelle height of 120 m above lowest astronomical tide (LAT), with a maximum height to blade tip of 195 m. They would be seen, both individually and collectively, as large visual elements set within a simple open setting comprised predominantly of sea, coastal edge and sky. As the wind turbines would be sited close to land, from within the wider study area, where visible, they would be seen both with and without the sea context, rising above the predominantly undulating landscape. The wind turbines would also be seen, admittedly by a far fewer number of visual receptor groups, in views from the sea where they would be seen against a backdrop of either the Aberdeenshire deposition coastline with farmland behind or against Aberdeen city and Girdle Ness headland.

22 The Zone of Theoretical Visibility (ZTV) (see Figure 19.7) illustrates that visual effects arising from the offshore wind turbines would be greatest when seen in views within an approximately 15 km radius of the site and for areas extending north along the coast from where clear views of the EOWDC are possible. This is also demonstrated by the assessment of significant effects at nine of the fifteen viewpoints which lie within 15 km of the EOWDC. Appendix 19. 3 provides wireframes and photomontages of each viewpoint. Inland, theoretical visibility is highest primarily to the north and north-west of the site in the more open gently undulating farmland. The city and its suburbs, combined with the more pronounced landform to the south and west limit views of the EOWDC within these areas of Aberdeenshire.

23 The visual effects would ease considerably with distance from the site. However, given the size of the wind turbines, they would still be a noticeable, but not significant, feature from the northern coastline at distances of over 20 km away. The landform and components of the landscape at this distance obscure or reduce the prominence of the wind turbines so that they become a minor element in the view. The magnitude and extent of visual effects is also reduced by distance as the proposed development would be seen to shift from being the main focus of view to occupying a more peripheral or oblique position within the field of view.

24 The visual impact on Aberdeen is limited by the densely built up nature of a city. Only in the more open elevated areas of the city are the wind turbines likely to be clearly visible, and then they would be seen within a busy and dynamic cityscape.

25 The significance of effect for Local Residents within close proximity to the EOWDC (approximately 3 km) is judged as major where properties are orientated towards the sea and direction of the proposed wind turbines.

26 Other land receptor groups include the visitors and walkers of the Coastal Path where the significance of effect would be major to major-moderate along those parts of the path in close proximity to the EOWDC, reducing to negligible with distance.

27 Any significant visual effects on receptors within the sea would be temporary due to the generally transient nature of views available from marine vessels making passage. There would, however, be overall moderate effects on those receptors out at sea, such as recreational sailors, who have an interest and enjoyment in the surrounding seascape.

19.3.4 Cumulative Effects

28 The assessment of cumulative effects found that, due to the offshore location of the EOWDC and the fact that the majority of the many wind farms within Aberdeenshire are beyond 20 km from the site, the combined and successional cumulative effects were mostly minor or negligible and no more than moderate in significance for visual, seascape and landscape cumulative effects. Appendix 19.3 provides cumulative ZTVs and cumulative wireframes from a selection of the viewpoints.

29 As a consequence of being the closest wind farm (11-19 km) to the EOWDC, the existing and consented Hill of Fiddes, Ardgrain, Tillymaud, and Mains of Bogfechel wind turbines and the in-planning Woodlands Farm and Hill of Fechel are the most frequent wind farms to be seen in theoretical views with the EOWDC. However, these wind farms are approximately half the height of EOWDC and with only between one and three wind turbines, they have a relatively confined visual envelope which reduces the cumulative effect.

30 Although there are no significant combined cumulative effects, the sequential cumulative effects (ie those seen by the travelling public) of EOWDC are potentially greater given the large number of wind farms within the study area.

31 The sequential cumulative assessment from the main roads within the study area showed that the EOWDC would potentially extend the visibility of turbines further than currently exists along the A90 and A96 thus creating localised moderate to moderate-minor sequential effects. Along the other roads studied, the EOWDC would become part of an existing sequential effect and not significantly add to it due to distance and angle of view.

19.3.5 Construction and Decommissioning Stages

32 During the construction phase the effect of increased activity of construction vessels travelling to the site, the presence of jack-up barges and the progressive construction of the wind turbines would constitute the main effect, albeit temporary. During this phase there would be some minor effects on the surrounding seascape. There would also be minor effects on the associated visual receptors and general visual amenity during construction operations which, although temporary, may be more significant than during the operational stages due to the increase in activity and vessel movements. The existing baseline of marine activity in the area helps to moderate impacts to some degree.

33 During the decommissioning phase, there would also be visual effects associated with the decommissioning activity. This would be similar to that of the construction phase and relatively insignificant as there is an existing baseline of marine activity in the area. As the anticipated length of decommissioning would be slightly less than for the construction phase, these impacts would be more temporary than for the construction period. Following

the decommissioning stage there would be no residual effects on the seascape, landscape or visual receptors.

19.3.6 Overview

34 Table 19.2 summarises the potential seascape, landscape and visual impacts which have been assessed as major or major-moderate, and also the associated cumulative impacts. The inherent characteristics of the EOWDC suggest that there are very limited opportunities for incorporation of mitigation measures although the scheme has been designed to minimise the risk of aesthetically visually uncomfortable arrangements.

TABLE 19.2 **Summary of Impacts**		
Receptor	**Significance of Effect**	**Significance of Cumulative Effect**
Regional Seascape Units		
Aberdeen Beach	**Major-Moderate to Moderate**	Moderate/Minor to Negligible

19.4 Summary

35 Upon evaluation, the seascape, landscape, visual, and cumulative effects arising from the proposed EOWDC development have not been found to be inappropriate, although they would fundamentally change the character of the Aberdeen Bay seascape and views from the nearby coastline within approximately 15 km. Where visibility permits beyond this distance, the EOWDC wind turbines would be a noticeable but increasingly minor feature in views. Offshore, the EOWDC would be a visible feature for a considerable distance across the expansive open sea and would thus provide an identifiable focal point and visual reference within the maritime setting. It should also be considered that the nearby city and harbour, designated anchorage area, airport and heliport, and oil industry related activities such as the demonstration drilling platform, provide an environment where the EOWDC would not be an incongruous addition ie vessels are a common feature on the Aberdeen Bay seascape.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 2: Site Selection

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

2 SITE SELECTION

2.1 Site Selection

1 The European Offshore Wind Deployment Centre (EOWDC) site location has been determined through a long process of examining the constraints, undertaking consultations, and conducting surveys, studies and assessments.

2 The concept of an offshore wind farm in Aberdeen originated in 2002 following approach by AREG to AMEC Wind Energy. The concept of a Renewable Energy Centre in Aberdeen was discussed and included an onshore wind turbine and a number of offshore wind turbines. AMEC Wind Energy began to look at an offshore layout stretching up the coastline and initial visualisations were carried out by the Macaulay Institute.

3 Aberdeen Bay was considered suitable for development as it is capable of providing ideal conditions, for example:

- wind speeds likely to be in excess of 8 metres per second (m/s) at 60 m
- water depth consistent with commercial offshore developments
- not directly inside any area designated for nature conservation (see Figure 2.1) although consideration given to areas nearby
- not within a major international shipping route but consideration given to the maritime industry in the area (see Figure 2.2)
- proximity to electricity transmission network

4 A joint venture was formed in 2005 in the proportions AMEC 75 % and AREG 25 %. With the sale of AMEC Wind Energy to Vattenfall, the joint venture now comprises Vattenfall Wind Power Ltd 75 % and AREG 25 %. The company AOWFL has a board of directors drawn from the two constituent organisations.

5 The wind farm layout has undergone a number of alternative iterations from 2004 to 2010 which are described in Table 2.1 and shown on Figure 2.3 and Figure 2.4. These alternative layouts have primarily been a result of consultation with Aberdeen Harbour Board, the aviation industry, the Ministry of Defence and key environmental stakeholders.

6 In 2005, a Scoping Opinion was sought on a wind farm development layout which was located approximately 1 km from the Aberdeenshire coast (See LABER007 Figure 2.3, Frame 2). This site comprised an area following the coastline between Girdle Ness and Newburgh, with the study area for development covering approximately 26 km^2. It was proposed that the wind turbines would be aligned in two rows either side of the 10 m water depth contour. The wind farm at that time comprised approximately 33, three-bladed wind turbines, with an individual wind turbine capacity of up to 5 MW.

7 The current layout (LABER039) comprises 11 wind turbines located approximately between 2 and 4.5 km offshore, see Figure 1.2. This layout has been driven by both biological and human constraints as identified on Figures 2.1 and 2.2 these are primarily:

- proximity to designated sites
- helicopter routes to the north
- coastal bird populations to the west

- shipping to the east
- proximity to Aberdeen Harbour to the south

8 Aberdeen is ideally placed, both in terms of location and supply chain expertise, to drive offshore renewable technologies forward and the EOWDC would be the focal point for the next phase of development for this world-renowned energy industry hub.

TABLE 2.1 Site Layout Iterations			
Internal Layout Reference	**Number of Wind Turbines**	**Date**	**Wind Turbine Layout Description**
LABER002	18	October 2004	Initial layout (based on 10 m water depth constraint) extended north to Newburgh Bar and increased indicative rotor diameter to 120 m and separation between wind turbines to suit.
LABER007	33	February 2005	Layout followed the coastline between Girdle Ness and Newburgh. Two rows of wind turbines were designed to be aligned either side of the 10 m water depth contour. This is the layout included in the previous Scoping Report 2005.
LABER008	24	September 2005	Similar to LABER007, this layout follows the coastline between Girdle Ness and Newburgh. There are two distinct groups, a northern one and a southern one, with a gap in the middle to accommodate a 4 nm helicopter corridor (Shrub – Balis). Both groups have three columns of wind turbines. Outer wind turbines now in water depths up to 20 m. Layout created for discussion.
LABER011	23	January 2006	Updated aviation constraints (including Bridge of Don alternative route) were used to create this layout along with a water depth limit of 25 m. Layout wind turbines have a 120 m rotor diameter. Layout created for discussion.
LABER012	10	September 2008	From the previous layout, the columns closest and furthest from the shore were both removed (for bird and shipping interests) along with the two northern most wind turbines of the remaining 12 (for Black Dog Firing Range impact), leaving 10 wind turbines. Layout submitted to the Ministry Of Defence for re-assessment.
LABER015	10	March 2009	Wind turbine locations similar to subset of LABER011. Wind turbine locations differ slightly due to increased separation to accommodate a 126 m rotor diameter. Created with the intention of a 10 wind turbine layout not extending as far south as LABER012, in order to avoid Bridge of Don alternative helicopter corridor constraint.
LABER021	15	September 2009	Layout created based on LABER015. Five wind turbines added in total. Two coastal wind turbines removed, extra row added to south (but outside helicopter constraint) and three wind turbines added as eastern column. One wind turbine added into the Black Dog Firing Range giving a total of two in this area.
LABER027	12	October 2009	Layout based on new internal agreed list of constraints: - outside existing northern and alternative southern helicopter constraints - within geophysical survey area

TABLE 2.1
Site Layout Iterations

Internal Layout Reference	Number of Wind Turbines	Date	Wind Turbine Layout Description
			- outside of MoD Black Dog Firing Range - no closer to coast than layout LABER021. Layout designed to consider multiple rotor diameters of 90 m, 126 m and 150 m so that outer row accommodates largest rotor diameter. The layout was limited by the necessary spacing between wind turbines. Layouts LABER022 to 026 informed this layout through several variations for discussion.
LABER028	11	November 2009	Following a response from the MoD the wind turbine which was located within the MoD Black Dog Firing Range was removed.
LABER032	16	April 2010	Following further consultation with NATS, it became apparent that there is a possibility of moving the northern helicopter route further north allowing room for two more wind turbines at the north of the site. Also three wind turbines were added to the east of the site as the geophysical survey boundary constraint was relaxed due to this expansion to the north. The decision to have wind turbines beyond the geophysical survey boundary was driven by desire to increase distance from Aberdeen Harbour.
LABER033	11	April 2010	The six southernmost wind turbines were removed to increase distance from the harbour and shipping. The entire site was slightly shifted down to accommodate an extra wind turbine to the north of the site such that it doesn't lie within the helicopter constraint.
LABER034	11	April 2010	Entire layout was rotated using northernmost wind turbine as a turning point to align the rows of wind turbines to the proposed realigned helicopter constraint. Layout created for discussion.
LABER037	12	April 2010	New layout based on latest constraints of revised northern helicopter route, MoD Black Dog Firing Range and maintaining a distance from the harbour similar to LABER036. Layout is a regular grid of 3 rows and 4 columns of wind turbines.
LABER039	11	April 2010	Removed the easternmost wind turbine of LABER037 to increase distance from shipping routes.

European Offshore Wind Deployment Centre
Environmental Statement

Chapter 20: Cultural Heritage

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

20 CULTURAL HERITAGE

20.1 Introduction

1 This chapter of the Environmental Statement (ES) considers the potential impact of the EOWDC upon the setting of nationally important onshore cultural heritage assets. The assessment was undertaken by Headland Archaeology. The cultural significance of cultural heritage assets is often tied to their relationship with their surroundings; consequently development may affect the significance of an asset without affecting its physical fabric by degrading the contribution of setting. This chapter assesses the potential for setting impacts to occur as a result of the EOWDC.

2 The following technical reports support this chapter and can be found as:

- Cultural Heritage Baseline Technical Report (Appendix 20.1)
- Cultural Heritage Environmental Impact Assessment Technical Report (Appendix 20.2)

20.1.1 Methodology Consultation

3 The following consultation was undertaken

- Aberdeen City Council
  Aberdeen City Council was approached in order to establish whether they had specific concerns or requirements for data to be provided, in particular visualisations. Comments were also invited upon the proposed scope of the assessment.

  Robert Forbes, The Planning Officer, indicated that he did have some concern regarding potential impacts upon the setting of Girdle Ness Lighthouse, and requested that visualisations from elevated points to the south and south-west of the lighthouse should be provided in order to help assess the potential impact upon views of the lighthouse.

  The potential impact upon the setting of the lighthouse has been assessed using wireframes and a site visit. The wireframes presented with this report are photographs illustrating various views of the lighthouse. However, photomontages have not been prepared. The wireframes give an adequate demonstration of the scale of the wind turbines in relation to the lighthouse in views from the south, whilst the photomontages for the Torry Battery and Kincorth Hill viewpoints (SLVIA Viewpoints 07 & 12 respectively) provide an indication of the EOWDC's appearance from the vicinity of the lighthouse and from high ground to its southwest. The inclusion of photomontages for Nigg Bay would not afford any substantive information that is not available from that presented here.

  The Archaeology Unit indicated that all consultation was to be undertaken through the Planning Officer.

- Aberdeenshire Council Archaeology Service
  Aberdeenshire Council Archaeology Service was approached in order to establish whether they had specific concerns or requirements for data to

be provided, in particular visualisations. Comments were also invited upon the proposed scope of the assessment.

The Archaeology Service indicated that it had no concerns regarding potential setting impacts.

- Historic Scotland
  Historic Scotland was approached in order to establish whether they had specific concerns or requirements for data to be provided, in particular visualisations. Comments were also invited upon the proposed scope of the assessment.

  No specific concerns were noted. However, it was suggested that the assessment be accompanied by visualisations to illustrate the potential impact upon the setting of Straloch Garden and Designed Landscape (GDL), Hare Cairn and Forvie Chruch and deserted village, as well as those proposed for the Seascape, Landscape and Visual Impact Assessment (SLVIA) for Dunnottar Castle and Torry Battery. It was suggested that assets in the vicinity of Straloch GDL, such as Tillygreig hut-circles (SM2450) be considered.

  Visualisations have been included for Torry Battery (Viewpoint 07 of SLVIA) and from near Forvie Church (Viewpoint 09 of SLVIA). No visualisations have been presented for Straloch GDL or Dunnottar Castle, as there is no intervisibility, or Hare Cairn or Tillygrieg hut-circles, as there is no potential for a significant impact upon its setting from the EOWDC.

- Scottish Natural Heritage (SNH)
  SNH was approached in order to establish whether they had specific concerns or requirements for data to be provided, in particular visualisations. Comments were also invited upon the proposed scope of the assessment (e-mail dated 1st March 2011). SNH had indicated early in the project's lifespan that impacts upon the setting of cultural heritage assets should be considered by the Environmental Statement (ES).

  SNH indicated that the proposed scope of the study was acceptable (e-mail dated 25th March 2011) and did not require any further visualisations.

20.1.2 Key Guidance Documents

4 The following guidance documents have been referred to:

- COWRIE (2007a) Historic Environment Guidance for the Offshore Renewable Energy Sector
- COWRIE (2007b) Guidance for Assessment of Cumulative Impacts on the Historic Environment from Offshore Renewable Energy
- Historic Scotland (2008) Scottish Historic Environment Policy (SHEP)
- Historic Scotland (2009) Assessment of Impact upon the setting of the Historic Environment Resource
- Historic Scotland (2010) Managing Change in the Historic Environment: Setting

20.1.3 Data Information and Sources

5 Two concentric study areas have been used to gather and present the baseline data:

- Inner study area (Figures 20.1, 20.2, and 20.3): This extends 10 km from the outermost proposed wind turbines. Within it data have been gathered for all designated nationally important assets (scheduled monuments, Category A listed buildings and Inventory Gardens and Designed Landscapes (GDL)) and conservation areas; and
- Outer study area: this extends 40 km from the proposed wind turbines to take in the area for which the Zone of Theoretical Visibility (ZTV) has been prepared for the Seascape, Landscape and Visual Impact Assessment (SLVIA). Within it assets specifically identified by consultees as being of concern have been considered.

6 There is no guidance regarding appropriate study areas for cultural heritage setting impact assessments. The study area has been defined in order to take in those assets that are most likely to be affected by the proposed development. Assets further inshore are less likely to be affected as their setting is less likely to relate to the sea.

7 Data were gathered from the following data sources:

- Databases of designated assets held by Historic Scotland
- National Monuments Record of Scotland (NMRS)
- Aberdeen City Council Sites and Monuments Record (SMR); and
- Aberdeenshire Council Historic Environment Record (HER)

8 The results of the desk-based study were augmented by site visits undertaken on 8th and 9th March 2011.

20.2 Baseline Assessment

9 The baseline assessment considered all nationally important cultural heritage assets within the inner study area. Assets in the outer study area were considered where raised by consultees.

10 It was established that there are 18 scheduled monuments (Figure 20.1), 86 Category A-listed buildings (though there are only 62 individual listings (Figures 20.2 & 20.3) and ten conservation areas within the inner study area (Figure 20.4). In the outer study area Straloch Inventory Garden Designed Landscape (GDL) (Figure 20.4), Dunnottar Castle, Tillygrieg hut-circles, Baron's Cairn, Cat Cairn and Loirston cairn (Figure 20.1) were considered.

11 The baseline assessment established that there is no potential for impacts upon the setting of all but two of the listed buildings: Orrok House and Girdle Ness Lighthouse. There is no potential for impacts upon nine of the scheduled monuments in the inner study area. Also there is no potential for impacts upon the setting of the ten conservation areas, Straloch or Dunnottar Castle. Fourteen assets have been taken through to the assessment phase. Assets not taken through to assessment are listed in Appendix 20.1.

20.3 Impact Assessment

12 The impact assessment methodology is detailed in Appendix 20.2.

13 Potential impacts of greater than negligible significance have been identified in five cases. Potential impacts upon Hare Cairn, the Peaterseat cairns, Torry Battery and Orrok House have been assessed as being of minor significance and those upon Girdle Ness Lighthouse as being of minor to moderate significance. The assessment is detailed in Appendix 20.2. For the remaining 8 assets, it was concluded that the EOWDC would have negligible impact on their setting.

14 The impacts would commence during the construction phase and would persist through the lifetime of the EOWDC, ceasing upon decommissioning.

15 The potential for cumulative impacts has been considered resulting from the Ocean Laboratory being added to the EOWDC. No potential cumulative impacts have been identified.

TABLE 20.1
Summary of Impact Assessment

Potential Impact	Significance Level	Mitigation	Residual Significance	Monitoring
Impact upon the setting of Torry Battery	Minor	None proposed	Minor	None proposed
Impact upon the setting of Orrok House	Minor	None proposed	Minor	None proposed
Impact upon the setting of Girdle Ness Lighthouse	Minor to Moderate	None proposed	Minor to Moderate	None proposed
Impact upon setting of Peterseat cairns	Minor	None proposed	Minor	None proposed
Impact upon setting of Hare Cairn	Minor	None proposed	Minor	None proposed

20.4 Summary

16 The cultural heritage impact assessment has identified potential impacts upon the setting of five nationally important cultural heritage assets: the scheduled Torry Battery, Peterseat cairns and Hare Cairn and the A-listed Orrok House and Girdleness Lighthouse. The impacts upon Torry Battery, the Peterseat cairns, Hare Cairn and Orrok House have been assessed as being of minor significance and those upon Girdle Ness Lighthouse as being of minor to moderate significance. No mitigation is proposed in relation to these impacts and they would persist throughout the lifetime of the EOWDC and cease upon decommissioning.

European Offshore Wind Deployment Centre
Environmental Statement

Chapter 21: Commercial Fisheries

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

21 COMMERCIAL FISHERIES

21.1 Introduction

1 This section of the Environmental Statement (ES) summarises the assessment of the potential impacts on commercial fishing from construction, operation and decommissioning of the proposed European Offshore Wind Deployment Centre (EOWDC). For the purpose of this study, commercial fishing is defined as any legal fishing activity undertaken for declared taxable profit. Brown and May Marine have undertaken this commercial fisheries assessment.

2 The following technical reports support this chapter and can be found as:

- Commercial Fisheries Baseline Technical Report (Appendix 21.1)
- Environmental Impact Assessment Technical Report (Appendix 21.2)

21.1.1 Methodology Consultation

3 Consultation with local stakeholders was undertaken by the Scottish Fishermen's Federation (SFF) between 2008 and 2010, particularly with the skippers of the vessels which were identified to fish in the area of the development. In addition, the local District Fisheries Officer provided valuable information for this assessment.

4 The individuals and organisations consulted were:

- Aberdeen District Fisheries Office (281010)
- Fisheries Research Services (211107)
- Scottish Fishermen's Federation (211107)
- Sid McLean – Boy Paul – Peterhead (170111)
- Ricky Greenhowe – Skua II- Aberdeen (170111)
- John Anderson – Tern – Aberdeen (170111)
- Stuart Willox – Maddie Marie – Peterhead (170111)
- Scottish Inshore Fish Producers Association (December 2007 &150211)

21.1.2 Key Guidance Documents

5 The key guidance documents used for both the baseline and impact assessment are as follows:

- Offshore Wind Farms, Guidance Note for Environmental Impact Assessment in Respect of FEPA and CPA Requirements - Version 2; Cefas, MCUE, Defra, DTI, June 2004
- Strategic Environmental Assessment (SEA) of Draft Plan for Offshore Wind Energy in Scottish Territorial Waters: Volume 1: Environmental Report; Marine Scotland 2010
- UK Offshore Energy – Strategic Environmental Assessment; DECC, January 2009
- Recommendations for Fisheries Liaison; FLOW, May 2008
- Fisheries Liaison Guidelines – Issue 5; UK Oil & Gas, 2008
- Guidelines to Improve Relations between Oil & Gas Industries and Near-shore Fishermen, UKOOA (renamed UK Oil & Gas), August 2006

- Fishing & Submarine Cables – Working Together, International Cable Protection Committee (CPC), February 2009
- Options and Opportunities for Marine Fisheries Mitigation Associated with Wind farms, COWRIE 2010; and
- Scoping Response - Marine Scotland (2011)

21.1.3 Data Information and Sources

6 The principal data and information sources used were:

- International Council for the Exploration of the Sea (ICES)
- Marine Management Organisation (MMO)
- Marine Scotland, Marine Science (MS)
- European Commission- Fisheries (Europa)
- Scottish Fisheries Protection Agency (SFPA)
- Brown & May Marine in-house databases

21.2 Baseline Assessment

7 This section provides a brief description of the current commercial fisheries baseline for the EOWDC (salmon and sea trout fisheries have been assessed separately).

8 There is currently no single data source or recognised model for establishing commercial fisheries baselines within small discrete sea areas such as wind farms. The following description has, therefore, been derived using data and information from a number of sources:

- ICES statistical rectangles
- daily log sheets of vessels over 10 m in length
- surveillance sightings recorded by fishery protection aircraft and surface craft as a means of policing fisheries legislation in UK territorial waters and
- satellite tracking of all EU registered fishing vessels 15 m and over in length which are monitored approximately every 2 hours

9 The average landing values (2000-2009) of fish caught in ICES rectangles 43E7 and 43E8 are £89,468 and £1,125,276 respectively. Within 43E7, the main target species is crab using creels, whilst in 43E8 scallops and haddock are the main targets using dredges and otter trawls. Both ICES rectangles are large in relation to the area of sea occupied by the proposed development, as illustrated in Figure 21.1. The majority of landing values (approximately 80%) in ICES rectangle 43E7 are recorded as landed in Aberdeen, for ICES rectangle 43E8 approximately 40 % of the landing values are recorded as being landed in Aberdeen.

10 To date, there have been only low levels of fishing activity within the boundaries of the proposed EOWDC site, largely as a result of the poor productivity of the area. Four local vessels were identified as operating within the general area of the site, all of which are inshore demersal trawlers. These vessels are 11 m and under in length, with two registering their home port as Aberdeen and two Peterhead. The fishing grounds of these vessels were stated to be between Aberdeen Harbour Fairway Buoy and the buoys off the

Black Dog Firing Range, with the main target species being plaice. In addition to trawling, three of the vessels have the capacity to deploy creel gear.

11 From the consultation undertaken and the evidence obtained, it is apparent that the area of the proposed EOWDC constitutes only a small proportion of the fishing grounds of the identified vessels.

12 Analysis of Vessel Monitoring System (VMS) data for over 15 m vessels indicates that vessels with plots recorded within the site are steaming through it to more productive fishing grounds further afield rather than actually fishing within it. The nearest scallop dredging areas are on the Bennachie ground, which lies in the deeper offshore waters beyond Aberdeen Bay. The nearest nephrops grounds are identified well to the south of the site, off the coast of Montrose. Potting, largely by virtue of the habitat requirements of the main target species, is concentrated in areas to the south and the north of the site.

21.3 Impact Assessment

13 The assessment aims to describe the magnitude of effect of each potential impact and the sensitivity of each environmental receptor based on importance and recoverability.

14 The criteria used in the assessment are as follows:

- spatial extent of the effect (national, regional, local and site-specific)
- duration of effect (long term/ permanent (>10 years), medium(5-10 years), short term(1-5 years) or temporary(<1 year))
- scale of effect
- recoverability of the receptor (high, medium, low or none); and
- importance of the receptor (high, medium, low or none)

15 The impact significance is then given as major, moderate, minor or negligible guided by the matrix in Table 21.1.

TABLE 21.1
Matrix for Significance of Impact

	Sensitivity of Receptor				
Magnitude of Effect based on spatial, duration and scale of effect		**Very High**	**High**	**Medium**	**Low**
	Very High	Major	Major	Major	Moderate
	High	Major	Major	Moderate	Minor
	Medium	Major	Moderate	Moderate	Minor
	Low	Moderate	Minor	Minor	Negligible
	Negligible	Minor	Negligible	Negligible	Negligible

16 Some of the potential impacts described within this report are based upon incomplete knowledge and data gaps. In such instances, the assessment may be based upon a number of assumptions and, therefore, a degree of uncertainty will exist.

17 Where the significance of a potential impact is classified as moderate or major, it is considered to be a potentially significant effect. Impacts that were classified as moderate or major during construction, decommissioning and operation of EOWDC are listed in Table 21.2 below.

TABLE 21.2 Impact Assessment				
Construction and Decommissioning				
Potential Impact	**Significance Level**	**Mitigation**	**Residual Significance**	**Monitoring**
Damage to fishing gears by presence of seabed obstacles and obstructions	Negligible to Major if damage occurred	Contractors' obligations and standard offshore practices would prevent , or in case of accidental incidents, remove dropped objects	Negligible	None proposed
Safety issues for fishing vessels (collision with construction vessels)	Negligible to Major if damage occurred	Implementation and adherence to standard offshore safety procedures. Involvement of the SSF for liaison and information distribution	Negligible	None proposed
Operational				
Potential Impact	**Significance Level**	**Mitigation**	**Residual Significance**	Monitoring
Complete loss of, or restricted access to traditional fishing grounds	Negligible (for larger vessels) Moderate (for local vessels)	Certain fishing practices may resume within the operational site with some modification to operating practices	Negligible to beneficial (for larger vessels) Minor (for local vessels)	None proposed
Damage to fishing gears by presence of seabed obstacles and obstructions	Minor to Major if damage occurred	Contractors' obligations and standard offshore practices should ensure objects are removed. Any scour protection rock placement would be adjacent to wind turbines	Negligible	None proposed
Safety issues for fishing vessels (collision with wind turbines)	Minor to Major if collision occurred	Implementation and adherence to standard offshore safety procedures	Negligible	None proposed
Damage to fishing gear/vessels from exposed cables	Minor to Major	Cable burial to 0.6 m depth. Implementation and adherence to standard offshore procedures. Cable route surveys	Negligible to Minor	None proposed

18 Cumulative impact assessments used the same methodology and potential impacts for the standard impact assessment. Cumulative impact assessments have been undertaken on all existing and any reasonably foreseeable project/development activities. The elements that are considered to have the potential to contribute to cumulative impacts are:

- commercial shipping movements (discussed in Chapter 15 Shipping and Navigation)
- other offshore wind farms. As the closest wind farms are 58 km and 117 km from the EOWDC site, it is considered to be of negligible significance

- potential Ocean Laboratory. It is proposed that an Ocean Laboratory may be installed within the site and would be subject and separate application and EIA. As such, at this stage it is only assessed in terms of its cumulative effect

19 Cumulative impacts are, for the most part, expected to be of negligible significance. This is a consequence of the little offshore development, either existing or planned, in the vicinity of the site. Furthermore, as the EOWDC is expected to result in very few impacts above minor significance and those which do occur would be temporary and localised, the contribution of the development to cumulative impacts is expected to be minimal.

20 In-combination impacts, for the purposes of this assessment, describe impacts in relation to the Habitats Directive and have therefore been scoped out of the assessment. Any impacts relating to salmon are dealt with in the Chapter 22 Salmon and Seat Trout Impact Assessment.

21 It should be noted that current trends in fishing activity indicates that levels are unlikely to increase over the lifetime of the project. The current baseline is therefore taken as the worst realistic case in terms of the types and levels of fishing activity. The realistic worst case site layout is assumed to be the highest density of wind turbines within the site ie 11 wind turbines.

21.4 Summary

22 To date, there have been very low levels of fishing activity within the boundaries of the proposed EOWDC site. Four inshore demersal trawlers were identified as operating in the general area, ranging in length between 8 and 11 m. The main activity for these vessels is trawling for plaice, although the vessels also have the capacity to deploy other methods such as creeling for crabs and lobster. From the consultation undertaken it was apparent that the EOWDC site represents only a small proportion of the vessels' fishing grounds.

23 Taking the low levels of fishing activity, the small area of the site and the limited number of wind turbines to be installed, the potential impacts on commercial fishing of the proposed EOWDC are, for the most part, predicted to be of negligible significance.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 22: Salmon and Sea Trout

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

22 SALMON AND SEA TROUT

22.1 Introduction

1 This section of the Environmental Statement (ES) summarises the assessment of the potential impacts on salmon and sea trout derived from the construction, operational and decommissioning phases of the proposed European Offshore Wind Deployment Centre (EOWDC). This assessment has been undertaken by Brown and May Marine.

2 The following technical reports support this chapter and can be found as:

- Salmon and Sea Trout Ecology and Fisheries Baseline Technical Report (Appendix 22.1)
- Salmon and Sea Trout Environmental Impact Assessment Technical Report (Appendix 22.2)

22.1.1 Methodology Consultation

3 Consultation meetings were held with all the salmon fishery boards located within the North East region and with representatives of the netting fishery in the North East.

4 These were as follows:

- Ugie District Salmon Fishery Board (26th October 2010)
- Ythan District Salmon Fishery Board (26th October 2010)
- Don District Salmon Fishery Board (27th October 2010)
- Dee District Salmon Fishery Board (17th January 2011)
- Esk District Salmon Fishery Board (27th October 2010)
- Usan Fisheries (Montrose) (17th Fenruary 2011)

5 In addition to the above meetings, questionnaires were circulated to all the District Salmon Fishery Boards in Scotland, through the Association of Salmon Fishery Boards (ASFB), and to netsmen, through the Salmon Net Fishing Association of Scotland. This process was aimed at gathering information at a national level and to note the main concerns of the boards and the netsmen with regards to wind farm developments in Scotland.

22.1.2 Key Guidance Documents

6 The key guidance documents used for the undertaking of the baseline and impact assessment technical reports are as follows:

- Strategic Environmental Assessment (SEA) of Draft Plan for Offshore Wind Energy in Scottish Territorial Waters: Volume 1: Environmental Report; Marine Scotland 2010
- Offshore Wind Farms, Guidance Note for Environmental Impact Assessment in Respect of FEPA and CPA Requirements - Version 2; Cefas, MCUE, DTI, June 2004
- Marine Scotland Scoping Response (December 2010 and January 2011 update)
- Scottish Natural Heritage Scoping Response (29th September 2010)

- Habitats Regulations Appraisal Draft Plan for Offshore Wind Energy in Scottish Territorial Waters: Appropriate Assessment Information Review. Marine Scotland (2011)

22.1.3 Data Information and Sources

- Marine Scotland Review of Migratory routes and behaviour of Atlantic salmon, sea trout and European Eel in Scotland's coastal environment: Implications for the development of marine renewables (Malcolm *et al*., 2010)
- Scottish Natural Heritage Literature review on the potential effect of electromagnetic fields and subsea noise from marine renewable energy developments on Atlantic salmon, sea trout and European eel (Gill and Barlett, 2010)
- Consultation with District Salmon Fishery Boards
- Collaborative Offshore Wind Research Into the Environment (COWRIE) Publications
- Monitoring Surveys undertaken in Operational Wind Farms
- Marine Scotland Science (MSS)
- Association of Salmon Fishery Boards (ASFB)
- Salmon Net Fishing Association of Scotland
- North East Region District Salmon Fishery Boards and Fisheries Trusts
- Atlantic Salmon Trust
- Monitoring Surveys undertaken in Operational Wind Farms
- Other publically available research literature

22.2 Baseline Assessment

7 This section provides a brief description of the salmon and sea trout ecology and fisheries baseline for the EOWDC.

8 The study areas used for the undertaking of the baseline assessment are shown in Figure 22.1. The local area includes the salmon fishery district located in the immediate vicinity of the EOWDC, the Don, whilst the regional area includes all the salmon fishery districts within the North East region: Ugie, Ythan, Don, Dee and Esk. Given the migratory behaviour of salmon and sea trout and the relative importance of the fishery across the country, the baseline also includes a national focus.

9 The behaviour of salmon and sea trout in the marine environment, particularly on the Scottish east coast, is not fully known and a degree of uncertainty exists regarding salmon and sea trout migratory routes, their behaviour in coastal waters and navigation mechanisms.

10 Salmon and sea trout smolts migrate seawards in the spring, generally from April to June. The seaward migration in both species is thought to be an active process with fish swimming close to the surface and these does not appear to be a period of acclimation when moving from fresh to salt water.

11 Salmon post-smolts make limited use of the estuarine environment moving quickly to the open sea towards their feeding grounds. Limited research carried out to date suggests post-smolts may travel relatively close to the coast in the initial phases of their migration.

12 Salmon originating in rivers from Aberdeenshire southwards are thought to migrate back from their feeding grounds through the North Sea, approaching the coast as far south as Northumberland and then starting a northerly coastal migration towards their home rivers. Grilse (one sea winter salmon) enter the rivers from early summer until shortly before spawning in autumn, whilst multi sea winter salmon are those fish that enter the rivers over a greater period of time.

13 Unlike salmon, sea trout post-smolts are not believed to travel to distant waters to feed; instead they generally remain in coastal waters. In the North East region sea trout generally enter the rivers from June to September with peak runs varying between rivers.

14 The right to fish for salmon in Scotland is a heritable right, whether in inland waters or at sea. The fisheries are managed by their owner or leaseholder under a framework of regulations laid down by central government. Under Scottish legislation the term salmon applies to both salmon and sea trout.

15 In the salmon fishery districts located in close proximity to the proposed EOWDC, the Ythan, Don and Dee, the majority of the total salmon and sea trout catch comes from the rod-and-line fishery with some fixed engine (bag and stake) fisheries. Fixed engine fisheries are of greater relative importance in other districts within the regional area, such as the Ugie and more significantly the Esk.

16 The Don is the salmon fishery district located in the immediate vicinity of the proposed EOWDC. The majority of the reported catch in the district is by rod-and-line, a high percentage of which is by catch and release. Reported catches by the net fishery are comparatively low, with no net-and-coble currently taking place in the district and fixed engines recording very low reported catches in recent years.

22.3 Impact Assessment

22.3.1 Impact Assessment Methodology

17 The assessment aims to describe the magnitude of effect of each potential impact and the sensitivity of each environmental receptor based on importance and recoverability. The impact assessment has been carried out taking the installation of eleven 8.5 m diameter monopiles as the worst case scenario. In reality, however, as the EOWDC is an experimental development to trial various foundations types, it is expected that less than eleven monopiles would be installed.

18 As stated above data gaps exist with respect to the salmon and sea trout baseline and therefore for the purposes of the impact assessment certain assumptions have had to have been made.

19 The Rivers Dee, Don and Ythan are closest to the development and the assumption has been made that fish from these rivers are more likely to transit the site. It is also recognised however that fish from other rivers, both within the region (eg North Esk, South Esk, Ugie) and from other Scottish areas (eg Moray Firth, North, etc) may on occasions also be present in the vicinity of the development.

20 The following assumptions based on the behavioural patterns of salmon and sea trout taking a precautionary approach have been made for fish originating in the Dee, Don and Ythan Salmon Fishery Districts:

- juvenile salmon and sea trout transit through, or in close proximity to, the site on their seaward migration
- adult salmon (grilse and MSW) and sea trout transit through, or in close proximity to, the site on their return migration
- sea trout are present in the vicinity of EOWDC and transit the site as part of their foraging activity

21 The criteria used in the assessment are as follows:

- spatial extent of the effect (national, regional, local and site-specific)
- duration of effect (Long term/ permanent (>10 years), medium (5-10 years) short term (1-5 years) or temporary (<1 year))
- scale of effect
- recoverability of the receptor (high, medium, low or none); and
- importance of the Receptor (high, medium, low or none)

22 The impact significance is then given as major, moderate, minor or negligible guided by the matrix in Table 22.1.

TABLE 22.1
Matrix for Significance of Impact

		Sensitivity of Receptor			
Magnitude of Effect based on spatial, duration and scale of effect		**Very High**	**High**	**Medium**	**Low**
	Very High	Major	Major	Major	Moderate
	High	Major	Major	Moderate	Minor
	Medium	Major	Moderate	Moderate	Minor
	Low	Moderate	Minor	Minor	Negligible
	Negligible	Minor	Negligible	Negligible	Negligible

23 Where the significance of a potential impact is classified as moderate or major, it is considered to be a potentially significant effect.

24 The same methodology used for the assessment of potential impacts has been used in the cumulative impact assessment. The other developments and activities considered to have potential to result in a cumulative impact are as follows:

- other offshore wind farm developments
- offshore oil and gas developments
- introduction of Marine Protected Areas (MPAs)
- aggregate dredging
- potential Ocean Laboratory
- other offshore works

25 A summary of the significance of the impacts derived from the construction, decommissioning and operational phase of the EOWDC, including cumulative impacts is given in Table 22.2 below.

TABLE 22.2
Impact Assessment

Construction and Decommissioning

Source of Potential Impact	**Potential Impact**	**Receptor**	**Significance Level**	**Mitigation**	**Residual Significance**	**Cumulative Impact**	**Monitoring**
Noise	Direct Impact: Lethal effects and hearing damage	Adult and juvenile salmon and sea trout	Negligible	Soft-start piling	Negligible	None expected	Appropriate and relevant monitoring would be assessed through discussion with relevant stakeholders and regulators
	Disturbance/ Delay/Barrier to Migration	Salmon and sea trout juveniles	Minor to Moderate	Installation schedule to be discussed with relevant stakeholders and regulators	Negligible to Minor	Negligible	
		Salmon and sea trout adults	Minor	Installation schedule to be discussed with relevant stakeholders and regulators	Negligible to Minor	Negligible	
	Key prey species	Adult sea trout	Negligible	None required	Negligible	None expected	
Increased sediment concentrations	Direct effects/ Disturbance/ Delay/Barrier to Migration	Juvenile and adult salmon and sea trout	Negligible to Minor	None required	Negligible to Minor	None expected	None planned
Operational							
Source of Potential Impact	Potential Impact	Receptor	Significance Level	Mitigation	Residual Significance	Cumulative Impact	Monitoring

TABLE 22.2
Impact Assessment

Noise	Disturbance/ Delay/Barrier to Migration	Adult and juvenile salmon and sea trout	Negligible	None required	Negligible	None expected	None planned
	Feeding						
EMFs	Disturbance/ Delay/Barrier to Migration	Adult and juvenile salmon and sea trout	Negligible to minor	None other than cable burial	Negligible to minor	Negligible	None planned
Presence of Wind Turbines	Disturbance/ Delay/Barrier to Migration	Adult and juvenile salmon and sea trout	Negligible	None required	Negligible	None expected	None planned

26 As stated, the impact assessment has been based on the installation of 11 monopiles. As EOWDC is a test site, the exact type of foundations and installation schedules have yet to be decided. Once the information is available on actual foundation types, any mitigation and monitoring that may be deemed appropriate or necessary would be assessed through discussion with the relevant stakeholders and regulators at the appropriate time.

27 Given the socio-economic importance of the salmon and sea trout fishery in Scottish rivers and coastal waters, the potential for the fishery to be impacted directly through loss of fishing area, restricted access or interference with fishing activities, and indirectly as a result of the ecology of salmon and sea trout being impacted, have been evaluated. A summary of the potential impacts on the salmon and sea trout fishery is given in Table 22.3 below.

TABLE 22.3
Salmon and Sea Trout Fishery Impact Assessment

Construction and Decommissioning				
Potential Impact	**Receptor**	**Potential Impact**	**Mitigation**	**Residual Impact**
Loss of or Restricted Access to Fishing Areas	Coastal netting during cable installation	Moderate	Liaison and consultation with relevant stakeholders	Negligible
	Coastal netting during other construction activities	Negligible		
	Rod and line fisheries			
Interference with fishing activities	Coastal netting during cable installation	Negligible		Negligible
	Coastal netting during other construction activities			
	Rod-and-line fisheries			
Loss or reduction of catch	Netting and rod-and-line fisheries	Negligible to minor		Negligible to minor
Operation				
Potential Impact	Receptor	Potential Impact	Mitigation	Residual Impact
Loss or reduction of catch	Netting and rod-and-line fisheries	Negligible	Liaison and consultation with relevant stakeholders	Negligible

22.4 Summary

28 Scottish salmon populations are recognised as being of national and international importance. In addition to their ecological value, salmon and sea trout are species of importance from a socioeconomic perspective on a local, regional and national level in Scotland.

29 The significance of the impact derived from the construction, operational and decommissioning phases of the proposed EOWDC on salmon and sea trout is not expected to be above minor, provided adequate mitigation measures and consultation with relevant stakeholders are carried out, especially during

construction. It is accepted that there is uncertainty regarding the behaviour of salmon and sea trout and the implications of responses to factors such as noise and EMFs. For this reason, once detailed construction information is available, appropriate and robust mitigation and monitoring would be discussed with the relevant stakeholders and regulators.

30 Similarly, provided that adequate liaison with stakeholders and fishing interest is carried out, it is not expected that the construction/decommissioning and operational phase of the proposed EOWDC would result in direct impacts on salmon and sea trout fisheries (eg loss of fishing area, restricted access, interference with fishing activities).

31 Indirect impacts on the fishery through loss or reduction of salmon and sea trout catches, would in effect, be directly related to the effects on the ecology of the two species as assessed above. As given in Table 22.2 above, the significance of the residual impacts on salmon and sea trout is predicted to range from negligible to minor. It is however recognised that the scale and magnitude of the potential impacts would vary between districts and would be primarily related to the relative value of the rod and line fisheries within individual districts and the timing and importance of runs within specific rivers.

32 The Atlantic Salmon (*Salmo salar*) is a qualifying species for the River Dee SAC and River South Esk SAC. Atlantic salmon from the relevant SACs may also occur in either the proposed developments in the Moray Firth or the Firth of Forth.

33 Assuming mitigation, in-combination impacts ie cumulative impacts of plans or projects on a European site, are not anticipated (see Appendix 29.1 Information to Inform the HRA).

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 23: Socioeconomics, Recreation and Tourism

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

23 SOCIOECONIMICS, RECREATION AND TOURISM

23.1 Introduction

1 The purpose of this chapter is to assess the socio-economic impacts associated with the European Offshore Wind Deployment Centre (EOWDC), including direct employment and supply chain effects, impacts on tourism and recreation, and impacts on the offshore wind energy sector as a whole, due to the opportunity for research and development. This assessment has been carried out by DTZ Consulting. The assessment has been achieved through reference to secondary literature, consultation with relevant stakeholders, and economic modelling of impacts. The scope of the assessment is the Inner Study Area (Aberdeen and Aberdeenshire), Wider Study Area (Scotland), and the UK.

2 The following technical reports support this chapter and can be found as:

- Socioeconomic, Recreation and Tourism Baseline Technical Report (Appendix 23.1)
- Socioeconomic, Recreation and Tourism Environmental Impact Assessment (EIA)Technical Report (Appendix 23.2)

23.1.1 Methodology Consultation

3 DTZ consulted with the following individuals in April 2011 (all by telephone) to inform the Baseline Assessment and Impact Assessment:

- Colin Parker, Chief Executive, Aberdeen Harbour
- Matt North, Port Manager for the Port of Dundee, Forth Ports
- Steven Paterson, Chief Financial Officer, Peterhead Port Authority
- Eric May, Marine Renewable Section Leader, Marine Scotland
- Robert Forbes, Aberdeen City Council
- Eric Wells, Aberdeenshire Council
- Roddy Mathieson, Aberdeenshire Council
- Alistair Reid, Aberdeenshire Council and Energetica Project
- Paul Reynolds, Offshore Wind Development Manager, RenewableUK
- Sara Budge, Project Director, Energetica
- Dr Graham Russell, RYA Scotland

23.1.2 Key Guidance Documents

4 This assessment has been undertaken in accordance with the following guidance on economic assessment:

- HM Treasury (2003) Green Book
- BIS (2010) Impact Assessment Guidance
- English Partnerships (2008) Additionality Guide: Third Edition
- BIS (2009) Guidance for Using Additionality Benchmarks in Appraisal
- Surfers Against Sewage (2009) Guidance on Environmental Impact Assessment of Offshore Renewable Energy Development on Surfing Resources and Recreation

23.1.3 Data Information and Sources

5 The following key sources of data were used to inform the baseline assessment and EIA technical reports:

- BWEA (2009) UK Offshore Wind: Charting the Right Course
- Ernst & Young (2009) Cost of and financial support for offshore wind
- Marine Scotland (2011) Economic Assessment of Short Term Options for Offshore Wind Energy in Scottish Territorial Waters: Costs and Benefits to Other Marine Users and Interests
- Office of National Statistics (2003-2009) Mid Year Population Estimates
- Office of National Statistics (2009) Annual Population Survey
- Office of National Statistics (2009) Claimant Count

23.2 Baseline Assessment

6 There is a significant renewable energy resource in Scotland, coupled with a high level of government commitment to renewable energy generation. The Scottish Government is committed to achieving a headline target of 20 % of total Scottish energy use from renewable sources by 2020. Scotland has a quarter of Europe's offshore wind potential. The Crown Estate has granted exclusive development rights for 11 offshore wind zones in Scotland. Offshore wind is in its infancy and there is a clear need for demonstration and deployment centres such as the EOWDC. The project, therefore, has an excellent fit with policy.

7 The project has been successful in gaining EU funding of up to €40m from the European Economic Recovery Plan. This award is in recognition of the project's potential role in supporting development of the European offshore wind industry by proving technologies and techniques.

8 At a local level, Aberdeen City and Aberdeenshire recognise the importance of the energy sector to the local economy. The 'Energetica' project has been developed which sets out a vision as to how the Inner Study Area can see energy, tourism, other industries and quality of life factors combine to raise the profile and economic performance of the region.

9 The Inner Study Area can be characterised as follows in terms of socio-economics, tourism and recreation:

- apopulation of 457,300 people in 2009, which has grown by 4.8 % since 2003 (a faster rate than the UK or Scotland)
- high levels of employment in the working age population (79.4 % of the working age population are employed, compared to 71.9 % in Scotland)

- low level of unemployment (2.8 % in the Inner Study Area compared to 7.1% in Scotland)
- a highly qualified workforce (24 % of the workforce is degree qualified, compared to 20.5 % in Scotland)
- the Inner Study Area is less dependent on public sector employment than other parts of Scotland
- the Inner Study Area has a significant Oil and Gas sector – comprising 25,700 workers, and accounting for over 60 % of UK employment in the oil and gas industry. This provides a firm foundation for development of new energy sources such as offshore wind, given the complementarity of skills required.
- the three principle ports within the Inner Study Area are Aberdeen, Peterhead, and Fraserburgh. Aberdeen Port is the major supply base for the North Sea oil industry employing around 11,000 people and Peterhead is the UK's biggest fishing port, landing 149,200 tonnes of fish in 2009 valued at £118 million (27 % of the total Scottish market)
- 1.5 million tourist trips were made to Aberdeen and Grampian in 2009, contributing £344 million of expenditure to the local economy. The region attracts a high number of Scottish and UK tourists. A relatively high proportion of tourist trips into the region relate to business tourism – almost three quarters of visitors to Aberdeen City are business-related. The most significant tourism investment in the inner study area is the Trump Corporation's investment at Menie Estate which will increase tourist income in coming years
- the coastline of the Inner Study Area is used for a variety of recreational activities including sailing (although only to a moderate extent relative to other parts of Scotland), sea angling, surfing, canoeing, kayaking, windsurfing and kitesurfing. Fraserburgh is a particularly popular surfing location and regularly holds surf competitions and events, such as the UK Surf Tour and Fraserburgh Surf Festival

10 Looking forward, the Inner Study Area is expected to experience a weak recovery from the recession. Forecasts show that the economy is expected to grow by an average of 2.7 % per annum in the period 2011-2015 in the Inner Study Area, compared to 2.9 % in Scotland, and 3.4 % in the UK. Employment in the Inner Study Area is expected to decline by 12,100 jobs from 2008 to 2011; after which it is expected that there will be a gradual recovery, with job numbers increasing by 6,000 in the period 2011 to 2018. Over the period 2008-2018 as a whole, the worst affected industries in terms of job losses are expected to be Manufacturing and Oil and Gas industries.

23.3 Impact Assessment

23.3.1 Impact Assessment Methodology

11 The scope of this assessment is to consider the impacts of the development across the areas listed below.

- socioeconomic – employment and economic impacts associated with the construction, operation and decommissioning of the project, including supply chain and income effects
- tourism – considering the impact on tourism in the local area
- recreation – considering the impact on coastal recreational activities

- research and development – considering the possible impact of the deployment centre on the UK offshore wind industry as a whole, due to the opportunity for research, development and testing of equipment

12 The impact methodology is primarily based on a quantitative assessment of the economic impacts in terms of job and Gross Value Added (GVA). The level of significance is assessed as follows:

TABLE 23.1 Impact Methodology		
Magnitude of the Effect (based on spatial extent, duration, and scale)		
Spatial Extent of Effect assessed at the level of • Inner Study Area (Aberdeen & Aberdeenshire) • Wider Study Area (Scotland) • UK	**Duration of Effect** • Long-term/ permanent (more than 10 years) • Medium-term (existing for 5 to 10 years) • Short-term (existing for 1 to 5 years) • Temporary effect (existing for less than a year)	**Scale of Effect:** •As there are no specific standards or guidelines, the impacts are assessed relative to baseline conditions, or a 'No Development' scenario.
Sensitivity of the Receptor		
The sensitivity of the receptor (which in this case is assumed to be the economy, population, businesses and workforce in the study area) has been judged in terms of the level of unemployment in the area.		

13 Impacts are assigned a rating of major, moderate, minor or negligible; based on the magnitude of the effect and sensitivity of the receptor as follows:

TABLE 23.2 Matrix for Significance of Impact					
	Sensitivity of Receptor				
Magnitude of Effect based on spatial, duration and scale of effect		**Very High**	**High**	**Medium**	**Low**
	Very High	Major	Major	Major	Moderate
	High	Major	Major	Moderate	Minor
	Medium	Major	Moderate	Moderate	Minor
	Low	Moderate	Minor	Minor	Negligible
	Negligible	Minor	Negligible	Negligible	Negligible

14 For the purposes of this assessment, only the offshore works associated with the EOWDC have been considered. The onshore works will be subject to a separate EIA, but have been considered briefly within this assessment as a cumulative development. The cumulative impact assessment has also considered the interaction with other planned offshore wind developments on the East coast of Scotland, totalling around 7.5 GW of capacity.

15 In conducting this assessment, consideration has been given to the possible range of impact scenarios, based around the following key aspects of the project:

- scale – it has been assumed that 84MW of capacity (comprising 11 wind turbines) would be deployed within the EOWDC, with an estimated total capital cost of £260.4 million
- timing – construction would take place from 2013-2014 and the EOWDC would be operational for a period of up to 22 years. Following which, there would be a decommissioning period of up to 5 months

- sourcing of components – based on analysis of project expenditure, it has been estimated that a total of around 38 % of capital expenditure would be retained within the Wider Study Area (Scotland), of which around 18 % would be retained within the Inner Study Area
- usage of local ports – It has been assumed that the construction and operational ports would both be within the Inner Study Area (ie Peterhead and Aberdeen)

23.4 Summary

16 Total capital expenditure during the two-year construction phase has been estimated at £260.4 million. It has been estimated that this would support 738 job-years worth of employment, and £40 m of Gross Value Added (GVA) in Scotland; of which 296 job-years and £16 million of GVA would be in the Inner Study Area (Aberdeen and Aberdeenshire). The impact related to the Inner Study Area would relate mainly to the construction and assembly of turbines and foundations. The additional impact in the rest of Scotland relates to the supply chain activity such as the manufacture of foundations and potentially also wind turbines.

TABLE 23.3
Summary of Impact: Construction Phase (2 years)

Total Employment (job-years)	**Direct & Indirect**	**Induced**	**Total**
Inner Study Area	248	48	296
Wider Study Area (Scotland)	531	207	738
UK	955	n/a	n/a
Gross Value Added (£ million, discounted)	**Direct & Indirect**	**Induced**	**Total**
Inner Study Area	£13.8	£2.3	£16.1
Wider Study Area (Scotland)	£29.5	£10.0	£39.6
UK	£53.1	n/a	n/a

17 In terms of the operational phase of the project – this is anticipated to be 22 years in duration, and therefore is judged to have a 'Long-term' effect. Once fully deployed, it is anticipated that the EOWDC would require a local team of around 25 jobs for operational and maintenance activities within the inner and wider study area. Over the 22 year operational life of the development, this would support 768 job-years worth of employment and £23 million of GVA at the Scotland level as summarised below.

TABLE 23.4 Summary Operational Impacts over lifetime of project (22 years)			
Total Employment (job-years)	**Direct & Indirect**	**Induced**	**Total**
Inner Study Area	553	108	661
Wider Study Area (Scotland)	553	216	768
UK	693	n/a	n/a
Gross Value Added (£ million, discounted)	**Direct & Indirect**	**Induced**	**Total**
Inner Study Area	£17.4	£3.0	£20.4
Wider Study Area (Scotland)	£17.4	£5.9	£23.4
UK	£21.9	n/a	n/a

18 The decommissioning phase is expected to be temporary, lasting for up to five months. It has been estimated that the total expenditure on decommissioning would be £33.3 million, and this would support 248 job-years of employment and £7.7m of GVA at the Scotland level.

TABLE 23.5 Summary of Impacts from Decommissioning Phase (up to 5 months)			
Total Employment (job-years)	**Direct & Indirect**	**Induced**	**Total**
Inner Study Area	178	35	213
Wider Study Area (Scotland)	178	69	248
UK	178	n/a	n/a
NPV of GVA	**Direct & Indirect**	**Induced**	**Total**
Inner Study Area	£5.8	£1.0	£6.8
Wider Study Area (Scotland)	£5.8	£2.0	£7.7
UK	£5.8	n/a	n/a

19 The impact of the proposed development on tourism is considered to be of negligible significance.

20 The impact of the proposed development on recreational activities is considered to be of negligible significance.

21 The impact of the proposed development on research and development and the offshore wind industry has also been considered at both a local and national level. The view of consultations was that the proposed deployment centre would have a positive impact on the offshore wind sector. The following quotations highlight the significance of that impact:

'The development of offshore wind still faces many challenges to commercial deployment. The operation of the EOWDC will make a strong contribution to knowledge sharing for new components, designs and access methodologies for construction, operations and maintenance to be executed in the marine environment.' ***Chris Bronsdon, Chief Executive, Scottish European Green Energy Centre (SEGEC)***

'The European Offshore Wind Deployment Centre will provide invaluable opportunities for R&D, helping the industry to grow with real confidence. Innovative projects such as this will help the UK to maintain its position as the

world leader in offshore wind. This will in turn encourage more investors to come forward, creating thousands of jobs in the rapidly-expanding offshore wind sector.' ***Maria McCaffery, Chief Executive of RenewableUK***

'This is potentially a great opportunity for Scotland's research community to actively engage in the development of an important means to generate low carbon electricity. Particularly important will be the deployment of the Ocean Laboratory, a wide range of turbines and support structures as possible and access to these for independent evaluation in order to aid future developments.' ***Professor Paul Mitchell of the University of Aberdeen's School of Engineering***

'The EOWDC is a major component of ACSEF's flagship project, Energetica. As a pioneering offshore wind project, it will be at the cutting edge of the development of new technologies and presents significant opportunities for Aberdeen City and Shire to build a viable, robust supply chain around offshore wind, particularly in the areas of development, operation and maintenance' ***Sara Budge, project manager for Energetica, Aberdeen City and Shire Economic Future (ACSEF)***

'This is a real opportunity for Aberdeen and the North-east [of Scotland] to place itself at the forefront of this aspect of the renewables industry. There is fierce completion not just in Scotland but across the rest of Europe to gain recognition as a leader in the field and this project will provide an extremely valuable testing site for manufacturers to demonstrate their products and to gather vital data on performance.' ***Bob Collier, Chief Executive of Aberdeen & Grampian Chamber of Commerce***

22 Overall, the assessment demonstrates that the project would have a significant positive impact on the economy of the Inner Study Area, Scotland and the UK. Over the lifetime of the project, it is estimated that it would support over 1,750 job-years worth of employment in Scotland, supporting over £70 million of Gross Value Added. It would also provide benefits to the wider offshore wind energy sector by providing opportunities for testing, research and development, and training. This would accelerate the deployment of offshore wind projects progressing through The Crown Estate's 'Round 3' and Scottish Territorial Waters licensing processes by providing the opportunity to demonstrate new equipment in the marine environment. The impacts on tourism and recreational activities are considered to be of negligible significance.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 24: In Air Noise

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

24 IN AIR NOISE

1 This chapter describes the effects of noise from the proposed European Offshore Wind Deployment Centre (EOWDC) due to the construction and operation of the wind turbines at onshore locations along the shoreline to the north of Aberdeen. The assessment has been undertaken by Hayes McKenzie Partnership Ltd.

24.1 Introduction

2 A baseline noise survey was carried out to establish the existing background noise at the four closest residential properties to the proposed EOWDC. An additional two locations were also surveyed, which are representative of properties further inland where the influence of noise from the sea will be lower. The noise impact on residential properties during the operation and construction phases of the proposed EOWDC has been assessed.

3 The following technical reports support this chapter and can be found as:

- In Air Noise Baseline Technical Report (Appendix 24.1)
- In Air Noise Environmental Impact Assessment Technical Report (Appendix 24.2)

24.1.1 Methodology Consultation

4 A Request for an Environmental Impact Assessment (EIA) Scoping Opinion was made to Marine Scotland in August 2010. None of the responses received identified specific requirements for in-air noise assessment for residential properties onshore.

5 The Environmental Health Officers of Aberdeen City Council and Aberdeenshire Council have been consulted regarding the assessment methodology and the choice of measurement locations for the baseline noise survey:

- Andrew Gilchrist, Aberdeen City Council (6th January 2011)
- John Dawson, Aberdeenshire Council (6th January 2011)

24.1.2 Key Guidance Documents

6 The following documents have been used in the assessment:

- Scottish Executive (2011). Planning Advice Note PAN 1/2011: Planning and Noise
- Scottish Executive (2010). Web based ‘renewables advice’
- DTI Working Group on Noise from Wind Turbines (1996). The Assessment and Rating of Noise from Wind Farms ETSU-R-97
- Aberdeenshire Council (2005). Use of Wind Energy in Aberdeenshire: Guidance for Developers – Supplementary Planning Guidance Part 1
- Institute of Acoustics Bulletin Vol 34 no 2, March/April 2009 Prediction and Assessment of Wind Turbine Noise
- British Standards (2009). BS 5228:2009 Code of practice for noise and vibration control on construction and open sites – Part 1: Noise

- The Scottish Government (2011). Technical Advice Note – Assessment of Noise

7 The documents listed above have all been written for the purpose of assessing onshore developments but have been adopted for this project as providing suitable guidance on assessing background noise and deriving noise limits for the onshore residential properties.

8 Advice on long-range sound propagation over sea has been taken from:

- Mathieu Boué (2007). Report for Swedish Energy Agency: Long-range sound propagation over the sea with application to wind turbine noise.

24.1.3 Data Information and Sources

- Oldbaum Services Limited (2011a). Wind speed data spatial translation – Method Statement for Aberdeen Offshore Wind Farm Limited
- Hayes McKenzie Partnership Ltd. (2011). Measurement of background noise data and rainfall
- Oldbaum Services Limited (2011b). Wind speed data spatial translation – Wind data analysis for Aberdeen Offshore Wind Farm Limited
- Menck: Noise Reduction Skirt, Product sheet, accessed online: http://www.menck.com/products/noise-reduction/
- World Health Organisation (2000): Guidelines for Community Noise
- World Health Organisation (2009): Night Noise Guidelines for Europe

24.2 Baseline Assessment

9 An assessment has been carried out for the existing noise environment at six locations along the shoreline closest to the proposed development to the north of Aberdeen.

10 Noise monitoring equipment was left at the measurement positions for a period of 21 days from 15th February to 8th March 2011. The locations are shown on Figure 24.1. The meters were programmed to measure a number of statistical noise indices, including the LA90, together with the maximum and minimum levels and the LAeq (the Equivalent Continuous A-Weighted Sound Pressure Level) over consecutive 10-minute periods. Results were automatically stored at 10-minute intervals and synchronised to wind speed measurements to allow for later correlation between the two.

11 The baseline survey has been carried out to derive noise limits for the proposed development according to guidance normally used for onshore wind farms. This guidance has been used as there is currently a lack of Planning Policy Guidance for offshore wind farms with respect to noise impact on onshore residential properties.

24.3 Impact Assessment

24.3.1 Impact Assessment Methodology

12 For the impact assessment of noise from the construction and the operational phase of the EOWDC, following table has been used.

TABLE 24.1
Magnitude of Impact

Descriptor for Magnitude of Impact	Generic Criteria of Descriptor
Major adverse	Loss of resource and/or quality of resource; severe damage to key characteristics, features or elements
Moderate adverse	Loss of resource, but not adversely affecting the integrity; partial loss of/damage to key characteristics, features or elements
Minor adverse	Some measurable change in attributes, quality or vulnerability; minor loss of, or alteration to, one (maybe more) key characteristics, features or elements
Negligible adverse	Very minor loss or detrimental alteration to one or more characteristics, features or elements
No change	No loss or alteration of characteristics, features or elements; no observable impact

13 Noise levels at properties onshore have been calculated and compared with noise limits derived from the ETSU guideline for wind farms and the British Standard BS5228:2009 Part 1 for construction noise. Based on the potential exceedance of the noise limits, the magnitude of the impact has been allocated.

14 The predicted levels and measured background noise levels indicate that for all dwellings located onshore, wind turbine noise would meet the amenity and night-time noise criteria proposed within ETSU-R-97. In terms of this guideline for wind farm noise, no significant impact is expected. The noise contours are shown on Figure 24.1.

15 Prediction of the pile driving noise during the construction phase shows exceedance of the night-time noise limits adopted from BS5228:2009 Part 1 (BSI, 2009) at all properties. This is based on a worst case scenario of a monopile of 8.5 m diameter. It has therefore been proposed that for monopiles construction times should be limited to daytime hours unless suitable noise mitigation can be found and verified by measurements. The restrictions for smaller piles at night time may not be required and would be evaluated when the final pile sizes are known against the same criteria.

16 Prediction of the pile driving noise during daytime show exceedance of the LAeq daytime noise limits adopted from BS5228:2009 Part 1 (BSI, 2009) at three assessed properties by 1 decibels (dB). With a suitable noise management policy it is expected that the impact during daytime hours would be minor adverse. As the construction period with high noise levels is only for a limited time and as methods to screen the sound at source could potentially be employed this impact could be reduced even further.

17 The decommissioning phase is not expected to cause any significant effect as noise levels from shipping and taking down the wind turbine parts would be significantly lower than the piling noise from the construction phase.

18 The cumulative assessment of potentially constructing and operating the potential ocean laboratory has shown no increase to the current impacts of constructing and operating the wind farm on its own.

TABLE 24.2
Summary of Impact Assessment

Potential Impact	Significance Level	Mitigation	Residual Significance	Monitoring
Sleep disturbance during piling at night	Major	No piling during night	Negligible	No
Stress, annoyance during piling daytime	Minor to Moderate	Screens and good information policy	Minor	Determine real sound levels and check efficiency of potential mitigation measures
Exceedance of noise limits during operation day	Negligible	Not required	Negligible	No
Exceedance noise limits operation night,	Negligible	Not required	Negligible	No
Construction noise from other machinery	Negligible	Not required	Negligible	No
Operational noise from diesel generator	Negligible	Not required	Negligible	No

24.4 Summary

19 Analysis of the measured background noise data has been performed in accordance with ETSU-R-97 to determine the pre-existing background noise environment at six residential properties. Predictions of wind turbine noise have been made, based upon a generic sound power level typical for an up to 10 MW generating capacity wind turbine. The calculation procedure adopted is considered to be worst-case. The predicted levels and measured background noise levels indicate that for all dwellings located onshore, wind turbine noise would meet the amenity and night-time noise criteria proposed within ETSU R 97. Prediction of the pile driving noise during the construction phase shows exceedance of the night-time noise limits proposed in BS5228:2009 Part 1 at all properties. It has therefore been proposed that construction times should be limited to daytime hours unless suitable noise mitigation can be found and verified by measurements.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 25: Energy Use and Emissions

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

25 ENERGY USE AND EMISSIONS

25.1 Introduction

1 This chapter reports on the energy use and emissions that are expected to be generated during the lifecycle of the European Offshore Wind Deployment Centre (EOWDC) project and puts these into the context of reductions in greenhouse gas emissions that offshore wind power deliver in comparison to conventional gas and coal based power generation. This chapter has been prepared in conjunction with Genesis Oil and Gas Consultants.

2 The First Minister for Scotland wants renewable sources to generate the equivalent of 100 % of Scotland's gross annual electricity consumption by 2020. Similarly, a target has been set for renewables sources to provide the equivalent of 11 per cent of Scotland's heat demand by 2020.

3 The Scottish Government's Climate Change Act, sets a target of reducing emissions by 80 % by 2050, including emissions from international aviation and shipping. It also sets a world-leading interim target for a 42 % cut in emissions by 2020.

4 In their annual energy statement the Department of Energy and Climate Change (DECC) report that it is likely that demand for electricity will double over the coming 40 years, as a result of the need to electrify large parts of the heat and transport sectors (DECC, 2010). Furthermore, for the UK to meet its obligations on reducing emissions of greenhouse gases, the electricity being consumed will need to be almost exclusively from low carbon sources. In the first quarter of 2010 nearly 80 % of the UK's electricity was generated by burning gas and coal. This needs to change and offshore wind will be crucial to delivering the UK's renewable and low carbon targets.

25.1.1 Methodology and Data Information and Sources

5 The following information sources have been used:

- DECC (2010) Annual Energy Statement, Departmental Memorandum. The Department of Energy and Climate Change (DECC), 27th July 2010

- Scottish Government (2011) Carbon Payback Calculator Guidance

- Parliamentary Office of Science and Technology, October 2006, post note 268, Carbon footprint of electricity generation
- Renewable UK (2011) (formerly BWEA) http://www.bwea.com/

25.2 Impact Assessment

25.2.1 Construction Emissions

6 The EOWDC is likely to be installed offshore in stages, with the foundation section installed first, then the tower, the nacelle and finally the rotor.

7 For estimating emissions, it has been assumed that the foundations and transition pieces would be transported to site by a specially built installation vessel or barge. The barge may be self propelled or towed onto station using a tug vessel. Once *in situ*, the foundation structure would be up-ended by crane and installed onto the seabed. The transition piece would be installed by crane. A dive support vessel, and/or speciality rock placement vessel may be used to provide protection to seabed infrastructure. The export cables and inter-array cables would be installed using a cable lay vessel. Throughout the operations support vessels would be needed to transfer personnel and to act as guard vessels, to maintain the navigational safety distances, during construction.

8 Once the EOWDC is operational small maintenance vessels are expected to be needed on a daily basis to service the wind turbines, with larger vessels needed for any major repairs.

9 In order to determine emissions the activities were broken down into construction and operational phases. The expected duration of construction activities were calculated to provide the number of vessel days expected to install the foundations, wind turbine and cables (Table 25.1). The development scenarios with the highest number of days and vessels were chosen in the calculation of construction emissions to illustrate the worst case scenario.

Table 25.1
Vessel Fuel Use during Construction Activities (11 wind turbines)

Vessel type	Duration (days)	Working Consumption * (tonnes/day)	Total fuel use (tonnes)
Barge	132	18	2,376
Tug	20	50	1,000
Jack-up crane vessel	182	20	3,640
Dive support vessel	20	18	360
Standby vessel	207	0.7	145
Total	561	-	7,521

*Fuel use consumption taken from Institute of Petroleum (2000)

Table 25.2 Vessel Fuel Use during Operation (1 year of operation)			
Vessel type	**Duration (days)**	**Working Consumption * (tonnes/day)**	**Total fuel use (tonnes)**
Maintenance vessel* (Based on maximum 12 hour working day)	150	0.7	105
Jack-up crane vessel	20	20	400
Total	170	-	505

*Fuel use consumption taken from Institute of Petroleum (2000)

10 Information on vessel days was combined with emission factors for diesel consumption by engines to estimate emissions from both the construction and operational phases of the EOWDC (Table 25.3). It has been assumed that all the construction hours arise in a single year and that emissions from maintenance activities would be annual from year 2 onwards.

Table 25.3 Total Emissions from Construction and Maintenance Activities								
Vessel	**Tonnes Diesel Consumed (tonnes)**	**Emissions (tonnes)**						
		CO_2	**NO_x**	**N_2O**	**SO_2**	**CO**	**CH_4**	**VOC**
Emissions Factors (EEMS, 2008)	-	3.2	0.059	0.0002	0.004	0.0157	0.00018	0.002
Construction (Year 1)	7,521	20,416	447	2	30	118	1	15
Maintenance (annual)	505	1,371	30	0.1	2	8	0.1	1
Maintenance (22 years)	1,1110	30,162	660	2.2	44	176	2.2	22
Total construction and maintenance	18,631	50,578	1107	4.2	74	294	3.2	37

11 Operational emissions would arise principally from the activities associated with maintaining the vessels, and are significantly lower than the construction activities. The vessels used in the decommissioning activities are not yet known, however it is expected that vessels similar to that used for the construction activities would be used in a decommissioning capacity. Hence, the installation emissions can be seen to represent the worst case decommissioning emissions.

25.2.2 Emission Reductions Achieved from Wind Energy

12 A comparison of the lifecycle of different electricity generation systems currently used in the UK was undertaken by the Parliamentary Office of Science and Technology in 2006, this report concludes that while all electricity generation technologies emit CO_2 during their lifecycle, and that no CO_2 is actually generated from the wind turbines themselves during the operational stage, offshore wind power ranks as one of the lowest carbon footprints generating 5.25 g CO_2 equivalents/kWh. The only operational CO_2 emissions as part of the EOWDC are activities associated with maintenance of the wind turbines.

13 Electricity generated from offshore wind turbines is able to replace the output of coal and gas fired power stations as these are the most flexible plants on the grid and can relatively easily increase and decrease production capability to meet demand. Wind energy does not replace electricity from nuclear power stations because these operate at 'base load', that is they would be working for the whole time that they are available. The energy savings in tCO_2 have been presented in relation to a variety of conventional energy sources including coal fired plant, grid mix and fossil fuel mix, the savings of tCO_2 per year and over the course of the 22 years of operation are presented along with the associated emission factors are presented in Table 25.4.

14 The emissions reductions in tonnes has been calculated using the following formulae:

CO_2 = (A*0.35*8,760*Emission factor)

Where:

- A = the rated capacity of the wind energy development in MW (the EOWDC would include 11 three bladed wind turbines with a maximum power generation of up to 100 MW)
- 0.35 is a constant, assumed capacity factor for offshore, which takes into account the intermittent nature of the wind, the availability of the wind turbines and array losses
- 8,760 is the number of hours in a year

Table 25.4
Emission Factors for Coal Fired Plant, Grid Mix, and Fossil Fuel Mix Emissions

Source	Emission factor tCO_2 MWh^{-1}	Emission reductions per year tCO_2	Emission reductions 22 years tCO_2
Grid mix	0.43*	131,838	2,900,436
Fossil fuel mix	0.607**	186,106	4,094,336
Coal fired plant	0.86*	263,676	5,800,872

*Defra (2002)
**(DECC, 2007; DBERR, 2007)

15 This would lead to emission reductions that are between 131,838 – 236,676 tCO_2 per year and 2,900,436 – 5,800,872 tCO_2 for the up to 22 years that the EOWDC may be operational.

25.2.3 Energy Balance and Pay Back Time for the EOWDC

16 The comparison of energy used in the manufacture with the energy produced by a power station is known as the energy balance. One of the measures of this is the 'pay back' time that is, the time taken for the EOWDC to generate the equivalent amount of energy as used in its manufacture. At this stage in the process the energy costs associated with the wind turbine manufacture are not known so a full lifecycle carbon analysis or calculation of the pay back time is not possible. In carrying out overall system calculations there may be a requirement for a backup figure to be included in line with Scottish guidance, this figure would be 15 % installed capacity or 5 % of the actual output (Scottish Government, 2011 Carbon Payback Calculator).

17 A comparison of the lifecycle emissions saved by the generation of the electricity at the EOWDC, using the lowest emissions reductions of the grid mix (2,900,436 tCO_2), against the emissions generated during the installation

and maintenance over the lifecycle of the project (50,578 tCO_2). The atmospheric emissions generated by installation and maintenance represent only 1.74 % of the emissions that are saved, which is a small proportion of the total savings.

18 Although the emissions associated with the manufacture are not known at present it is expected that the payback of electricity would be accomplished within 10 months, as Renewable UK state "the average wind farm in the UK will pay back the energy used in its manufacture within three to ten months, and over its lifetime the wind turbine will produce over 30 times more energy than was used in its manufacture" (Renewable UK, 2011).

25.3 Summary

19 The main atmospheric emissions would be generated during the manufacture, construction and maintenance of the EOWDC. Once the wind farm is operational the only emissions would be as a result of the regular maintenance trips. The EOWDC is expected to pay back the energy required within a maximum of 10 months. The generation of renewable energy from wind power is expected to result in a significant saving of greenhouse gas emissions in comparison to generating electricity produced from conventional coal and gas power stations.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 26: Electromagnetic Interference

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

26 ELECTROMAGNETIC INTERFERENCE

26.1 Introduction

1 This chapter considers the potential implications of the European Offshore Wind Deployment Centre (EOWDC) in relation to the potential for electromagnetic interference.

2 The following technical reports have been used when completing this chapter and can be found as:

- Navigational Risk Assessment (Appendix 15.1)

3 Wind turbines can cause electromagnetic interference (EMI) by two means:

- physical interference – caused by the wind turbine providing a second path between the transmitter and receiver of the signal causing "scattering" of the signals. This can lead to a phenomenon called "ghosting" on television screens
- electrical interference – caused by electrical signals generated within the wind farm infrastructure, principally the wind turbine. Modern wind turbines are designed to minimise the emission of such interference

4 Wind farms have the potential to cause adverse effects on communication systems, which use electromagnetic waves as the transmission medium (for example, television, radio or microwave links). The nature of the interference depends on the size of the structure relative to the wavelength of the radiation. Provided careful attention is paid to siting, wind turbines should not cause any significant problems of electromagnetic interference.

5 In the unlikely event of the EOWDC causing television interference the developer would agree to rectify any problems associated with the project.

26.1.1 Methodology Consultation

6 In order to assess the potential impact of EMI by the proposed development consultations were undertaken with the following stakeholders:

- Joint Radio Company (JRC) (8th July 2010 4th April)
- Atkins Ltd (21st June 2010 and 4th April 2011)
- OFCOM (15th June 2010 and 4th April 2011)

7 An on-line tool to estimate potential television interference provided by the BBC was also used as a source of information about the potential impact from the project on 16 June 2011.

8 In August 2010 the Scoping Report for the EOWDC project was sent out to the following stakeholders for comment:

- British Telecom (Radio Network Protection Team)
- Joint Radio Company (JRC)
- Atkins Ltd
- OFCOM

26.1.2 Data Information and Sources

9 The Office of Communications (OFCOM) holds a central register of all civil and radio communications operators in the UK and acts as a central point of contact for identifying specific consultees relevant to site.

26.2 Baseline Assessment

26.2.1 Television Reception

10 Television reception can be affected when viewers are within the shadow of a wind farm. This is a problem more closely associated with onshore wind farm developments where signals from the main masts could be influenced by the installation of wind turbines.

11 An on-line tool to estimate potential television interference provided by the BBC indicates that no households would be affected by the development of the EOWDC.

26.2.2 Microwave and Other Telecommunications

12 Contact was made with OFCOM regarding the proposal. Information on the site centre and the radius of the development was submitted.

13 OFCOM responded that there are currently no fixed link ends within or fixed paths that cross the site in respect of microwaves.

14 For scanning telemetry the information was passed to both the Joint Radio Company (JRC) and Atkins Ltd both of whom responded with no objection to the proposal.

26.2.3 Maritime Communication and Navigation

15 The Navigational Risk Assessment (NRA) (Appendix 15.1) carried out in 2011 highlighted that there are no anticipated impacts upon maritime communication and navigation devices as a result of electromagnetic interference associated with the development of the EOWDC.

26.3 Impact Assessment

26.3.1 Television Reception

16 The BBC assessment tool highlighted that there is no possible interference predicted for any households, the impact is therefore considered to be negligible.

26.3.2 Microwave and Other Telecommunications

16 None of the consultees mentioned in Section 26.1.1 raised objections to the proposal and no impacts were predicted. Therefore the impact is considered to be negligible.

26.3.3 Maritime Communication and Navigation

17 The NRA indicates that there are no anticipated impacts upon maritime communication and navigation, therefore possible impacts are considered to be negligible.

26.3.4 Mitigation and Monitoring

18 No specific mitigation of monitoring is envisaged. In the event of an impact the situation would be analysed and suitable mitigation measures would be taken so that there are no residual impacts as a result of this development.

26.4 Summary

20 There are not likely to be any detrimental effects from EMI as a result of the EOWDC proposal. If any problems are identified during construction, operation or decommissioning, it is likely that these could be resolved quickly and satisfactory.

European Offshore Wind Deployment Centre
Environmental Statement

Chapter 27: Other Marine Users

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

27 OTHER MARINE USERS

27.1 Introduction

1 This section of the Environmental Statement (ES) considers other marine users in the EOWDC development area that could be potentially impacted by the development. This assessment was undertaken by Genesis Oil and Gas Consultants. The following activities were considered for assessment:

- oil and gas industry
- pipelines, cables and telecommunications
- other wind power resources
- dredging and disposal sites
- commercial shipping and navigation
- salmon net fisheries and recreational fishing
- Ministry of Defence firing range
- Drums Link firing range
- recreational sailing
- surfing
- kite surfing
- canoeing and sea kayaking

2 Figure 27.1 illustrates other marine users within the vicinity of the EOWDC.

3 A number of the other marine users are discussed in other sections of this ES (eg commercial shipping and navigation; and fisheries), such users will be discussed briefly here with further details provided in their appropriate sections.

27.1.1 Methodology Consultation

4 The following organisations and stakeholders were consulted during the assessment:

- RYA (14th February 2011)
- MoD (10th December 2009)

27.1.2 Key Guidance Documents

5 The assessment of other marine users was under taken based on the following guidance and literature:

- Aberdeen Harbour Board. (2005). Dredging Aberdeen Harbour: A Presentation to the Scottish Branch of the Hydrographic Society. Retrieved May 2011, from The Hydrographic Society: http://www.ths.org.uk/documents/ths.org.uk/downloads/dredging_aberdeen_harbour.pdf
- Marine Scotland. (2008). Scottish Salmon and Sea Trout Catches, 2008, Fisheries Series No. Fis/2009/1. Retrieved 2011 May from http://www.scotland.gov.uk/uploads/documents/SCSB08.pdf.

- RenewableUK. (2011). Operational wind farms. Retrieved May 2011, from RenewableUK - the voice of wind and marine energy: http://www.bwea.com/ukwed/operational.asp
- RYA. (2009). The RYA's position on offshore energy developments - December 2009. The Royal Yachting Association (RYA).
- The BMF. (2010). UK leisure, superyacht and small commercial marine industry - key performance indicators 2009-10. Surrey: The British Marine Federation (BMF).
- Visit Scotland. (2009). Visit Scotland Tourism Statistics.
- RYA Personal Communication 14 February 2011

27.2 Impact Assessment Methodology

6 The structure of this assessment is as follows:

- a summary of the baseline data related to other users of the sea
- an assessment of the impact of the project on other users of the sea
- a summary of findings from the above for this ES

7 As a number of the other marine users have been dealt with in other parts of this ES, the baseline data will be included in this chapter as opposed to in a separate baseline report.

8 Potential impacts of the development on other marine users were identified and assessed. Potential impacts were assessed in terms of their magnitude (based on spatial duration and scale of effect) and the sensitivity of the receptor to the impact. A combination of the sensitivity of the receptor and the magnitude of effect was used to determine the significance of the impact Table 27.1. From this impacts were deemed either; major, moderate, minor or negligible. For those impacts that were considered to be significant (moderate or major) additional mitigation measures were considered to demonstrate that the risk was as low as reasonably practicable (ALARP).

TABLE 27.1
Matrix Used to Assign Level of Significance of Impact

Magnitude of Effect (spatial extent, duration of effect and scale)	**Sensitivity of Receptor (based on importance and recoverability)**			
	Very High	**High**	**Medium**	**Low**
Very High	Major	Major	Major	Moderate
High	Major	Major	Moderate	Minor
Medium	Major	Moderate	Moderate	Minor
Low	Moderate	Minor	Minor	Negligible
Negligible	Minor	Negligible	Negligible	Negligible

27.3 Baseline and Impact Assessment

9 This section presents a description of each of the marine users identified above and an assessment of the potential impacts caused by the proposed EOWDC. Additional mitigation measures for impacts that were deemed significant are discussed also, and impacts that are deemed negligible, or discussed in other sections of this ES, were not explored further.

27.3.1 Offshore Oil and Gas Industry

10 As discussed in the socioeconomic assessment (Chapter 23), oil and gas exploration and production is a significant contributor to employment within Aberdeen and Aberdeenshire (ie the development area).

11 There are currently no oil and gas fields within the EOWDC nor is there any related infrastructure. The closest pipelines are gas pipelines entering into the St Fergus Gas Terminal, which is north of Peterhead. Therefore there would be no impact on oil and gas installations from the wind farm development.

12 Although no oil and gas infrastructure exists within the development area, Aberdeen harbour is an important communications link for the industry. The wind farm's impacts on shipping and navigation are detailed in Chapter 15 Shipping and Navigation.

13 Due to the location of the development and the measures in place to mitigate impacts on shipping and navigation it is anticipated that the impacts on the oil and gas industry would be negligible.

27.3.2 Pipelines, Cables and Telecommunications

14 There are two abandoned telecommunications cables within the vicinity of the EOWDC (Figure 27.1), there are no other cables within development area.

15 It is possible, depending upon the chosen subsea cable route that the abandoned telecommunications cables may have to be crossed. The design of any crossing would be agreed with the owner of the cable to ensure that the integrity of all the assets is maintained. Thus, impacts on pipelines and cables are anticipated to be negligible.

27.3.3 Other Wind Farms

16 A number of onshore wind farms are located within the Aberdeen area however, there are no offshore developments within the wider Aberdeen area (RenewableUK, 2011).

27.3.4 Dredging and Disposal Sites

17 There are currently only two licensed dredging areas in Scotland, neither of which is located within the development area. However, occasional maintenance dredging activities occur in Aberdeen Harbour.

18 Maintenance dredging is required to widen the Harbour after sediment build up. Current proposals for Aberdeen harbour are for the mouth to be dredged by 8 m and dredging further in port to reach 7 m, this is scheduled for 2012. Previous dredging of the Harbour took place in 2005 with a total of 190,000 m^3 of material dredged and deposited approximately 90 km from the Harbour (57o07 N, 02o00 W)(Aberdeen Harbour Board, 2005). As this dredging is occasional and assuming a similar disposal site would be used, the impacts of the EOWDC on maintenance dredging are anticipated to be negligible.

19 There is a disused explosive dumping ground approximately 6.4 km from the EOWDC site. As this is no longer in use, and no activities associated with the development of the EOWDC would disturb this ordnance deposit, the impacts are considered to be negligible.

27.3.5 Shipping

20 The navigational impacts are assessed in more detail in the ES chapter on navigation (Chapter 15).

27.3.6 Fishing

21 There are 11 salmon fisheries along the coastline of the Aberdeen and Aberdeenshire area spanning across two fisheries districts, the Don and Ythan (see Figure 27.1).

22 The impact assessment Salmon and Sea Trout (Chapter 22) and Commercial Fisheries (Chapter 21) consider impacts to fisheries in more detail.

27.3.7 Ministry of Defence Operations

23 A firing range is situated to the north of the EOWDC, the Black Dog Firing Range (Figure 27.1). The Black Dog Firing Range is a small arms firing range on the coast with an associated exclusion zone at sea.

24 Following consultation with the Ministry of Defence (MoD) the layout of the wind farm was altered. Along with the wind turbines closest from shore being removed for shipping interests, the two northern most wind turbines were removed due to potential impacts on the Black Dog Firing Range, one of which was within the boundaries of the firing range's safety exclusion zone. . Other MoD operationsare discussed in Chapter 17.

27.3.8 Drums Link Firing Range

25 The Drums Link Firing Range is situated to the north of the EOWDC. The Aberdeen Full Bore Gun Club owns this private range and uses it for small bore and low power rifles as well as muzzle loading pistol shooting. The exclusion zone extends 2 km offshore. No modifications to the gun clubs activity are required as part of the development of the EOWDC and the impact upon this user group is expected to be negligible.

27.3.9 Surfing, Kite-surfing, Windsurfing and Canoeing

26 There are a number of other widespread water-borne recreational activities of importance. The British Marine Federation (BMF) estimated that in 2009 across Scotland 52,869 adults participated in surfing, 23,952 in windsurfing and 37,416 in canoeing. Fraserburgh, which is located within the development area, is a particularly popular surfing location and regularly holds surf competitions and events such as the UK Surf Tour and Fraserburgh Surf Festival. There are a number of popular surfing and windsurfing sites along the coast of the development area including:

Lossiemouth, Spey Bay, Sandend Bay, Cullen, Banff, Pennan, Stonehaven and St Combs.

27 The principal surfing area within Aberdeen Bay is the beach, where depending upon the prevailing swell conditions surfers are either located at the northern area of the beach; south of the mouth of the Don, or to the north of the entrance to Aberdeen Harbour.

28 Kite surfing has become increasingly popular in recent years. The kite surfing areas are different from those chosen by surfers. The presence of groynes along Aberdeen beach creates suboptimal conditions for kite surfers. The main kite surfing locations are Cruden Bay, Fraserbough and Balmedie, with Balmedie being the most popular destination for kite surfing.

29 Kite surfers tend to surf within the immediate proximity from the shoreline where the waves are largest for performing aerial tricks. Kite surfers tend to transit back and forth along the shoreline area, and rarely venture more than 2 km offshore.

30 Windsurfing is lower in popularity than either surfing and kite surfing in Aberdeen. Windsurfers can be seen infrequently during all times of the year throughout Aberdeen Bay.

31 Surf kayakers can occasionally be seen amongst the surfers at Aberdeen beach and they utilise the same areas. The area south of Aberdeen along the sea cliffs is routinely used for sea kayaking, and this sport is typically done during the calmer summer moths.

32 The EOWDC is located approximately 2 to 4.5 km from shore and north of the main surfing areas, but close to Balmedie which is used for kite surfing. There is not expected to be any detrimental effect upon the wave period, wind quality, as a result of the development of the EOWDC and the impacts upon these water sports is anticipated to be negligible.

27.3.10 Recreational Sailing

33 This section explores potential impacts of the wind farm on recreational sailing.

34 According to the Royal Yachting Association (RYA), recreational boating and sailing tourism contributes approximately £300 million to the Scottish economy. Sailing activity in the east of Scotland occurs mainly in the Firth of Tay and Firth of Forth and along the southern section of coastline in this region. The RYA (2009) highlights two potential impacts on recreational boating as a result of offshore wind farms:

- navigational safety
- loss of routes and sailing and racing areas

27.3.11 Navigational Safety

35 This is covered within Chapter 15 Shipping and Navigation.

27.3.12 Loss of Routes and Sailing and Racing Areas

36 The main concern associated with an offshore wind farm and recreational sailing routes is "squeezing." Recreational routes differ from commercial routes as recreational crafts are essentially aiming to avoid major commercial routes by travelling in shallower adjacent waters or taking other routes entirely (RYA, 2009). The approaches to the port of Aberdeen harbour can be very busy with vessels entering and leaving. Many recreational vessels follow an inshore route from the Forth of Peterhead and vice versa, often at night to take advantage of favourable tidal flow. Only some recreational vessels are equipped with radar and AID and great care is needed to avoid commercial vessels entering or leaving Aberdeen. Therefore, there is the danger of "squeezing" recreational crafts between the commercial shipping routes and the development (RYA, Pers Comm., 14th February 2011).

37 The layout of the wind farm has been designed to minimise impacts on other users of the sea, including the removal of the eastern most wind turbine to increase distance from commercial shipping routes. This will, in turn, reduce the risk of squeezing recreational users between the development area and commercial shipping routes. Furthermore, due to small crafts being excluded from safety zones they can navigate within the EOWDC.

38 Some recreational vessels within the development area would choose to sail further offshore to avoid the development, therefore effective marking and lighting would be essential and needs to be considered from the point of view of recreational craft as well as much larger commercial vessels. (RYA, Personal Communication, 14th February 2011).

39 Wind farms can have significant negative impacts on an event site (eg racing areas) through interference with wind speed and / or turbulence. However, most general day sailing and racing areas are close to the shore and in more sheltered waters, thus the development is unlikely to impact such activities (RYA, 2009).

27.4 Summary of Impacts

40 As discussed above the proposed development has the potential to impact a variety of other marine users, however, most impacts are anticipated to be negligible.

27.4.1 Mitigation and Monitoring

41 Mitigation measures to control impacts on MoD operations, fishing, shipping and navigation and tourism are discussed in their own sections within this ES.

27.5 Summary

42 There are a number of other marine users that could be potentially affected by the development, however, as this impact assessment has shown the impacts are anticipated to be negligible for all other marine users. With the appropriate mitigation measures in place, including all wind turbines being appropriately lit and marked, along with the layout of the development, it is

not anticipated that other marine users would be significantly impacted by the proposed development.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 28: Mitigation, Management and Monitoring

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

28 MITIGATION, MANAGEMENT AND MONITORING

28.1 Introduction

1 Information on mitigation, management and monitoring proposals are presented in the individual impact assessment chapters within this Environmental Statement and are detailed further in the draft Environmental Management Plan (EMP), which has been prepared and is presented in Appendix 28.1. This chapter explains the purpose behind the EMP and presents an outline of the draft EMP structure.

2 The EMP document will undergo several revisions. The version presented here in order to accompany the submission is the draft EMP. Upon receiving consent approval for the proposed European Offshore Wind Deployment Centre (EOWDC, this would be finalised).

3 The aim of the EMP is to ensure that all aspects of environmental management are carried out in accordance with relevant legislation and best practice guidelines.

4 This is to be achieved by taking a fully integrated approach to project management through the complete cycle of preparation, planning, action, monitoring, checking and review.

5 The EMP would be implemented prior to construction in consultation with statutory authorities, with a suite of complementary management plans corresponding to different aspects of the construction activity. The documents would be tailored specifically to ensure compliance with the consent conditions for the project and current environmental best practice. The following documents would be incorporated:

- Commitments Register
- Monitoring Protocol (as per statutory consents)
- Incident Reporting and Non Conformance Procedure
- Emergency Response Plan
- Collision Risk Management Plan
- Marine Pollution Contingency Plan
- Dropped Objects and Materials Recovery Plan
- Archaeology Plan
- Noise, Dust and Vibration Management Plan
- Waste Management Plan

6 The final EMP would be in place well before construction begins to take full account of all pre-construction monitoring requirements.

28.2 Structure of this Document

7 This EMP is divided in to three sections:

- Part 1 provides background and supporting information for the EMP
- Part 2 details in a series of Summary Briefing Notes, the environmental impacts identified to date and the associated commitments made with regard to environmental management, impact mitigation measures and

consent conditions, all of which the Applicant is obliged to carry out. These commitments derive from this ES
- Part 3 provides an introduction to outline construction method statements

8 It should be noted that further commitments could be contained in any consent granted to the project. At such time these commitments would be fully incorporated in to the EMP.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 29: Information to Inform a Habitats Regulations Appraisal

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

29 INFORMATION TO INFORM A HABITATS REGULATIONS APPRAISAL

29.1 Introduction

1 The purpose of this document is to provide a summary of the information required to inform any possible Habitats Regulations Appraisal that may be required to be undertaken by the competent authority with respect to the proposed European Offshore Wind Deployment Centre (EOWDC) as required under the EU Habitats and Birds Directives. The Information to Inform the Habitats Regulation Appraisal can be found as Appendix 29.1.

2 The document aims to identify all qualifying species or habitats that, based on data collected at the proposed development site, have the potential to be impacted. A high level assessment on the risk of a possible adverse effect has been undertaken and a conclusion made on the level of risk to a qualifying species or habitat.

3 This assessment is based on site specific data collected from the surveys undertaken so far and, where appropriate, relevant data from other offshore wind farms. The aim of this assessment is to identify species or habitats that may be required to be assessed by the competent authority as part of a Habitats Regulations Assessment and if required an Appropriate Assessment.

European Offshore Wind Deployment Centre
Environmental Statement

Chapter 3: Description of the Proposed Project

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

3 DESCRIPTION OF THE PROPOSED PROJECT

3.1 Introduction

1 The European Offshore Wind Deployment Centre (EOWDC) is an innovative offshore wind turbine deployment facility proposed off the Aberdeenshire coast close to Blackdog.

2 The vision of the project is:

"To deploy new equipment, systems, processes, and initiate R&D to improve the competitiveness of offshore wind energy production, whilst generating environmentally sound, marketable electricity and to increase the supply chain capabilities in Scotland, the wider UK and Europe."

3 The EOWDC would include 11 three bladed wind turbines with a maximum power generation of up to 100 MW. It is more likely that the power generation would be around 84 MW which is based on the following assumption:

- 4 x 6 MW wind turbines
- 4 x 7.5 MW wind turbines
- 3 x 10 MW wind turbines

4 The wind turbines connected by inter-array cabling would export the electricity onshore to a new substation and then to the National Grid. Additional onshore facilities may include a deployment centre with a research and development centre.

5 This section of the Environmental Statement (ES) describes the details for the proposed offshore elements of the EOWDC, together with a description of the construction, operation, maintenance, decommissioning and their associated timescales.

6 Brief details of the onshore elements are also included for information only as the onshore elements would be included in a separate application as discussed in Chapter 1 Introduction. The exact construction process would depend upon the final details of the equipment to be installed, preferences of the construction contractor, availability of installation plant and, most notably, developments in technology in the near future. In addition, as many of the wind turbines and supporting equipment are still under development, only high level details and envelopes are available at present and are presented within this chapter.

7 The description provided here is based on current best practice, as employed recently on sites both in the UK and across Europe. Where possible, the impact of alternative foundation design or new technologies, practices, and their associated construction techniques are considered.

8 Should additional technologies or methodologies become available these would be considered against this Environmental Impact Assessment (EIA).

3.2 Objectives of the Development

9 As well as delivering renewable electricity to the National Grid, the EOWDC would encourage research, development, knowledge sharing, industry competition and competitiveness by allowing developers and supply chain companies to test a variety of products and applications, including reliability and capacity, in a real time offshore environment prior to commercial deployment. Environmental Management System

10 The successful contractors would need to take into account:

- the requirements of third parties
- the potential impacts and effects outlined in this ES
- the requirements for any mitigation measures and monitoring
- the results of site investigation surveys; and
- any conditions in the consents

11 The Contractors would be required to implement their own Environmental Management System (EMS). The contractors would produce detailed Method Statements and Risk Assessments covering construction activities, such as piling, in accordance with the requirements of this ES and any measures agreed with the statutory authorities. These Method Statements would be subject to approval by the design engineers and in accordance with the approved method statements and standards. Throughout the construction phase, contractors would be audited against their method statements and risk assessments, company policies (including this ES), and UK statutory health, safety and environmental requirements. Health and Safety Management

12 All construction activities shall comply with UK health and safety legislation, in particular the Construction (Design and Management) Regulations 2007, and be conducted in accordance with industry best practice as developed by the UK Health and Safety Executive and RenewableUK. Additionally, all contractors shall be required to comply with the Project's Health and Safety Policy and procedures.

3.3 Site Location and Physical Characteristics

3.3.1 Site Location

13 The EOWDC is located approximately 2.4 km from the coastline of Aberdeenshire at Blackdog. The total area of the wind turbine layout is approximately 4.3 km^2 which is situated within a 20 km^2 lease boundary awarded by The Crown Estate. Water depth on the wind turbine locations ranges from 20 m to 30 m below Lowest Astronomical Tide (LAT). Figure 3.1 shows The Crown Estate Lease Boundary. The wind turbine location coordinates are shown in Table 3.1 and The Crown Estate lease boundary coordinates are shown in Table 3.2.

14 The optimum site layout for offshore structures including the wind turbines is based on several conditions including:

- optimum wind capture
- ground geology conditions
- seabed obstructions including munitions and wrecks

- water depth
- foundation choice
- construction limitations
- scour potential
- operation and maintenance requirements
- electrical layout (array cables, etc.) and
- stakeholder considerations

15 It is proposed that the project may be constructed in two phases. The actual deployment of wind turbines is at this stage not known and the numbers deployed in 2013 and 2014 are variable but for the purposes of the EOWDC assessment, the following has been assumed for the phasing:

- 2013 - 4 wind turbines installed
- 2014 - 7 wind turbines installed

16 It should be noted that this is indicative (ie there could be six wind turbines installed in 2013 and five wind turbines installed in 2014) or all 11 wind turbines could potentially be installed in 2013. Each individual impact assessment has considered which is worst case, a phased deployment over two consecutive years or a full deployment within one phase.

3.3.2 Physical Characteristics

17 The EOWDC project would comprise of various components and construction activities as listed below:

- 11 wind turbines with a total rating of up to 100 MW
- potential for an Ocean Laboratory with meteorological mast (which would be subject to a separate application)
- foundations (gravity, monopile, tripod, suction caisson/bucket, jacket) and scour protection on seabed if required
- transition pieces including access ladders/fenders and landing platforms depending on the foundation
- marine lights/foghorns/or other buoys and markings to the requirements of the Northern Lighthouse Board, International Association of Marine Aids to Navigation and Lighthouses (IALA) and Marine Coastguard Agency (MCA)
- aviation lights to the requirements of Civil Aviation Authority (CAA)
- inter-array cables
- export cables to shore
- onshore cables
- miscellaneous cable joints/cable protection and cable/pipeline crossings
- temporary pre-assembly construction facilities onshore
- onshore substation
- boat landing (quay site in the harbour)
- operation and maintenance facilities depending on wind turbine selection

3.4 Site Layout

18 The wind turbine layout is illustrated in Figure 3.2. The figure shows the locations of wind turbines and an indicative position for the potential Ocean Laboratory.

19 The figure also illustrates the export cable corridor and inter-array cable options.

20 Table 3.1 lists the proposed wind turbine locations, however the exact position of the wind turbine may move slightly due to local seabed restrictions such as archaeology, seabed obstructions or pile refusal. It has been assumed that this move would be no more than 100 m. Figure 3.3 shows the indicative wind turbine spacing for the site.

TABLE 3.1
Wind Turbine Coordinates (UTM30N (WGS84 Datum))

Turbine ID	Easting (m)	Northing (m)
1	559820	6340967
2	559719	6341842
3	559619	6342717
4	560481	6341400
5	560374	6342325
6	560269	6343249
7	561224	6341887
8	561111	6342868
9	560999	6343849
10	561931	6343472
11	561811	6344515

21 The 22 year lease agreement with The Crown Estate includes an area of 20 km^2 and the installed nominal power must not exceed 100 MW. As this is a deployment centre to test first of run wind turbines there may be a requirement to change out the machines at an earlier date than the full potential operating life of the wind turbine.

Table 3.2
Coordinates of Crown Estate Lease Boundary (UTM30N (WGS84 Datum))

Lease Boundary Node (as shown on Figure 3.2)	Easting (m)	Northing (m)
1	559430	6345131
2	563485	6346152
3	561740	6340780
4	557684	6339759

22 Wind turbine technology is developing at a fast pace, so to ensure the project is adequately future proof, wind turbines in the range of 4 MW to 10 MW have been proposed for the purpose of this EIA, even though 10 MW is currently not available. With a maximum installed capacity of 100 MW, the project may contain a range of wind turbines ranging from 4 MW to 10 MW and the mix may also vary over time. Table 3.3 lists some maximum parameters of the 4 MW and 10 MW machines

TABLE 3.3 Wind Turbine Parameters		
Parameter	**4 MW**	**10 MW**
Maximum Height of Nacelle (above LAT)	100 m	120 m
Maximum Rotor Diameter	120 m	150 m
Maximum Tip Height (above LAT)	160 m	195 m

3.4.1 Construction Laydown Areas

23 At the port of shipping, during the construction period, space on the quay would be required for mounting and temporary storage of foundations, pre-assembly of the wind turbines, cables and other components of the project. It may be the case that several mobilisation ports may be utilised for different activities depending on vessel transits and restrictions. In addition, space at the quayside would be required for the vessels used for the establishment of the project (jack-up platforms, barges, tugs, cable vessels etc.) to anchor during downtime periods. Table 3.4 shows typical anticipated laydown areas associated with the construction of a typical wind farm.

TABLE 3.4 Typical Laydown Areas	
Activity	**Construction Area (m^2)**
Storage of piles and assembly of transition pieces	100,000
Storage are for cable contractor (cable drums)	10,000
Pre-assembly of wind turbines	40,000 + offices and storehouse for components
Storage area for towers at paint shop	27,000
Storage area for bays at factory	27,000

3.5 Access Arrangements to the Site

3.5.1 During Construction

24 During the construction period, the crews/workers are most likely to reside in either onshore accommodation or accommodation on board the work vessel (depending on work hours and availability). If necessary, the daily transport between local port and the site would take place by transfer vessels.

3.5.2 During Operation

25 When operational, the wind turbines would be monitored remotely from an onshore operational/storage base. Service personnel would travel to the site as required for planned and unplanned maintenance work. The wind turbines would be accessed by transfer vessels. There would be at least one boat landing arrangement on the foundations. There are no plans to use helicopters for maintenance of the wind turbines, but the wind turbines may be equipped with a heli-hoist platform for possible future maintenance and Health and Safety activities.

3.5.3 Exclusion Zones

26 For health and safety reasons, exclusion zones would be sought during the construction operational and decommissioning phases. These are discussed further below.

3.5.3.1 During Construction

27 In the construction phase, advisory zones or safety (exclusion) zones of 500 m around the construction works would be sought to keep construction and non-construction vessels separate. These safety zones would be reviewed monthly and clearly marked using buoys. Notifications would be issued in accordance with statutory procedures. The vessels laying the cables to shore would have their own advisory or safety (exclusion) zone extending up to 500 m in addition to a 250 m safety zone either side of the cable corridor. There would be close liaison with port authorities and Maritime Coastguard Agency (MCA) particularly when working in close proximity to marked navigation channels and other anchorage areas. Where necessary guard vessels may also be employed should operations be phased/broken.

3.5.3.2 During Operation

28 It is thought likely operational safety (exclusion) zones would be sought for and should if granted take effect when construction exclusions finish. A navigational safety (exclusion) zone would then likely apply between 50 m and 100 m around each wind turbine foundation tower. The potential impact of these safety (exclusion) zones on navigational interest and fishing interest are discussed in Chapters 15 Shipping and Navigation and 21 Commercial Fisheries. Potential exclusion zones are shown in Figure 3.4.

3.6 Wind Turbines

29 The Applicant is proposing to install 11 three bladed horizontal axis wind turbines. As this is a deployment centre the exact models and types of wind turbine would only be chosen through assessment of wind turbines during detailed engineering and chosen on the basis of various selection criterias, including testing, operational and commercial aspects. The wind turbines may be replaced in the future life of the project to allow testing of newer wind turbines. An in-principle design of a wind turbine is shown in Plate 3.1. A mixture of wind turbines are expected on the site as these are pre-commercial deployments and therefore there are likely to be two to four of each type of wind turbine, not all 11 would be is the same.

Plate 3.1 3 MW Wind Turbines Installed at the Kentish Flats Offshore Wind Farm (Photographer Chris Laurens)

30 The wind turbines would likely begin generating electricity at 3 m/s hub height, achieving their maximum power output in winds greater than approximately 13-14 m/s hub height. They would continue generating up to wind speeds of 25 to 30 m/s where they would be designed to automatically shut down.

31 The blades would most likely be made of fibre-reinforced epoxy. The towers would be made in sections of tubular steel with an approximate diameter ranging from 5 m to 8.5 m at the foundations tapering to 3.5 to 5 m at the top.

32 On top of the tower the nacelle is placed containing among others the generator and controls.

33 The transformer would be placed in either the nacelle or in the tower. It transforms the electricity to minimise the loss through the cable to the substation.

3.6.1 Colour Scheme

34 Colour scheme of the turbine tower, nacelle and blades is likely to be light grey RAL 7035, white RAL 9010 or equivalent.

3.6.2 Dimensions and Airdraft

35 A schematic drawing of a wind turbine with maximum dimensions is shown in Figure 3.5. Minimum blade tip clearances of the wind turbines being considered for EOWDC is 22 m above MHWS.

3.6.3 Oils and Fluids

36 The wind turbine would contain the following approximate quantities of mineral lubricating and hydraulic oils:

- Gear box oil: Approximately 0–1,000 litres of mineral oil
- Hydraulic oil: Approximately 200–300 litres
- Yaw/pitch motor oil: Approximately 20 -100 litres
- Transformer oil: Approximately 0-3,000 litres
- Cooling fluids: Approximately 0-1,000 litres

37 The nacelle, tower and rotor would be constructed to accumulate any leaks from the construction and operation. Thereby leaks to the environment would be minimised.

3.6.4 Noise and Vibration from Operating Wind Turbines

38 Noise emissions from wind turbines could be separated into two categories: aerodynamic and mechanical noise. Aerodynamic noise occurs when the wind is passing the blades and mechanical noise is emitted from the engineering components of the wind turbine such as gearbox and generator. Although the larger wind turbines that are being considered for EOWDC site are not yet under production and therefore the noise characteristics have not been measured, the wind turbine manufacturers predict that the wind turbines would have a noise output of no greater than 110 dB(A) at hub height measured according to the IEC 61400-11 standard.

3.6.5 Installation of Wind Turbines

3.6.5.1 Base Case Method

39 The wind turbines are expected to be installed using an crane of suitable size located on a jack-up vessel. A jack-up vessel is a barge or ship that once in position lowers its legs onto the seabed and when the legs are sufficiently stable the vessel then jacks itself up out of the water. Jack-up vessels come in a range of specifications and can either be self propelled or require the assistance of tugs and anchor handling vessels to locate.

40 The wind turbines would be transported to site either on the jack-up vessel or to the jack-up on a barge or another jack-up. The installation crane lifts the wind turbine parts from the jack-up/barge onto the foundation, see Plate 3.2.

Plate 3.2 Jack Up Installation Barge at Ormonde Offshore Wind Farm

41 Experience has shown that it normally takes 24 hours to position the jack-up and erect a wind turbine requiring a total of 4–5 lifts per wind turbine to complete installation. Normal procedure would be that the bottom tower is mounted first followed by the top section. Following the top section the nacelle and the rotor/blades are mounted.

3.6.5.2 Alternative Methods

42 As part of the Deployment Centre aspect of the project, the Applicant would look for alternative methods for wind turbine installation. This may include installation of the wind turbine and foundation as a single operation or utilising dynamically positioned vessels rather than jack-up vessels.

43 Should alternative methods be utilised the impact on the marine environment would be the same or less than that described and evaluated above.

3.6.6 Material Requirement

44 Typical weights for EOWDC wind turbine (10 MW):

- rotor including blades: 120 tonnes fibreglass (three blades) and 150 tonnes steel
- nacelle: 70–600 tonnes mainly steel
- tower: 700 tonnes steel

3.6.7 Control Functions and Safety Features

45 All wind turbines would be designed to allow for the following safety features:

- manual yawing of the wind turbines shall be possible via the remote control
- remote parking of the wind turbines in an oriented stop, to allow for heli-hoist operation

3.6.8 Emergency Provisions

46 The wind turbines would be equipped with emergency provisions for personnel of the service team. The personnel of the service teams would be trained to work with these emergency provisions.

47 Emergency escape and access hatches to the wind turbine nacelle would be designed as far as practical to be capable of being opened from the outside in order to allow rescuers (eg helicopter winch-man) to gain access through the nacelle to the tower if personnel of the service team are unable to assist and when a sea-borne approach is not possible.

48 Ladders for access to the foundation platform for use in emergency or refuge would be placed in the optimum position taking into account the prevailing wind, wave and tidal conditions.

3.6.9 Wind Farm Marking and Lighting

49 All wind turbines would be marked with clearly visible unique identification characters. Characters would be visible from all sides of the wind turbine and would comply with requirement in MCA Marine Guidance Notice MGN 275 (M) (MGN 275) that they should be visible from at least 150 m from the structure and be permanently lit by down-lights to minimize light pollution. As an alternative to permanent down-lights the option of Light Emitting Diodes (LEDs) to mark the identification characters is included.

50 Logos and identification would be included on the offshore structures including Vattenfall, the European Union (EU) Flag and other manufacturer requirements.

51 The wind farm would be designed and constructed to satisfy the requirements of the Civil Aviation Authority (CAA) and the Northern Lighthouse Board (NLB) in respect of marking, lighting and fog horn specifications. The typical arrangement using the Navigation Risk Assessment layout (see Chapter 15) is shown in Figure 3.6. This arrangement would be adjusted in consultation with CAA and NLB, MCA and IALA.

52 The CAA has issued “Lighting of Wind Turbine Generators in United Kingdom Territorial Waters” in accordance with Annex A to 8AP/51/06/19 dated September 2003. The guidelines have been applied to the typical arrangement as follows.

53 For aviation purposes, wind turbines would be marked with aviation lighting in line with the following:

- each wind turbine located at the corner would be fitted with aviation lighting
- in addition, aviation lighting would be installed along perimeter wind turbines so a maximum gap of 3.5 km between lighting

54 Lights would be fitted to be visible in all directions without interruption (the shadowing effect of passing blades is not considered to be an interruption in this context):

- the angle of the plane of peak intensity shall be elevated to between 3 and 4 degrees above the horizontal plane
- not more than 45 % or less than 20 % of the minimum permitted peak intensity shall be visible at the horizontal plane
- not more than 10 % of the minimum peak intensity shall be visible at a depression of 1.5 degrees or more below the horizontal plane

55 The navigational marking specifications for the typical arrangement would be agreed with the Northern Lighthouse Board (NLB). The Applicant proposes the following in accordance with IALA Recommendation 0-139 (see Figure 3.6):

- wind turbines foundations and towers would be painted yellow from highest astronomical tide (HAT) to 12 m above Highest Astronomical Tide (HAT)
- the wind turbines in the periphery of the wind farm would be marked with yellow flashing lights and potential fog horns as shown in Figure 3.6
- navigation lights would only be installed at the correct elevation on outer boundary wind turbines
- an uninterruptible power supply would be installed

3.7 Foundations

56 This section is applicable for all offshore wind farm structures requiring foundations including:

- wind turbines
- potential Ocean Laboratory including meteorological mast

3.7.1 Foundation Concepts

57 Foundation selection for an offshore wind farm development is generally influenced by the following factors:

- type of wind turbine/hub height that would be mounted onto the foundation
- wind turbine dynamic loads
- wind turbine access and maintenance requirements
- Mean Sea Level (MSL) and variations in water depth due to tide and meteorological conditions
- dynamic wind and wave loading especially with respect to fatigue
- extent of local scour and global seabed movements ie seabed stability
- soil conditions on which foundation would bear including drivability/drill ability

- transportation/logistics
- material costs/manufacturing costs and limits
- installation limits with respect to crane capacities, piling, drilling equipment, etc
- cable entry to foundation base

58 The Front End Engineering Design (FEED) studies and tendering process would establish, within the limits of this EIA, which types of foundations are the most cost effective and innovative for the EOWDC project. The following foundation concepts may be considered:

- gravity foundation
- monopile in steel
- steel tripod or piled concrete tripod
- jacket structure
- suction bucket

59 As part of this process, the installation of the foundation and the equipment requirements would also be considered. In addition, wind turbine and foundation manufacturers would also be involved to ensure all optimisation and innovation is considered.

60 There is likely to be a mix of foundations deployed on the site ie not all 11 foundations would be of one type, ie there would not be 11 monopiles installed on the proposed EOWDC site.

3.7.1.1 Gravity Foundation

61 The gravity foundation concept is typically installed in water depths from 0 to 30 m. Most are concrete based but steel based concepts are being developed. A concrete gravity foundation may be manufactured completely from reinforced concrete or a mixture of concrete and steel sections to provide an optimised design.

62 The gravity foundation is constructed such that the base structure has sufficient ballast and surface area to stay in place even at extremely high loading, ie a 50 or 100 year storm.

63 The concept can have slightly different designs in terms of shape and structure ie could be circular in plan or square. The concept and requirements may contain sufficient weight in the design itself for operation or ballast may be added once the structure is located in place. Ballast may be sand, stone or seawater.

64 Dimensions of the gravity base foundation are likely to vary across the site depending mainly on wind turbine size and water depth and seabed geology.

65 Future detailed geophysical and geotechnical investigations would determine locations where the seabed conditions are suitable for gravity foundations. The gravity foundation may be equipped with a 0.5 to 2 m high steel skirt penetrating into the seabed below the bottom plate. This skirt would protect the foundation against scour in the period until scour-protection is in place, if required.

Dimensions

66 The gravity foundation with hollow shaft for a typical wind turbine has the following dimensions as presented in Diagram 3.1:

- maximum outer shaft diameter: 6.5 m
- shaft wall thickness: 0.6 m
- base plate diameter: 20 – 40 m
- base plate thickness: 3 – 9 m
- weight (dry): 2,500 – 9,000 tonne

Manufacturing and Transportation

67 The foundations would be pre-manufactured onshore. Either directly on barges in a harbour, on the quayside or in the case of a towed foundation within a slipway. For the purposes of the ES the fabrication of gravity foundations could be either overseas or in the UK. If manufactured in the UK then the consideration would be given to the provision of a temporary concrete casting facility at a local port with adequate space, draft and facilities (Dundee, Aberdeen or Invergordon).

68 The gravity bases would be shipped directly to the offshore site.

Material Requirement

69 Amounts of material per concrete gravity foundation:

- concrete: 2,000–8,000 tonnes
- steel-reinforcement: 200–1,000 tonnes
- ballast: 0–4,000 m^3 based on sand
- stones for scour protection: up to 2,000 m^3

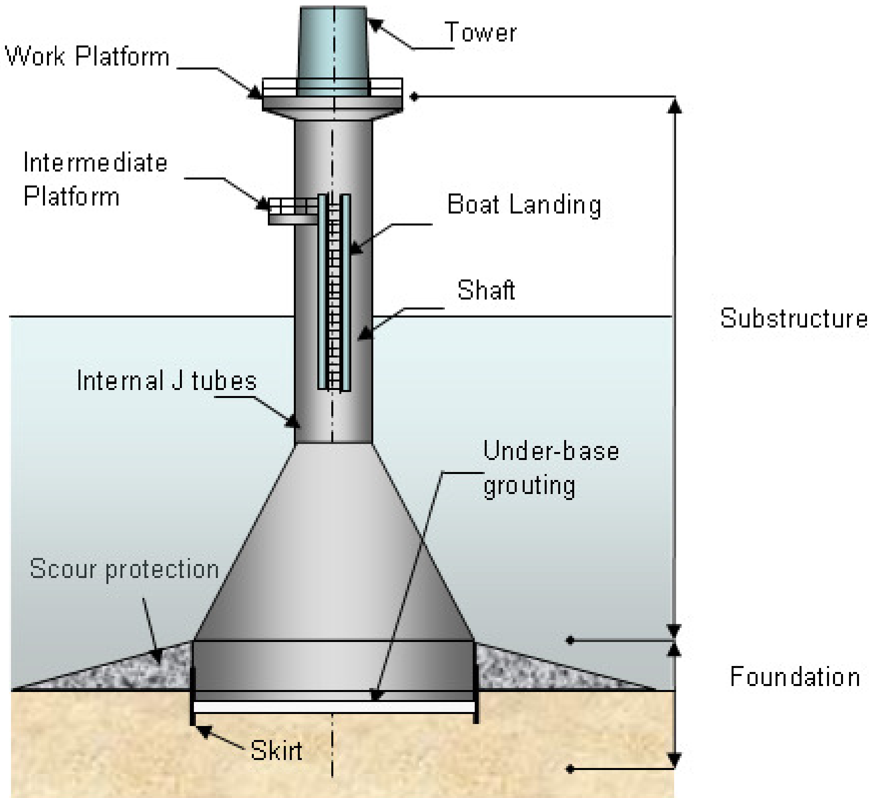

Diagram 3.1 Gravity Base Foundation (Courtesy of GL Garrad Hassan)

3.7.1.2 Steel Monopile

70 In the UK and most other countries (except Denmark) the steel monopile is the most common foundation type used for offshore wind turbines mainly due to suitable ground conditions for the monopile installation.

71 Usually steel monopiles are driven into the seabed from a jack-up barge using a hydraulic hammer which is available in various capacities for either operation above or below the water surface.

72 An alternative installation method includes drilling to assist piling operations ('drive, drill and drive'). Drilling may be applied where ground conditions make driving more difficult.

73 The ability to fully drive piles to a required depth may be limited in the EOWDC site by:

- layers of consolidated glacial material
- Old Devonian sandstone at 25-35 m depth below seabed

74 The drive, drill and drive methodology has been used successfully at other wind farm sites with soil conditions similar to EOWDC. The basic steps of the drive, drill and drive methodology includes:

- driving the monopile down to the obstruction layer
- drill out pile internals (diameter of drill is approx 10–20 % less than internal of monopile) to final pile depth
- drive monopile to final depth

Dimensions

75 Example dimensions of the steel monopile foundations for the EOWDC are given below and the arrangement is shown in Diagram 3.2:

- outer shaft diameter: 4 – 8.5 m
- shaft wall thickness: 0.06 – 0.15 m
- overall length: 50-75 m
- seabed penetration: 30 m +
- weight (dry): 300–1500 tonnes depending on depth

Manufacturing and Transportation

76 The foundations are pre-fabricated onshore. Steel plates are delivered from steel mills to fabricators who roll and weld the plates together into a monopile structure. Once fabricated the monopiles are transported to site either directly or through an interim port.

77 An approximately 10 m long transition piece consisting of a piece of steel pile equipped with a flange in the top may be grouted on the outside of the top of the driven steel pile-fixing the top flange perfectly horizontal. Alternatively a heavy flange might be in place already during the driving sequence.

Material Requirement

78 Typical material amounts per foundation:

- steel: 300 – 1,000 tonnes
- concrete for fixing of transition piece: 25–100 tonnes
- gravel/rock for scour protection: 150–1,250 m^3

79 The volumes do not include for additional volumes of grout or concrete that may be used to secure the monopile in rock.

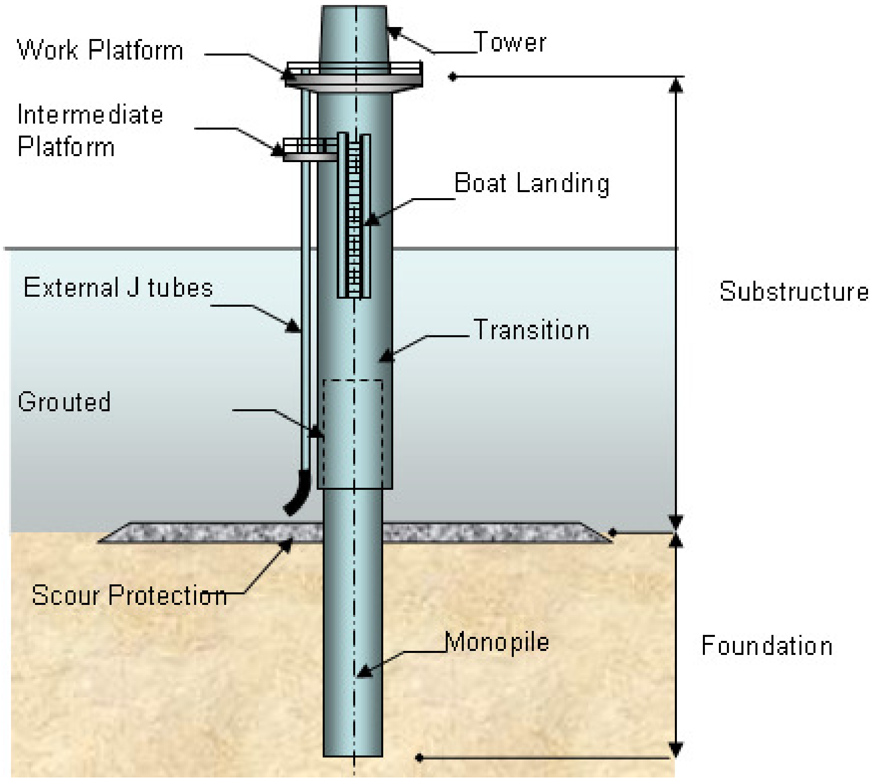

Diagram 3.2 Monopile Foundation (Courtesy of GL Garrad Hassan)

3.7.1.3 Steel Tripod / Piled Concrete Tripod

80 The steel tripod has been extensively used in the oil and gas industry for small, generally unmanned offshore platforms. The concept consists of a steel tube construction above seabed, and of three steel piles driven into the seabed.

81 The concept has only been used a few times for wind turbines, but may be an option for EOWDC for use in areas of greater water depths. Example dimensions are provided below and the arrangement is shown in Diagram 3.3:

- main shaft diameter: 5.5 m
- base footprint width: up to 25 m diameter
- seabed penetration (securing piles): 25 – 35 m
- securing pile diameter: 2.5 m
- overall height: 15 – 35 m (15 m above mean sea level)
- weight: 400 – 1,200 (excluding securing piles) tonnes
- number of piles: 3 (total up to 500 tonnes)

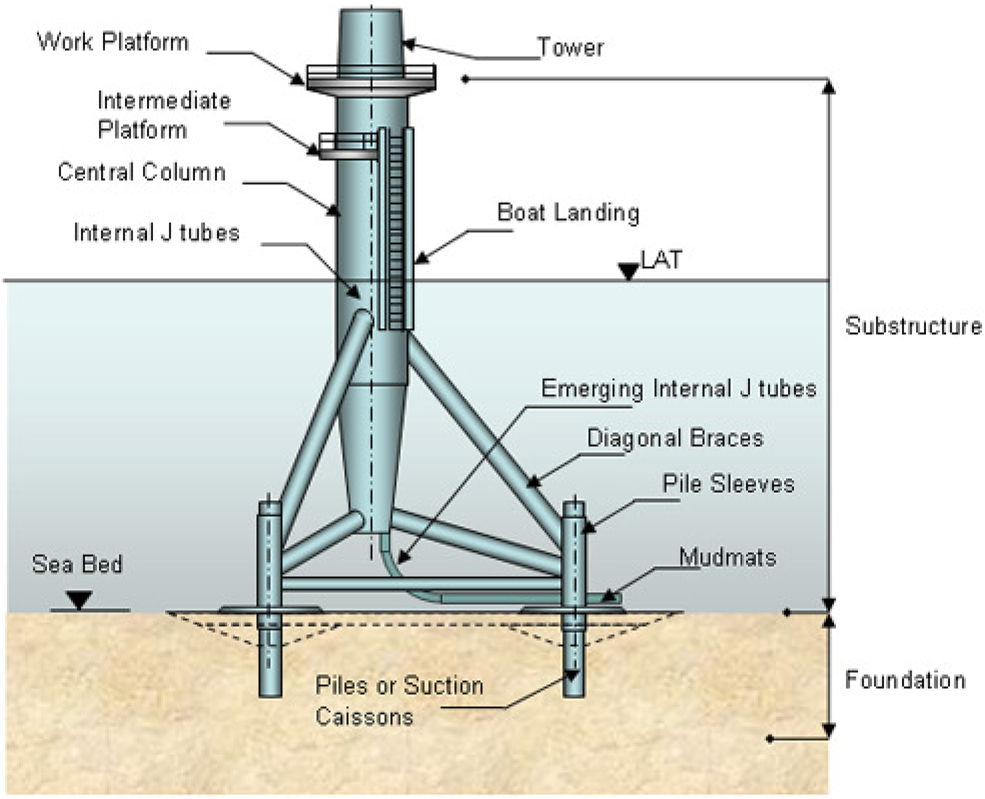

Diagram 3.3 Steel Tripod Foundation (Courtesy of GL Garrad Hassan)

Transportation

82 Transportation methods are similar to that of monopiles, including transporting out on barge and lifting off on-site by crane from a separate installation vessel. A disadvantage is that good weather conditions are required to allow pickup and transfer. Transportation directly on a jack-up or floating crane vessel is also possible.

Material Requirement

83 Typical amounts per foundation:

- steel: 400 – 1,200 tonnes
- concrete for fixing of transition piece: 25 – 100 tonnes
- grout for fixing of piles: 25 – 100 tonnes

Piled Concrete Tripod

84 The piled concrete tripod is a composite construction using steel piles and a concrete and steel construction above the seabed. An additional strength of the concept is a possibility to use the high stiffness of the concrete shaft to replace flexible steel-tower to heights up to 20 – 30 m above mean sea level. While the split of concrete and steel is not fixed a typical split would be steel piles, concrete base and a concrete shaft/tower. The parts are connected with grouted joints. Manufacturing, material requirement, seabed preparation, scour protection and installation methods for this option are similar to those of the gravity foundation.

3.7.1.4 Steel Jacket

85 The steel jacket has been extensively used in the oil and gas industry for small as well as large platforms. The concept consists of a steel tube construction above seabed, and of four steel piles driven into the seabed.

86 The concept has recently been used on the Ormonde Offshore Wind Farm, and may be an option for EOWDC. Example dimensions are provided below and the arrangement is shown in the Diagram 3.4:

- base footprint width: up to 25 m square
- seabed penetration (securing piles): 25 – 35 m
- securing pile diameter: up to 2.5 m
- overall height: 15–35 m (15 m above mean sea level)
- weight: 400–1200 (excluding securing piles) tonnes
- number of piles: 4 (total up to 600 tonnes)
- maximum width of structure above LAT: 21 m

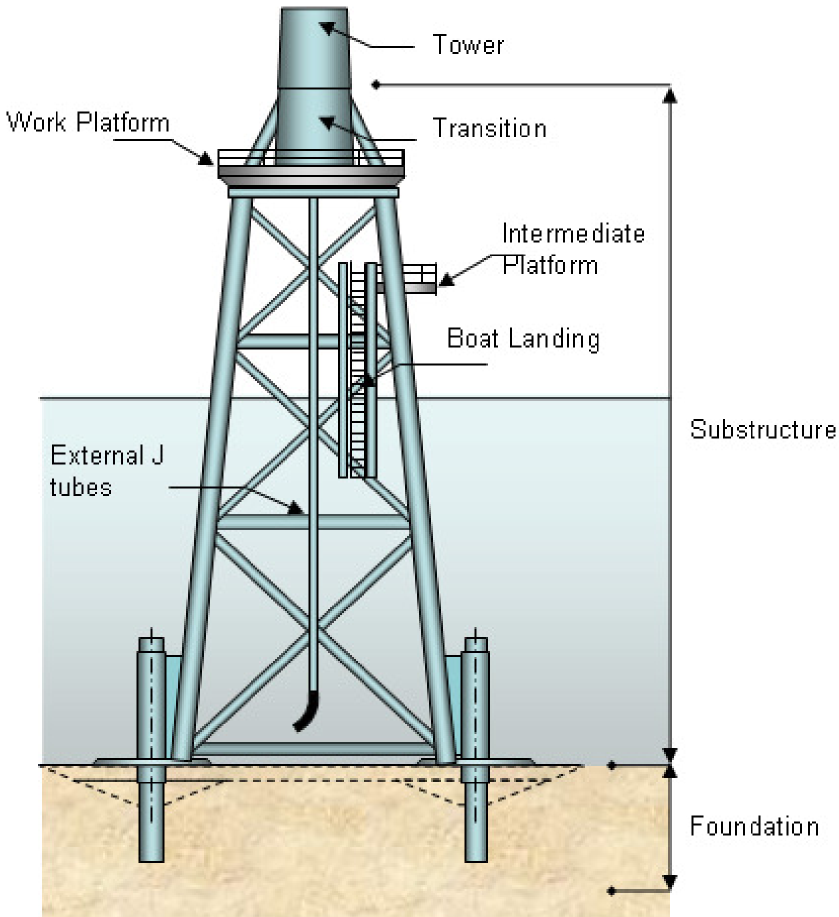

Diagram 3.4 Steel Tripod Foundation (Courtesy of GL Garrad Hassan)

Transportation

87 Transportation methods are similar to that of monopiles, including transporting out on barge and lifting off on site by crane from a separate installation vessel. An advantage of this method is that the installation vessel can remain on site. A disadvantage is that good weather conditions are required to allow pickup and transfer. Transportation directly on a jack-up or floating crane vessel is also possible.

Material Requirement

88 Typical amounts per foundation:

- steel: 400–1200 tonnes
- grout for fixing of piles: 25–100 tonnes

3.7.1.5 Suction Caisson / Bucket

89 The suction caisson/bucket foundation concept is typically installed in water depths from 20 – 50 m. The foundation is generally manufactured completely from steel.

90 The suction caisson is designed so a vacuum can be formed once in contact with the seabed which would then allow the pile to suck into and embed to the required depth. Overturning and gravity loads are resisted by a combination of skin friction around the skirt and to a lesser extent the bearing pressure on the top of the bucket.

91 The concept can have different designs parameters in terms of number of suction buckets and size and shape of buckets. This is a function of install ability and soil and load problems.

92 Dimensions of the suction caisson foundation are likely to vary across the site depending mainly on wind turbine size and water depth and seabed geology.

93 At the site of EOWDC future detailed geotechnical investigations would determine locations where the seabed conditions are suitable. Suction buckets are generally suitable for clay conditions without gravel or boulders and may have limited application at EOWDC, however they could provide a new concept that could be applicable to other sites in the UK.

Dimensions

94 Suction caisson foundations vary greatly depending on design and location and may be a shallow bucket of 20 m diameter or a cluster of deep cans penetrating 18 m deep.

- maximum outer shaft diameter: 6.5 m
- shaft wall thickness: 0.1 m
- maximum base diameter: 20 m
- penetration: up to 18 m
- weight (dry): 600–1,500 tonnes

Manufacturing and Transportation

95 The foundations would be pre-manufactured onshore in a similar manner to monopiles and tripods. For the purposes of the ES the fabrication of foundations could be either overseas or in the UK. If manufactured in the UK then consideration would be given to the provision adequate quayside draft and lifting at the manufacturing facility.

96 The foundations would be shipped directly to the offshore site.

3.7.2 Foundation Installation

3.7.2.1 Gravity Base

Soil Disposal

97 The worst case volume of sediment per gravity foundation has been calculated assuming preparation over a circle with a diameter of 40 m and down to a depth of 1 m.

98 The volume of sediment = $(40\ m/2)^2$ * pi * 0.5 m =628 m^3 of sediment (sand) per gravity foundation.

Expected Noise levels

99 There is expected to be no major noise generation during the installation operations other than general noise from vessels, lifting operation and ballasting which would all be significantly less than monopile piling operations (see section 3.7.2.2).

Seabed Preparation

100 At the EOWDC site the seabed generally consists of sand overlying clay, with the thickness of the top layer of sand varying across the site. In some instances, some levelling or soil removal may be necessary across the base of the foundation. The amount of soil removal or replacement would be evaluated during detailed engineering, however it is expected to be less than the height of local sand waves which are up to 1 m in places. Levelling would be done by using either local sand or a gravel bed. Preparation of the seabed is expected to last 1 – 4 per foundation. It is expected that the seabed may be prepared for one foundation at a time immediately prior to foundation installation.

Installation

101 Installation is likely to be carried out from a floating vessel, either a shear-leg barge or a purpose made barge. The gravity based foundations may be floated using a tug prior to ballasting operations when at location.

Scour Protection

102 Subject to soil conditions a gravity foundation may require scour protection. The basic method of protection is use of gravel and possibly boulders at the periphery of the base plate. A 1 – 1.5 m thick layer of gravel 10 – 15 m extending from the outer edge of base plate perimeter is typical. This might be assisted by a skirt penetrating 0.5 – 2 m into the seabed in the periphery of the base, as presented in Diagram 3.1. Across the site, the seabed appears to be sand overlying clay of varying depths. If the sand is a sufficiently thin veneer, some small amount of scour of the overlying sand may be tolerated in the design.

3.7.2.2 Monopile

Seabed Preparation

103 Generally, seabed preparation is not required although some removal of obstructions may be required but is unlikely.

Installation

104 Monopiles could be transported to site by:

- sealing ends and floating out to the installation vessel
- transporting out on a transportation barge and lifted off on site by crane from a separate installation vessel
- transported out directly on crane vessel (either jack-up type or floating)

105 Once on site the piles are lifted up by a crane on the installation vessel and held in place until driven to final depth.

106 Pile driving of a single monopile could take from less than 2 hours to up to 24 hours if the geology and pilling operation proves to be difficult. It is estimated that on average it would take 4 – 6 hours to drive a single monopile. The overall installation time would however be longer as the pile must first be lifted, stabbed and the hammer located on top of the pile. The total length of operation may be up to 5 days as the worst case.

107 Generally installation of only one monopile at a time occurs as mobilising multiple vessels for a development the size of EOWDC would not be feasible.

Soil Disposal

108 Driving of monopiles is not expected to create any sediment spill of significance. However should ground conditions require some drilling this may cause sediment spill. Detailed assessment of this impact is detailed in the coastal processes study as presented in Chapter 8 Costal Processes.

109 The drilled hole would be slightly less than the inside diameter of the monopile but for the purpose of this description the outside diameter of the monopile would be used (slightly conservative assumption).

110 Total volume of sediment in this case would therefore be = $(8.5\ m/2)^2 * pi * 37m = 2,100\ m^3$ of sediment

111 The sediment that would be disturbed would consist of sand in the upper layers with clay and sandstone in the lower layers. The drilling activity, if required, could last from one day to five days depending on the ground conditions.

Expected Underwater Noise Levels during Installation of Monopiles

112 Pile driving using an impact hammer is potentially the greatest noise concern with this type of foundation system. High noise levels are produced by the repeated striking of the hammer to drive the pile to depth.

113 However as monopiles are the most common type of foundation system used for wind farms, the factors affecting the noise level are documented and the expected noise level at EOWDC has been assessed.

114 Factors that are affecting the noise levels include:

- seabed substrate
- bathymetry
- pile diameter
- piling equipment

115 No piles of 8.5 m diameter have previously been installed. An assessment of the underwater noise level produced by piling these monopiles has been made and is included as Appendix 3.1. Should noise mitigation measures be required, this would be addressed in the construction procedures.

3.7.2.3 Steel Tripod/ Piled Concrete Tripod

Steel Tripod Soil Disposal

116 Generally, no seabed preparation would be required for the tripod structure other than levelling to position the mud mats. Worst case seabed preparation would involve sediment removal for drilled piles.

117 Volume of sediment = 2.5 m x 2.5 m x Pi/4 x 3 x 35m = 515 m^3 per tripod foundation.

Piled Concrete Tripod Soil Disposal

118 Soil disposal and seabed preparation for a piled concrete tripod is expected to be similar to steel tripod. It is therefore referred to the soil disposal section for steel tripod for sediment volumes.

Expected Noise levels

119 The noise levels during installation of a piled steel or concrete tripod foundation is expected to be less than for monopile installation due to the decrease in pile diameter and therefore piling force which has been found to result in lower levels of underwater sound, however the number of piles increases to three (Nedwell, et al. 2007).

3.7.2.4 Jacket

Installation

120 At site the jacket structure is lifted into position by the installation vessel crane. The jacket is then fixed to the seabed by driving piles through the feet by use of hydraulic hammer. An alternative would be to install a guide frame and pre-install the piles prior to jacket installation. Once driven the piles are fixed to the piled sockets by grouting or swaging. Prior to lifting the jacket into position, seabed preparation may be required to ensure the jacket is level prior to piling. The jacket would be temporarily supported on mudmats prior to piling.

Soil Disposal

121 Generally, no seabed preparation would be required for the tripod structure other than levelling to position the mud mats. Worst case seabed preparation would involve sediment removal for drilled piles.

122 Volume of sediment = 2.5 m x 2.5 m x Pi/4 x 4 x 35mm = 687 m^3 per foundation.

Expected Noise Levels

123 The noise levels during installation of a steel jacket foundation are likely to be less than that for monopile installation due to the decrease in pile diameter and therefore piling force required.

3.7.2.5 Suction Caisson/ Bucket

Seabed Preparation

124 It is not anticipated any seabed preparation would be necessary.

Installation

125 Installation is likely to be carried out from a floating vessel, either a shear-leg barge or a purpose made barge. Floating to site of the suction caisson foundations with tug control may also be an option with ballasting operations when in place.

Scour Protection

126 Subject to soil conditions the foundation may require scour protection. The basic method of protection is use of gravel and possibly boulders at the periphery of the base plate. A 1 – 1.5 m thick layer of gravel 10 – 15 m extending from the outer edge of base plate perimeter is typical.

Expected Noise Levels

127 The noise level during installation of a suction pile type foundation is expected to be small in comparison to monopile installation and likely to be comparable to gravity based installation with the principal noise sources being the installation vessels.

128 There is expected to be no major noise generation during the installation operations other than general noise from vessels, lifting operation and subsea pumping.

3.7.3 Levelling of the Foundation

129 Transition pieces could be used to connect the wind turbine tower to the foundation. The transition piece provides a means to adjusting non-verticality tolerances of installed foundations, and makes the pile design very simple, basically only a straight tube, with only minor attachments for fixing of anodes or cable ducts.

130 There have been a number of issues with failure of grouting of transition pieces. An aim of this project would be to investigate and possibly trial alternative connection and levelling methods. Alternative methods may include use of a jacking mechanism on the platform or foundation to level the connection flange for wind turbine installation.

131 Some types of foundation, such as suction caisson could be levelled by controlling the level of seabed penetration.

132 A second alternative to using a transition piece is the use of a flange welded directly onto the monopile. Welding *in-situ* requires that the upper piece of around 1 m is cut off the monopile after hammering.

133 Specific flange geometry is required to optimise the flow of the shock waves from the hammer impact through the pil*e.* Any inclination of the pile has to be compensated by shim plates or an inclined adapter piece. This option has the potential of a reduction of offshore vessel time as well as saving on grout curing time. However, damage of the flange or high fatigue of the flange is a risk.

134 The transition piece, which does not undergo significant loading during installation, could be fully equipped with all electrical or electronic components prior to installation.

135 Traditionally, the transition piece is joined to the pile with a radial connection of high performance grout. The tower itself is mounted on an internal L-flange on top of the transition piece however alternatives would also be investigated.

3.7.4 Scour Protection

136 There are two main design options to address seabed erosion, either allow for scour in the design or install scour protection such as rock dumping.

137 The amount of local scour around a monopile without scour protection is expected to be less than 2 times the monopile diameter. Allowance for scour in the design would lead to increases in penetration depths and potentially wall thickness of monopiles, and therefore additional fabrication and handling weights both leading to increases in the cost.

138 For other foundation designs such as gravity based, skirts may be added around the perimeter of the foundation to penetrate the seabed and provide a hard barrier for undermining of the foundation.

139 Scour protection of loose rock, rough gravel or mats around the base of the pile to a diameter of 2 – 3 times the pile is the most likely solution, though the choice of solution can only be made after detailed design of foundation, taking into account a range of aspects including soil data, tidal, depth of water, foundation option, maintenance strategy, cost of options.

140 Installation may involve a specialised rock placement vessel. Once the vessel has positioned itself alongside the specified rock dump location the hydraulically operated dozer blades pushes the rock material over the ships side or bags with boulders are lifted into location. Alternatively rock is transported to site by barge where it is then grabbed and dropped onto location by excavating bucket (either positioned on same barge or separate installation vessel). The final option involves mats being transported to site on the installation vessel, whereby they are picked up and lowered onto location around the base of the foundation.

3.7.5 Sediment Spill during Installation

141 Table 3.5 summarises the sediment volumes that may be excavated or released during the installation process. The sediment can either be cast-aside or disposed on a licensed disposal ground. Disposal licenses would be applied for from Marine Scotland as appropriate prior to any disposal activities taking place. For the sediment spill modelling it is considered a worst case assumption that the sediment is cast-aside next to the foundations.

TABLE 3.5 Sediment Spill during Installation			
Foundation Type	**Volume of Sediment**	**Sediment Composition**	**Comments**
Gravity Base	628 m^3	Sand/some glacial till possible	Assumes average 0.5 m excavation of 40 m diameter circle
Monopile Driven	Negligible	N/A	-
Monopile Drilled	2,100 m^3	Sand/some glacial till/some sandstone	Assumes average inner pile diameter of 8.5 and length if 37 m.
Tripod	Negligible	N/A	Assumes driven piles
Suction Caisson/Bucket	Negligible	N/A	Assumes driven piles

3.7.6 J-tubes

142 The j-tubes hold and protect the cables to and from the structure. They could be attached to the inside or outside the foundation structure. If the j-tubes are run on the inside they would penetrate the structure near the seabed. If run on the outside the j-tubes would be supported on a number of supports connected to the main structure. The j-tubes could be made of steel or thick walled plastic type tubes.

3.7.7 Corrosion Protection

143 In the aggressive offshore environment, steel foundations have to be protected against the corrosion. In principle there are several options - Surface protection in the form of painting and /or metallic coating. Treatment of the surface is particularly relevant for the part of the structure above water and in the splash zone. Another alternative include an allowance for corrosion (designing the structure with sufficient steel to allow waste due to corrosion).

144 Below the splash zone (permanently submerged structure) corrosion protection would be administered by paint and cathodic protection. This may be in the form of an impressed current system or anodes which corrode in preference to the structure.

3.8 Meteorological Masts

145 One anemometer mast may be required for EOWDC to monitor wind over the project life, however this could be integrated with the Ocean Laboratory which would be the subject of a separate planning application.

146 A potential location is shown on Figure 3.2.

147 The combined Ocean Laboratory and anemometer mast would consist of a platform mounted on a foundation, which depending on the loading would be smaller than wind turbine foundations, but follow a similar design. The platform, located approximately 20 m from LAT may be up to 20 m square and house various measuring, survey and research apparatus. Should an anemometer mast be required, the mast would be installed on the platform and extend to the hub height of the largest wind turbine. The Ocean

Laboratory may be powered by a separate cable from shore or by diesel and electrical generators located on the platform.

148 The combined Ocean Laboratory and anemometer mast would include all required navigation and aviation warning requirements in accordance with other aspects of the project.

149 The source noise level of 90 dB(A) at 1 m distance for the diesel generator has been estimated.

150 Outline parameters for the Ocean Laboratory are shown in Table 3.6.

TABLE 3.6
Ocean Laboratory Parameters used in Cumulative Assessment

Maximum Height above LAT (m)	120 m
Platform size	20 m x 20 m
Height of platform above LAT	18-20 m
Depth of Platform	Maximum 4 m including containers and ancillary equipment
Foundation Type/Size	As wind turbines
Maximum Noise Output at source	90dBA at 1m (Diesel generators)

3.9 Cables

3.9.1 Introduction

151 The wind turbines would be electrically connected by inter-array cables. Indicative options for the layout of the inter-array cables are shown on Figure 3.7. The final positions of the cables would be determined once the wind turbine types and locations are finalised and following the detailed site investigation which would establish in more detail the positions of any seabed obstructions that would need to be avoided. It is likely that the final inter-array cable layout would be a mix of more than one of the options presented in Figure 3.7 determined by slot allocation for the wind turbines.

152 It is expected there may be up to four export cables installed on the site. The export cables would collect the power from the wind turbines on the west or south edge of the site and export it to shore. It is expected that the maximum power would be in the region of 35 MW per cable with a 33 kV operating voltage.

153 Subject to further detailed electrical engineering studies, the array and export cables are likely to be 33 kV three-core cables with optical fibres incorporated for communications. Three-core designs are better than single-core designs in the marine environment as losses in the cable armour wires, and a resulting derating of the cables, are considerably less along with a single installation and therefore less disturbance. The external magnetic and secondary electric fields outside three-core designs of cables are also considerably less than those for single-core cables. Single-core subsea cable designs have not been considered within this ES.

154 Assuming the use of currently available models, each wind turbine would generate electricity at 690 V or higher and would have its own transformer

and switchgear within the tower or nacelle to step-up the voltage to the inter-array and export cable circuits collection voltage of likely 33 kV.

155 The total length of inter-array and export cable would be approximately 39 km. This is based on the following:

- up to 13 km for the inter-array cables
- up to 26 km for the export cables (1 x 5 km, 1 x 6 km, 1 x 7 km, 1 x 8 km)

156 This actual lengths would be depndent on the number of wind turbines and the electrical design employed.

3.9.2 Cable Protection

157 Cables would be buried in the seabed to a sufficient depth, which would be determined by a burial protection study. In determining the burial depth, consideration must be given to potential threats such as fishing gear and small anchors (larger anchors are excluded by an exclusion zone) and seabed movement. Consideration would also be taken of long-term seabed movement. Based on the surveys undertaken, seabed mobility would be restricted to the top layer of sand. Typical burial depths would be in the range of 0.6 m – 3 m.

158 It is possible that the export cables could cross redundant telecom lines. As the cables are redundant, permission may be provided to cut through the cables prior to installation. A second crossing philosophy would be to provide a surface crossing of the cables. In this case, the EOWDC cables would be laid on the seabed and protected on the exposed section by concrete mattresses.

3.9.3 Cables Design

159 The inter-array and export cables are likely to use a voltage of 33 kV and be a sea-armoured three-core cable, with copper conductors. A typical cable is shown in Plate 3.3. Table 3.6 shows the size and weight of three typical cables and it is expected that up to 800 mm^2 cable would be used for the export cable. A smaller size may be used for cables serving fewer turbines and for inter-array cables. The cables may also contain a fibre optic, for communication purposes.

TABLE 3.6
Example of 33 kV Cable Sizes

Conductor cross section	**Diameter**	**Weight in air**	**Weight in sea water**
120 mm^2	110	18 kg m^{-1}	10 kg m^{-1}
240 mm^2	120	24 kg m^{-1}	14 kg m^{-1}
300 mm^2	125	28 kg m^{-1}	16 kg m^{-1}
400 mm^2	130 mm	32 kg m^{-1}	20 kg m^{-1}
500 mm^2	150 mm	36 kg m^{-1}	22 kg m^{-1}
630 mm^2	160 mm	42 kg m^{-1}	24 kg m^{-1}
800 mm^2	170mm	52 kg m^{-1}	30 kg m^{-1}

Plate 3.3 Cut Away Image Showing a Typical Undersea Cable (Courtesy of DUCO)

Table 3.7
Typical Cable Corridor

Section	Water Depth	Approx Corridor Width	Temp Construction Corridor
Landfall	5 m	10 – 150 m	650 m
Approach to wind turbines	15 m	150 – 1,000 m	1,500 m
Inter-array Cables	15 – 30 m	10 m	510 m

3.9.4 Cable Landfall

160 There are potentially up to four cables to make landfall along the coastline. The landfall location has not been confirmed at present as is subject to many factors including detailed investigation of potential routes, substation locations and consideration of the potential environmental impacts of the chosen location.

161 It is understood that the shoreline is similar throughout the corridor location, therefore the proposed methods may be employed at any location. Methods under consideration include:

- horizontal directional drilling (HDD)
- dredged cofferdam
- plough pulled off the beach

162 It should be noted that only the works that are below Mean High Water Mark are assessed in this ES.

3.9.4.1 Horizontal Directional Drilling

163 Horizontal directional drilling may offer a solution with lower environmental impacts to the intertidal area, however is more suited to harder seabed materials and may have a limited application on the EOWDC. Softer seabed materials may require the use of drilling muds to support the hole on a temporary basis.

164 The hole would be drilled from behind the dune area under the tidal zone to exit the seabed a suitable distance from the shore. Each hole would be supported either temporarily with drilling mud or a steel liner to allow the cable to be pulled through.

3.9.4.2 Dredged Cofferdam

165 An alternative solution is to provide an open trench temporarily supported by coffer dams in which the cables are laid. This solution involves removing soils to the required burial depth over a width of approximately 10 m between high water mark and location where subsea trenching can commence. The trenching walls would be supported by sheet pile driven into the beach and seabed, which would also keep the trench dry for work.

166 Following completion, the beach would be reinstated with original materials.

167 This method could require removal of 12,000 m^2 of material for a 400 m long excavation which would be locally stored and reinstated after cable installation.

3.9.4.3 Plough Pulled off the Beach

168 The third solution generally utilised for single cables is to pull the plough up the beach beyond the high water mark and then commence trenching of the cable down the beach using a vessel to pull the plough over the cable into the sea. For this project, this operation would need to be repeated three up to four times.

169 As the chosen method depend on many factors including soil conditions, number of cables and availability of equipment and access, this would be assessed further during detailed engineering and procurement phases.

3.9.5 Onshore Cabling (Information Only)

170 Should the substation not be located behind the cable landfall, onshore cabling would be required to connect the cable jointing bays to the onshore electrical substation. The trench per circuit is approximately 0.75 m wide by 1.2 m deep, with 2 m distance between circuits. Therefore a maximum cable route width of 12 m would be appropriate for four circuits.

3.9.6 Cable Jointing (Information Only)

171 The offshore cables would be jointed to the onshore cables inside pre-cast concrete enclosures located close to the landing area. This would be behind the beach if required and would therefore form part of the onshore planning

application. Each of the four sunken enclosures, one for each export cable, is approximately 7 m long x 2 m wide and 1.5 m deep, with the top surface below ground level. Following installation, these enclosures would be covered with a layer of topsoil. Access to these enclosures would only be required during the operations phase of the wind farm for emergency purposes and they do not need be maintained.

3.10 Substation (Information only)

172 The proposed onshore substation location has not been finalised and is expected to be in one of three locations between Blackdog and the Aberdeen Exhibition and Conference Centre in land that is designated for industrial development or future development. Details are included for information only but would be subject to a separate planning application.

173 In addition the substation location would also include the following facilities:

- site control room
- office and amenities
- facilities relating to the development centre, which may include additional office and training facilities and a permanent exhibition
- possible energy storage and or Flexible Alternating Current Transmission Systems(FACTS) devices

3.10.1 Transmission Cables (Information Only)

174 The transmission infrastructure to the National Grid network would be part of the scope of work undertaken by Scottish and Southern Energy (SSE) and National Grid and therefore does not form part of this EIA.

3.11 Construction

3.11.1 Offshore Construction

3.11.1.1 Introduction

175 This section presents an overview of the proposed methods of construction for the project. While as much care as possible has been taken to explore and document the most suitable construction methods, it must be noted that construction contractors have not been appointed and the Applicant would also look towards innovative methods for construction which may be more efficient or cost effective. Options for this may include:

- use of larger vessels which would require less trips
- use of smaller vessels / different vessels suited for the specific water depths at different parts of the site
- installation of wind turbine and foundation in one operation

176 As such, this should be considered provisional and would be updated for each phase prior to construction.

3.11.1.2 Access to Site

177 Construction in the marine environment is potentially hazardous, and in the interests of safe working the project should be permitted to take advantage of as much construction time in favourable conditions as is possible. Construction activity is expected to continue, subject to site weather conditions, for 24 hours per day until construction is complete and may take place at all times of the year.

3.11.1.3 Safety Zones

178 The Applicant will request advisory safety zones or apply to the Secretary of State for Trade and Industry for a temporary offshore construction safety zone under Section 95 of the Energy Act 2004. The purpose of this zone is to protect the safety of project plant and personnel, and the safety of third parties during the construction and commissioning phases of the wind farm.

179 Although the stated safety zone encompasses the entire wind turbine area, the extent of the safety zone at any one time would be dependent on the locations of construction activity, and a rolling safety zone may therefore be proposed.

180 It is intended that third parties would be excluded from any safety zone during the construction period, and that the zone(s) would be marked in accordance with Trinity House Lighthouse Service recommendations. Regular Notice to Mariners would be issued as construction progresses.

181 For the export cables, an advisory safety zone would be implemented to the extent permitted by legislation and by the relevant regulatory authorities.

3.11.1.4 Construction Vessels

182 The types of construction vessels to be used would be selected post-consent, however the main types of vessels for each tasks are presented in Table 3.8.

TABLE 3.8 Likely Types of Construction Vessels		
Task Likely	**Type of Construction Vessel**	**Comments**
Pile Installation	Jack-up barge Dynamic Positioning (DP) vessel	Potential for support barge, tug(s) and work boats as support craft
Gravity Base Installation	Floating Barge (eg Shear Leg) DP vessel	Potential for support barge, tug(s) and work boats as support craft
Tripod	Floating Barge (eg Shear Leg) DP vessel	Potential for support barge, tug(s) and work boats as support craft
Wind Turbines	Jack-up barge	Such vessels now able to carry multiple units in one trip
Scour Protection	Construction barge or dedicated rock dumping vessel	
Cable Installation	Dedicated cable lay vessel (anchored barge or Dynamic Positioned vessel)	
Crew transfer, wind farm commissioning	Workboat	To conform to the MCA Workboat Code

183 The predicted number of movements (between port and the site) relating to the construction phase are shown in Table 3.9 and Table 3.10:

TABLE 3.9 Phase 1 Construction Vessel Movements		
Activity	**Frequency**	**Total Vessel Movements (approx)**
Pile Installation	One visit per two piles	2
Gravity Base Installation Crane barge on site at all times	One support barge visit per base	4
Wind Turbines	Two visit per turbines	8
Scour Protection	One visit per turbine	4
Cable Installation	One visit per five inter-connecting cables and one trip/export	5
Crew transfer, wind farm commissioning	Six visits per turbine	24
		TOTAL 45

TABLE 3.10 Phase 2 Construction Vessel Movements		
		Total Vessel Movements (approx)
Pile Installation	One visit per two piles	4
Gravity Base Installation Crane barge on site at all times	One support barge visit per base	7
Wind Turbines	Two visits per turbine	14
Scour Protection	One visit per turbine	7
Cable Installation	One visit per five inter-connecting cables	2
Commissioning	Six visits per turbine	42
		TOTAL 72

184 To optimise the construction programme, it is likely that installation of wind turbines, foundations and cables would be undertaken on the site at the same time, although not necessarily in the same part of the site. Therefore it is likely that 1 - 5 vessels (including support craft) may be on site at any one time.

3.11.1.5 Lighting and Marking

185 The construction area would be depicted on Admiralty Charts by the UK Hydrographic Office, and information pertaining to construction would be disseminated through the Notice to Mariners procedure together with regular communication with local and regional stakeholders.

186 The construction area and incomplete structures would be lit and marked in accordance with the protocol recommended by THLS.

3.11.1.6 Construction Programme

187 An indicative construction programme is presented below, based upon two construction seasons:

- Phase 1 2013
  - 4 x 6.5 MW wind turbines installed
- Phase 2 2014
  - 4 x 7.5 MW wind turbines installed
  - 3 x 10 MW wind turbines installed

188 To optimise the construction programme, it is likely that installation of wind turbines, foundations and cables would be undertaken on the site at the same time, although not necessarily in the same part of the site.

3.11.1.7 Construction Management (Environmental)

189 During construction (and decommissioning) some discharges to the atmosphere would arise from the marine vessels required to undertake these stages of the development.

190 There are no anticipated solid discharges into the marine environment during the construction phase.

191 A comprehensive Environmental Management System would be implemented prior to construction in consultation with statutory authorities, with a suite of complementary management plans corresponding to different aspects of the construction activity. The Environmental Management System would form a component part of the construction contract for the development. The documents, which would be tailored specifically to ensure compliance with the consent conditions for the project and current environmental best practice, include the following:

- Environmental Management System
- Environmental Management Plan including Commitments Register
- Monitoring Protocol (as per statutory consents)
- Incident Reporting and Non Conformance Procedure
- Emergency Response Plan

- Collision Risk Management Plan
- Marine Pollution Contingency Plan
- Dropped Objects and Materials Recovery Plan
- Archaeology Plan
- Noise, Dust and Vibration Management Plan
- Waste Management Plan
- Health and Safety Plan

3.11.1.8 Foundation Installation Vessels

192 The different types of foundations would be installed using different methodologies, however fall into the following main categories:

- float to location and ballast
- lift to location and ballast
- lift to location and secure to seabed

Float to Location and Ballast

193 This is restricted to gravity base foundations that could be towed to site by tugs and once in the final location, ballasted to secure to the seabed. Typically the foundation may require 2 - 3 tugs for the tow and positioning operation. Additional vessels (such as rockdumpers) may be necessary for the ballasting operations and scour protection. Seabed preparation may be required prior to installation.

Float to Location and Lift

194 This method could be utilised for some foundation types including monopiles. With this method the foundation would be towed to location by tugs (in the case of a monopile, the ends would be sealed). Once on location a crane vessel (either jack-up or Dynamically Positioned (DP) vessel) lifts the foundation and control location and orientation as the foundation approached the seabed.

195 For this installation method, 1 – 2 tugs would be utilised for the tow and the crane vessel for the lift operation. Additional vessels may be required for seabed preparation prior to installation and scour protection following installation.

Lift to Location and Secure on Seabed

196 Using this method, the foundations are transported to site utilising either a barge or the installation vessel. The foundation would generally be seafastened to the deck of the vessel. Once at location the seafastening would be removed and the foundation lifted to location and secured to the seabed by ballasting or pilling. This method would be suitable for all foundation types.

197 Additional vessels would also be required for seabed preparation prior to installation and scour protection after.

3.11.1.9 Wind Turbine Installation Vessels

198 Although offshore contractors have varying construction techniques, the installation of the wind turbines would likely require one or more jack-up barges, possibly one of the vessels currently in the market and/or a purpose-

built wind turbine installation vessel. Most of these large vessels stand on the seabed and create a stable lifting platform by lifting themselves out of the water. The area of seabed taken by the vessel feet varies between vessels and maybe up to 800 m^2 (in total), or with leg penetrations of up to 6 m to 8 m for leg designs reliant on leg wall friction (dependant on seabed properties). These holes would be left to in-fill naturally. Based on a worst case scenario and taking into account multiple operations (including barge jack-up for wind turbine and foundation installation), this could entail an area of impact of up to 4200 m^2 per wind turbine/ foundation. Alternatively, a DP vessel may be used for the installation work, which does not leave footprints. The wind turbine components would either be stored at an adjacent port and transported to site by support barge or the installation vessel itself, or transported directly from the manufacturer to the wind farm site by barge or by the installation vessel. The wind turbine would typically be installed using multiple lifts – the tower (1-2 lifts), nacelle (1 lift), hub/blades (1- 4 lifts). A support jack-up barge, support barge, tug, safety vessel and personnel transfer vessel may also be required.

200 It is expected that wind turbines would be installed on the foundation at a rate of one every one to two days.

201 As an alternative the project would investigate other options for innovative installation which would reduce the number of lifts, installation time and impact.

202 The works would be planned for 24 hours per day, with lighting of each barge or vessel (if using multiple barges) at night, and accommodation for crew on board.

3.11.1.10 Cable Installation

203 The installation of the inter-array and export cables is likely to be carried out by a specialist cable lay vessel, with the cables stored either on reels or a carousel designed to carry the necessary lengths and maintain the minimum bend radius.

204 The vessel is likely to be fully equipped with specialised cable lay equipment, including cable tensioners and a full survey suite to provide details of the final cable positions. The vessel would follow the cable route either through use of a four or eight point moving system or a fully DP (Dynamically Positioned) or a DP assisted operation. The vessel is likely to be specifically mobilised to undertake the work and would be selected for the ability to work in the shallow water and tidal conditions that prevail on site. A typical DP vessel is shown in Plate 3.4, however barge based vessels may also be utilised.

205 Depending on the vessels used for the installation, for the shallow water sections beyond the landfall it may be necessary to use additional barges or anchored platforms to allow for the cable installation.

Plate 3.4 Dynamically Positioned Cable Lay Vessel (Courtesy of Technip)

206 All the subsea cables would be buried in order to provide protection from all forms of hostile seabed intervention, such as fishing activity (trawler and otter boards), dragging of anchors and the minor risk of dropped objects. The subsea cables are also buried to ensure stability in the tidal conditions and eliminate the risk of free-spans causing cable fatigue.

207 The degree of cable burial proposed relates to a combination of the anticipated ground conditions as well as the perceived threat, and as such it is not proposed to bury deeper than is considered necessary.

208 The final method of cable installation and depth of burial would be determined at a later date and would vary depending on more detailed soil condition surveys and equipment selected.

209 The cables are likely to be buried using a combination of two or three techniques. Typical tools from each are shown in plates 3.5, 3.6 and 3.7.

Ploughing

210 Ploughing would be carried out using an underwater cable plough that executes a simultaneous lay and burial technique by lifting a wedge of sediment, allowing the cable to fall into this trench. A separate operation may be necessary to fold the sediment back on top of the cable. Such an operation mobilises very little sediment. The trench could typically be controlled to match the burial depth requirement which maybe between 0.6 m and 3 m deep. The trench width for the greatest depth maybe up to 10 m wide depending on soil conditions and would displace 405, 000m^3 over the 26 km cable length, with a potential for a loss of 10.38 m^2 of habitat per metre of cable laid.

Jetting

211 Cable burial from a ROV (Remote Operated Vehicle) that utilise high-pressure water jets to fluidise a narrow trench into which the cable is located. A working assumption for the trench dimension is 0.5 m wide and up to 2 m

deep. The jetted sediments settle back into the trench and with typical tidal conditions the trench coverage is reinstated over several tidal cycles. This could be undertaken in a single operation or multiple operations.

Mass Flow Excavation

212 Cable burial using mass flow excavation where a propeller is placed above the target and a jet of water is directed to the target to wash the seabed away in a specific location. The cable is then laid into the open trench. The propeller can then be reused to provide infill or allow natural backfill.

213 As the export cables are relatively short, it is proposed to install the export cables in the same way as the inter-array cables, should conditions allow.

214 The seabed in the proposed export corridor and inter-array area consists of sand overlaying glacial clays. The method chosen would depend on the depth of overlaying sand and detailed analysis of the soils along the proposed route.

Plate 3.5 ROV Jet Trenching Tool (Courtesy of Technip)

Plate 3.6 Subsea Plough (Courtesy of Technip)

Plate 3.7 Mass Flow Excavation Tool (Courtesy of RoTech)

215 Depending upon installation method chosen, the cable approaches to each wind turbine j-tube (the cable "bight") would not be buried in the final few metres. It is proposed that these cable sections would be subsequently buried using appropriate techniques to be agreed prior to construction (mattress installation, diver air lifting etc).

216 Alternatively, a shallow rock, grout bag berm, or cast iron casing may have to be installed where other burial techniques are unsuccessful.

3.12 Wind Farm Operations and Maintenance

3.12.1 Access to the Site and Safety Zones

217 Operation and maintenance of the offshore wind farm would continue 24 hours per day, 365 days per year, and therefore the Applicant would require access to site at any time.

3.12.1.1 Safety Zones

218 The Applicant would likely apply for safety zones under Section 95 of the Energy Act 2004 for the following safety zones during wind farm operation:

- each structure including (wind turbine) structure would there under have a safety zone of 50-100 m radius prohibiting entry for non-project vessels

3.12.2 Wind Farm Control

219 The wind turbines are configured so that they operate with a minimum of supervisory input. The wind turbines are monitored and controlled by micro-processors installed within the wind turbine tower. Should a wind turbine develop a fault, the status of the fault is diagnosed, and if necessary the turbine is automatically shut down for safety purposes a fault signal is sent to the onshore operator. The wind turbine operation is based upon a "fail-safe" philosophy.

220 All information relating to on-site conditions (wind speed, direction, etc), wind turbine status and generated output is held within a central Supervisory Control and Data Acquisition (SCADA) system linked to each individual turbine micro-processor. The SCADA system is controlled from an operations base ashore, and allows for the remote control and shutting down of any individual wind turbine (or a number of wind turbines) should circumstances dictate.

3.12.3 Wind Farm Inspection and Maintenance

221 The EOWDC would be serviced and maintained throughout the life from a local port, possibly Aberdeen or Peterhead. Following the commissioning period of a commercial wind farm scheduled servicing interval for the wind turbines would usually be every twelve months. As this project is a test centre it is expected that there may be more visits for data gathering etc.

222 Maintenance of the wind farm is normally separated into three different categories:

- physical periodic inspections
- scheduled maintenance
- un-scheduled maintenance

223 The integrity of the installation needs to be checked on a regular basis by remote monitoring and physical inspections of foundations, sea cables and scour protection which is likely to be undertaken at a frequency of 1–5 years.

Maintenance of scour protection may require periodic installation of additional scour protection material.

3.12.4 Physical Periodic Inspections

224 Periodic inspections would be carried out to determine the technical condition of the offshore installation. These inspection campaigns take half a day for the wind turbine and the top part of the foundation and half a day for the underwater inspections. The execution of these inspections would be planned in the periods of the year with the best access conditions, preferably in summer.

225 The periodic inspections would be carried out according to the supplier's and project specifications. The work scope typically includes function and safety tests, visual inspections, analysis of oil samples, inspection of subsea cables and scour protection.

3.12.5 Scheduled Maintenance

226 Scheduled maintenance applies primarily to inspections and work on wear parts like replacement of brake pads and filters, check of bolts, lubrication, oil change on gear box or hydraulic systems susceptible to failure or deterioration in between the periodic overhauls. A scheduled maintenance of each turbine is likely to take place every twelve months.

227 Scheduled maintenance would be performed using relatively small crew vessels from the local harbour.

3.12.6 Unscheduled Maintenance

228 Unscheduled maintenance applies to any sudden defects. The scope of such maintenance would range from small defects easy to solve with the crew vessels used for the scheduled maintenance to complete failure or breakdown of main components. For the replacement of main components like gearboxes, generators or blades bigger jack-up barges would be needed. The replacement of main components is not to be expected in the first fiver operational years.

3.12.7 Operation Management (Environmental)

229 There are no anticipated direct discharges to the atmosphere during normal operation of the wind turbines.

230 There are no anticipated solid discharges into the marine environment during normal operation of the wind turbines. All waste generated during operation, for example associated with maintenance, would be collected and disposed of by licensed waste management contractors to licensed waste management facilities onshore.

231 There are no anticipated direct aqueous discharges to the marine environment during normal operation of the wind turbines However, there is a small risk of accidental discharges from the wind turbines array or marine vessels associated with operations and maintenance.

232 During the operations phase of the wind farm an Environmental Management System, based upon the system implemented for the construction phase, would be in place. The system would ensure that the environmental monitoring, as specified in the statutory consents, is undertaken and reported, and that the wind farm is operated and maintained in an environmentally responsible manner.

233 It is anticipated that the following aspects would be featured in the Environmental Management System during the operational phase:

- Environmental Management System
- Environmental Management Plan
- Environmental Monitoring Protocol
- Emergency Response Plan
- Incident Reporting and Non Conformance Procedure
- Collision Risk Management Plan
- Marine Pollution Contingency Plan
- Waste Management Plan
- Dropped Objects and Materials Recovery Plan

234 The plans would generally be shorter versions of the corresponding construction plan – however, if major unscheduled maintenance works are required the construction plans may need to be invoked if larger construction vessels are required.

3.13 Wind Farm Decommissioning

3.13.1 Introduction

235 The Applicant recognises the importance of considering the decommissioning process at an early stage, and is committed to decommissioning the wind farm to the standard wind industry protocol at the agreed time. The implementation of the Energy Act 2004 includes an outline protocol for decommissioning. The following sections provide a description of the current intentions with respect to decommissioning, with the intention to review the statements over time as industry practices and regulatory controls evolve.

3.13.2 Programme for Decommissioning

236 As part of the implementation of the Energy Act 2004, some provisions relating to decommissioning are to be proposed. The anticipated sequence of events at present is as follows:

237 The developer submits a decommissioning plan at the time of gaining consent (precise timings to be refined). This plan would be costed and would have an outline schedule attached. Over the lifetime of the project, the plan would be reviewed and updated if necessary. When the wind farm is ready to be decommissioned, the operations take place in accordance with the agreed documentation

238 Post decommissioning monitoring would be performed in accordance with the approved decommissioning plan.

3.13.3 Facilities to be Decommissioned

239 The key offshore components of the proposed EOWDC to be decommissioned are:

- 11 wind turbines and their associated foundations
- inter-array cables between the wind turbines
- export cables for connection to the electricity transmission network
- scour protection around foundations

240 At the end of the operational life of the project (approximately 22 years) it is anticipated that all structures above the seabed would be completely removed by reverse lay, that is, the reverse construction sequence.

3.13.3.1 Wind Turbines

241 The structures above the seabed would be removed piecemeal in the reverse order of the construction procedure, using offshore cranes or, alternatively, the entire structure could be removed in a single activity using a heavy lift vessel. At the end of their individual life, the offshore wind turbines would be removed and either refurbished or recycled. The wind turbines are designed to allow removal. A typical decommissioning process for a wind turbine is set out below:

- de-energize and isolate from Grid (may be undertaken in phases)
- mobilise suitable heavy lift vessel(s) to the wind farm location
- remove rotor component parts
- cut wind turbine inter-array cables adjacent to the substructures
- remove nacelle including generator
- remove wind turbine tower
- transport all components to an onshore site at which they would be processed for reuse, recycling or safe disposal

3.13.3.2 Foundations

242 For steel foundations, piles would be cut to a sufficient target depth below the seabed to ensure that they do not become exposed. All salvaged steel to be lifted on a barge and transported to land. A jack-up type vessel would typically be used for this operation.

243 Reinforced concrete or steel gravity based structures, would be demolished by the use of demolition tools, jackhammers, diamond saw, or hydraulic splitting with the resultant material recovered for reuse.

244 The exact method of removal would be in line with regulations in place at the time of decommissioning.

3.13.3.3 Cables

245 With respect to subsea cables, it is likely that these would be removed unless it can be demonstrated that they do not pose a risk to other users of the sea and removing them leads to a greater impact on the environment than leaving *in situ*.

246 The export cables and inter-array cables would be buried to a depth ranging between at least 0.6 and 3 m below seabed. Further studies would examine if the proposed burial depths of these cables are likely to be sufficient to leave in situ. If the option to leave *in situ* is proposed then contingency plans would be put in place to ensure appropriate actions are carried out if the cables do become exposed.

European Offshore Wind Deployment Centre
Environmental Statement

Chapter 30: Summary

30 SUMMARY

1 This document and supporting volumes have assessed the potential effects of the construction, operation and decommissioning of the proposed European Offshore Wind Deployment Centre (EOWDC).

2 The assessments presented have used detailed, site specific, baseline information gathered over a number of years, through: desk study, site surveys and consultation with both statutory and non statutory organisations.

3 Assessments have made using Environmental Impact Assessment criteria, guidance and best practice (where relevant), and are presented in relation to the following topics:

- seascape, landscape and visual impact
- ornithology
- marine ecology, intertidal, sediment and water
- geology and bathymetry
- offshore ordnance
- coastal processes
- bats
- cultural heritage
- offshore archaeology
- marine mammals
- electromagnetic interference
- statutory designations and conservation
- shipping and navigation
- aviation
- Ministry of Defence
- commercial fisheries
- salmon and sea trout
- socio-economics, recreation and tourism
- in-air noise
- energy and emissions
- other marine users

4 The design of the project has been sensitive to many environmental (physical, biological and human) and technical issues, many potential impacts have been removed or reduced.

5 Environmental Impact Assessments have been carried out assuming a worst case scenario. This ensures that any possible negative impacts upon the environment resulting from the development of the EOWDC would never be more than, and are likely to be less than, the findings of the EIA.

6 As a result of the worst case scenario being modelled the potential for a major significant impact has been identified within the seascape, landscape and visual assessment and in some instances behavioural disturbance and displacement during possible construction activities is considered to be of moderate to potentially major significance for marine mammals. A number of mitigation strategies have been suggested in order to minimize any impacts upon marine mammals.

7 Where assessments have identified the potential for significant effects, possible mitigation measures have been proposed. These measures include the provision of a draft Environmental Management Plan (EMP) that accompanies this document and an obligation to produce a Marine Mammal Protection Plan.

8 It should be noted that significant effects can be reversible. When the proposed EOWDC is decommissioned at the end of the 22 year Crown Estate Lease period the wind turbines would be dismantled and removed.

Environmental Statement

Chapter 4: EIA Methodology, Scoping and Consultation

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

4 ENVIRONMENTAL IMPACT ASSESSMENT (EIA), SCOPING AND CONSULTATION

4.1 Scoping

1 Regulation 7 of the Electricity Works (Environmental Impact Assessment) (Scotland) Regulations Scotland 2000 makes provision for developers to seek a formal opinion on the scope of what should be included in the ES.

2 In August 2010, a 'Request for an Environmental Impact Assessment Scoping Opinion' was made to Marine Scotland for a proposed deployment centre in Aberdeen Bay (see Appendix 4.1). In October 2010 two figures were updated within the Request for Scoping Opinion document to show the Maritime and Coastguard Agency (MCA) designated anchorage area (2a and 12a) and these were sent to Marine Scotland (see Appendix 4.1).

3 The request contained information on the proposal, the proposed content of this Environmental Statement (ES) and the proposed desk and study methods which would be used to collect information for the studies presented in the ES.

4 The request was circulated to a large number of statutory and non-statutory consultees. Copies of scoping responses from these consultees are presented in Appendix 4.2. Table 4.1 below provides a summary of the main responses received during this scoping process and where in the ES they are addressed. The issues highlighted in the table are arranged in order of topic and are not attributed to individual consultees.

TABLE 4.1
Summary of Scoping Responses Received

Topic	Issues	Relevant Section
Shipping and Navigation	Location of EOWDC should not change and no additional wind turbines added. Proximity of Maritime and Coastguard Agency Designated Anchorage Area. Notice to Mariners, Radio Navigation Warning and publication in appropriate bulletins will be required stating nature and timescale of works. NRA to be carried out in accordance with MCA MGN 271. Recreational sailing should be considered.	EOWDC remains as Layout 039. Export cable corridor is outwith the designated anchorage area. Chapter 15
Ornithology	Appropriate duration of survey data at the time of ES submission. Impacts to red-throated diver and common scoter, does the methodology allow sufficient data to assess these species. Consideration of migrant waterfowl.	Chapter 10
Marine Mammals	Ensure mitigation and monitoring of impacts is robust.	Chapter 12
Seascape, Landscape and Visual	Flexible approach of study area. Consideration of effects as result of differing wind turbines.	Chapter 19
Cultural Heritage	Potential impacts on the setting of assets should be considered.	Chapter 20
Aviation	Potential impact upon operations with Aberdeen Airport. Significant helicopter operations in the area. EOWDC to be charted on aviation maps. If development progresses need to provide details to Defence Geographic Agency. Requirement for a coordinated regional wind turbine development plan, aimed at meeting renewable energy priorities whilst addressing aviation concerns and minimising proliferation issues.	Chapter 16
Ministry of Defence	Unacceptable interference to the Air Defence radar at Buchan.	Chapter 17
Coastal Processes	Highly mobile seabed. Dynamic seabed leading to possible scour and erosion around base of turbines leading to increase in material in suspension which	Chapter 8

TABLE 4.1 Summary of Scoping Responses Received		
Topic	**Issues**	**Relevant Section**
	could impact dredging regime at Aberdeen. EOWDC could impact harbour and beach profile of Aberdeen beach. Need to address cumulative effects of devices on coastal processes upon density and location with respect to existing renewable and coastal developments. The baseline assessment should identify the following features and processes in the environment: • sediments (eg composition, contaminants and particle size) • hydrodynamics (waves and tidal flows) • sedimentary environment (eg sediment re-suspension, sediment transport pathways, patterns and rates and sediment deposition) • sedimentary structures (eg protected banks) • typical suspended sediment concentrations With regards to hydrodynamic modelling, model performance should be checked in order to demonstrate accuracy and should include sensitivity analysis or estimate of errors in order to enable confidence levels to be applied to model results. It would be helpful to see a series of contour plots showing the magnitude and spatial extent of +(ve) and –(ve) changes in current velocities between the 'pre development' and 'post development' scenarios. The assessment should also identify and quantify the relative importance of high energy low frequency events eg storm events, versus low energy high frequency processes. Ythan estuary is not in area considered for far-field effects. Significant changes in sediment mobility should be considered here. Esnure development is unlikely to have adverse effects on erosion on adjacent coast. Ensure no obstructions to net northerly sediment movement in the Bay.	
Marking of Turbines	Aviation Warning Lighting - project will fall under requirements of Air Navigation Order 2009 Article 220.	Chapter 3

TABLE 4.1
Summary of Scoping Responses Received

Topic	Issues	Relevant Section
	Rotor blades, nacelle and upper 2/3 of supporting mast of wind turbines should be painted white. Final marking and lighting recommendations to be made in a formal response through CPA consultation process and will be based on IALA Recommendation O-139 with statutory sanction from the Northern Lighthouse Board prior to deployment. Marking needs to be considered for recreational craft as well as much larger commercial vessels.	
Socioeconomics, Recreation and Tourism	Relevant economic information connected with the project to be supplied Recreational sailing should be considered. Danger of squeezing recreational craft between commercial shipping routes and the development should be considered.	Chapter 15, Chapter 23 and Chapter 27
Planning	Onshore elements and offshore elements should be separated.	Chapter 1
Marine Ecology	As single grabs are now being collected does this mean that the sampling strategy is randomly stratified? Sampling should take into account pollution around Balckdog. River basins comprise all surface waters (including transitional (estuaries) and coastal waters) extending to 3 nautical miles seaward from the Scottish territorial baseline. Any proposed development within these waters must have regard to the requirements of the Water Framework Directive to ensure that all surface water bodies achieve 'Good Ecological Status' and that there is no deterioration in status. The Water Framework Directive requires the consideration of chemical, ecological and hydromorpholgical status. The data held on 'Cruden Bay to Don Estuary' coastal water body should also be included in the baseline dataset. This water body is currently classified at high ecological status. Any proposed development within these waters must have regard to the requirements of the Water Framework Directive (WFD) to ensure that all surface water bodies achieve 'Good Ecological Status (GES)' and that there is no deterioration in status.	Chapter 9 and Chapter 8

TABLE 4.1 Summary of Scoping Responses Received		
Topic	**Issues**	**Relevant Section**
	The WFD requires the consideration of chemical, ecological and hydromorpholgical status. A baseline assessment of existing intertidal and subtidal habitats and species should be submitted. This should include any UK Biodiversity Action Plan habitats and species (eg maerl, sea pens, eel grass, horse mussels). Ensure references for biotope names is inserted (Marine Scotland response) Collieston beach is bounded by a breakwater/pier and the meiofaunal distributions may reflect this artificial situation. Therefore the sediment and the fauna distributions are localised for this area and may not represent soft sediment shores from the area of interest. Beach profiling to quantify erosion / modification, and the outcome discussed with Marine Scotland prior to any action being taken.	
Salmon and Freshwater Pearl Mussel	The ecological status of surface water bodies which may be affected by the proposal should also be considered alongside the discussion of protected areas for salmon and freshwater pearl mussel.	Chapter 9 and Chapter 22
Migratory Fish/ diadromous fish	The proposed development will need to consider, in the first instance through a desk study, potential impacts on migratory fish including salmon (*Salmo salar*), sea trout (Salmo trutta), sea lamprey (*Petromyzon marinus*), river lamprey (*Hyperoplus lanceolatus*)and sandeels (*Ammodytes marinus*) during all phases of the project. The potential for offshore renewable projects to impact on migratory fish will vary depending on the design and location of the development in relation to the migration routes of adults and juveniles. Specific questions raised by Marine Scotland to be discussed in the assessment.	Chapter 9 and Chapter 22
Commercial Fishing	Ongoing discussion with fishing stakeholders required. Cumulative impacts of fishing with other marine activities should be addressed. Fishing baseline information to be	Chapter 21

TABLE 4.1 Summary of Scoping Responses Received		
Topic	**Issues**	**Relevant Section**
	updated.	
Site Information	Maps should be included in the ES showing the areas of seabed likely to be affected by the footprint of the turbine bases and cabling, and the area of intertidal zone that is likely to be affected by shoreline infrastructure development.	See Figures (Volume 3)
Timing of Works	The Schedule of Mitigation should include a timetable of works that takes into account all environmental sensitivities, such as fish spawning, which have been raised by SEPA, SNH or other stakeholders.	Chapter 28
Environmental Management	A Construction Environmental Management Document (CEMD) is a key management tool to implement the Schedule of Mitigation. Recommend that the principles of the CEMD are set out in the ES drawing together and outlining all the environmental constraints and commitments, proposed pollution prevention measures and mitigation as identified in the ES.	Chapter 28
Waste Management	Details of how waste will be minimised at the construction stage should be included in the ES, demonstrating that: • construction practices minimise the use of raw materials and maximise the use of secondary aggregates and recycled or renewable materials • waste material generated by the proposal is reduced and re-used or recycled where appropriate on site	Chapter 28
Conservation	Advice on designated sites and European Protected Species should be sought from SNH. For marine and transitional Special Areas of Conservation (SAC) and Special Protected Areas (SPA), these are Water Framework Directive Protected Areas. Therefore, their objectives are also River Basin Management Plan objectives. A Report to Inform the Habitats Regulation Appraisal should be included in the Application.	Chapter 14 and Chapter 29
Assessment methodology	If one or more type of foundation is to be deployed then the Rochdale approach should be applied differently ie cumulative impacts between each different type of foundation. Assessment to be carried out on the worst case scenario for wind turbines eg maximum rotor diameter Approach to assessment to be based on	All

TABLE 4.1 Summary of Scoping Responses Received		
Topic	**Issues**	**Relevant Section**
	rigorous professional judgement. Cumulative and in combination impact assessment to consider other east coast wind farm sites.	
Operation and Maintenance	Gearbox oil changes method statements and contingency plans required Major turbine service every 12 months – is this based on historic info?	Chapter 3 To be provided at appropriate time. Text based on Vattenfall O&M current experience.
Safety Zones	Section 36A does not apply in Scottish Waters. Situation may have changed.	Chapter 3 and Chapter 15
Research and Development	ES to include an outline of construction and post construction monitoring plan including research proposals.	Potential future research opportunities are covered in relevant chapters.

4.2 The Environmental Impact Assessment Regulations

5 The EIA for this project comprises the following sections:

- Non-Technical Summary
- Introduction including Legislative Framework
- Site Selection
- Project Description
- Physical Environment Baseline Description and Impact Assessment
  - Meteorological Conditions
  - Geology and Bathymetry
  - Offshore Ordnance
  - Coastal Processes
- Biological Environment Baseline Description and Impact Assessment
  - Marine Ecology to include Intertidal Ecology, Sediment and Water Quality
  - Ornithology
  - Bats
  - Marine Mammals to include Underwater Noise
  - Electromagnetic Fields
  - Conservation
- Human Environment Baseline Description and Impact Assessment
  - Shipping and Navigation
  - Aviation
  - Ministry of Defence
  - Archaeology
  - Seascape, Landscape and Visual
  - Cultural Heritage
  - Commercial Fisheries
  - Salmon and Sea Trout
  - Socioeconomics, Recreation and Tourism
  - In-Air Noise
  - Energy Use and Emissions
  - Electromagnetic Interference

    - Other Marine Users
- Draft Environmental Management Plan
- Information to Inform a Habitats Regulation Appraisal
- Summary of Environmental Impact Assessment and Mitigation Measures
- Supporting Technical Appendices

6 Each Environmental Impact Assessment section aims to comprise the following information:

- Introduction
- Methodology and Guidance
- Baseline Methodology
- Impact Assessment Methodology
- Description of the Baseline Environment
- Impact Assessment – Construction, Operation and Decommissioning
    - Potential Impact
    - Mitigation
    - Residual Impact
    - Monitoring
- Cumulative Impact Assessment
- In-combination Impact Assessment

4.2.1 Impact Assessment Methodology

7 In the case of each impact, the assessment aims to describe the magnitude of effect (ie the change created by an activity in terms of spatial extent, duration and scale) and the sensitivity of each receptor. The combination of the effect and the sensitivity of the receptor are then used to derive the significance of the impact. The criteria that have been are given below:

4.2.1.1 Spatial Extent of Effect

- a national/international effect
- a regional effect
- a local effect (within 5 km of the site)
- a site-specific effect

4.2.1.2 Duration of Effect

- a long-term/permanent effect (more than 10 years)
- a medium-term effect (existing for 5 to 10 years)
- a short-term effect (existing for 1 to 5 years)
- a temporary effect (existing for less than a year)

4.2.1.3 Scale of Effect

- above accepted standards/guidelines
- within accepted standards/guidelines
- where there are no standards/guidelines available, the impact relative to background conditions

4.2.1.4 *Recoverability of the Receptor*

- high
- medium
- low or none

4.2.1.5 *Importance of the Receptor*

- high
- medium
- low

8 The impact significance is then given as *major*, *moderate*, *minor* or *negligible*, using the matrix in Table 4.2 as a guide in the assessment process. Not all assessments directly follow this but have used this as a guide.

TABLE 4.2
Matrix for Significance of Impact

	Sensitivity of Receptor				
Magnitude of Effect based on spatial, duration and scale of effect		Very High	High	Medium	Low
	Very High	Major	Major	Major	Moderate
	High	Major	Major	Moderate	Minor
	Medium	Major	Moderate	Moderate	Minor
	Low	Moderate	Minor	Minor	Negligible
	Negligible	Minor	Negligible	Negligible	Negligible

4.2.2 Cumulative and In-combination Impact

9 An important part of the EIA process is to consider cumulative and in-combination impacts.

4.2.2.1 *Cumulative Impact*

10 Schedule 3 of the Electricity Works (Environmental Impact Assessment) (Scotland) Regulations Scotland 2000 requires that the potential for *cumulative impact* should be considered and where appropriate, assessed.

11 Cumulative impacts include, but may not be limited to, impacts that arise from the following existing and reasonably foreseeable development activities:

- other wind farms
- aggregate extraction and dredging
- navigation and shipping
- established fishing activities
- existing and planned construction subsea cables and pipelines
- potential port / harbour development
- oil and gas installations

12 The cumulative assessment addresses where predicted how impacts of the EOWDC construction and operation could interact with impacts from other industry sectors within the same region and impact sensitive receptors. This

may be through direct effects or spatially/temporally separated impacts on the same population of a receptor.

4.2.2.2 In-combination Impacts

13 The Conservation (Natural Habitats, & c.) Regulations 1994 (as amended) require that a Habitats Regulations Appraisal (HRA) must be conducted by a competent authority. The HRA considers the implications for European sites in view of the European sites conservation objectives, in respect of any plan or project which is not directly connected with or necessary to the management of the European site for conservation purposes and which is likely to have a significant effect on the European site either alone or *in-combination* with other plans or projects.

14 Therefore the term 'in-combination' is used when considering the impacts of the proposals with other plans or projects on European sites.

4.3 Consultation

15 As the proposal for the EOWDC has evolved over a number of years, there have been many individual stakeholder meetings involving a wide range of environmental, marine and aviation interests and over 24 public exhibition events. These discussions and events have allowed consultation with key interests and the general public on their views and comments regarding the proposal. The project has held extensive consultation with various statutory and non statutory bodies which have been useful in identifying issues which have been addressed through the EIA process and also in determining the location of the current application (see Chapter 2 Site Selection).

4.3.1 Public Exhibitions

16 Following an initial stakeholder workshop which took place in July 2005, a series of local consultation public exhibitions were publicised. These were held from 31st October to 10th November 2005 in Aberdeen and six other coastal North East communities. The exhibitions were organised to coincide with the ongoing feasibility study for the proposed development by Aberdeen Offshore Wind Farm Limited. Response sheets were collected and display materials were made available for inspection with representatives of the project team present to answer questions. The 2005 public exhibitions were held at:

- The Palace Hotel, Peterhead 31 Oct, 2-8 pm
- The Kilmarnock Arms Hotel, Cruden Bay 1 Nov, 2-8 pm
- Oceanlab, Newburgh 2 Nov, 2-8 pm
- Kirk Centre, Ellon 3 Nov, 2-8 pm
- Collieston Community Centre 4 Nov, 2-8 pm
- White Horse Inn, Balmedie 7 Nov, 2-8 pm
- Aberdeen Exhibition and Conference Centre, 8 Nov, 2-8 pm
- Tullos Primary School foyer, Aberdeen 9 Nov, 3-8 pm
- Beach Ballroom, Aberdeen 10 Nov, 2-8 pm

17 Following the 2005 consultation and ongoing stakeholder dialogue, a further series of public exhibitions was publicised and held in June 2006. The events

explained the proposed layout changes of the scheme following feedback received on environmental issues surrounding the Ythan Estuary and operational issues faced by local helicopter operators. Response sheets were collected and display materials were made available for inspection with representatives of the project team present to answer questions. The Public Consultation Exhibitions displayed a revised 23 wind turbine scheme and took place during the last two weeks in June at:

- The Palace Hotel, Peterhead 19 June, 2-8 pm
- The Kilmarnock Arms Hotel, Cruden Bay 20 June, 2-8 pm
- Oceanlab, Newburgh 21 June, 2-8 pm
- Kirk Centre, Ellon 22 June, 2-8 pm
- Collieston Community Centre, 23 June, 2-8 pm
- White Horse Inn, Balmedie 26 June, 2-8 pm
- Aberdeen Exhibition and Conference Centre, 27 June, 2-8 pm
- Tullos Primary School foyer, Aberdeen 28 June, 3-8 pm
- Patio Hotel , Aberdeen 29 June, 2-8 pm

18 These early periods of consultation helped to identify new stakeholders and interest groups in proximity to the proposal. Feedback from these stakeholders helped shape the final project design. Dialogue with stakeholders has continued as the project has moved towards the development of the EOWDC concept and the Vattenfall, Technip and Aberdeen Renewable Energy Group partnership.

19 In November 2010 briefing events for Aberdeen City and Shire councillors were held at the Town House in Aberdeen. Public exhibition events were publicised and run in November 2010 which outlined the European Offshore Wind Deployment Centre proposal and the revised 11 wind turbine layout. Response sheets were collected and display materials were made available for inspection with representatives of the project team present to answer questions. The events took place at :

- The Palace Hotel, Peterhead 22 November, 2-8 pm
- Udny Arms Hotel, Newburgh 23 November, 2-8 pm
- Kirk Centre, Ellon 24 November, 1-7pm
- Beach Ballroom, Aberdeen 25 November, 2-8 pm
- White Horse Inn, Balmedie 26 November, 2-8 pm

4.3.2 Additional Consultation

20 On the 18th February 2011 a briefing event was held for Energy Communications contacts at Aberdeen Town House. In March 2011 a project briefing session was run at the Scottish Parliament in Edinburgh for MSPs.

21 Since 2005 the project team has also presented the proposals to local community council meetings, and also responded to other ad-hoc requests for presentations / display stands including the Aberdeen Highland Games 2006.

22 The project has been a key focus of the All-Energy show over the last six years, and updates on progress were delivered at the opening business breakfast and during the main session presentations. In addition to press and media coverage, Councillor, MP & MSP briefings were given during the two day shows.

23 At the 2011 show a call was made to European Innovators. Wind turbine manufacturers, supply chain companies, universities and research establishments were all briefed in the project to identify possible involvement.

24 Information & briefings regarding the project were also available at the Aberdeen City and Shire stand at Offshore Europe 2005/2007/2009.

25 The project has featured in regular updates at meetings of the Aberdeen Renewable Energy Group.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 5: Meteorological Conditions

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

5 METEOROLOGICAL CONDITIONS

5.1 Introduction

1 Information on the meteorological conditions is required to inform the design of wind farm projects. This section outlines the baseline data collected to date.

5.1.1 Key Guidance Documents

2 This study uses existing data from Dyce airport and the Met Office, and therefore follows their existing protocols. The guidelines for wind measurements to calculate power performance for turbines (IEC 61400-12-1) is currently being revised to cover remote measuring techniques (such as Light Detection and Ranging device (LIDAR) and Sound (or Sonic) Detection And Ranging (SoDAR). As these guidelines have not been completed the LIDAR measurements followed accepted principles as stated in the installation manual.

5.1.2 Data Information and Sources

3 In 2008a LIDAR was deployed by Natural Power, east of the Bridge of Don, to the north of Aberdeen. This instrument transmits a beam of light upwards, and measures the return signal (reflected from particles in the air) to assess the wind speed and direction at different heights above the sensor. It is therefore a remote sensing device for measuring wind parameters.

4 Wind data were recorded from 31 October 2008 to 22 January 2009, and the results have been reported in the following report:

- Prevailing (2009) Aberdeen Offshore Wind Farm: Analysis of LIDAR Data (00028-001-R: 7 October 2009)

5 A description of the data collection is given in Table 5.1

TABLE 5.1
Summary of LIDAR Measurements

Measurement device	Natural Power ZephIR
Location	OS Grid Reference 395024 810254
Monitoring period	31 October 2008 to 22 January 2009
Wind speed measurement heights*	27 m, 70 m, 90 m, 125 m, 153 m
Data recorded	Horizontal and vertical wind speed, wind direction, turbulence, temperature, pressure, humidity
Configuration	Cloud correction turned on

* Note: 1 m added to the LIDAR measurement heights to account for height of device

6 In addition to the LIDAR data, the following data from the Dyce Meteorological Station were also considered:

- hourly data from 1 November 2008 to 31 January 2009
- wind speed and direction data collected from January 2001 to January 2009

5.2 Baseline Assessment

7 The climate along the east coast of Scotland is heavily influenced by the weather systems and large scale currents in the North Atlantic. Weather patterns are particularly governed by variation in the North Atlantic Oscillation (a difference in pressure between the Icelandic Low and the Azores High). Large scale westerly circulation dominates, bringing frequent depressions across Scotland (DTI, 2004).

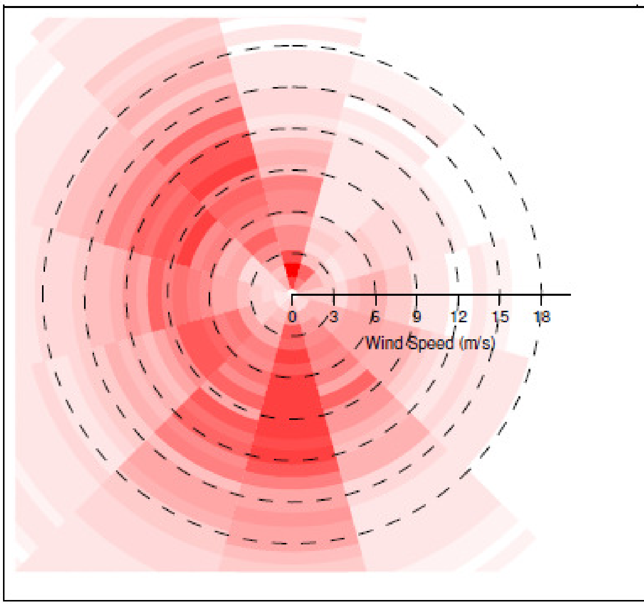
8 The North Sea climate is characterised by large variations in wind direction and speed, a high level of cloud cover and relatively high precipitation (OSPAR, 2000; DTI, 2004). The local climate along the north-east coast is dependent to a large extent on the shelter from winds from the north and west. Predominant winds are from the south and west. Wind strengths along this stretch of coast are variable and generally affected by local topography.

9 Mean annual rainfall in the central North Sea is 400 – 600 mm (OSPAR, 2000; DTI, 2004).

10 Coastal fog (“haar”) is common during spring and summer along the east coast of Scotland, with up to 14 days per month recorded in exceptional years (North Sea Pilot, 1997; DTI, 2004). Visibility statistics show that fog (visibility less than 1000 m) is most common in July and August. June to August is also when thunderstorms occur (MetOffice, 2011a).

11 Correlations of the concurrent wind speed at Dyce and the LIDAR using hourly, daily and weekly averaging periods were conducted and the daily correlation used to derive the long-term mean wind speed of 8.74 ms^{-1} at a height of 90 m (Prevailing, 2009).

12 Data from the Dyce site have been used to derive the long-term site wind rose using a Measure-Correlate-Predict methodology. The Dyce wind rose was scaled to the predicted long-term mean wind speed of 8.74 ms^{-1} at 90 m at the LIDAR location. The resultant wind rose is shown in Diagram 5.1.2 (source: Prevailing, 2009). This shows that the predominant wind directions are from the south (17.9 %) and north-north-west (13.4 %).



Sector	Probability
0	9.1%
30	2.8%
60	2.0%
90	2.4%
120	4.4%
150	8.4%
180	17.9%
210	12.2%
240	8.8%
270	7.9%
300	10.6%
330	13.4%

Diagram 5.1 Estimated Long-term Wind Rose at the LIDAR Llocation at 90 m

13 The meteorological conditions for the EOWDC area are summarised in Table 5. 2.

TABLE 5. 2 Meteorological Conditions at EOWDC Area	
Long-term wind speed*	8.7 ms^{-1}
Predominant wind speed – summer**	4.6 ms^{-1}
Predominant wind speed – winter**	5.2 ms^{-1}
Prevailing wind direction – summer**	South
Prevailing wind direction – winter*	South
Air temperature – annual average+	4.6 – 11.2 °C
Days of air frost – annual average+	53.6
Hours of sunshine – annual average+	1409
Rainfall – annual average+	816.3 mm
Days of rainfall ≥1mm – annual average+	134.2

*Long-term wind speed predicted at 90 m above ground level for LIDAR location (Prevailing report). Further offshore data collection would clarify this figure
**Dyce Station; summer (June, July & August), winter (December, January & February) measured at 10 m above ground level
+Craibstone 1971-2000 averages
Sources: *DTI (2004); +MetOffice Website (2011b)

5.3 Impact Assessment

14 The meteorological data are presented for information only, and an analysis of the wake effects is not required within the Environmental Statement (ES).

5.4 Summary

15 Short-term wind data were collected onshore adjacent to the EOWDC site and correlated with long-term data from Dyce Meteorological Station. These showed the average wind speed to be 8.7 ms^{-1} at 90 m height, and the predominant wind direction to be from the south.

16 Haar fog is common in the summer months, with July and August having the highest duration of low visibility.

Chapter 6: Geology and Bathymetry

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

6 GEOLOGY AND BATHYMETRY

6.1 Introduction

1 A review of the offshore sediments and geology in Aberdeen Bay indicates that the seabed sediments are defined as non-solid sediments laid down by the actions of the sea during the early Holocene. The sediments in this region reflect its glacial history and hydrodynamic regime. There is little input of sediment from land with most inputs being derived from peat deposits. The sediments off Aberdeen consist predominantly of sand and slightly gravelly sand (DTI, 2004).

2 Below the seabed, Pleistocene deposits off the Aberdeenshire coast vary from soft red-brown, grey-brown and pink-grey muds to compact grey clays with scattered pebbles that are interpreted as glacial till. The soft muds probably date from late Devensian to Early Flandrian, being deposited during the retreat of the last ice sheet. The underlying bedrock along the coast between Aberdeen and Stonehaven comprises sandstones, conglomerates, mudstones and cherts.

3 Forvie is designated as a geological conservation statutory review site. This is a non statutory designation which reflects the area's earth science interest in relation to coastal geomorphology.

4 Surveys that obtained bathymetric, seabed and sub-bottom data are critical to the project, providing a basis for the foundation design work, and informing the coastal process modelling and marine ecological and archaeological impact assessments.

6.1.1 Key Guidance Documents

5 There are no formal guidance documents to inform the geology assessment, but several project reports have been used to provide baseline information.

6.1.2 Data Information and Sources

6.1.2.1 Surveys

6 Site specific studies were undertaken that collected on-site survey data and also incorporated more general information from background literature such as British Geological Survey charts.

7 In 2007, EMU Ltd. was commissioned to undertake a geophysical and seabed habitat survey of the site as proposed at that time (Layout 011, see Frame 4, Figure 2.3). The survey included swath bathymetry data, sidescan sonar imaging, shallow seismic profiling, magnetometer readings and use of an Acoustic Ground Discrimination System (AGDS) with video ground-truthing (EMU Ltd, 2008). The survey was completed using the vessel *FPV Morven* between 12th and 18th September 2007.

8 Following a change in site location as outlined in Chapter 3 Site Selection, Osiris Hydrographic & Geophysical Projects Ltd (Osiris Projects) was commissioned to undertake a geophysical and benthic sampling survey of the current site (Layout 039, see Figure 3.2) and potential cable corridor area.

9 This second survey area slightly overlapped with the previous survey area to enable comparison between the two surveys and ensure consistency of data. The survey was completed using the vessel *MV Lia* between 3rd September and 26th October 2010.

10 The areas of both surveys can be seen on Figure 6.1.

6.1.2.2 *Project Reports*

11 In addition to the surveys, a geotechnical desk study was undertaken to determine the soil properties within the site.

12 These studies are reported in the following documents:

- EMU Ltd (2008b) Geophysical and Seabed Habitat Assessment of the Proposed Aberdeen Offshore Wind Farm
- Osiris Ltd (2011) Aberdeen Offshore Wind Farm Geophysical Survey Report – Volumes 2a and 2b
- Setech Ltd (2009) Geotechnical Desktop Study

6.2 Baseline Assessment

6.2.1 General Description

13 The geological succession in the area has been charted as:

- Superficial sediments
- Quaternary sediments
  - Forth Formation – St Andrews Bay Member
  - Forth Formation – Largo Bay Member
  - Wee Bankie Formation
- Bedrock
  - Devonian Sandstone
  - Ultrabasic and other coarse grained igneous rocks related to the Belhelvie gabbro mass

14 BGS described the superficial sediments as gravelly shelly sands ranging in thickness from less than 0.5 m to 2.0 m in thickness.

15 Underlying these are the Quaternary sediments. The fine to coarse sands (St Andrews Bay Member) are anticipated to be up to 20 m thick, underlain by silty clays and gravelly clays (Largo Bay Member). Beneath these is the glacial till deposit of the Wee Bankie Formation. This comprises sandy gravelly clays with frequent cobbles, occasional boulders and thin layers of sand and silty clay, together with coarser sand and gravel deposits.

16 The bedrock beneath the Quaternary deposits consists of Upper Devonian sandstones and conglomerates. However, the BGS data indicate that ultrabasic rocks are present at the central inshore section of the site (Osiris, 2010). These are rich in ferromagnesian minerals.

17 There is no evidence at this stage to suggest that shallow gas will be present at the proposed site.

18 The UK is an area of low seismicity and the risk to offshore structures is considered to be correspondingly low. The Dee Valley Fault strikes

diagonally across Aberdeen Harbour, however it is unlikely to affect ground conditions below the project area (Setech, 2009).

6.2.2 Geophysical and Seabed Habitat Survey Results

19 The survey reports include presentations of the data for:

- depth: swath bathymetry
- seabed features: AGDS, drop-down video, sidescan data and magnetometer contacts
- sub-seabed geology: sediment isopach charts and geological cross sections

20 **Bathymetry:** The seabed slopes consistently offshore, deepening to the east-north-east. This even increase in water depth was apparent in both geophysical surveys. The depths within the 2010 survey area range from 0.8 m to 35.1 m below Lowest Astronomical Tide (LAT) (Osiris, 2011).

21 In the shallow inshore section, depths increase from 0.8 m to 6 m in an irregular channel. To the east of this channel, there is a series of linked narrow bank features running parallel to the shore. In places, the depth decreases to 2m below LAT. These banks are asymmetrical, with the steeper side facing west. The seabed then slopes east-south-east with decreasing gradient between 1 in 110 and 1 in 140 to the 25 m contour, continuing to decrease further offshore at a gradient of 1 in 300.

22 The depths within The Crown Estate lease boundary range from 11 m to 35 m below Chart Datum (CD). The data from both surveys are shown in Figure 6.2.

23 **Seadbed features:** The sidescan sonar showed the sediments over most of the survey area were predominantly slightly silty sands, which are frequently shelly (see Figure 6.3). Along the western border of the survey areas there are outcrops of glacial (clayey) till. There are also patches of gravel to the north. The till and gravel are exposed due to erosional forces of the tides and waves preventing net deposition. This means the gravels are reworked during storm periods changing the nature of the sediment morphology (Osiris, 2011).

24 Depositional ripple features are apparent towards the intertidal area (Emu, 2008), with megaripples within the gravel areas and other features in the silty sand up to 1,500 m from the shoreline (Osiris, 2011).

25 Several trawl scars were visible in the sonar data, plus numerous targets, most of which are interpreted as boulders. A wreck and possible area of associated debris have been identified near the proposed site of Wind Turbine 8 (see Chapter 18 Archaeology for more details).

26 The 2007 data identified 59 magnetic targets, being dominated by several large readings in the north-west of the survey area. These were the result of submerged geological features.

27 In the 2010 data, there was a total of 262 anomalies in the magnetometer readings. These included three outfall pipes running out from shore and the route of a disused telecoms cable. There was also an area of high magnetic readings in the west of the site, associated with submerged geology as described in the 2007 data. An igneous intrusion probably related to the Belhelvie gabbro mass was highlighted.

28 Only one medium-sized magnetic anomaly was considered to be of anthropogenic origin and of concern; this is located adjacent to Wind Turbine 3 and could be the remains of an unknown wreck or aircraft crash."

29 There were numerous small magnetic anomalies across the site. Given the possibility of ordnance in the area these may indicate small metallic objects such as unexploded ordnance (UXO).

30 The drop-down video confirmed that silty sand was common across the area, with ripple marks of 20-40 cm wavelength. Inshore, there was a lower mud content than offshore. There were occasional patches of shelly fragments.

31 **Sub-seabed geology:** The surveys confirmed a surface veneer of sandy sediments, which is absent in some locations nearshore (where the till outcrops at the surface) increasing to over 10 m thickness offshore. Nearshore, this is thickest in the sand bar features described above. In the north-west there may also be layers of peat near the surface.

32 These surficial sediments overlie a sequence of glacial (Quaternary) sediments with evidence of erosional surfaces and variable lithology (Emu, 2008). At the top of this sequence is the fine to coarse shelly sand of the Forth Formation. This is not present across the whole site, as patches of till outcrop at the surface; its deepest extent is 36 m below seabed in the north-west corner of the survey area (Osiris, 2011). Beneath this is the glacial till of the Wee Bankie Formation. There is a ridge feature extending west-north-west/east-south-east across the central eastern section of the proposed site. This is approximately 2 km long and 150 m wide, possibly representing a terminal or recessional moraine (Osiris, 2011). In the west, distinct lenses of sediment are apparent lying directly on the rockhead. These coincide with the high magnetometer readings and are interpreted as reworked local igneous material contained within the till deposit. This means the geology will be of variable engineering strength (Emu, 2008).

33 The rockhead is expected to be Devonian Old Red Sandstone which occurs at a depth of 5-10 m below the seabed in the west, deepening to over 30 m below seabed at the eastern boundary.

34 Further information on the habitat can be found in Chapter 9 Marine Ecology, Intertidal Ecology, Sediment and Water Quality.

6.2.3 Geotechnical Study Results

35 Setech (Geotechnical Engineers) Ltd. conducted a geotechnical desk study in early 2009. This used the Emu survey data plus existing borehole information from the BGS. The comparison of these datasets confirmed that the presence of Holocene sediments underlain by glacial Wee Bankie Formation, which rests directly on the Devonian Old Red Sandstone.

36 There is limited geotechnical information available, and therefore only general assumptions can be made regarding strength. The Wee Bankie Formation is described as soft to very stiff clay (increasing with depth), with borehole logs indicating C_u (undrained shear strength) values of 30 to >150 Kn/m^2. However, verification of the strength of both this and the bedrock is needed to determine engineering parameters for foundations.

6.3 Impact Assessment

6.3.1 Impact Assessment Methodology

37 From the geophysical and geotechnical studies undertaken, the only environmental impact anticipated on the geology and bathymetry is potential scour, which is considered in Chapter 8 Coastal Processes, or removal of material directly where the foundations are installed. Consequently, a formal impact assessment is not considered appropriate here.

6.3.2 Impact Assessment

38 Construction would not alter the geology of the site other than in localised areas directly impacted by the installation of wind turbine foundations. This is dependent upon the size of the foundation used, but is not considered to be significant for any of the options under consideration. It is anticipated that during decommissioning, foundations would be removed to below the seabed surface.

6.3.3 Summary

39 The geology of the site comprises silty sand at the surface, lying above glacial till, which in turn lies on Devonian Old Red Sandstone.

40 The only anticipated impacts would be potential scour due to the turbine foundations, which is considered in Chapter 8 Coastal Processes and direct loss of sediment where the foundations are installed. This would be dependent on the type and size of foundations used but is not considered to be significant.

41 However, to inform the engineering considerations, further geological work would be undertaken for the project. Following the recommendations by Setech (2009), a full site investigation would be conducted to obtain site specific data on soil conditions. This would confirm the potential strength parameters of the Wee Bankie Formation, and would also verify the bedrock composition, competency and strength as an addition to the geophysical survey and the desktop study. This survey would be conducted as part of the pre-construction survey.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 7: Offshore Ordnance

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

7 ORDNANCE

7.1 Introduction

1 This section outlines the information available with respect to unexploded ordnance (UXO) across the proposed European Offshore Wind Deployment Centre (EOWDC) site. The Health & Safety at Work Act and the construction (Design & Management) Regulations (1994) do not require UXO studies to be undertaken. In light of history of ordnance in Aberdeen Bay area, the Applicant commissioned UXO threat assessments and developed mitigation strategies to ensure the safety of those working on the project.

7.1.1 Key Guidance Documents

2 In 2009, CIRIA (the construction industry research and information association) produced a holistic UXO risk management framework for onshore UXO: "Unexploded ordnance (UXO) A guide for the construction industry". While not directly applicable to offshore UXO, the same principles apply in the marine environment (where no formal guidance exists at this time).

3 This has therefore been applied to the studies undertaken in 2010 in conjunction with marine and renewable experience (6 Alpha, 2010).

4 Other sources of guidance included:

- Maritime Coastguard Agency (MCA)
- British Marine Aggregate Producers Association (BMAPA)
- Health & Safety Executive (HSE)

7.1.2 Data Information and Sources

5 Three studies have been undertaken to inform the project on the risk of UXO across the site. The first was undertaken in 2007 by BACTEC International Limited, and was a risk assessment for the area around Layout 011 (see Frame 4, Figure 2.3).

6 The second and third were completed in 2010 by 6 Alpha Associates, describing the UXO risk and then proposing possible mitigation methods.

7 These used the following data sources (6 Alpha, 2010):

- Royal Navy (Northern Diving Unit), Scotland
- The National Archives, Kew
- Naval Historical Centre, Portsmouth
- UK Hydrographic Office, Taunton
- 6 Alpha database

7.1.2.1 Project Reports

8 The reports written specifically for this project were:

- BACTEC International Limited (2007) Explosive Ordnance Threat Assessment of the Aberdeen Offshore Wind Farm
- 6 Alpha Associates (2010) Unexploded Ordnance (UXO) Risk Situation Report and Risk Assessment/Method Statement Review
- 6 Alpha Associates (2010) Unexploded Ordnance (UXO) Threat & Risk Assessment with Mitigation Strategy. Project: Aberdeen Offshore Wind Farm. This is also included as Appendix 7.1.

7.2 Baseline Assessment

9 Initially, the risk of encountering UXO was considered to be high (BACTEC, 2007). However, with the change in location, the majority of the site is now considered to be low risk, with a medium risk only occurring in a buffer around Black Dog Rifle Range.

10 There are a number of potential sources for UXO (BACTEC, 2007; 6 Alpha, 2010):

- military ranges (Royal Navy and British Army)
- munitions dumping grounds
- sea mines (British and German)
- anti-aircraft artillery (AAA) projectiles
- coastal gun batteries
- unexploded bombs
- wrecks
- convoy routes

11 While most of the ordnance is from World Wars (WW) I and II, it rarely becomes inert or loses effectiveness with age.

12 There are four firing ranges in the area (Figure 7.1), but only Black Dog Rifle Range is close enough to affect the proposed EOWDC (and two are beyond the extent of the figure). This facility was a WWII military land service ammunition site, and is now a small arms range.

13 There is one munitions dumping ground in the area, but this is directly east of Aberdeen (Figure 7.1) and considered too far south for munitions to have migrated to the proposed site.

14 There was a defensive mine field off the east coast of Scotland that was cleared after WWII, although clearance methods are not considered 100 % effective. However, this is 18 km from the proposed development and therefore too far away to be impacted.

15 Aberdeen was regularly bombed throughout WWII, and an AAA battery was deployed at Black Dog. However, the locations of any unexploded shells cannot be determined through desk study, and therefore must be acknowledged as a background risk across the whole area. The SS Archangel was sunk by bombs to the north of the proposed site (Figure 7.1) which confirms bombing activity in the area.

16 There have been no munitions wrecks identified in the area.

7.3 Impact Assessment

17 The 6 Alpha report presents a semi-quantitative risk assessment for the project. This classifies areas as Low (Tolerable or Partly Tolerable risk), Medium (Intolerable risk) and High (Highly Intolerable risk).

18 In the areas classed as Low, there is a “remote to possible” chance of encountering UXO, mainly from the background risk of unexploded bombs or AAA.

19 In areas classed as Medium, it is “likely to very likely” that ordnance would be encountered. These areas should be avoided if possible. If not, then a full UXO survey should be undertaken, including diver or ROV (remote operated vehicle) inspection of any finds. Two of the wind turbines are located within an area classed as medium.

20 In areas classed as High, it is “almost certain” that ordnance will be encountered, and these should be avoided.

21 Figure 7.1 shows the classification across the EOWDC site. The majority of the site is classed as Low, ie only a remote chance of encountering UXO. However, there is Medium risk in a buffer around the Black Dog Rifle Range, so it is considered highly likely that there is a chance of encountering UXO. This buffer encompasses Wind Turbines 2 and 3, which means that further UXO specific investigation would be required at these sites before installation begins. This could be a UXO geophysical survey with a diver or ROV inspection of any possible finds.

7.4 Summary

22 A risk assessment for encountering UXO was undertaken for the proposed EOWDC site (6 Alpha, 2010). This concluded that the main ordnance threat was due to the Black Dog Firing Range, extending beyond the range itself and specifically affecting Wind Turbines 2 and 3, where further investigation would be required. Outside this area, there is a low UXO risk to this project, which is considered to be the “background residual risk”.

European Offshore Wind Deployment Centre

Environmental Statement

Chapter 8: Coastal Processes

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

8 COASTAL PROCESSES

8.1 Introduction

1 ABPmer was commissioned by the Applicant to undertake an assessment on coastal processes. This section defines the baseline (existing) coastal processes within the study area and presents the potential impacts of the development relative to this baseline regime. In order to assess the potential effects of EOWDC relative to the baseline (existing) coastal environment, a combination of qualitative assessment of site data, empirical evaluation and detailed numerical modelling has been used to establish the potential magnitude and significance of the predicted changes. These effects have been assessed using the 'worst case' characteristics of the proposed development, as provided by the project. Considerations of the proposed effects upon the tide and wave regimes have been made and the subsequent impacts upon a series of receptors determined, including the offshore seabed morphology and littoral sediment regime. Comment has also been made to address relevant concerns raised by consultees, as fully presented in Appendix 4.2.

2 The following technical reports support this chapter and can be found as:

- European Offshore Wind Deployment Centre: Coastal Processes Baseline Report (Appendix 8.1) and
- European Offshore Wind Deployment Centre: Coastal Processes Assessment Report (Appendix 8.2)

8.1.1 Methodology Consultation

3 The scope of present considerations undertaken for coastal processes considers the specific issues raised through project consultation in combination with the generic project requirements, as detailed in present guidance.

4 A series of coastal process topics were raised as a result of the consultation of the Environmental Impact Assessment (EIA) Scoping Report (Appendix 4.1). Responses from four organisations were provided which have concerns relevant to coastal process issues. The full list of organisations whom submitted responses relevant to coastal processes at the current development are:

- Aberdeen Harbour Board Scottish Natural Heritage (SNH) Scottish Environmental Protection Agency (SEPA) and
- Marine Scotland

8.1.2 Key Guidance Documents

5 Guidance on the generic requirements, including spatial and temporal scales for coastal process studies is provided in six main documents:

- 'Offshore wind farms: guidance note for Environmental Impact Assessment in respect of Food and Environmental Protection Act (FEPA) and Coast Protection Act (CPA) requirements: Version 2' (Department for

Environment, Food and Rural Affairs (Defra), Centre for Environment, Fisheries and Aquaculture Science (Cefas) and Department for Transport (DfT), 2004)
- ‘Guidance on Environmental Impact Assessment in Relation to Dredging Applications’ (Office of the Deputy Prime Minister, 2001);
- ‘Nature Conservation Guidance on Offshore Wind Farm Development’ (Defra, 2005)
- ‘Marine Renewable Energy and the Natural Heritage: An Overview and Policy Statement’ (Scottish Natural Heritage, 2003)
- ‘Coastal Process Modelling for Offshore Wind Farm Environmental Impact Assessment’ (COWRIE, 2009); and
- Consenting, EIA and HRA Guidance for Marine Renewable Energy Deployments in Scotland’ (EMEC & Xodus AURORA, 2010)

8.1.3 Data Information and Sources

6 The main data and information sources are summarised as follows, for further details on these data sources the reader is referred to Appendix 8.1.

- Five months of metocean survey between 12th September and 13th February 2008 (Emu, 2008a)
- Geophysical surveys covering the original study area (Emu, 2008b) and the EOWDC site (Osiris, 2010)
- Geotechnical review of existing borehole information (Setech, 2009)
- Grab samples covering the previous site collected by the Fisheries Research Services (FRS) (Titan, 2008), covering the EOWDC site collected in 2010 by the Centre for Marine and Coastal Studies (CMACS Ltd) and covering the intertidal are adjacent to the EOWDC (Appendix 8.1) Beach profiles collected by ABPmer(Appendix 8.1); and
- Water level data collected in Aberdeen Harbour by the British Oceanographic Data Centre’s (BODC) National Tide and Sea Level Facility (NTSLF) between 1980 and 2005

7 Reports from other previous work have also been compiled that describe various aspects of the study area, the principal studies are summarised below:

- Aberdeen Bay Coastal Protection Study (Halcrow Crouch Ltd, 1999)
- Coastal Cells in Scotland, Cell 2 (HR Wallingford, 2000)
- Coastal processes and management of Scottish estuaries, The Dee, Don and Ythan Estuaries (Stapleton and Pethick, 1996)
- Beaches of Northeast Scotland (Ritchie et al, 1977); and
- SEA 5 (DTI, 2005)

8.2 Baseline Assessment

8 The baseline, or pre-construction, phase considers the coastal processes prior to any wind farm works. The investigation of this phase is relevant as it provides a condition to which the coastal processes during all other phases can be compared. It should be noted that any changes to the coastal processes within the lifetime of the array due to natural variability will also be compared to this phase.

9 The pre-construction phase forms the baseline which has been discussed within the preceding report (Appendix 8.1).The proposed development is located between 2 and 4.5 km offshore in water depths ranging from 10 to 30 mCD (below Chart Datum). The seabed has a gentle gradient from the offshore to the shoreline, which increases in a shoreward direction. There is no evidence of large-scale bedform features within the proposed EOWDC site (Emu, 2008a; Osiris, 2010). In the shallower areas west of the site some seabed features are present including wave-induced ripples, areas of exposed glacial material and a shore parallel ridge (Figure 8.1).

10 Tidal range within the proposed site is 3.4 m and 1.7 m under mean spring and neap tidal conditions, respectively. Peak tidal currents have been measured at less than 1.1 m/s (near-surface) within the proposed EOWDC site, decreasing in magnitude towards the shore. Average near-bed and surface speeds recorded are approximately 0.22 m/s and 0.33 m/s, respectively. The peak flow occurs at approximately the times of high and low water, with slack water occurring mid-tide. The tidal axis is orientated approximately shore parallel, flooding towards the south-southwest and ebbing towards the north-northeast (Figure 8.2). Flood currents are slightly stronger than those of the ebb tide. The rectilinear nature of the tide increases from near-surface to the mid-water column.

11 The most frequently occurring waves within the proposed EOWDC site (based on observations made during a 5 month winter survey) are between 0.5 and 1.0 m significant wave height and originate from the southeast. The largest wave heights recorded within this period are of the order of 5.5 m and originate from the east (Figure 8.3). Further offshore, due to the absence of coastal sheltering, northerly wave directions predominate.

12 Analysis of the exposure conditions (tides, waves) in view of the surficial seabed sediments experienced within the array has been undertaken to assess the potential mobility of the seabed. Within the proposed EOWDC site, the seabed material has been observed to be predominantly sand (grain diameter 150 micrometre (µm)) with some mud and gravel in places. The presence of different size fractions acts to provide some armouring to the seabed. It is shown that both tidal and wave processes influence sediment mobility, with tides having a greater influence in the offshore. Analysis of tidal currents measured near the seabed shows that tidal asymmetry within the lower water column results in a net northerly transport of the typically present sand sized sediment. However, the seabed sediment transport regime within the wind farm boundary is not particularly active with respect to these size fractions.

13 The net direction of longshore transport has been shown to be in a northerly direction and under the control of waves (the more frequent waves originate from the southeast). This is evidenced by the rivers that have typically been deflected to the north due to the sediment deposition at the mouths. However, the southerly orientation of a spit across the mouth of the River Ythan at the northerly end of the bay indicates the potential for net southerly directed littoral transport in this part of the bay. Wave refraction causes some southerly directed transport in the far southern part of the bay adjacent to the mouth of the Dee. The rate of littoral transport decreases towards the north of Aberdeen Bay as a consequence of its changing alignment, an observation which is supported by the fining of beach sediment towards the north.

However, under extreme storm events, the potential alongshore transport potential is much greater in the north of the Bay than the south.

14 Aberdeen Bay is characterised by dune backed sandy beaches. Some aeolian exchange of dry sediment occurs between the dunes and the beach, with the beach supplying sediment to the dunes under ‘normal’ wind and wave activity. Some sediment may also be released back onto the beach during storm events through wind erosion and wave erosion in conjunction with high water levels. The overall erosion of the beach indicates that current sediment sources are not adequate to maintain the beach profile. This is probably due to the limited transfer of sediment from offshore.

8.3 Impact Assessment

8.3.1 Impact Assessment Methodology

15 A combination of qualitative assessment of site data, empirical evaluation and detailed numerical modelling has been used to establish the potential magnitude and significance of the predicted changes. These effects have been assessed using the ‘worst-case’ characteristics of the proposed development, as provided by the project. These are presented in Table 8.1.

TABLE 8.1 **Scenarios Assessed for Coastal Processes**	
Potential Impact	**Likely scenario assessed**
Phase: Construction and decommissioning	
Increase in suspended sediment concentrations as a result of installation / removal activities	Foundation Installation: 2,100 m^3 of sediment disturbed for the installation of each monopile foundation. Total of 11 structures with an installation period of 5 days per wind turbine/foundation. Monopile with diameter of 8.5 m and maximum burial depth of 37 m. Sediment disturbed includes combination of mud and fine sand, released in-situ next to structures. Cable Installation: 405,000 m^3 of sediment disturbed for 26 km of cable installation using mass excavation methods. Installed at rate of 500 m/hr and 5 m/hr in water depths greater and less than 2 m, respectively. Maximum depth and width of trench 3 m and 10.38 m, respectively. Sediment disturbed includes combination of mud and medium sands.
Phase: Operational	
Changes to processes acting within Aberdeen Bay. Including: (i) Changes to the tidal and wave regimes as a result of the presence of the turbine foundations. (ii) Changes to the seabed form receptor	Array consisting of 11 Gravity Base Structures with base diameter 40 m, tapering to 6.5 m at 10 m below Lowest Astronomical Tide (LAT). Cumulative effect allows for the addition of Ocean Laboratory located approximately 300 m from the nearest turbine. Represented as a Gravity Base Structure with dimensions as per the array structures.
Introduction of seabed scour as a result of the presence of construction equipment and turbine foundations.	Includes monopile, jacket, tripod, gravity base and suction caisson/bucket structures. Cumulative effect allows for the addition of Ocean Laboratory located approximately 300 m from the nearest wind turbine. Represented as a Gravity Base Structure with dimensions as per the array structures.
Changes to processes acting to maintain the Aberdeen Bay coastline	Array consisting of 11 Gravity Base Structures with base diameter 40 m, tapering to 6.5 m at 10 m below LAT.

16 Numerical models from the Danish Hydraulics Institute (DHI) have been applied to assess the effects of the potential development upon the existing coastal processes within the site and the wider sub-tidal area. Another numerical model ‘XBeach’ has also been used to determine potential changes to the beach morphology and nearshore (littoral) regime. The potential for localised scour around the turbine foundations has been assessed using empirical methods on the basis of foundation design information and the baseline understanding of tidal, wave and sedimentary environments.

17 When assigning significance to an impact, the methodology can be summarised as follows:

- the magnitude of the effect (Table 8.2) is determined based on a combination of the spatial extent, the duration and the scale of the effect; and

- the sensitivity of the receptor is determined by considering the recoverability and the importance of the receptor and assigning a value of very high, high, medium or low

18 Using a combination of these criteria, impacts are assigned an impact significance rating of major, moderate, minor or negligible (Table 8.3).

19 This approach to impact assessment is based on matrix as supplied by the Applicant (See Table 4.2). It is important to note that this approach assumes that all impacts are adverse or detrimental in nature, however, some impacts might actually have beneficial implications for the receptor concerned.

TABLE 8.2
Outline Criteria for Assessing the Magnitude of the Effect (adapted from AOWFL, 2010a)

Rating	Spatial extent criteria	Duration criteria	Scale criteria
Very High	National/ International	>10 years	Very high level of change compared to background
High	Regional	5 – 10 years	High level of change compared to background
Medium	Local (<5km)	1 – 5 years	Medium level of change compared to background
Low	Site specific	<1 year	Low level of change compared to background
Negligible	Restricted to the immediate vicinity	Negligible	Negligible level of change compared to background

TABLE 8.3
Matrix Used to Assign Level of Significance (Adapted from AOWFL, 2010a)

Magnitude of effect (based on combination of criteria in Table 1)	Sensitivity of Receptor			
	Very High	High	Medium	Low
Very High	Major	Major	Major	Moderate
High	Major	Major	Moderate	Minor
Medium	Major	Moderate	Moderate	Minor
Low	Moderate	Minor	Minor	Negligible
Negligible	Minor	Negligible	Negligible	Negligible

8.3.2 Potential Impacts: Construction and Decommissioning Phases

8.3.2.1 Changes to Processes Acting within Aberdeen Bay as a Result of the Presence of Construction Equipment

20 The temporary presence of construction equipment is not considered to affect the tide and wave regimes. Consequently any impacts upon seabed morphology would be small in magnitude, temporary and localised.

21 In terms of coastal processes, the offshore seabed form is considered to be of low importance as it does not have any designated features and is considered to be of medium recoverability (due to the weak tidal conditions limiting the frequency and magnitude of sediment mobility).

22 The potential impact has been assessed of negligible magnitude, low sensitivity and therefore of negligible significance.

8.3.2.2 Seabed Changes as a Result of the Presence of Construction Equipment and Wind Turbine Foundations eg Scour

23 Construction vessels may use jack-up legs or a number of large anchors to hold station during construction operations. These (in conjunction with an additional limited amount of sediment scouring) may leave indentations on the seabed, post construction. The maximum footprint of the construction equipment would result from the use of one 6-legged jack and one 6-legged barge per wind turbine installation, with a total footprint per wind turbine of 4,200 m^2. This amounts to 0.021 % of the EOWDC lease area per wind turbine location.

24 The relative seabed immobility may mean that the indentations persist over the short-term. However, due to the small area of the potential indentations, this impact is considered to be of negligible magnitude.

25 The potential impact has been assessed of negligible magnitude, low sensitivity and therefore of negligible significance.

8.3.2.3 Potential Impact: Increase in suspended sediment concentrations as a result of installation / removal activities

26 During the installation of the foundation structures and cables, there is the potential for sediment re-suspension and subsequent dispersal. The scoping exercise identified sensitive receptors within nearby European designated sites and also concerns regarding sediment deposition within Aberdeen Harbour.

27 Sediment re-suspension and dispersal has been considered using numerical modelling techniques. Sediment resuspension rates vary between operations and are dependent upon the duration of works and the sediment volume released. The scenarios tested are provided in Table 8.1.

28 The localised resuspension of material by construction equipment during both foundation installation and cable burial leads to sediment dispersal in suspension both within the site and the wider area. Whilst sediment is being actively released, material in suspension initially accumulates within Aberdeen Bay. Once installation activities cease, the remaining suspended sediment is more widely dispersed, reverting to ambient background levels.

29 Results indicate that suspended sediment concentration levels are typically <8 mg/l and <40 mg/l, above natural background levels, for the foundation and cable works, respectively. Localised maximum concentrations of 100 mg/l and 90 mg/l, above natural background levels, also occur for the foundation and cable works, respectively but these are shown to be short-lived. Measured suspended sediment concentrations within the EOWDC array are shown to a maximum of 43 mg/l (Emu, 2008). The results are illustrated in Figures 8.4 and 8.5. Concentrations are given as depth-averaged values and as such may be slightly higher towards the bed and lower towards the water surface. Cable burial using mass excavation tools is

shown to produce a greater increase in suspended sediment concentration levels relative to the foundation installation works.

30 Due to the fine nature of the sediments suspended by the construction activities (Table 8.1), there was found to be little potential for measurable deposition of material within Aberdeen Bay and so upon sensitive receptors. It was found to be more likely that the material would become widely dispersed in the offshore environment.

31 A very small proportion of the total volume of sediments suspended may be entrained into Aberdeen Harbour by normal tidal exchange. The largest total volume of silt sized sediment potentially resuspended by the installation of foundations would result from 11 gravity bases and is equivalent to a maximum of 0.2 m unconsolidated sediment thickness, if deposited directly and evenly over an area equivalent to that of Aberdeen Harbour. Naturally occurring processes of advection, dispersion and sediment settlement in the coastal environment make it highly unlikely that any significant proportion of the total sediment volume disturbed would actually enter and subsequently settle inside the harbour. It is also unlikely that all foundations would be gravity bases, given the nature of the EOWDC development, further reducing the total sediment volume and the potential for its accumulation elsewhere.

32 A very small proportion of the total volume of sediments suspended may be entrained into Aberdeen Harbour by normal tidal exchange and as a consequence of the one-off short-term (52 hour) cable installation activity. It is, however, considered that, given the short-term duration of the installation works combined with the naturally occurring processes of advection, dispersion and sediment settlement in the coastal environment, it is highly unlikely that any significant proportion of the total sediment volume disturbed would actually enter and subsequently settle inside the harbour. Should the mass excavator tool not be used, the total sediment volume would be further reduced as would the potential for its accumulation elsewhere.

33 The potential impact within the Aberdeen Harbour has been assessed of low magnitude, medium sensitivity and therefore of minor significance.

34 Localised, temporary increases in sediment concentrations are shown to occur into areas designated for conservation at a European level. Some of the designations are for the onshore dune and coastal habitat features which would not be affected by temporary increases in marine suspended sediment levels. The marine exposed area affected by localised changes in suspended sediment concentration changes is along the Buchan Ness to Collieston coast. The temporary, localised concentration elevations above natural background levels, which may occur here are less than 8 mg/l.

35 The potential impact within designated sites has been assessed of low magnitude, high sensitivity and therefore of minor significance.

8.3.3 Potential Impacts: Operational Phase

8.3.3.1 <u>Changes to Processes acting within Aberdeen Bay</u>

36 Sediment transport within Aberdeen Bay is controlled by both the tidal and wave regimes, with the latter shown to exert a sizeable, relative, contribution

to the mobilisation of seabed sediments. The wave regime is shown to have a predominant influence upon the littoral sediment transport (Section 8.3.3.3). The absence of significantly large bedforms within the offshore area is probably due to a combination of weak tidal currents not creating bedforms and wave events further flattening the seabed during storm events.

37 The analyses of impacts on both the tidal and wave regime have demonstrated no significant impacts; whilst tidal currents may be slightly modified (<0.05 m/s) this does not occur at the time of peak flow and so the naturally occurring range of speeds remains unaffected (Figure 8.6). With respect to water levels, the analysis showed no measurable increases or decreases in this parameter. Significant wave heights (Hs) are reduced in the lee of the wind turbines by a small amount (< 0.1 m) for frequent, low energy wave conditions. For the most frequently occurring wave conditions (Hs 0.5 to 1.0 m from the south-east), wave height changes of less than 0.05 m are more common (Figure 8.7). As expected, it is under the larger wave heights that the largest absolute differences and spatial extents of effect are observed. The largest reported reduction in wave height is localised to within the immediate lee of individual wind turbines and is markedly less elsewhere (< 0.01 m at the shoreline) (Figure 8.7).

38 The combined changes to the tidal and wave regimes are not expected to have any significant impacts on the offshore sediment regime.

39 In terms of coastal processes, the offshore seabed form is considered to be of low importance as it does not have any designated features and is of medium recoverability due to the weak tidal conditions.

40 The potential impact has been assessed of negligible magnitude, low sensitivity and therefore of negligible significance.

8.3.3.2 Introduction of seabed scour as a result of the presence of turbine foundations

41 Currents and wave induced flow would interact with the foundations, resulting in accelerated flow and elevated turbulence at the seabed adjacent to the structure's edge. The resulting increase in bed shear stress and potential for sediment mobilisation results in sediment scour whereby a depression is formed in the seabed around the base of the foundation. The rate of scour development is generally rapid enough for the equilibrium scour depth (for the given flow conditions in unconsolidated non-cohesive sediments) to be achieved over a period of a few tides. Using empirical relationships, the equilibrium scour depth for each foundation type resulting from a combination of both waves and currents was calculated and summarised in Table 8.4.

TABLE 8.4
Summary of Scour Characteristics Assuming a Uniform Erodible Sediment

Parameter	**Foundation Option**				
	Monopile	**Jacket***	**Tripod**	**Gravity Base**	**Suction Caisson**
Equilibrium Scour Depth (m)					
Steady Current	11.05	3.25	3.25	7.2	3.6
Waves	Negligible	0.5	2.2	1.6	0.8
Waves and current	≤ 11.05	≤ 3.25	≤ 3.25	18	9
Group Scour	N/A	~1	~1	N/A	N/A
Scour Extent					
Scour extent from foundation ** (m)	18	5	5	12	6
Scour footprint ** (m^2)	1,445	1,472	1,101	1,865	466
Foundation footprint (m^2)	57	20	15	1,257	314
Scour Volume**					
Scour volume (m^3)	6,228	749	884	6,214	777

* Bed prep volume negligible if corner piles are inserted without drilling
** Extent and area excluding the foundation. Values based upon the scour depth for steady currents. Footprint and volume values per foundation.
Whilst these calculations assume an uniform erodible sediment, the presence of the Wee Bankie formation at, approximately, 10m to 20m below the seabed is likely to restrict the scour depth.

42 In terms of scour depth, the gravity base structure has the potential to cause the largest impact due to its large dimensions. However, the estimated maximum depth (18 m) is unlikely to be attained due to the potential constraints arising from the sub-surface geology with a till surface (termed the Wee Bankie Formation) at, approximately, 10 m to 20 m below the present seabed level (Osiris, 2010). This layer is described as a soft to very stiff clay with occasional sand and gravel lenses (SEtech, 2009). Group scour is expected to be minimal and the risk for global scour is considered to be negligible.

43 The extent of scour from the edge of each foundation is also shown in Table 8.4. This is calculated assuming the profile of the scour pit is an inverted cone with slopes at the angle of repose for sand (32°). The footprint or area of the scour pit (excluding the foundation footprint) is also provided, together with the footprint of the foundation for comparison. The gravity base foundation would result in the greatest total scour footprint; the suction caisson would produce the least. Table 8.5 summarises the total foundation and scour footprints and as a proportion of the lease area.

44 The time required for the majority of scour pit development around each foundation within the EOWDC is estimated to be within the order of 6 to 12 hours (under flow conditions sufficient to induce scour). This makes the assumption of a mobile uniform non-cohesive sediment substrate. Symmetrical scour would only develop following exposure to both flood and ebb tidal directions. Waves do not typically cause rapid initial scour directly, but can increase the rate of initial scour development.

45 The potential impact has been assessed of medium magnitude, low sensitivity and therefore of minor significance.

TABLE 8.5 Summary of Predicted Scour as a Proportion of the Lease Area					
Parameter	**Foundation Option**				
	Monopile	**Jacket***	**Tripod**	**Gravity Base**	**Suction Caisson**
Number of devices	11	11	11	11	11
Seabed footprint of all devices (m^2)	624	216	162	13,823	3,456
Proportion of total site area (%)	0.003	0.001	0.001	0.069	0.017
Seabed footprint of all devices + scour (m^2)	16,625	7,354	12,269	34,339	8,585
Proportion of total site area (%)	0.083	0.037	0.061	0.172	0.043

8.3.3.3 Changes to Processes Acting to Maintain the Aberdeen Bay Coastline

46 The main control on the nearshore sediment transport (littoral) regime is wave processes and therefore the impact assessment is focussed upon this aspect.

47 Potential impacts on the littoral regime were assessed for both frequent, low energy and infrequent, high energy wave events and directions experienced within the study area. Therefore the climate assessed was that resulting from winds (and waves) coming from, at the offshore boundary northeast (60 °N); east (90 °N); southeast (120 °N); and south-southeast (150 °N) at speeds of 8, 12 or 16 m/s. These wave conditions were suitably transformed in the model by processes of refraction and shoaling across the study area and the nearshore bathymetry, simulating naturally occurring modification to wave height, period and direction in the area. The relative difference in the morphological response of 3 km of shoreline in the developments lee was calculated by comparing pre- and post-construction scenarios.

48 'Natural' cross-shore profile changes occur in response to different (naturally occurring) wave conditions. The beach response is also spatially variable and ultimately dependent upon the initial local morphology. As would be expected, the magnitude of the beach response increases with increasing wave height. Absolute beach elevation changes are less than 0.2 m when significant wave height (Hs) is less than 1 m; conversely, to induce a beach elevation change greater than 0.5 m requires a wave height, Hs of larger than 3 m, with an associated peak wave period (Tp) greater than 10 s. For context, more than 45 % of wave heights recorded by the project specific, 5 month, metocean campaign (EMU, 2008) are less than 1 m and the 10 in 1 year return period wave condition, as derived from a longer (30 years) data set, at the AWAC site is 2.1 m (Hs) and 7.3 s (Tp) (Appendix 8.1). The metocean survey therefore shows that the conditions required to result in a +0.5 m beach profile change can be considered as infrequent events.

49 The additional presence of the EOWDC is shown to result in small additional changes (+0.05 m) under everyday events and slightly larger (+0.2 m) under the less frequent events (Figure 8.8). The development has been shown to slightly reduce significant wave height at the adjacent shoreline and so is most likely to result in a reduced variability in beach elevations. Changes to the frequency or magnitude of beach level change attributable to the EOWDC are within the range of those occurring naturally and as such would likely be indistinguishable from the natural variability. Therefore, the changes that may be induced by the EOWDC are considered to be of low magnitude.

50 The potential impact has been assessed of low magnitude, medium sensitivity and therefore of minor significance.

8.3.4 Potential Impacts: Cumulative Effects

8.3.4.1 Changes to Processes Acting within Aberdeen Bay as a Result of the Cumulative Presence of Wind Turbine Foundations and the Ocean Laboratory

51 As with the wind farm array, the presence of the Ocean Laboratory has the potential to impact on the local tidal and wave regimes as they interact with the structure. Any changes to these regimes may have a resultant impact on the sediment regime (both offshore and coastal) and therefore requires consideration.

52 A comparison of Figures 8.6 and 8.9 indicates that the cumulative impacts of the Ocean Laboratory and the EOWDC does not induce a greater magnitude of change to the tidal regime beyond that predicted by the EOWDC alone. Flow speed changes are predicted in the immediate vicinity of the Ocean Laboratory structure, but these are no greater than those predicted in the immediate vicinity of each of the wind turbines. A comparison of Figures 8.7 and 8.10 indicates that the cumulative impacts of the Ocean Laboratory and the EOWDC does not induce a greater magnitude of change to the wave regime beyond that predicted by the EOWDC alone.

8.3.4.2 Introduction of seabed scour as a result of the cumulative presence of turbine foundations and the Ocean Laboratory

53 As with the wind turbine foundations, the Ocean Laboratory has the potential to create scour around its base. The scour extents calculated for the range of substructures considered in Section 8.3.3.2 indicates that scour is unlikely to extend more than 30 m from the centroid location of any structure. It is therefore not anticipated that there would be any interaction of scour between the foundations of the Ocean Laboratory and other wind turbines.

54 Additionally, the foundations are located within a staggered grid such that the rows are not tidally aligned, making it unlikely that there would be any interaction between the tidal wake of one foundation and another one downstream.

TABLE 8.5
Summary of Impact Assessment

Potential Impact	Significance Level	Mitigation	Residual Impacts	Monitoring
Phase: Construction and decommissioning

8.4 Summary

55 Considerations of the proposed impacts upon the tide and wave regimes have been made and the subsequent effects upon a series of receptors determined. These receptors include the offshore sediment transport pathways, offshore seabed morphology and littoral sediment transport pathways. Comment has also been made to address relevant concerns raised by consultees. The assessment was undertaken using 'worst case' characteristics of the proposed development, as provided by the project. It is shown that the majority of potential impacts are considered to be of negligible significance. Exceptions are scour development, short term changes to suspended sediment concentrations and subsequent localised deposition, and slight changes in the coastal response to naturally occurring storm events, which are all considered to be of minor significance

Environmental Statement

Chapter 9: Marine Ecology, Intertidal Ecology, Sediment and Water Quality

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

9 MARINE ECOLOGY, INTERTIDAL ECOLOGY AND SEDIMENT AND WATER QUALITY

9.1 Introduction

1 The construction, operation and decommissioning of an offshore wind farm will inevitably have some impact upon the physical properties of the seabed in the near vicinity of the wind turbines and cables, as well as on the nature of the overlying water. Consequently, this could have impacts upon the benthic communities, fish and, ultimately, on their predators (marine mammals and birds). The Institute of Estuarine and Coastal Studies (IECS) at the University of Hull was commissioned by the Applicant to assess the impact of the proposed European Offshore Wind Deployment Centre (EOWDC) in Aberdeen Bay on the marine ecology of the area. The assessment was carried out using a combination of knowledge of the existing environment (baseline conditions), the proposed project design (worst case) and the likely response of the environment to any potential changes (impacts) from the development (construction, operation and decommissioning).

2 The assessment covers all the aspects of the EOWDC development (wind turbines, foundations, cabling). The potential Ocean Laboratory would be subject to a separate consent application and is therefore considered within the assessment of cumulative impacts only.

3 The following technical reports support this chapter:

- Marine Ecology, Intertidal Ecology and Sediment and Water Quality Baseline Technical Report (Appendix 9.1)
- Marine Ecology, Intertidal Ecology and Sediment and Water Quality Environmental Impact Assessment Technical Report (Appendix 9.2)

9.1.1 Methodology Consultation

4 In order to investigate the potential effects on benthic, fish and shellfish communities in the proposed development area, consultation with appropriate regulatory and other key institutes and organisations was undertaken. Consultees included Scottish Natural Heritage (SNH), Marine Scotland, Scottish Environmental Protection Agency (SEPA) and Aberdeen City Council. A detailed list of consultees is reported in the EIA Technical Report (Appendix 9.2).

9.1.2 Key Guidance Documents

5 The key guidance documents used for the baseline and impact assessment are as follows:

- IEEM, 2010. Guidelines for Ecological Impact Assessment in the United Kingdom. Final document.
- Environmental impact assessment: guide to procedures http://www.communities.gov.uk/documents/planningandbuilding/pdf/157989.pdf
- CEFAS, 2004. Offshore wind farms: Guidance note for Environmental Impact Assessment in respect of FEPA and CPA requirements. Version

2. Prepared by the Centre for Environment, Fisheries and Aquaculture Science (CEFAS) on behalf of the Marine Consents Unit (MCEU). 45pp.
- SNH, 2010. Renewable energy and the natural environment. SNH.

6 Further key guidance documents are indicated in Appendix 9.2.

9.1.3 Data Information and Sources

7 The principal data information and sources were:

- EOWDC Baseline Technical Report for the European Offshore Wind Development Centre (Appendix 9.1)
- OSPAR, 2006. Review of the Current State of Knowledge on the Environmental Impacts of the Location, Operation and Removal/Disposal of Offshore Wind-Farms. Publication Number: 278/2006
- OSPAR, 2008. Assessment of the environmental impact of offshore wind-farms. Publication Number: 385/2008

8 The EOWDC Baseline Technical Report includes the results of site specific surveys undertaken. These include:

- EMU Ltd (2007) Geophysical and seabed habitat assessment of the then Aberdeen Offshore Wind Farm
- OSIRIS Projects Ltd (2010) Geophysical survey of the EOWDC
- Centre for Marine and Coastal Studies Ltd (CMACS Ltd) (2011) Benthic survey of the EOWDC

9 Further baseline data sources are indicated in the EIA Technical Report (Appendix 9.2).

9.2 Baseline Assessment

10 The seabed sediments in the proposed EOWDC are largely homogeneous, with a gradation related to depth and distance from the shore. At inshore stations, medium-fine well-sorted sands dominate, whereas sediments further offshore and at deeper sites are dominated be fine-very fine muddy sands.

11 Overall, sediment contamination in the area is in line with the background contamination levels reported for the North East Atlantic Sea. The concentrations of all contaminants measured during the site specific survey were below the Probable Effects Level (PEL) throughout the area. All hydrocarbons, organotin and polychlorinated biphenyls (PCB) concentrations were below the limit of detection.

12 The intertidal substratum is mainly comprised of sandy shores with an intertidal fauna dominated by mobile crustaceans (such as haustorid amphipods). Sedentary species are less abundant as would be expected given the moderate exposure of the shores in this area.

13 The sublittoral benthic community changes mainly along the gradient of depth/distance offshore. Lower numbers of species and abundance are found in the infaunal community of the inshore shallower stations, where the polychaetes *Nephtys cirrosa* and amphipods dominate. Higher numbers of species and abundance are present further offshore, where the polychaetes

Notomastus latericeus, the bivalves *Nucula nitidosa* and *Tellina fabula* and brittle stars *Ophiura* spp. dominate. These two communities are described by the two biotopes: SS.SSA.IFiSa.NcirBat (inshore) and SS.SSA.CMuSa.AalbNuc (offshore).

14 The invertebrate epifaunal community present in the proposed project area is sparse and composed mainly of brittle stars, brown shrimp (*Crangon crangon*) and swimming crab (*Liocarcinus holsatus*). The most common and abundant fish species are dab (*Limanda limanda*) and plaice (*Pleuronectes platessa*). These species are more abundant as juveniles at shallower inshore stations suggesting the possible presence of nursery grounds in the area. Other common fish species in the area are whiting (*Merlangius merlangus*) and hooknose (*Agonus cataphractus*), these more abundant offshore. Commercially important species (e.g. whiting, cod *Gadus morhua*, Norway pout *Trisopterus esmarki*), although present in the proposed development area, are associated mainly with deeper waters.

15 No known spawning grounds are present in the proposed development area. Spawning grounds do occur: further offshore (for herring (*Clupea harengus*)), on coarser sediments (for sandeel (*Ammodytes marinus*)) or on muddier sediments (for *Nephrops*) than those present in the proposed development site.

16 No statutory designated marine protected areas have been identified within the proposed development area. There are however several protected species that are known to use the area. These include Atlantic Salmon (*Salmo salar*) which is a Annex II species listed on the Habitats Directive and which requires the establishment of Special Areas of Conservation (SACs). Atlantic Salmon have been addressed further within Chapter 22 Salmon and Sea Trout. The River Dee SAC also contains populations of the freshwater pearl mussel (*Margaritifera margaritifera*). This is a rare and threatened species, being one of the primary reasons for the selection of the River Dee SAC. It is highly dependent on the presence on Atlantic salmon and sea trout (*Salmo trutta*) as hosts for their larvae and therefore has the potential to be affected by the EOWDC.

9.3 Impact Assessment

9.3.1 Impact Assessment Methodology

17 The assessment has used the combination of development options which is considered to have the greatest potential for detrimental impact on the marine ecology of the area. The impacts assessed are therefore considered to be the worst case and assume that the development would comprise 11 wind turbines of 10 MW capacity constructed over a single phase. The foundation and scour protection options have been assessed using a worst case for each receptor group.

18 The various receptors that may be affected by the development (namely intertidal benthos, subtidal benthos, epibenthos, shellfish and fish) have been considered in relation to the phases of the EOWDC lifecycle, ie construction, operation and decommissioning. Impacts arising from decommissioning activities have been assumed to be similar to those generated from

construction works, although in most cases the magnitude of potential impact would be considerably lower.

19 In order to assess the magnitude of an effect, its spatial extent, duration and scale have been taken into account by gathering this information from available literature and previous assessments of similar effects. The assessment of the sensitivity of a receptor has been based on its importance and recoverability, as gathered from the baseline technical report, and, where available, from additional assessments of impacts on the same or similar receptor.

20 The evaluation of the magnitude of effect and of the sensitivity of receptor has then been combined in a final assessment of the impact significance, following the matrix in Table 9.1.

TABLE 9.1
Matrix for Significance of Impact

		Sensitivity of Receptor			
Magnitude of Effect based on spatial, duration and scale of effect		**Very High**	**High**	**Medium**	**Low**
	Very High	Major	Major	Major	Moderate
	High	Major	Major	Moderate	Minor
	Medium	Major	Moderate	Moderate	Minor
	Low	Moderate	Minor	Minor	Negligible
	Negligible	Minor	Negligible	Negligible	Negligible

9.3.2 Impact Assessment

21 Impacts on intertidal and subtidal benthic assemblages have been assessed in relation to: the release of toxic material, sediment disturbance, re-suspension and re-deposition, underwater noise, vibrations and Electromagnetic Field (EMF) emissions, hydrographic modifications, temperature increase (around the cable routes) and habitat loss (either temporary and permanent) and gain (introduction of artificial habitats). For benthic and epibenthic communities, these impacts have been assessed as being of negligible to minor significance, due to their general low to medium magnitude and to the high recoverability of the receptors.

22 Impacts on fish from piling noise during construction/decommissioning have been assessed as of minor to potentially moderate significance (Table 9.2). This is based on the precautionary approach adopted in the assessment of the possible effect on herring spawning grounds, given the lack of specific data on their local distribution within the area of influence of the impact.

23 Potential impacts on the River Dee SAC populations of freshwater pearl mussel (*Margaritifera margaritifera*) are directly related to impacts on salmon and sea trout which are discussed in Chapter 22 Salmon and Sea Trout. Impacts on salmon and sea trout are not expected to be above minor provided adequate mitigation measures and consultation with relevant stakeholders is carried out, particularly for the construction phases of the project.

TABLE 9.2 Summary of Impact Assessment				
Potential Impact	**Significance Level**	**Mitigation**	**Residual Significance**	**Monitoring**
Construction / Decommissioning				
Underwater noise and vibration on Fish	Minor to Moderate	Noise mitigation at source (eg soft-start procedure)	Minor to Moderate	Monitoring would be agreed with the relevant statutory authorities

9.3.3 Cumulative and In-Combination Impact Assessment

24 The only foreseeable development in Aberdeen Bay that has been considered in the context of cumulative assessment is the potential Ocean Laboratory, which is anticipated to result in a negligible/minor adverse impact. The impacts arising from the construction, operation and decommissioning of this structure are likely to be broadly similar (in type) to those assessed for the proposed EOWDC. However, given the smaller scale of the potential Ocean Laboratory, these impacts are likely to be of lower magnitude compared to those from the proposed EOWDC. Any additive effects are considered to be minimal in the context of existing predicted impacts. There are no other activities or developments that are in close proximity to the development that are anticipated to result in any adverse cumulative or in-combination impacts.

9.4 Summary

25 The proposed site contains physical, chemical and biological characteristics which resemble those of much of the surrounding area of Aberdeen Bay. No important sensitivities have been identified, except for the possible presence of salmonid migration routes and associated freshwater pearl mussel populations, addressed within Chapter 22 Salmon and Sea Trout, and of herring spawning grounds (which occur within the influence of piling noise during the construction of the proposed development).

26 Potential impacts on the marine ecology of the area arising from the construction, operation and decommissioning of the proposed development are generally considered to be of negligible to minor significance, and no significant cumulative impacts have been identified. Although the potential for moderate impacts on sensitive fish has been identified from the piling noise generated during construction, the basis for this assessment level is largely precautionary due to information paucity on the actual distribution of specific herring spawning grounds in the area.

27 The possibility of cumulative impacts arising from the installation of the proposed Ocean Laboratory on the proposed EOWDC site has been considered, but is expected to be minimal.

28 The assessment has not identified any potential adverse impacts on protected species or habitats when the development has been considered in context of other plans or projects.

Company Experience
ABPmer is a specialist consultancy providing high quality scientific advice for interests relating to the marine environment. Major clients include ports, coastal authorities, nature conservation bodies, government departments, marine industries and other engineering and environmental consultancies.

Staff resources are managed and developed in four key areas:
•Coastal Processes;
•Data (including field survey and GIS);
•Modelling; and
•Environment.

In relation to the present study, ABPmer is recognised as a leading authority on coastal process investigations for offshore wind farms, both in terms of advancing generic science and offering project specific services. Our experience and expertise in relation to offshore wind developments includes:

•Oceanographic/metocean survey and survey design;
•Coastal process studies;
•Production of Environmental Impact Assessments and Environmental Statements; and
•Metocean analysis for operation, maintenance and design.

ABPmer is a longstanding member of Renewable UK, REA and is represented at the Offshore Renewable Energy Environmental Forum (OREEF).

Key Staff

Project Director:	Mr Bill Cooper
Project Manager:	Dr. Claire Hinton
Quality Manager:	Dr. David Lambkin

Offshore Renewables (and related) Experience

Anatec's experience in relation to assessments for offshore renewables includes carrying out the following:

- Site Selection Screening (Rounds 1-3, Scottish Round, Pentland Firth Marine Round and other ad-hoc areas upon request)
- Provision of Shipping Data (merchant, fishing & recreational craft)
- Radar Surveys (covering sites in Scotland, England, Wales and Northern Ireland from onshore and offshore).
- Risk Modelling (meeting MCA and DECC Standards)
- Assessment of Mitigation Measures
- Consultation/Liaison
- Cumulative Assessment
- TWA & CPA application support
- Expert Witness for Robin Rigg Parliamentary Committee & Scarweather Sands Public Enquiry

In the past seven years, Anatec have completed navigational risk assessments for the majority of Round 1 and 2 Offshore Windfarm sites in the UK, including.

- Robin Rigg, Solway Firth (Consented)
- Rhyl Flats, Liverpool Bay (Consented)
- Burbo Bank, Liverpool Bay (Consented)
- Scarweather Sands, South Wales (Consented)
- Cromer, North East Norfolk (Consented)
- Inner Dowsing, Lincolnshire (Consented)
- Lynn, Lincolnshire (Consented)
- Walney Offshore Wind Farm (Consented)
- London Array (Consented)
- Ormonde (Consented)
- Greater Gabbard (Consented)
- West of Duddon Sands(Consented)
- Cirrus Shell Flat Array (Withdrawn)
- Lincs (Consented)
- Sheringham Shoal(Consented)
- Docking Shoal (In Progress)
- Race Bank (In Progress)
- Humber Gateway (Consented)
- Westermost Rough (In Progress)

We also performed the navigation risk assessments for the SW Wave Hub project off St Ives, the Wave Dragon project off Milford Haven and EMEC Fall of Warness Tidal Site in Orkney. Other wet renewables projects Anatec has been involved in include site assessment reviews for Trident Energy and Lunar Energy.

Brown & May Marine Ltd

Summary of Experience

Brown and May Marine Ltd has been undertaking studies and services relating to various interfaces that occur between commercial fishing and, offshore renewable energy, offshore oil and gas developments and cable installations since 1982. Given below are examples of the work undertaken.

Commercial Fisheries Components of EIA's

The commercial fisheries components for the EIA's and ES's have been completed for the following offshore wind farm developments in the UKCS:

- Scarweather Sands - Green Energy, Swansea Bay 2004 – 2005
- Walney 1&2 - Dong Energy, Eastern Irish Sea, 2005 – 2008
- West of Duddon Sands - Scottish Power, Eastern Irish Sea 2005 – 2006
- Shell Flats 2 - Scottish Power, Eastern Irish Sea 2006 – 2007
- Lincs - Centrica, Wash 2006 – 2007
- Docking Shoal - Centrica, Wash 2007 – 2008
- Race Bank - Centrica, Wash 2007 – 2008
- Dudgeon - Warwick Energy, North Sea 2007 – 2008
- Gunfleet Sands 2 - Dong Energy, Thames Estuary 2007 – 2008
- Aberdeen Offshore Wind- Amec, Aberdeen Bay 2007 – 2008
- Westermost Rough - Dong Energy, North Sea 2008 – 2009

We are currently engaged in commercial fisheries works for ten Round 2 and 2.5 wind farms and six Round 3 wind farms.

Fisheries Liaison

Fisheries liaison work, public meeting attendance, and compensation assessment and advice provided for:

- Dong Energy
- Warwick Energy
- Centrica
- Scottish Power
- Vattenfall
- SSE Renewables
- EON
- Seagreen
- Sea Energy
- EDP Renovaveis

Experience in Scottish Waters

Brown and May Marine Ltd (BMM) have more than thirty years experience undertaking commercial fisheries assessments in Scottish waters.

In 1980 BMM staff undertook a Commercial Fishing Interaction Study for Shell Expro's Flags pipeline in the Northern North Sea, the first study specific to commercial fishing activities to be undertaken in the UK. This work contributed to the pipeline being awarded the first trenching dispensation in the UK Continental Shelf.

Over the past thirty years in excess of a hundred commercial fishing studies have been carried out in Scottish Waters for the offshore oil and gas and subsea cables industries.

BMM has established a strong working relationship with the Scottish Fishermen's Federation (SFF) for over twenty five years, working together on a range of projects not only in Scottish waters, but using their fishing experience to aid projects further afield.

BMM additionally has good working relationships with Marine Scotland, having worked closely with both the Science department (formerly Fisheries Research Services) and the formerly named Scottish Fisheries Protection Agency (SFPA), as well as with various district fisheries officers.

BMM has experience of the Scottish Atlantic salmon fisheries, and have liaised in the past with both commercial and recreational stakeholders and statutory consultees.

Examples of recent work undertaken in Scottish waters during the past 18 months are listed below:

- BP West of Shetland – Commercial Fishing Study and Interaction Frequency
- Conoco – Philips – Commercial Fishing Interaction Study for Jasmine pipeline
- Aberdeen Offshore Windfarm - Commercial Fishing Assessment and Impact Assessment
- Aberdeen Offshore Windfarm – Salmon and Sea trout Baseline Assessment
- Enagas: Experience sharing with the SFF. A series of visits organised by BMM subsequent to a Commercial Fishing Study undertaken in the Mediterranean to facilitate sharing the SFF experience of fishing in waters shared with the offshore oil and gas industry.
- Airtricity: FLO to the proposed Beatrice offshore wind farm development. FLO to the proposed Islay and Kintyre offshore wind farm developments. Contracted to undertake the commercial fishing aspect of the EIA (Ongoing).
- Scottish Power: FLO and EIA advice for Islay tidal energy project

The works we are currently undertaking are listed below:

- Beatrice Offshore Wind Farm- Commercial Fisheries EIA, Salmon & Trout EIA, and overall Fisheries Liaison Officer
- Moray Offshore Wind Farm- Commercial Fisheries EIA, Salmon & Trout EIA, Natural Fisheries EIA, and overall Fisheries Liaison Officer
- Aberdeen Offshore Wind Farm- Commercial Fisheries EIA, Salmon & Trout EIA, and overall Fisheries Liaison Officer
- Firth of Forth Offshore Wind Farm- Commercial Fisheries EIA and overall Fisheries Liaison Officer
- Inch Cape Offshore Wind Farm- Overall Fisheries Liaison Officer
- Neart Na Gaoithe Offshore Wind Farm- Commercial Fisheries EIA, Salmon & Trout EIA, and overall Fisheries Liaison Officer

- Islay & Kintyre Offshore Wind Farm- Commercial Fisheries EIA and overall Fisheries Liaison Officer

Genesis Oil & Gas Consultants Ltd. was formed in 1988 and now employs over 700 engineers and scientists spread across main offices in Aberdeen, London, Paris, Perth (Australia); with smaller offices in Norway, Abu Dhabi and Brazil. We specialise in the energy industry with major projects world-wide. Our key skills are in offshore engineering, safety and the environment addressing all project phases from planning and concept design to operational support both for traditional oil & gas and the renewable energy sectors.

One of the challenges for offshore wind power is the difficulties in designing, installing, operating and maintaining rotating equipment in remote locations in the harsh North Sea environment. This challenge is dealt with on a daily basis by engineers in the oil and gas industry and the expertise possessed by Genesis is directly transferable into the renewable energy market. Our work on permitting (safety & environment) and foundation selection and design are areas where we have brought significant experience to the renewable market.

The key skills provided by Genesis are:

- Consents management and Environment Impact Assessment, onshore and offshore;
- Concept design;
- Foundation selection and design;
- Environmental studies including bird impact studies, underwater noise modelling, habitat assessments and marine mammal studies;
- Project execution and management services;
- Safety assessments;
- Rotating equipment design and support;
- Power system and network studies;
- Reliability and availability prediction for machinery and power output;
- Instrumentation and SCADA design; and
- Operational support

Examples of our client work has included environmental, safety and engineering support to the European Offshore Wind Deployment Centre where we have been responsible for engineering and environmental support to the project, safety support to the Beatrice wind farm and concept design for the Havsul offshore wind farm.

Major projects include:

- Environmental and engineering support to EOWDC with input to major sections of the Environmental Statement and the production of specialist studies on habitats, other users of the sea, marine mammals and noise. Genesis has also been involved in providing planning and engineering support including, structural and electrical studies.
- Engineering support to the Havsul offshore wind farm in Norwegian waters providing key advice on the selection and design of the foundations.
- Genesis provided technical safety support to the Beatrice Demonstrator project where our role included facilitating and participating in hazard identification sessions and writing the draft safety case for operation of the project as an appendix to the existing Beatrice Safety Case.
- Genesis provided advice to SeaEnergy Renewables on suitable HSE management system structure and the development of HSE plans.

HarmonicQuay is the trading name for Dr Genevra Harker, and provides project management, environmental and oceanographic expertise to the energy sector, with the main focus on renewable energy projects. Building on initial experience in the offshore oil and gas industry Dr Harker has worked on numerous UK offshore wind farms including Neart na Gaoithe, Hornsea Zone, Dogger Bank Zone, Race Bank, Docking Shoal, Lincs, Lynn, Inner Dowsing, Gunfleet Sands, Scarweather and Shell Flats. She has also worked on desk studies for wind farms in France and the US.
For the EOWDC, her main role was technical reviewer.

Summary of Expertise

Hayes McKenzie Partnership Ltd (formerly Hayes McKenzie Partnership) have been specialising in the measurement, assessment and control of noise from wind farm sites for 20 years. During that time this has included work on over 600 proposed, consented or completed wind farm sites in the UK, Continental Europe, USA, Canada, Australia, New Zealand and Asia; source noise measurements on around 30 turbine types, measurements of residential noise levels at around 30 existing wind farms and provision of expert witness evidence for over 70 UK public inquiries. Our clients have included most of the major UK wind farm developers and have included many successful applications, including those gained at Public Inquiry.

All consulting staff are members or associate members of the Institute of Acoustics and Dr McKenzie sits on the joint Institute of Acoustics / Institute of Environmental Assessment Working Group on Environmental Noise Impact Assessment and BERR Working Group 3, Small and Micro Wind Turbines. They were invited contributors to the Australian Standard Acoustics – Measurement, prediction and assessment of noise and wind turbine generators. The company currently has 9 full time consultants and 3 administrative staff and sources all measurement equipment from its own stocks. It is a member of the Association of Noise Consultants.

Key Staff Involved

Dipl.-Ing. Sylvia Broneske MIOA

After graduating from the University of Applied Sciences, Hamburg, Germany with a degree in Environmental Engineering, Sylvia Broneske worked as an Engineer and Consultant in the Site Assessment department of the wind turbine manufacturer Enercon GmbH, Germany.

Her scope of duties included noise and shadow impact assessment for wind farm developments; supervising noise measurements of Enercon wind turbines; advising co-workers, authorities, clients/developers and wind farm neighbours on wind turbine noise-related issues; solving complaints about wind farm noise and optimisation of noise-critical Enercon wind farm sites; calculating periods of shadow flicker and programming the ENERCON shadow shutdown system to prevent shadow flicker at surrounding properties.

In 2007 she joined Hayes McKenzie Partnership Ltd. in Salisbury and is now an acoustic consultant responsible for the preparation of Environmental Impact Assessments for wind farm developments; other noise assessment work for planning

purposes; planning condition compliance tests and source noise measurements of wind turbines, recently in particular of several small wind turbines.
She has given lectures on noise from wind turbines on several occasions, including the 2007 UK Institute of Acoustics one-day meeting on Windfarm Noise and the Wind Turbine Noise Conference in Aalborg/Denmark in 2009. She has recently been invited to speak at a two day conference on wind farm noise in the UK at the KCE Akademie in Germany.

She is currently undertaking an MSc course in Sound and Vibration at the Institute of Sound and Vibration Research (ISVR) at the University of Southampton, continuing to work part-time at Hayes McKenzie Partnership. She is a member of the Institute of Acoustics and of the Verein Deutscher Ingenieure, the German equivalent of the Institute of Mechanical Engineers.

Robin Woodward BSc AMIO

Robin graduated from the ISVR/University of Southampton with a BSc in Acoustics and Music. He joined HMPL in 2010 and is currently carrying out the deployment of measurement equipment for environmental noise surveys in connection with wind farm developments in England and Scotland, the analysis of data and noise predictions and assists with the preparation of Environmental Impact Assessments.

Malcolm D Hayes BSc MIOA – Director of Hayes McKenzie Partnership Ltd

Member of DTI Working Group on Noise from Wind Turbines and of Eskdalemuir Seismic Array Working Group; Member of the Organising Committee for International Conference on wind turbine noise Berlin (2005), Lyon (2007), Aalborg (2009) and Rome (2011)

HEADLAND
ARCHAEOLOGY Ltd

Headland Archaeology (UK) Ltd

Headland Archaeology (UK) was founded in 1996 and has since grown to become the largest archaeological company in Scotland, with offices in Edinburgh, Glasgow, Hereford and Leighton Buzzard, whilst the Irish arm has offices in Cork, Galway and Dublin. Headland offers a wide range of services and specialises in major projects such as the M74 Completion Project, Glasgow, A1 and A4 road schemes, Northern Ireland, Clyde Wind Farm, South Lanarkshire, and Upper Forth Crossing, Clackmannanshire.

Headland is a Registered Organisation of the IfA and abides by its Code of Conduct. The company is Achilles Category B2 accredited.

Headland has considerable experience of conducting EIAs throughout the UK, and has particularly extensive experience in relation to wind farms

UNIVERSITY OF Hull
Institute of Estuarine & Coastal Studies

Institute of Estuarine & Coastal Studies (IECS) at the University of Hull

Summary of Experience

The Institute of Estuarine and Coastal Studies (IECS) has been undertaking research and consultancy work in the estuarine and marine environment since 1982 and has both extensive survey and analysis facilities, together with a range of expertise within our professional staff and Associates. IECS is a multi-disciplinary research and consultancy organisation set up to utilise the facilities and expertise in coastal margin science and management within the University of Hull. IECS covers a wide range of specialisms within the coastal environment ranging from the biological and physical environments (topography, vegetation, ornithology, benthic and pelagic fauna) to coastal planning, environmental quality, marine law and environmental impact assessment.

LDA DESIGN

Introducing LDA Design

Founded in 1979, LDA Design is a renowned independent design and environment business driven by a commitment to shape the world for the better. We provide tailormade solutions to every project. We help our clients regenerate communities, create special places, manage resources and realise their development and commercial goals.
LDA Design attracts people who are leaders in the planning, design, delivery and management of all types of change in the physical environment. We work on projects of all scales across the UK and internationally. Our talented and experienced team approaches each commission as a fresh, creative and practical challenge.
The special abilities of the practice include taking complex projects through an increasingly demanding planning system from concept to delivery. This collaborative and ideas-led approach to problem-solving, combined with the technical abilities we have cultivated over many years, uniquely positions us to meet the challenges arising from climate change and the need for development. Our strength lies in the way that we bring together the diverse skills and experience of our team in a working culture that combines creativity with pragmatism and commercial awareness.

Services and Areas of Expertise

LDA Design brings together all the services necessary for the creative and technical leadership of complex development, regeneration and environmental projects. These skills can be brought into a multidisciplinary team as a specialist expertise if necessary.

- Masterplanning
- Urban Design
- Regeneration
- Landscape Architecture
- Ecology
- Architecture
- Development Planning
- Strategic Land Promotion
- Green Infrastructure
- Rural Consultancy
- Environmental Impact Assessment
- Historic Environments
- Environmental Planning
- Renewable Energy
- Community Asset Management

Support Services
To support our work and goals we have further complementary professional skills in-house, including:

- Expert Witness / Public Inquiry
- Event and Exhibition Organisation
- Graphic Design and Animation
- Public Consultation
- Public Relations
- Media Liaison

Our clients include developers, land-owners, regeneration agencies, government departments, local authorities, renewable energy firms and educational establishments.

For a full client list and further information about us visit our website www.lda-design.co.uk

Wessex Archaeology

Company Experience
Wessex Archaeology is a market leader working in the archaeological and broader heritage world: above ground, below ground and underwater. Established 25 years ago, and today employing a professional staff of over 200, Wessex offers an unrivalled range of archaeological services.

Wessex Archaeology has been involved in over 200 coastal and marine schemes, both development-led and strategic, including numerous schemes relating to the offshore renewables industry and has undertaken both offshore and onshore work, including programmes specifically designed to assess archaeology / cultural heritage and impact on setting.

Wessex Archaeology has a strong track record in providing the full range of archaeological services required to support development schemes in respect of renewable energy projects. Wessex Archaeology's Coastal and Marine service expertise encompasses desk-based cultural heritage assessments for EIAs, REAs, strategic assessments and industry guidance, and further work in support of these studies in the form of geophysical survey and geo-archaeological investigations.

Wessex Archaeology's experience in the area of renewables encompasses over 20 offshore wind farms, a wave power generator, a tidal power generator and Historic Environment guidance for the whole offshore renewables sector.

European Offshore Wind Deployment Centre
Environmental Statement

Appendix 1.2: Household Calculations

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

Household Calculations

If consented and built it is expected that the EOWDC at 100 MW would generate up to 306,600 megawatt hours (MWh) of green electricity every year, which is equivalent to the total annual electricity needs of around 68,468 UK households*.

*This is calculated in the following way:

Number of hours in the year: 8760
Installed capacity: 100 MW
Assumed capacity factor for offshore wind: 35%
Average annual UK household electricity consumption: 4,478 kilowatt hours (kWh)

For example: (8760 x 100 x 0.35) x 1000 = 306,600,000 kWh divided by 4,478 = 68,468 homes.

Share of households that would have been provided with electricity from the EWODC in 2008: 68,468/102,900[1]= 66.5 %

Estimated share of households provided with electricity from the EOWDC in 2013: 68,468/108,150 = 63.3 %

[1] This assumes number of households in Aberdeen was 102,900 in 2008. This is based on the "Household Projections for Scotland 2008-based" from the General Register Office for Scotland (2010).

European Offshore Wind Deployment Centre
Environmental Statement

Appendix 1.3: Statutory and Regulatory Framework and Policies

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

STATUTORY AND REGULATORY FRAMEWORK

The construction and operation of the EOWDC will require a consent under Section 36 of the Electricity Act 1989 (as amended). The Electricity Act 1989 (Requirement of Consent for Offshore Generating Stations) (Scotland) Order 2002 requires Section 36 consent for the installation of any generating station with a permitted capacity of 1MW or above. Section 36A enables the Scottish Ministers when granting consent also to make declarations extinguishing rights of navigation.

Section 57(2) of the Town and Country Planning (Scotland) Act 1997 provides that the Scottish Ministers can direct that planning permission for development of the section 36 application or ancillary development can be deemed to be granted. The requirement for planning permission may apply to only a small portion of the export cable.

In formulating an application for a Section 36 consent the applicant is obliged to have regard to the desirability of preserving natural beauty, of conserving flora, fauna and geological or physiographical features of special interest and in protecting sites, buildings and objects or architectural, historic or archaeological interest. Furthermore the applicant is obliged to do what he reasonably can to mitigate any effects which the proposal would have on such matters. In considering any proposals the Scottish Ministers are obliged to have regard to the desirability of preserving the list of assets and also the extent to which the applicant has complied with their duty reasonably to mitigate any effects. The applicant is also obliged to avoid so far as possible causing injury to fisheries or to the stock of fish in any waters.

In addition to a Section 36 Consent the EOWDC will also require a marine licence in terms of the Marine (Scotland) Act 2010. This Act imposes a number of duties upon the Scottish Ministers in respect of the grant of any marine licence. It includes an obligation under Section 3 to act in a way which is best calculated to further the achievement of sustainable development, including the protection or where appropriate the enhancement of the health of that area. Furthermore in terms of Section 4 the Scottish Ministers are obliged to act in a way best calculated to mitigate, and adapt to, climate change so far as consistent with the purpose of the function concerned. In terms of Section 15 all public authorities are obliged to take authorisation decisions in accordance with appropriate marine plans unless relevant considerations indicate otherwise. Furthermore, in the determination of a marine licence application, Section 27 implies certain statutory requirements on the determination process. The Scottish Ministers must have regard to the need to protect the environment, human health and prevent interference with legitimate uses of the sea and such other matters as the Scottish Ministers consider relevant. These are all matters which have been considered and assessed within the Environmental Statement. The construction of EOWDC will constitute the construction of works within the Scottish marine area both in and over the sea and on and under the seabed. The Scottish Ministers must have regard to the effects of any use intended to be made of the works after they have been constructed.

Decommissioning

The decommissioning of the EOWDC has been considered and assessed within the Environmental Statement. The Energy Act 2004 only applies to decommissioning the EOWDC beyond the mean low water mark. The marine licensing regime will therefore deal with the intertidal decommissioning issues.

ENERGY POLICY

European Policy

Renewable Energy Directive (Directive 2009/28/EC)

The Renewable Energy Directive (Directive 2009/28/EC) is the primary guidance in respect of European Union renewable energy policy. The Directive: (1) establishes a common framework for the promotion of renewable energy throughout the European Union; and (2) sets legally binding targets on member states for the use of renewable energy, in particular requiring 20% of the overall energy consumption in the European Union to come from renewable sources by 2020 (Article 3 and Annex I). Unsurprisingly, wind power is explicitly stated to be a renewable energy source (Article 2(a)).

The Directive's policy of setting legally binding targets means that the UK must achieve 15% of its energy needs by renewable sources by 2020, from a base level in 2005 of 1.3% (Annex I). This is an ambitious target which will require a broad spectrum of renewable technologies, including a significant contribution from offshore wind power. Indeed, a European Union communication[1] takes the view that, "while land-based wind energy will remain dominant in the immediate future, installations at sea will become increasingly important."

UK Government Policy

Climate Change Act 2008

The Climate Change Act 2008 is legislation which legally binds the UK Government to ensure that net emissions of greenhouse gases in the UK are reduced by at least 80% by 2050 (from 1990 emission levels). By 2020, the 2008 Act requires a reduction of at least 34% from 1990 emission levels.

National Renewable Energy Action Plan for the UK

In response to Article 4 of the Renewable Energy Directive, the UK Government produced the *National Renewable Energy Action Plan for the UK* ("Renewable Energy Action Plan"). The Renewable Energy Action Plan seeks to outline the UK Government's strategy to meet its legally binding target of 15% of total energy needs being met by renewables by 2020. At page 7, the Renewable Energy Action Plan states:

> "Offshore wind is a key area for development. We will work to develop an offshore electricity grid to support our continuing commitment to being world leaders in this technology. This new generation of offshore wind power will play a key role in meeting our 2020 target."

Further, at page 87, the Renewable Energy Action Plan states:

> "The scale of the offshore wind potential around the UK strengthens the economic, policy and security of supply arguments for working to maximise this offshore renewable potential…"

A Prevailing Wind: Advancing UK Offshore Wind Deployment

In June 2009, the UK Government published *A Prevailing Wind: Advancing UK Offshore Wind Deployment* ("A Prevailing Wind"). This policy document outlines the UK Government's policies in respect of offshore wind. The UK government expects an offshore contribution of some 25GW by 2020. A Prevailing Wind notes, however, that "there is a need for new renewable energy infrastructure to meet the [UK] Government's climate change mitigation and energy objectives. That need is sufficiently great and urgent that it should be given substantial weight in determining an application which contributes to meeting the [UK] Government's climate change mitigation and energy objectives."[2]

Further, A Prevailing Wind pragmatically adopts the policy that "[t]here will by their nature be significant impacts from offshore wind farms wherever they are located, but these may be positive impacts and, where they are adverse they may be acceptable when weighed against the national need for new energy infrastructure."[3]

Scottish Government Policy

Notwithstanding that energy policy is a matter reserved to the UK Government, the Scottish Government has brought forward ambitious legislation (Climate Change (Scotland) Act 2009) and policies to advance renewable energy in Scotland, working closely with the UK Government to do so.

Climate Change (Scotland) Act 2009

The Climate Change (Scotland) Act 2009 is legislation which legally binds the Scottish Ministers to ensure that net emissions of Scottish greenhouse gases are reduced by at least

---

[1] Offshore Wind Energy: Action needed to deliver on the Energy Policy Objectives for 2020 and beyond, published 13 November 2008, COM (2008) 768 final

[2] *A Prevailing* Wind, ch 2.5

[3] *supra*, ch 2.7

80% by 2050 (from 1990 emission levels). By 2020, the 2009 Act requires a reduction of at least 42% from 1990 emission levels.

In addition to the targets set in the 2009 Act, on 18 May 2011 the First Minister announced a commitment to generating the equivalent of 100% of Scotland's own electricity demand from renewable resources by 2020, with offshore wind playing a key role in achieving this ambitious target.

Renewables Action Plan

In June 2009, the Scottish Government published its *Renewables Action Plan* ("RAP"), containing the Scottish Government's various policies towards renewable energy. According to the RAP, the Scottish Government expects offshore wind:

> "To make a significant contribution to 2020 renewables targets and beyond. To maximise economic benefits to the Scottish Economy, and enable a young industry to establish, whilst working in harmony with the marine environment."

Additionally, the RAP highlights the Scottish Government's ambition "to drive the success of the Scottish offshore wind industry, and facilitate the timely development and installation of offshore wind projects within the Scottish Territorial Waters…" and "to build Scotland's position as a key base for the offshore wind, innovation, manufacturing and installation, leveraging its oil and gas experience."

Blue Seas – Green Energy: A Sectoral Marine Plan for Offshore Wind Energy in Scottish Territorial Waters

Further to the RAP, in March 2011 the Scottish Government published its policy document aimed specifically at offshore wind energy, entitled *Blue Seas – Green Energy* ("Green Energy Plan"). The Green Energy Plan recognises offshore wind as an integral element in Scotland's contribution towards action on climate change and seeks to maximise the contribution that offshore wind energy makes to renewable energy generation in Scotland, whilst recognising that Scotland must compete with the rest of Europe and globally to maximise its share of the renewable energy market.

Green Energy Plan – Specific policies in/around North East waters

Policy recommendations of the Green Energy Plan for North East waters towards offshore wind energy development in the North East of Scotland include:

1. Recognition that the North East is a suitable location to progress the development of offshore wind; and
2. The development of the short term [offshore wind] option should be taken forward.

Renewables Road Map

On 2 June 2011, during a Scottish Government debate, Energy Minister Fergus Ewing announced to MSPs that the Scottish Government would publish a "renewables road map" in due course.

MARINE POLICY

UK Marine Policy Statement

The UK Marine Policy Statement (MPS) sets out the framework for preparing subsequent Marine Plans and taking decisions that will affect the marine environment. Consistent throughout the MPS is the intention that the marine planning system will help to promote the economic and social benefits intrinsically linked to proposed marine developments by placing a presumption in favour of sustainable development.[4]

Underlying the MPS are a number of key objectives, including a desire to "*achieve a sustainable marine economy and ensure a strong, healthy and just society*".[5] The policies can be read together, as by maximising sustainable marine economy, greater prosperity and opportunities will develop.

The MPS stipulates that any enforcement or authorisation decisions that directly, or which could potentially, affect the UK marine area must be made within the context of the relevant marine policy documents.[6] For the time being, this is limited predominantly to the MPS, as the national marine plans have still to be adopted.[7]

Continuing with the concurrent policies of economic and social prosperity, the MPS emphasises that a sustainable and affordable supply of energy is paramount to these key objectives and particularly that the marine environment will be at the forefront of sustainable solutions to the UK's energy supply and distribution.[8] Consequently, sustainable offshore development, whilst still considering relevant environmental protections, will be a priority for marine planning.[9] Offshore wind is noted as being integral to this strategy, as it is seen as currently the most mature of the offshore renewable energy technologies, and has the potential to have the most significant impact on security of energy supply, which in turn will mitigate the impact of climate change.[10]

Separately, the MPS draws attention to the potential impact of the ancillary electronic networks linked to offshore infrastructure and accepts that there is an inevitable environmental impact associated with underwater cables. However, the MPS notes that the impact from cable installations on the seabed is low and mainly a result of physical disturbance linked to their initial placement. As such, they tend to be of short duration with a relatively small area being affected.[11]

Draft Scotland National Marine Plan Statement

The draft National Marine Plan (NMP) sets out the policies for sustainable development of Scotland's seas and includes economic, social and marine ecosystems objectives. Included within the core objectives is the "*need to develop the marine sector to deliver both economic activity in Scotland and to assist the delivery of Scotland's climate change objectives*"[12]. As such, the Scottish Government's view is that there should be a presumption in favour of marine development.[13]

Particular to the offshore wind context, the NMP sets out that "*the continued exploitation of energy sectors will remain essential for the future growth of the Scottish economy and for our way of life*".[14] The Scottish Government intends to maximise the potential of the described benefits through exploitation of its marine energy resources, particularly though the development of onshore and offshore grid connection to both the UK and Europe. However, the draft also seeks to reach a balance by looking to limit as far as possible the

[12] Draft NMP, pg 13
[13] Draft NMP, pg 26, para 9.2
[14] *supra*, pg 59

cost to the Scottish marine environment.[15] This balance will still enable Scotland to capitalise on its wind energy potential to assist with the climate change objectives, which will in turn generate new economic activity and consequently benefit Scotland socially.[16]

This referenced economic and social benefit underlies the NMP's declaration that the Scottish Government is committed to promoting the increased use of offshore renewable energy sources, with the expectation that the development of offshore wind (and marine and tidal energy) can trigger significant economic growth in Scotland, including the creation of 30,000 jobs by 2020.[17]

Sectoral Marine Plan for Offshore Wind Energy in Scottish Territorial Waters

The Sectoral Marine Plan for Offshore Wind Energy in Scottish Territorial Waters (the "Plan") is a strategic planning document for the development of offshore wind energy in Scottish Territorial Waters. It represents the vision for the delivery of energy from offshore wind resources, and contains proposals for offshore wind development at regional level up to 2020 and beyond. It is to be interpreted in the context of both the National and Regional Marine Plans, whilst being integrated into and used to advise the emerging marine planning framework.

Specific to the North East Region (Moray Firth), the Plan finds that there are favourable conditions and significant potential for the development of offshore wind both within Scottish Territorial Waters and beyond into Scottish Offshore Waters.[18] It highlights the significant issues relevant to offshore development in the Region as those relating to fishing and the environment, with shipping appearing to be less significant. However, it qualifies the findings by noting that on the current evidence available, those issues highlighted could be addressed and mitigated during project planning.[19]

No doubt referencing the MPS and NMP, the Plan notes that the scale of development of offshore wind represents one of the biggest opportunities for sustainable economic growth within Scotland for a generation, with potential investment of £7.1 billion over the next decade and the creation of upwards of 28,000 direct jobs in Scotland by 2020,[20] a figure consistent with the NMP. The Plan also recognises that the infrastructure in place through the available ports and harbours offer viable locations to service the associated construction and maintenance activities. It further highlights that appropriate marine development could lead to Scotland capturing one-third of the UK energy supply market, which would in turn potentially secure an additional £100bn of investment.[21]

As well as the potential stake in the UK market, the Plan also highlights that Scotland could realise up to 25% of Europe's wind potential, and from an environmental perspective, the Plan expressly refers to offshore wind as an integral element in Scotland's ambitious contribution towards climate change.[22]

PLANNING POLICY

NATIONAL POLICY

National Planning Framework for Scotland – NPF2

The NPF2 reinforces the need for a sustainable economic growth together with sustainable development and climate change. Energy forms a key focus of the document and that is reflected in paragraphs 144 to 165. Renewable energy and in particular offshore wind is specifically supported. In addition technical constraints, such as upgrades to the electricity grid, have been given priority in respect of delivery. Paragraphs 204 and 205 identify the specific challenges and opportunities facing Aberdeen and Aberdeenshire. The concept of a global energy hub is supported, including building existing offshore strengths into new renewable and clean energy technologies.

SCOTTISH PLANNING POLICY – FEBRUARY 2010

The SPP replaced all existing Scottish Planning Policy documents and provides a comprehensive national policy context. At the outset the SPP identifies that the central purpose of the planning system is to achieve increasing sustainable economic growth. It identifies the importance of development plans in delivering this objective. This is further explained in paragraph 33 which seeks to encourage the planning system to enable growth whilst at the same time protecting and enhancing the quality of the natural and built environment. The SPP also identifies the importance of sustainable development in formulating the National Planning Framework and Development Plans. Climate change is also specifically recognised as an issue in paragraphs 40 to 44. Coastal Planning is dealt with in paragraphs 98 to 103. Paragraph 101 explicitly identifies that one of the activities to be taken into account in coastal planning is land based development associated with offshore renewable energy generation. The paragraphs also recognise the importance of the coastal area for recreation and from a conservation perspective. The policy relating to the Historic Environment is contained in paragraphs 110 to 124. The importance of Landscape and Natural Heritage to Scotland is reflected in paragraphs 125 to 164. This provides National Policy in relation to both landscape and nature conservation. In terms of renewable energy paragraphs 182 to 195 provide policy guidance. Offshore renewable generation is specifically considered in paragraph 192. National Policy supports the development of renewable energy but the document pre-dates subsequent increases in the targets for electricity to be generated from renewable sources (see Energy Policy above).

DEVELOPMENT PLANS

The development plan for the area includes:-

- The Aberdeen City and Shire Structure Plan, approved on 14 August 2009.
- The Aberdeenshire Local Plan adopted in June 2006.
- The City of Aberdeen Local Plan adopted in June 2008.

The currently adopted Local Plans were both drafted to conform to the former Structure Plan, North East Scotland Together, which was approved in June 2002. There are currently two proposed Local Plans which will replace the currently adopted Local Plans. The Development Plan Policy will only be directly relevant in respect of a small element of the offshore proposal relating to the export cables between the mean low water mark up until the mean high water spring tide level. In that regard the most relevant policies in that respect are likely to be those relating to coastal zones and also those relating to landscape, visual, cultural heritage and access and leisure. In addition, a number of the effects of the EOWDC will occur onshore and planning policy has been referred to in assessing some of the receptors within the Environmental Statement. These are documented in the individual technical reports.

THE ABERDEEN CITY AND SHIRE STRUCTURE PLAN

The Aberdeen City and Shire Structure Plan was drafted to be a more strategic document than the traditional Structure Plan and reflected the approach being introduced through planning reform. It is, therefore a document which adopts a strategic approach and which seeks to guide development up to 2030.

The plan provides the vision and aims. The aims include:-

- To grow and diversify the regional economy.
- Take on the urgent challenges of sustainable development and climate change.
- To protect and improve valued assets and resources including the built and natural environment and cultural heritage.

The spatial strategy moves away from that formerly advocated in the previous Structure Plan and there is a new focus on three key growth areas. These include Aberdeen City and a strategic area from Aberdeen to Peterhead, along the A90. Within the Aberdeen to Peterhead growth area the value of the development of the Menie Estate is recognised. The area is also to host the "Energetica" initiative which seeks to develop and diversify the economy with a strong focus on energy.

After setting out the spatial strategy the Structure Plan goes on to provide objectives. Those of most relevance include economic growth, sustainable development and climate change and the quality of the environment. In terms of economic growth there is a strong desire to continue to grow the Aberdeen City and Shire economies. The Energetica initiative is again specifically referred to in paragraph 4.3.

In respect of sustainable development and climate change the Structure Plan incorporates a target:-

> "For the City region's electricity needs to be met from renewable resources by 2020".

There is strong support for the technology which can help to contribute to the supply of renewable energy. The quality of the environment objective identifies the importance of both built, natural and cultural heritage assets.

ADOPTED LOCAL PLANS

Both adopted Local Plans deploy strategies which were incorporated within the former Structure Plan and which have been altered by the new Structure Plan. The weight to the strategic context is therefore reduced. Both Local Plans however include development control policies which are potentially of relevance.

THE ABERDEENSHIRE LOCAL PLAN

In respect of the Aberdeenshire Local Plan the policies of most relevance are likely to include:-

- Policy Env 1, Env 2 and Env 3 provide applicable policies relating to Onshore Conservation Sites ranging from international to local sites.
- Policy Env 5A – the policy relevant to the protection of National Scenic Areas.
- Policy Env 5B – deals with areas of Landscape Significance (It should be noted that the coastal areas from the development plan boundary north of Aberdeen up to north of Collieston is designated as an area of landscape significance).
- Policy Env 6 deals with Coastal Development. This policy deals with specific criteria for considering proposals on the developed coast and also the undeveloped coast. This will potentially be relevant to certain of the onshore infrastructure associated with EOWDC.
- Policy Env 17 – Conservation Areas.
- Policy Env 18 – Listed Buildings.
- Policy Env 19 – Archaeological Sites and Ancient Monuments.
- Policy Env 20 – Historic Gardens and Design Landscapes.
- Policies Emp 9 and Emp 10 provide policies in relation to tourist facilities and accommodation and support leisure and recreation.

- Policy NF 7 provides policy relating to onshore renewable energy facilities for onshore wind. It adopts a tiered approach to identification of suitable locations. This is no longer consistent with national policy.
- The plan also includes general development policies which relate to all land based development. This includes policies such as Gen 1 and Gen 2 which are of general application.

CITY OF ABERDEEN LOCAL PLAN

The adopted Local Plan also adopts a strategic context from the former Structure Plan but at the same time also provides development control policies which would potentially be of relevance. These are as follows:-

- Policy 22 – Onshore Renewables. This adopts a similar tiered approach which is no longer consistent with national policy.
- Policy 26 – Coastal Management. This has specific policies on the developed coastal zone and applies specific criteria to the undeveloped zone.
- Policy 29 – provides a framework and Policy 31 provides a landscape protection policy.
- Policy 16 – Archaeology.
- Policy 32 – Historic Gardens.
- Policy 34 – Natural Heritage generally.
- Policy 35 – Access and Recreational Areas.
- Policy 81 – Aberdeen Harbour.

PROPOSED LOCAL PLANS

THE ABERDEENSHIRE PROPOSED LOCAL DEVELOPMENT PLAN

The Aberdeenshire Proposed Local Development Plan picks up the Structure Plan spatial strategy at Section 4 including the identification of the specific developments associated with the strategic growth area between Aberdeen and Peterhead. It includes a major extension to Ellon at Cromleybank, and other business land, a major extension to Peterhead and a major extension to the community of Blackdog. The plan thereafter sets out more general development control policies which are to be supplemented by supplemental planning guidance. The relevant policies are likely to include:-

  - Policy 1 – Business Development. This specifically identifies the "Energetica" initiative as a key development. The general policy is going to be supported by supplemental planning guidance on the development of employment land. (SGbus1)
  - Tourist Facilities and Accommodation. (SGbus4)
  - Policy 4 – Special Types of Rural Land. This policy heading also includes Aberdeenshire Coastal Zone and it is intended that there will be supplemental guidance dealing with development in the Coastal Zone. (SG STRL Type 1 Development on the Coastal Zone).
  - Policy 11 – Natural Heritage.
  - Policy 12 – Landscape Conservation.
  - Policy 13 – Protecting, Improving and Conserving the Historic Environment.

ABERDEEN PROPOSED LOCAL DEVELOPMENT PLAN

The Proposed Aberdeen Local Development Plan is primarily a map based one supporting the development strategy for the city. Within the draft Local Plan there is a substantial housing and longer term business proposal to the northeast of the city at Dubford & Murcar. Significant development is also proposed further up the Don Valley at Grandhome. The Local Plan also provides updated development control policies including:-

- D5 – Built Heritage.
- D6 – Landscape.

- B14 – Aberdeen Airport and Aberdeen Harbour.
- NE7 – Coastal Planning. This again draws the distinction between developed coastal areas and undeveloped coastal areas.
- NE8 – Natural Heritage. The River Dee is a Special Area of Conservation (SAC) is specifically referred to in the text above.
- NE9 – Access and Informal Recreation.
- R8 – Renewable and low carbon energy developments.

Subsea Noise Modelling in Support of the European Offshore Wind Deployment Centre Development

J. R. Nedwell, A. G. Brooker and R. J. Barham

29 March 2011

Subacoustech Environmental Report No. E278R0216

Approved by Technical Director: Dr J R Nedwell

This report is a controlled document. The Report Documentation Page lists the version number, record of changes, referencing information, abstract and other documentation details.

1 UNDERWATER NOISE IMPACT ASSESSMENT

1.1 Introduction

1 Subacoustech Environmental has been contracted by Aberdeen Offshore Wind Farm Ltd to investigate the potential impacts that the noise generated by the construction of the European Offshore Wind Deployment Centre (EOWDC) off the coast of Aberdeen may have on marine fauna, by means of subsea noise propagation modelling. Of particular concern is the noise generated during impact piling operations to install the foundations of the wind turbines and it is this aspect that this report concentrates on.

2 The EOWDC will be located within an area approximately 2 km from the coast that extends eastwards to approximately 4.5 km offshore. The depth of the wind turbine positions range from approximately 19 m to 30 m. The proposed project will combine a small commercially operated wind farm with a test and research centre, allowing manufacturers to test “first of run” wind turbines and innovative foundation solutions along with related operation and maintenance access logistics. The project may also include an Ocean Laboratory which would allow environmental monitoring before, during and after deployments.

3 Aberdeen Bay is an important area for several species of marine mammal, most notably bottlenose dolphin (*Tursiops truncatus*) but also harbour porpoise (*Phocoena phocoena*), grey seals (*Halichoerus grypus*) and harbour seals (*Phoca vitulina*). In summer months white-beaked dolphins (*Lagernorhynchus albirostris*), Minke whales (*Balaenoptera acutorostrata*) and Risso’s dolphins (*Grampus griseus*) have also been sighted.

4 The sections below initially provide some background to the metrics and accepted criteria for the assessment of underwater noise so providing some background to the subject. The report then presents the results of the modelling in which an estimation of the various impact ranges is given including the ranges for lethality, physical injury, auditory damage and behavioural avoidance.

1.2 Measurement of Underwater Noise

1.2.1 Introduction

5 Sound travels much faster in water (approximately 1,500 m/s) than in air (340 m/s). Since water is a relatively incompressible, dense medium, the pressures associated with underwater sound tend to be much higher than in air. As an example, background levels of sea noise of approximately 130 dB re 1 µPa (a definition of these units are covered in section 1.2.2) for UK coastal waters are not uncommon (Nedwell *et al*, 2003 and 2007). This level equates to about 100 dB re 20 µPa in the units that would be used to describe a sound level in air. Such levels in air would be considered to be hazardous. However, marine mammals and fish have evolved to live in this environment and are thus relatively insensitive to sound pressure compared with terrestrial mammals. The most sensitive thresholds are often not below 100 dB re 1 µPa and typically not below 70 dB re 1 µPa (44 dB re 20 µPa using the reference unit that would be used in air).

6 For this reason it is generally of little use and potentially misleading to directly compare sound sources underwater to those in air. Table 1.2-1 presents a summary of the typical levels of noise for various sound sources in air (HSE, 2005) and in water (Nedwell *et al*, 2003, Nedwell *et al,* 2007, Urick, 1983 and Parvin *et al,* 2007). From these data it is clearly evident that the typical levels of underwater noise are far higher than those found in air. This should be borne in mind when considering quoted levels of underwater noise.

Table 1.2-1 – Summary of typical levels of noise from various sources in air (all values referenced to 20 µPa) and in water (all values referenced to 1µPa)

Typical noise levels in air		Typical noise levels in water	
Sound Source	**Typical noise level (dB re 20 µPa)**	**Sound Source**	**Typical noise level (dB re. 1 µPa)**
Quiet office	~40 dB	Background noise	100 – 130 dB RMS
Conversation	~60 dB	Fishing trawler	168 dB RMS @ 1 m range
Pneumatic road drill	~100 dB	Impact piling	243 – 257 dB peak to peak @1 m
Jet aircraft taking off 25 m away	~140 dB	Underwater explosive blast	285 dB peak pressure @ 1 m

1.2.2 Units of Measurement

7 Measurements of underwater sound are usually expressed using the decibel (dB) scale, which is a logarithmic measure of sound. A logarithmic scale is used because rather than equal increments of sound having an equal increase in effect, typically a constant ratio is required for this to be the case, that is, each doubling of sound level will cause a roughly equal increase in "loudness".

8 Any quantity expressed in this scale is termed a "level". If the unit is sound pressure, as is the case with underwater noise, it will be termed a "Sound Pressure Level" (SPL). A refinement is that the scale such as when used with sound pressure is that the pressure squared is applied rather than the pressure. If this were not the case, if the acoustic power level of a source rose by 10 dB the Sound Pressure Level would rise by 20 dB.

9 As the dB scale represents a ratio (that is, the result of dividing one quantity by another base quantity), it is used with a reference unit which expresses the base from which the ratio is expressed. For underwater sound, typically a unit of one microPascal (µPa) is used as the reference unit; a Pascal is equal to the pressure exerted by one Newton over one square metre. One microPascal equals one millionth of this. It is important to state the reference unit when describing the level of a sound in decibels as the use of a different reference pressure for a given measured sound pressure will result in a different value. For underwater noise, therefore, a noise level would be expressed as "120 dB re 1 µPa", for example.

1.2.3 Quantities of Measurement

10 A sound level may be expressed in many different ways depending upon the particular type of noise that is being measured, and the parameters of the noise that allow it to be evaluated in terms of a biological effect. For example,

measurement of underwater noise following the detonation of explosives indicates a clear peak in positive (high) pressure and only a much smaller peak in negative (low) pressure. As the resulting impact on any surrounding objects is likely to be related to the positive peak, it is usually appropriate to quote the peak (sometimes also referred to as zero-peak) level of the sound.

11 For impact piling, however, where the pressure wave is roughly equal in positive and negative peaks, the resulting impact is likely to be related to both the positive and negative pressure peaks. It is therefore more appropriate to quote the level in terms of “peak to peak” levels which is the maximum variation between the positive and negative pressures in the sound wave. The zero-peak sound levels have also been included in this report for completeness.

12 When noise and vibration is of a continuous nature such as that associated with drilling, boring, continuous wave sonar, or background sea and river noise levels, it is more appropriate to characterise the noise level over a longer period of time. The variation in sound pressure is therefore measured over a specific time period to determine the Root Mean Square (RMS) level of sound that is varying with time. This is the RMS Sound Pressure Level (RMS SPL) which can be considered to be a measure of the average unweighted level of the sound over the measurement period.

13 Where a particular noise source is expressed in terms of RMS SPL it is necessary to quote the time period over which the RMS level is calculated. For instance, in the case of a transient noise source such as a pile strike lasting say a tenth of a second this is critically important as the mean taken over a tenth of a second will be ten times higher than the mean taken over one second.

14 Another way of expressing sound levels used in this study is the Sound Exposure Level (SEL), which sums the acoustic energy over a measurement period, and effectively takes account of both the SPL of the sound source and the duration the sound is present in the acoustic environment. Where the SPL is a measure of the average level of the broadband noise, the SEL sums the cumulative broadband noise energy. Therefore, for continuous sounds of duration less than one second, the SEL will be lower than the SPL. For periods of greater than one second the SEL will be numerically greater than the SPL (i.e. for a sound of ten seconds duration the SEL will be 10dB higher than the SPL, for a sound of 100 seconds duration the SEL will be 20 dB higher than the SPL and so on).

1.2.4 Source Level and Transmission Loss

15 As sound propagates through water it reduces in level as a result of losses relating to energy dissipation (absorption) and also due to the sound energy simply spreading over a wider area (geometric spreading). Typically, a source of underwater noise is quantified in terms of a Source Level, which is the level of sound energy released by the source, usually described as the level of underwater noise at a range of 1 m from the source. In order to characterise the rate at which energy is lost a value for the Transmission Loss is often given. The level at a particular point in the water space is therefore the Source Level minus the Transmission Loss.

16 Over short distances, absorption effects have little influence on the Transmission Loss and can often be ignored. The Source Level itself may be quoted in any physical quantity, for instance, a piling source may be expressed as having a "peak to peak Source Level of 200 dB re 1 μPa @ 1m".

17 This simple but convenient formulation ignores the practical difficulty of estimating the Source Level. Since the measurements are usually made at some distance from the source and extrapolated back to the source, the true level at 1 m may actually be very different from the Source Level used in these equations.

18 It is often not realised that, since the value of Source Level quoted for a particular source is obtained by extrapolation; the value will depend on the model that is used to perform the extrapolation. Figure 1.2-1 illustrates this point. The diagram illustrates a set of measurements made of the noise from piling. In the simplest case, in order to draw conclusions about the data, it may be fitted to a straight-line model; this is shown in the figure by the green line. Such a model effectively assumes that the noise level attenuates only as a result of geometric spreading. This however will generally over-estimate the level for low and high ranges, since it ignores the effects of absorption of the noise. An improved model, including absorption, is represented by the red line and gives a better fit to the data, and indeed this simple form is usually adequate for modelling sound propagation from a source in deep water of roughly constant depth. However, in the case of shallow coastal waters, where the proposed project is situated, the depth may rapidly fluctuate between shallow water of a few metres and deep water of tens of metres or more. In these circumstances, the Transmission Loss becomes a more complex function of depth that depends heavily on the local bathymetry and hence should ideally be calculated using a more sophisticated model, such as Impulse Noise Sound Propagation and Impact Range Estimator (INSPIRE). Where these effects are included, as illustrated by the blue line, yet another value of Source Level may result; typically lower levels of noise may be predicted near to the noise source.

19 The variation in estimates of Source Level for the same dataset, when analysed in different ways, indicates how Source Level will in general be a function of the model that is used to express the noise levels.

20 Where actual measured underwater noise data from a particular activity is not available, ideally the most sophisticated model for that noise will be used in all cases. These tend to require a very advanced level of knowledge of how a particular sound behaves in the underwater environment and/or a large amount of information on the conditions at the particular site such as temperature, salinity, etc and of the substrate conditions. Where actual measured data from a similar activity is available the introduction of the numerous variables used in sophisticated models is not required, hence reliance of measured data is generally preferable.

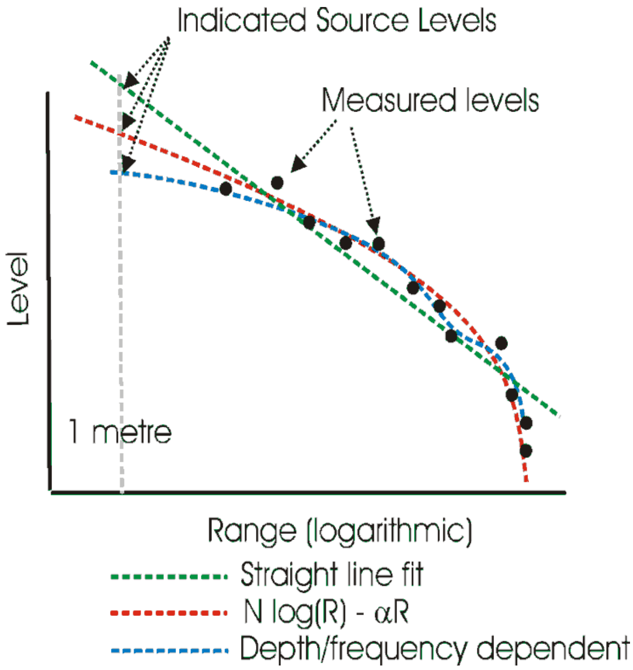

Figure 1.2-1 – Differences in Source Level estimation based on various models

1.3 Key Guidance Documents

21 The following documents have been used to inform this assessment:

- Nedwell J R, Turnpenny A W H, Lovell J, Parvin S J, Workman R, Spinks J A L and Howell D. (2007). *A validation of the dB_{ht} as a measure of the behavioural and auditory effects of underwater noise.* Subacoustech Report Reference: 534R1231, Published by Department for Business, Enterprise and Regulatory Reform.
- Southall B L, Bowles A E, Ellison W T, Finneran J J, Gentry R L, Greene C R, Kastak D, Ketten D R, Miller J H, Nachtigall P E, Richardson W J, Thomas J A and Tyack P L. (2007). *Marine Mammal Noise Exposure Criteria Aquatic Mammals*, Vol. 33 (4).
- Joint Nature Conservation Committee (JNCC), National England and Countryside Council for Wales. (2010). *The protection of marine European Protected Species from injury and disturbance;* Guidance for English and Welsh territorial waters and the UK offshore marine area. July 2009.

1.4 Data Information and Sources

22 The INSPIRE acoustic model is tested and validated against Subacoustech Environmental Ltd's extensive digital database of offshore noise measurements.

23 In addition, digital bathymetry supplied by SeaZone Solutions Ltd (License No. 052005.003) is used as an input to the INSPIRE noise propagation model.

1.5 Impact Methodology

1.5.1 Introduction

24 The methodology utilised in this impact assessment is similar to that used for numerous other studies carried out for the offshore wind industry. This approach utilises the proprietary Impulse Noise Sound Propagation and Impact Range Estimator (INSPIRE) model that has been specifically designed over five years to predict the likely level of underwater noise from impact piling operations. INSPIRE is a broadband model, that is, it does not calculate levels frequency by frequency, but in terms of the physics of the absorption of a pulse. INSPIRE uses a combination of loss caused by the spreading of the energy of the sound field (geometric loss) and loss caused by energy in the water column being absorbed in the underlying sea bed (absorption losses). This is used to estimate the likely transmission losses as the sound propagates away from the source; in this case impact piling. The model is therefore capable of estimating the effect of rapidly varying water depths that are commonly found in UK coastal waters. It has been validated against a wide range of actual measurements carried out by Subacoustech Environmental.

1.5.2 Pile Sizes

25 Currently available information suggests that the level of underwater noise from impact piling operations is closely related to both the pile size with sound levels increasing with pile size. The blow force applied to the pile also influences the noise levels produced; however, typically, blow forces also increase with pile size so these two factors are actually interdependent. The INSPIRE model also takes this into account via the inbuilt Source Level function.

26 Figure 1.5-1 shows a summary of Source Levels extrapolated from measured data on a number of impact piling operations using various pile sizes. It can be seen that as the diameter of the pile increases, the source level also increases. The estimated Source Level for an 8.5 m diameter pile is also plotted in Figure 1.5-1.

27 However, it should be noted that since the estimated Source Levels rely on extrapolation of data for other sizes of piles there is a degree of uncertainty associated with the estimate.

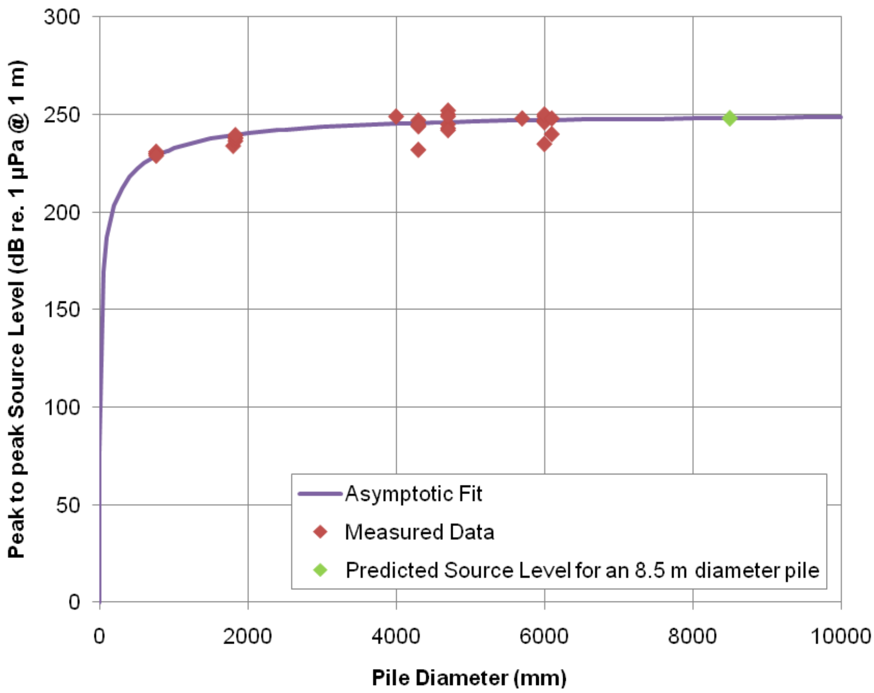

Figure 1.5-1 - Plot showing the asymptotic best fit to source level calculated from measured piling noise data for various pile sizes along with the predicted source level for an 8.5 m pile

1.5.3 Water Depths and Modelling Locations

28 The other main factor that affects the level of underwater noise is the local bathymetry, with sound attenuating at a faster rate over shallow water as opposed to deeper waters. The INSPIRE model uses digital bathymetric data provided by SeaZone Solutions Ltd, to input water depth data into the model.

29 Figure 1.5-2 shows a plan of the proposed EOWDC site along with the four wind turbine positions for which underwater noise modelling has been carried out. These are wind turbine positions 1, 3, 7 and 11. These four positions have been chosen to represent the greatest variation across the site in terms of location and to a lesser extent water depths, ranging from approximately 20 m LAT to the west to just under 30 m to LAT to the east.

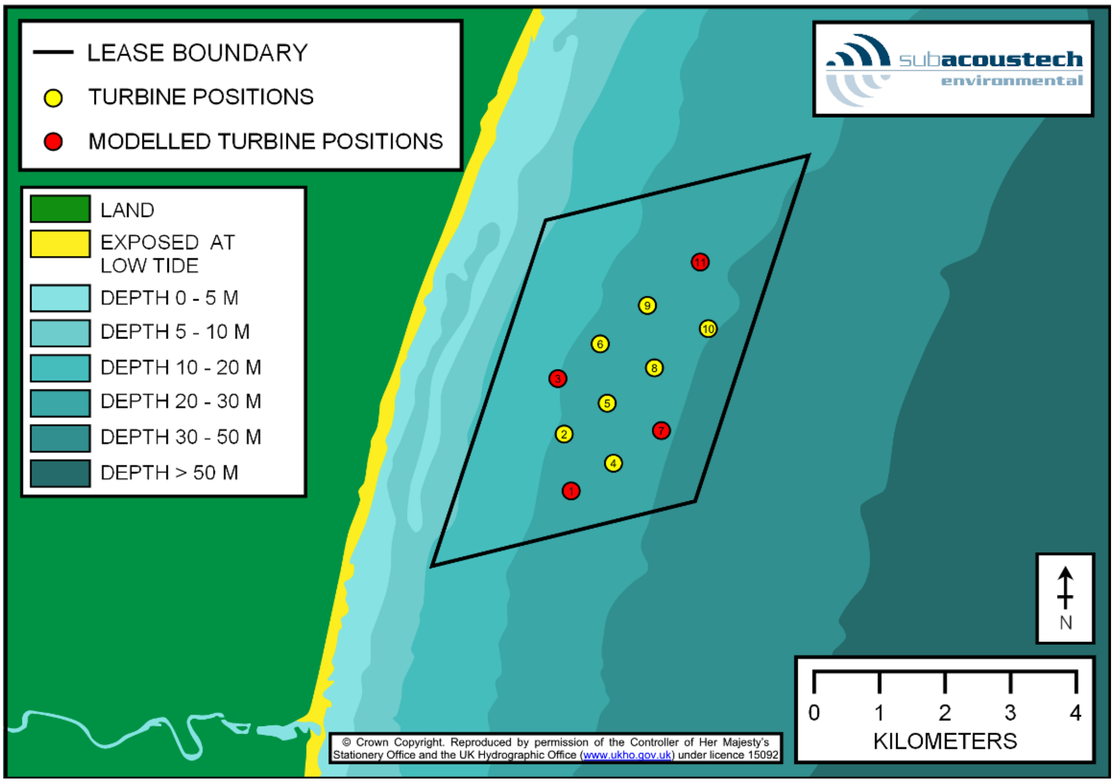

Figure 1.5-2 Map showing the four modelled wind turbine positions (Wind turbines 1, 3, 7 and 11) at the proposed EOWDC site

30 It should be noted that the INSPIRE acoustic model is not exact and does not use a Source Level / Transmission Loss (SL-TL) formulation; however, the testing and validation of the model against actual measured impact piling data confirms that the model accurately predicts the likely noise levels from impact piling operations.

1.6 Impact of Underwater Sound on Marine Species

1.6.1 Introduction

31 Over the past 20 years it has become increasingly evident that noise from human activities in and around underwater environments may have an impact on the marine species in the area. The extent to which intense underwater sound might cause an adverse environmental impact in a particular species is dependent upon the incident sound level, frequency content, duration and/or repetition rate of the sound wave (see, for example Hastings and Popper, 2005). As a result, scientific interest in the hearing abilities of aquatic animal species has increased.

32 Popper *et al* (2006) suggest the use of unweighted sound exposure metrics such as peak level of underwater noise and the SEL of the noise, to develop an interim guidance for estimating the injury range for fish from pile driving operations. Similarly, a review of underwater noise from offshore wind farms on marine mammals (Madsen *et al*, 2006) discusses the use of frequency weighting of the underwater noise. The authors' comment that the impact of underwater sound on the auditory system is frequency dependent and thus,

ideally, noise levels should (as for humans) be weighted using the defined frequency responses of the auditory system of the animal in question.

33 The approach that has been adopted in this study is to use unweighted sound level metrics to define the potential for gross damage such as fatality, swim bladder rupture or tissue damage, since hearing is not involved in this process. In addition, frequency weighted measures of the sound based on the hearing threshold of the affected species have been applied to assess the perceived loudness of the noise for representative marine species, and hence the range at which an aversive response to the piling may be expected.

34 In addition to this, a further set of criteria proposed by Southall *et al* (2007) and subsequently used as the basis for draft Joint Nature Conservation Committee (JNCC) guidance on protection of marine mammals from injury and disturbance (JNCC, draft 2010) have been used in this assessment to estimate the possibility of auditory injury and behavioural disturbance occurring.

1.6.2 Lethality and Injury Impacts and their Associated Sound Levels

35 At the highest level, typically during underwater blast from explosives, sound has the ability to cause injury and, in extreme cases, the death of exposed animals.

36 Due to the current lack of information on potential lethal and physical injury effects from impact piling, this study has used the data from blast exposures to estimate impact zones. The wave forms from these two noise sources are rather different; the transient pressure wave from an impact piling operation has roughly equal positive and negative pressure amplitude components and a relatively long duration of up to a few hundred milliseconds. By contrast, blast waves have a very high positive pressure peak followed by a much lower amplitude, negative wave due to the momentum imparted to the water surrounding the explosive gas bubble. The pressure of a blast wave is normally quantified therefore in terms of the peak level, due to the dominance of the positive peak of the waveform. There is, therefore, a level of uncertainty as to whether a blast wave criterion can be directly applied to a transient waveform arising from an impact piling operation.

1.6.3 Observations of Lethality and Physical Injury

37 Lethal and direct physical injury from an underwater transient pressure wave are related to the peak pressure level, rise time and duration that the peak pressure acts on the body (usually measured by the impulse of the blast wave). The criteria that have been developed for assessing gross injury of this type are based on data from blast injury, at close range, to explosives. Injury has been related both to the incident peak positive pressure of the wave and to the impulse. To obtain an effective measure of the impulse of the wave, an estimate of the effective duration must be made by integrating over the waveform. A number of different techniques for assessing the duration of an impulsive waveform are described by Hamernik and Hsueh (1991) based on the studies by Coles *et al* (1968), Pfander *et al* (1980) and Smoorenburg (1982). The measure of impulse will, therefore, depend upon which technique is applied.

38 There is currently very limited data relating to fish kill from piling (Hastings *et al*, 2005), although the study by Caltrans (2001) during impact piling operations on the San Francisco to Oakland Bay Bridge indicated fish kill to a range of approximately 50 m. By fitting the results of Abbot *et al* (2002) to a spreading model, it is possible to estimate the peak to peak Source Level (SL) of the piling to be about 242 dB re 1 µPa @ 1 m. This equates to fish being killed when the peak pressure level exceeds about 208 dB re 1 µPa, which corresponds to an interim criterion that has been proposed by Popper, discussed in the following section.

39 Studies carried out on the effects of blast on various species of fish by Yelverton *et al* (1975) (also reproduced in Richardson *et al*, 1995) demonstrated that mortality rates were related to body mass and magnitude of the impulsive wave. The results show that a 50% mortality rate would occur in fish weighing 1 kg when exposed to an impulse of about 340 Pa.s (Pascals per second). According to this model, to cause the same mortality rate in fish weighing 10 kg they would have to be exposed to an impulse of approximately 800 Pa.s. The work indicates that there are levels below which a sound would cease to be lethal to a fish of a certain weight. While this sound level may not cause the swim bladder to rupture or kidney and liver damage that may be seen after lethal doses of sound, there may still be considerable tissue damage to susceptible organs such as the lungs, gastro-intestinal tract or eyes and hence possible long term survival implications.

1.6.4 Observations of Auditory Damage

40 At lower received SPLs, temporary and permanent hearing loss has been demonstrated by constraining marine animals within a high level sound environment for prolonged periods. Temporary hearing loss usually presents as a temporary hearing threshold shift (TTS) which is recoverable over a period of time. However, following prolonged exposure at levels sufficient to cause TTS, a permanent threshold shift (PTS) or deafness, results from the death of the sensory hair cells of the ear. TTS is thus symptomatic of hearing damage. Some information is available concerning hearing damage in fish. Cox *et al* (1986, 1987) suggested that goldfish (*Cassius auratus*) exposed to pure tones at 250Hz at 204dB re 1µPa and 500Hz at 197dB re 1µPa for two hours developed hearing damage, corresponding to levels of 142 – 147 dB_{ht}(*Cassius auratus*). Enger (1981) also noted auditory damage in cod (*Gadus morhua*) exposed at frequencies from 50 – 400Hz at 180dB re 1µPa for one to five hours, corresponding to a level of about 100 dB_{ht}(*Gadus morhua*). The dB_{ht} metric is explained in section 1.11.1.8 in the appendix of this report

41 Hastings *et al* (1996) found damage to the sensory hair cells of the oscar fish (*Astronotus ocellatus*) caused by exposure to a pure 300Hz tone (sound generated at a single frequency) at 180dB re 1µPa for one hour. Comparing these results to the audiogram given by Kenyon *et al* (1998), this corresponds to a level of 74 dB_{ht}(*Astronotus ocellatus*).

42 Smith *et al* (2004) discovered that goldfish had a 5 dB TTS in hearing following a ten minute continuous exposure to noise in the frequency range from 100 Hz – 10 kHz at a level of 170 dB re 1 µPa. Popper *et al* (in Hastings and Popper, 2005) exposed rainbow trout (*Oncorhynchus mykiss*) and channel catfish (*Ictalurus punctatus*) to Low Frequency Active Sonar signals

(a submarine detection system deployed by the US Navy) for three periods of 108 seconds at a received level of 193 dB re 1µPa (RMS) over the frequency band 160 – 325 Hz. A goldfish with a 10dB TTS took 24 – 48 hours to recover. Popper *et al* (2005) exposed broad whitefish (*Coregonus nasus*), a salmonid, to five airgun emissions having a received peak sound level of 205 dB re 1µPa (corresponding to a received mean SEL of 175 dB re 1µPa^2-s). No TTS was observed in the whitefish, whereas northern pike (*Esox lucius*) and Lake Chub (*Couesius plumbeus*) demonstrated a 10 – 15 dB TTS from which the recovery time was around 24 hours.

43 The recent review by Madsen *et al* (2006) highlighted that experiments with marine mammals demonstrated a near inverse relationship between sound exposure level and duration of exposure (i.e. the same equal energy noise dose relationship). This was based on data from Schlundt *et al* (2000) which indicated that this effect translates to marine mammal exposure to underwater sound. In the study, short duration sound exposures (one second continuous wave) at levels of approximately 130 dB above hearing threshold caused a small TTS hearing injury in the bottlenose dolphin. Longer duration exposures at levels of 80 – 90 dB above hearing threshold have been shown to induce TTS after many hours of exposure (Nedwell *et al*, 2007).

44 The data reviewed above highlights typical levels of sound and the exposure durations at which audiological injury in fish and marine mammals have been measured. In the context of exposure of fish and marine mammal species to underwater sound it is very unlikely that fish or marine mammals would experience auditory injury unless constrained in a very high level continuous sound field for a prolonged period. Although it should be noted that physical injury and fatality, which is discussed in more detail below, can occur for very high level, short duration exposures such as those for underwater blast.

1.6.5 Criteria for Assessing Lethality and Physical Injury

45 The following criteria have been applied in this study for levels of noise likely to cause physical effects (Parvin *et al* (2007)), based on data in the studies of Yelverton *et al* (1975), Turnpenny *et al* (1994), Hastings and Popper (2005):

- Lethal effect may occur in marine species where peak to peak levels exceed 240 dB re 1 µPa; and
- Physical injury may occur in marine species where peak to peak levels exceed 220 dB re 1 µPa.

1.6.6 Criteria for Assessing Audiological Injury

46 The concept of auditory injury from exposure to noise is well established for airborne sound exposure of humans. At a high enough level of sound, traumatic hearing injury may occur even where the time of exposure is short. Injury also occurs at lower levels of noise where the period of exposure is long. In this case, the degree of hearing damage depends on both the level of the noise and the time of exposure to it. To estimate the effect of impact piling taking place over a long period of time this concept of cumulative “Noise Dose” relationship has been used.

47 For complex or time varying signals the degree of hearing damage has been related to the Noise Dose of the noise. The Noise Dose combines the continuous noise level containing the same sound energy as the time varying signal (the equivalent level of noise, or L_{eq}), and the duration of exposure. This is usually given in terms of $L_{EP, D}$, which is the daily personal noise exposure. This approach appears to translate to the underwater exposure of marine mammals, since for single exposure sounds Ward (1997) developed a level against exposure duration guide indicating that for sounds from 126 to 144 dB above hearing threshold (i.e. dB_{ht}), hearing injury can occur for exposure periods from 60 seconds to 1 second respectively. The data from Schlundt *et al* (2000) also indicates that this effect translates to marine mammal exposure to underwater sound. In the study, short duration sound exposures (one second continuous wave) at levels of approximately 130 dB above hearing threshold caused a small Temporary Threshold Shift (TTS) hearing injury in the bottlenose dolphin.

48 A review by Madsen *et al* (2006) highlighted that experiments with marine mammals demonstrate a near linear relationship between sound exposure level and duration of exposure (i.e. an equal energy Noise Dose relationship). In other words, each doubling of the noise energy (3 dB increase) results in a halving of the acceptable noise exposure period. The same Noise Dose (and therefore potential for auditory injury) occurs, for instance, following an exposure of 90 dB above threshold for a period of 8 hours, 93 dB above threshold for a period of 4 hours, or 130 dB above threshold for a few seconds as shown in Table 1.6-1 below. Hearing impairment in the form of a TTS in hearing may occur where an animal is exposed to a these levels, and Permanent Threshold Shift (PTS) will occur with repetitive exposure. The higher the Noise Dose above this limit, the more rapid will be the damage.

Table 1.6-1 – Comparison of noise exposure level and duration for the same cumulative 90 $L_{EP, D}$ Noise Dose

Exposure Level dB(A) (dB_{ht})	Exposure Duration
90	8 hours
93	4 hours
99	1 hour
110	Approx. 5 minutes
120	Approx. 30 seconds
130	Approx. 3 seconds

49 In summary, it is likely that hearing impairment will occur where fish or marine mammals are exposed to continuous or repeated high level underwater sound for relatively long periods of time; for impact piling the noise exposure can build up over many pile strikes. The Noise Dose that the animals will accumulate will depend on the received level of the underwater sound, which varies with range, and hence with the behaviour of the animal, and the time period and repetition rate of the pile strikes.

50 Nedwell *et al* (2007) has suggested that the use of a 130 dB_{ht} level, similar to that used for human exposure in air, provides a suitable criterion for predicting the onset of traumatic hearing damage (that is, where immediate traumatic and irreversible damage occurs), which recognises the varying hearing sensitivity of differing species.

51 Based on the evidence of auditory damage from numerous studies, Southall *et al* (2007) propose a set of auditory injury criteria based on peak pressure levels and M-weighted Sound Exposure Levels (dB re. 1 μPa^2-s (M)) for various groups of marine mammals. These criteria are presented in Table 1.6-2 and the results of this study have also been presented in terms of this metric. A detailed description of the M-weighting metric and the groups of marine mammals considered is presented in the Appendix to this report.

Table 1.6-2 – Proposed injury criteria for various marine mammal groups (Southall et al., 2007)

	Sound type	
Marine mammal group	**Single pulses**	**Multiple Pulses**
Low Frequency Cetaceans		
Sound Pressure Level	230 dB re 1 μPa (peak)	230 dB re 1 μPa (peak)
Sound Exposure Level	198 dB re 1 μPa^2/s (M_{lf})	198 dB re 1 μPa^2/s (M_{lf})
Mid Frequency Cetaceans		
Sound Pressure Level	230 dB re 1 μPa (peak)	230 dB re 1 μPa (peak)
Sound Exposure Level	198 dB re 1 μPa^2/s (M_{mf})	198 dB re 1 μPa^2/s (M_{mf})
High Frequency Cetaceans		
Sound Pressure Level	230 dB re 1 μPa (peak)	230 dB re 1 μPa (peak)
Sound Exposure Level	198 dB re 1 μPa^2/s (M_{hf})	198 dB re 1 μPa^2/s (M_{hf})
Pinnipeds (in water)		
Sound Pressure Level	218 dB re 1 μPa (peak)	218 dB re 1 μPa (peak)
Sound Exposure Level	186 dB re 1 μPa^2/s (M_{pw})	186 dB re 1 μPa^2/s (M_{pw})

52 The Southall study criteria can be used for both single pulse noise sources and multiple pulse sources. This report presents estimated impact ranges for both of these in terms of pile driving to provide impact ranges for exposure to a single pile strike and also the accumulated exposure to multiple pulses over a typical installation. The accumulated exposure is taken into account using the dB_{ht} metric by the noise dose modelling outlined above: This has also been carried out for the M-weighting metric. This modelling is carried out using a similar method to the noise dose modelling by assuming a swim speed and starting range for the animals and, hence calculating the accumulated exposure as the animal moves away from the noise source. The M-weighted Sound Exposure Level at each range is calculated based on analysis of previously measured data from numerous impact piling operations.

53 Predictive underwater noise modelling can be used to estimate the range at which a marine mammal can receive sound levels that could cause audiological impairment. By using the impact ranges and factoring a degree of precaution these can be used to help inform standoff ranges (exclusion zones) for use in the mitigation during piling activities. That is, the range at which the animal can be at the onset of piling to ensure it can flee the area before receiving an exposure level that is likely to damage hearing.

54 Once again, similarly to the dB_{ht} noise dose modelling, the M-weighted SEL modelling does not take into account the mitigating effects of a soft start procedure. The accumulated exposure is calculated assuming a high blow force at the onset of piling. Where a soft start procedure is used the effect is likely to be mitigated as the initial exposure is reduced.

1.6.7 Criteria for Assessing Behavioural Response

55 Measurements of underwater noise are frequently presented in terms of the overall linear level of that sound, such as its spectral level or peak pressure. This, however, does not provide an indication of the impact that the sound will have upon a particular fish or marine mammal species. This is of fundamental importance when considering the behavioural response of species to activities generating underwater noise, as avoidance is associated with the perceived level of loudness and vibration of the sound by the species. Therefore, the same underwater noise may have a different impact on different species with different hearing sensitivities.

56 The dB_{ht}(*Species*) metric (Nedwell *et al*, 2007) has been developed as a means for quantifying the potential for a behavioural impact on a species in the underwater environment. As any given sound will be perceived differently by different species (since they have differing hearing abilities) the species name must be appended when specifying a level. For instance, the same construction event for salmon (*Salmo salar*) might have a level of 70 dB_{ht}(*Salmo salar*) and for bottlenose dolphin a level of 110 dB_{ht}(*Tursiops truncatus*). Table 1.6-3 below summarises the assessment criteria for the dB_{ht}.

Table 1.6-3 – Assessment criteria proposed by Nedwell *et al* (2007) used in this study to assess the potential behavioural impact of underwater noise on marine species

Level in dB_{ht}(Species)	Effect
90 and above	Strong avoidance reaction by virtually all individuals.
Above 110	Tolerance limit of sound; unbearably loud.
Above 130	Possibility of traumatic hearing damage from single event.

57 In addition, a lower level of 75 dB_{ht} has been used for analysis as a level of "significant avoidance." At this level, about 85% of individuals will react to the noise, although the effect will probably be limited by habituation.

58 In Southall *et al* (2007), a further set of criteria are also suggested, again based on the M-weighted Sound Exposure Levels to assess the likelihood of behavioural disturbance. These criteria are presented in Table 1.6-4 below and, as with the criteria for auditory injury proposed by Southall, it has also been used in this study.

59 Southall suggests the onset of temporary Threshold Shift (TTS) as a criterion for a behavioural effect of single impulsive noises. No evidence is offered to substantiate this criterion. This approach is considered highly speculative; for instance, humans can tolerate substantial levels of noise, well above an aversive level, of up to 130 dB(A) re 20 μPa, for short periods of time without exhibiting a TTS. The authors are not aware of any equivalent criterion for human exposure, where aversion is generally specified in terms of the level of the noise in dB(A).

Table 1.6-4 – Proposed Behavioural response criteria in terms of single pulses for various marine mammal groups (Southall *et al*., 2007)

	Sound type
Marine mammal group	**Single pulses**
Low Frequency Cetaceans	
Sound Pressure Level	224 dB re 1 µPa (peak)
Sound Exposure Level	183 dB re 1 µPa^2/s (M_{lf})
Mid Frequency Cetaceans	
Sound Pressure Level	224 dB re 1 µPa (peak)
Sound Exposure Level	183 dB re 1 µPa^2/s (M_{mf})
High Frequency Cetaceans	
Sound Pressure Level	224 dB re 1 µPa (peak)
Sound Exposure Level	183 dB re 1 µPa^2/s (M_{hf})
Pinnipeds (in water)	
Sound Pressure Level	212 dB re 1 µPa (peak)
Sound Exposure Level	171 dB re 1 µPa^2/s (M_{pw})

1.7 Selection of Species

60 The species upon which the dB_{ht} analysis has been conducted in this study have been based upon regional significance and also crucially upon the availability of a good peer-reviewed audiogram data shown in Figures 1.7-1 to 1.7-3.

61 The species of marine mammal considered in this study are:

- **Bottlenose Dolphin** – (Johnson, 1967) A marine mammal (toothed whale) with good high frequency hearing sensitivity. It is also used in this report an indicative surrogate audiogram for **Risso's Dolphin**. Although some audiogram data are available for the Risso's dolphin, the authors consider that the quality of the data is not confirmed. Hence the bottlenose dolphin has been used to provide a conservative over-estimate of potential impacts.
- **Harbour Porpoise** – A marine mammal (toothed whale) that, based on current peer reviewed audiogram data (Kastelein, 2002), is the most sensitive marine mammal to high frequency underwater sound.
- **White-Beaked Dolphin** – a marine mammal (toothed whale) with similar high frequency hearing to the bottlenose dolphin, but lower sensitivity to lower frequency noise (using the Striped Dolphin (*Stenella coeruleoalba*) audiogram (Kastelein, 2003) as a surrogate as the White-Beaked Dolphin audiogram (Nachtigall *et al*, 2007) does not cover the entire audiometric range.
- **Harbour (Common) Seal** – a pinniped that based on current peer reviewed audiogram data (Mohl, 1968, Kastak and Schusterman, 1978) the most sensitive seal species to underwater sound. It is also used as a surrogate audiogram for **Grey Seal**.

62 As there is no single published dataset for seal species that covers the full audiometric range, the analysis undertaken in this report is based on a weighting filter for the harbour seal that is the locus of the minimum threshold (most sensitive) data from several audiogram sources for the harbour seal. The data of Kastak and Schusterman (1998) is used for the frequency range from 100 Hz to 6.4 kHz, and the data from Mohl (1968) over the higher frequency range from 8 to 128 kHz.

63 The species of fish considered in this study are:

- **Herring** (*Clupea Harengus*) – A fish hearing specialist that, based on current peer reviewed audiogram data (Enger, 1967) is the most sensitive marine fish to underwater sound.
- **Salmon** – A fish with relatively poor hearing sensitivity and therefore they may be classed as hearing generalists. For this study the audiogram produced by Hawkins and Johnstone (1978) has been used.
- **Dab** (*Limanda limanda*) – A flatfish species with generalist hearing capability but that based on current peer reviewed audiogram data (Chapman and Sand,1974) is the most sensitive flatfish to underwater sound. It is also sometimes used as a surrogate for sole (*Solea solea*).

1.8 Anticipated Worst Case Scenario for the Impacts of Underwater Noise during the EOWDC Construction

64 The two primary variables that are likely to affect the levels of underwater noise during impact piling operations are water depths and the diameter of the pile. To account for the worst case scenario in terms of water depths, an adjustment to the Lowest Astronomical Tide (LAT) depths provided by

Seazone to give high water conditions at the site (4.064 m above the lowest astronomical tide, taken from an Oceanographic survey undertaken for the AOWFL) has been made (EMU Ltd., 2008).

65 In order to inform discussions with the design engineers so that a realistic worst case scenario in terms of pile diameter could be determined preliminary modelling was carried out during the early stages of the project for various sizes of piles. From the consultations with the engineers using this modelling as a guide it was decided by the client that the modelling should be carried out assuming piles of 8.5 m in diameter at each location. This preliminary modelling report is included as an appendix to this report in section 1.11.2.

66 The simplest evaluation of the behavioural effects of noise considers the area of sea excluded to an animal by the noise. Where this is large or includes important areas, such as spawning grounds, the risk of an environmental effect of the noise may be significant. An alternative approach, which includes the significance of the period of exposure, is to consider the time for which the area is excluded, for instance by considering the impact in terms of kilometres squared of area and days of seabed excluded. On this basis, the influence of persistent lower level sources may dominate over intermittent high level sources, like piling. Thus, on this basis, it may be important to consider the changes in both duration and level of an activity when assessing the relative impact of two different methods of construction.

1.9 Impact Assessment: Impact Piling of 8.5 m Diameter Monopiles

1.9.1 Introduction

67 Presented in the following pages are the results of the modelling undertaken by Subacoustech Environmental Ltd using the underwater noise modelling software, INSPIRE (currently version 2.0), for the proposed piling operations for the installation of 8.5 m diameter piles at the EOWDC.

68 Figure 1.9-1 shows four representative example transects extending from wind turbine position 11 illustrating the varying bathymetry in the areas around the proposed EOWDC site. Comparison of the water depths at a bearing of 20° from WTG 11 which extends towards the shore with the transect at a bearing of 60° which extends directly out into the deeper water clearly shows a very large variation on water depths. For relatively shallow coastal waters, sound typically propagates with fewer losses in deeper water than for shallow water. It would therefore be expected that maximum impact ranges will be predicted for the deeper water transects.

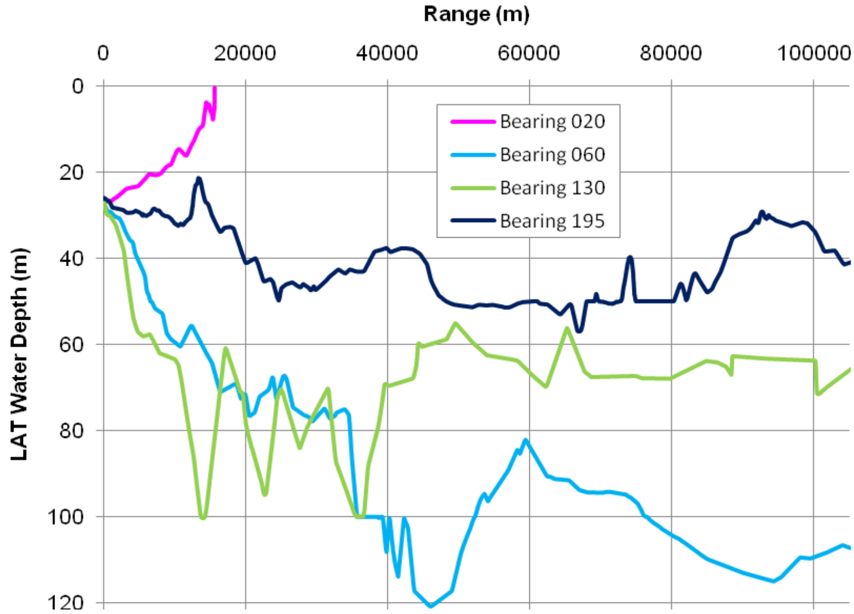

Figure 1.9-1 – Comparison of four representative depth profiles along transects from Wind turbine position 11, indicating the varying bathymetry around the proposed EOWDC site used for the INSPIRE modelling

69 Figure 1.9-2 shows the attenuation of unweighted peak to peak noise level against range for the four representative transects shown in Figure 3-1 for piling an 8.5 m diameter pile at wind turbine position 11. It can be seen that the shallower the water, such as for transects at bearings 020 and 195, the more rapidly the piling noise is likely to attenuate.

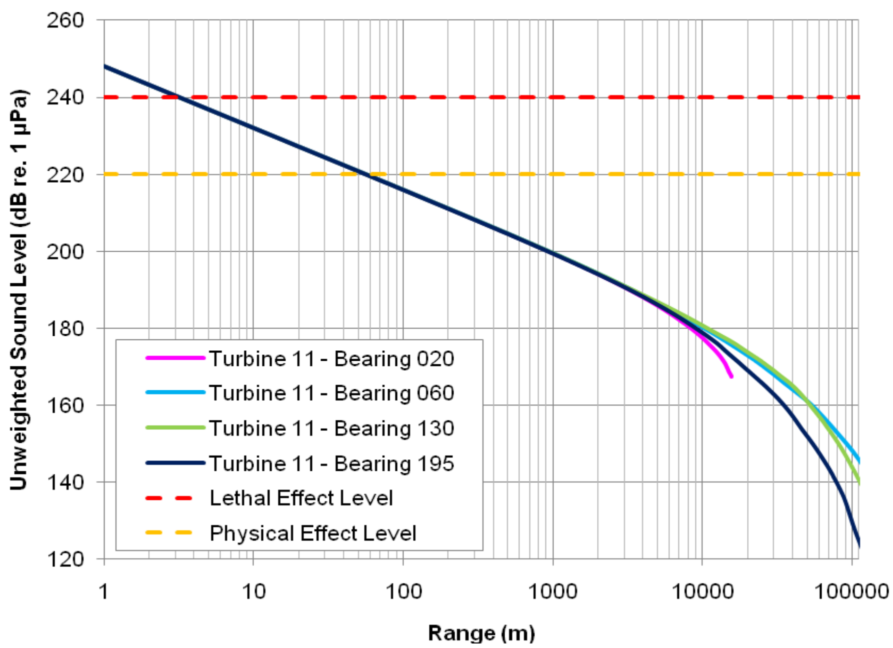

Figure 1.9-2 – Graph showing the unweighted peak to peak noise level with range for the four transects extending from wind turbine 11 shown in Figure 1.9-1

1.9.2 Unweighted Sound Levels; Potential for Lethality and Physical Injury to Marine Species

70 Table 1.9-1 shows the estimated ranges out to which lethal and physical injury may occur in marine species based on unweighted peak to peak sound levels and the criteria presented in section 1.6.5. The data indicate that marine species may suffer a lethal effect out to a range of approximately 3 m from the piling operation and that physical injury is likely to occur out to a range of 60 m. It should be noted that these impact ranges are based on the extrapolation of data from measurements taken at considerably greater ranges since it is generally not possible to carry out measurements this close to impact piling operations. “Near field” acoustic effects are likely to occur at close range to the piling operations so the levels of underwater noise maybe lower than those estimated by the INSPIRE model. It is therefore thought that lethality is therefore unlikely to occur in this case.

71 These impact ranges have been calculated using an estimated optimum blow force for installing an 8.5 m diameter pile. This is calculated using the piling logs from previous measurements undertaken by Subacoustech Environmental Ltd and extrapolating these figures to calculate an optimum blow force for a particular sized pile. In the case of an 8.5 m diameter pile it is estimated that a blow force of 1400 kJ (kilojoules) will be necessary to install the pile. However, this is dependent on the piling hammer used and ground type at the size.

72 Any residual risk of lethality and physical injury may be further mitigated by the use of a soft start procedure, or the use of acoustic mitigations devices such as seal scrammers or fish exclusion systems.

Table 1.9-1 – Summary of ranges out to which lethal effect and physical injury is expected to occur in marine species using the criteria proposed in Parvin *et al* (2007)

Peak to Peak Levels	Wind turbine 1	Wind turbine 3	Wind turbine 7	Wind turbine 11
Lethal Effect Range to 240 dB re. 1 µPa	3 m	3 m	3 m	3 m
Physical Injury Range to 220 dB re. 1 µPa	60 m	60 m	60 m	60 m

73 Figure 1.9-3 presents a contour plot of the estimated unweighted peak to peak levels of underwater noise from the four wind turbine positions, with each contour representing regions of the same unweighted sound level in 10 dB increments. It can be seen that the noise attenuates more rapidly in the slightly shallower waters directly to the east of the site, whereas the contours extend further to the north east where the water is deepest.

74 The figures indicate that there is likely to be relatively little variation in noise propagation for different wind turbine sites as the contours are all broadly similar in extent. This is likely due to the fact that the variation in water depths across the site is relatively small compared to the differences in water depths in the surrounding waters.

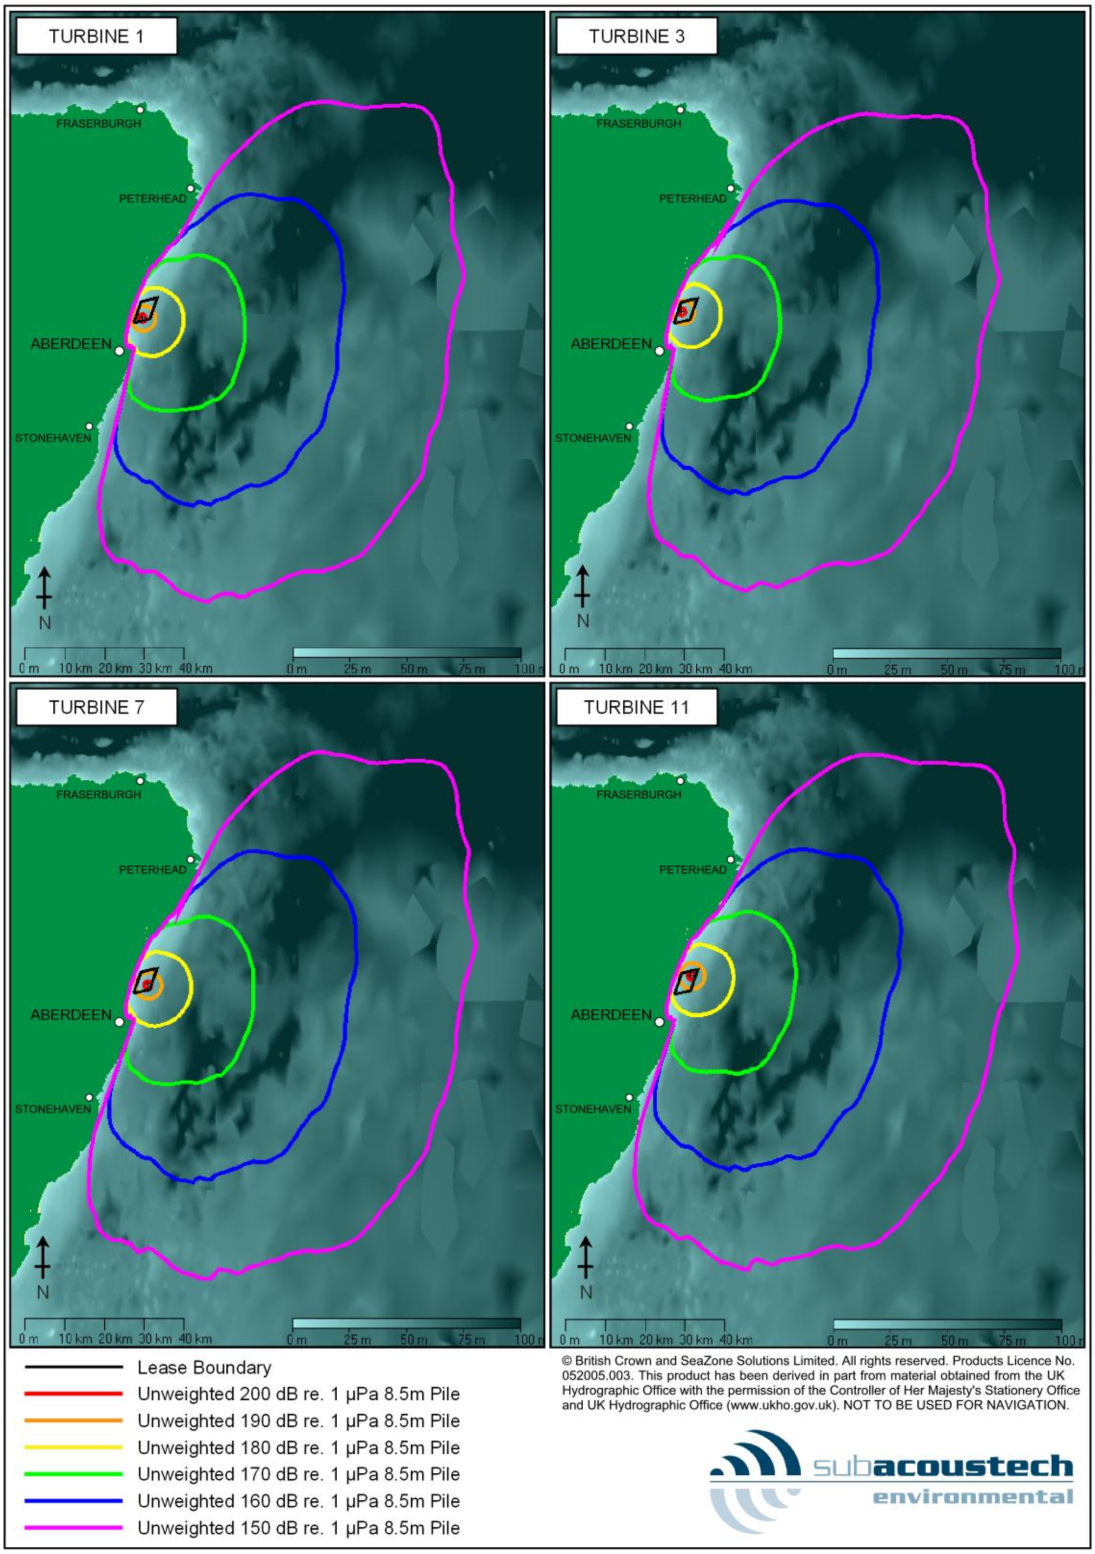

Figure 1.9-3 – Contour plots showing the estimated unweighted peak to peak noise levels from installing an 8.5 m diameter pile at the EOWDC site

75 Tables 1.9-2 to 1.9-4 summarise the estimated extent of underwater noise propagation in terms of three unweighted metrics, peak to peak level, peak level and sound exposure level calculated from single pile strikes analysed over a 0.5 second interval. It should be noted that the peak underwater noise levels, summarised in Table 1.9-3, have been calculated by reducing the

peak to peak noise levels predicted by the INSPIRE model by 6 dB. As the waveform of a pile strike is typically symmetrical about the ambient pressure level (equal high and low pressure excursions) it can be reasonably assumed that the peak pressure level is half of the peak to peak pressure level (a reduction of 6 dB). Also shown in Table 1.9-3 are the injury and behavioural avoidance impact ranges using the single pulse peak level criteria for species of cetacean and pinniped proposed by Southall *et al* (2007), outlined in tables 1.6-2 and 1.6-4.

76 Overall, the data indicate that the underwater noise is likely to propagate marginally further for wind turbine positions 7 and 11. This indicates the effect of wind turbines located to the east of the site, in close proximity to the deep water of the North Sea, as propagation losses are typically lower in deeper water.

Table 1.9-2 – Summary of the estimated mean ranges to various unweighted peak to peak noise levels during installation of 8.5 m diameter piles

Peak to Peak Levels	Wind turbine 1	Wind turbine 3	Wind turbine 7	Wind turbine 11
Range to 200 dB re. 1 µPa	920 m	890 m	960 m	940 m
Range to 190 dB re. 1 µPa	3.1 km	2.8 km	3.3 km	3.2 km
Range to 180 dB re. 1 µPa	7.2 km	6.5 km	8.1 km	7.8 km
Range to 170 dB re. 1 µPa	14 km	13 km	16 km	15 km
Range to 160 dB re. 1 µPa	25 km	24 km	27 km	27 km
Range to 150 dB re. 1 µPa	38 km	36 km	41 km	40 km

Table 1.9-3 – Summary of the estimated mean ranges to various unweighted peak noise levels during installation of 8.5 m diameter piles, including the PTS and TTS criteria shown in Tables 1.6-2 and 1.6-4

Peak Levels	Wind turbine 1	Wind turbine 3	Wind turbine 7	Wind turbine 11
Range to 230 dB re. 1 µPa (Cetacean Injury criteria, Southall *et al* 2007)	5 m	5 m	5 m	5 m
Range to 224 dB re. 1 µPa (Cetacean Behavioural avoidance criteria, Southall *et al* 2007)	15 m	15 m	15 m	15 m
Range to 218 dB re. 1 µPa (Pinniped Injury criteria, Southall *et al* 2007)	30 m	30 m	30 m	30 m
Range to 214 dB re. 1 µPa (Pinniped Behavioural avoidance criteria, Southall *et al* 2007)	60 m	60 m	60 m	60 m
Range to 200 dB re. 1 µPa	410 m	400 m	420 m	420 m
Range to 190 dB re. 1 µPa	1.5 km	1.5 km	1.6 km	1.6 km
Range to 180 dB re. 1 µPa	4.5 km	4.0 km	5.0 km	4.8 km
Range to 170 dB re. 1 µPa	9.6 km	11 km	11 km	10 km
Range to 160 dB re. 1 µPa	18 km	20 km	20 km	20 km
Range to 150 dB re. 1 µPa	30 km	33 km	33 km	32 km

Table 1.9-4 – Summary of the estimated mean ranges to various unweighted sound exposure levels (SELs) during installation of 8.5 m diameter piles

Sound Exposure Levels	Wind turbine 1	Wind turbine 3	Wind turbine 7	Wind turbine 11
Range to 200 dB re. 1 $\mu Pa^2/s$	20 m	20 m	20 m	20 m
Range to 190 dB re. 1 $\mu Pa^2/s$	100 m	100 m	100 m	100 m
Range to 180 dB re. 1 $\mu Pa^2/s$	510 m	500 m	520 m	520 m
Range to 170 dB re. 1 $\mu Pa^2/s$	2.2 km	2.1 km	2.4 km	2.3 km
Range to 160 dB re. 1 $\mu Pa^2/s$	6.8 km	6.1 km	7.6 km	7.3 km
Range to 150 dB re. 1 $\mu Pa^2/s$	16 km	14 km	17 km	17 km

1.9.3 *Estimates of Ranges at which Traumatic Hearing Damage may occur for Single Pulses*

1.9.3.1 The dB_{ht} metric

77 Table 1.9-5 shows the estimated impact ranges for traumatic hearing injury, using the dB_{ht} metric, for the marine species of interest, based on the 130 dB_{ht} criterion from Nedwell *et al* (2007). The results are given for each of the four locations modelled at the proposed EOWDC site. The 130dB_{ht} perceived level is used to indicate traumatic hearing damage over a very short exposure time of only a few pile strikes at most.

78 The largest estimated ranges out to which hearing damage may occur are for harbour porpoise with an estimated impact range of 570 m for impact piling an 8.5 m pile at both wind turbine positions 7 and 11. Of the marine mammals, the data indicate that the seal species are likely to suffer these effects out to the smallest ranges. The data indicate that salmon and dab are only likely to suffer traumatic hearing damage out to 20 – 30 m, however, it is estimated that herring are likely to suffer this effect out to considerably larger ranges of up to approximately 480 m.

79 It should be noted that, as with the lethality and physical injury criteria, and with all predicted behavioural avoidance criteria, the risk of hearing damage may be mitigated by the use of soft start for the piling operation, or the use of suitable acoustic mitigation devices such as seal scrammers or fish exclusion systems.

Table 1.9-5 – Summary of ranges out to which traumatic hearing injury is predicted to occur in various marine species using the 130 dB_{ht}(*Species*) criteria (Nedwell *et al, 2007)* while piling a 8.5 m diameter pile

Species	130 dB_{ht} Ranges			
	Wind turbine 1	Wind turbine 3	Wind turbine 7	Wind turbine 11
Bottlenose Dolphin Risso's Dolphin	290 m	290 m	290 m	290 m
Harbour Porpoise	560 m	550 m	570 m	570 m
White-Beaked Dolphin	240 m	240 m	250 m	240 m
Harbour Seal Grey Seal	120 m	120 m	120 m	120 m
Herring	470 m	460 m	480 m	480 m
Salmon	20 m	20 m	20 m	20 m
Dab	30 m	30 m	30 m	30 m

1.9.3.2 M-Weighted Sound Exposure Levels

80 Auditory injury criteria for marine mammals have been proposed by Southall *et al*. (2007) based on M-weighted SELs; SELs calculated from single pile strikes over a 0.5 second interval and then filtered using the M-weighting

criteria for low, mid and high cetacean groups as well as pinnipeds. This study has recently been used as the basis for draft guidance from the Joint Nature Conservation Committee (JNCC) on assessing the likelihood of a particular activity causing a disturbance to marine mammals. Modelling has therefore been carried out in order to provide the estimated mean impact ranges for the four groups of marine mammals specified in the Southall paper, in terms of these metrics. The results of this modelling assuming a single pulse (i.e. a single pile strike at the receiver) are summarised in Tables 1.9-6 to 1.9-9.

81 Tables 1.9-6 to 1.9-9 summarise the estimated impact ranges out to which auditory injury may occur, based on the single pulse Southall *et al* (2007) criteria. The largest estimated ranges are for the pinnipeds marine mammal group, with a mean range to likely auditory injury of between 120 and 130 m. For the three cetacean groups the largest impact ranges are predicted for the low frequency cetaceans followed by the mid frequency cetaceans with the smallest ranges predicted for the high frequency cetaceans. This is due to piling noise containing mainly low frequency components.

Table 1.9-6 – Summary of ranges out to which audiological injury to cetaceans in the low frequency cetaceans group may occur using the Southall *et al* (2007) criteria

Low Frequency Cetaceans	Auditory Injury Range 198 dB re. 1 μPa^2/s (M_{lf})
Wind turbine 1	20 m
Wind turbine 3	20 m
Wind turbine 7	20 m
Wind turbine 11	20 m

Table 1.9-7 – Summary of ranges out to which audiological injury to cetaceans in the mid frequency cetaceans group may occur using the Southall *et al* (2007) criteria

Mid Frequency Cetaceans	Auditory Injury Range 198 dB re. 1 μPa^2/s (M_{mf})
Wind turbine 1	10 m
Wind turbine 3	10 m
Wind turbine 7	10 m
Wind turbine 11	10 m

Table 1.9-8 – Summary of ranges out to which audiological injury to cetaceans in the high frequency cetaceans group may occur using the Southall *et al* (2007) criteria

High Frequency Cetaceans	Auditory Injury Range 198 dB re. 1 μPa^2/s (M_{hf})
Wind turbine 1	7 m
Wind turbine 3	7 m
Wind turbine 7	7 m
Wind turbine 11	7 m

Table 1.9-9 – Summary of ranges out to which audiological injury to pinnipeds (in water) may occur using the Southall *et al* (2007) criteria

Pinnipeds (in water)	Auditory Injury Range 186 dB re. 1 μPa^2/s (M_{pw})
Wind turbine 1	120 m
Wind turbine 3	120 m
Wind turbine 7	130 m
Wind turbine 11	130 m

1.9.3.3 dB_{ht}/M-weighting results comparison

82 It may be noted that these ranges disagree with those predicted using the dB_{ht} model, these M-weighted results are summarised for wind turbine position 1 alongside the equivalent dB_{ht} (*Species*) results for auditory injury in Table 1.9-10 shown below. The data indicate substantially lower ranges of effect for the species of cetacean when using the single pulse Southall *et al* (2007) criteria.

83 The recommendations of Southall are founded on re-interpretation of existing public-domain information, which the authors themselves note are “variable in quantity and quality.” Further, the recorded observations of the behavioural effects on marine animals caused by noise have been re-evaluated by Southall using SPL as a measure of level, and applying simple assumptions regarding transmission loss to estimate the received level of noise as an SEL. It should be noted however that the SEL of a noise source will very probably vary with range in a different way to that which has been assumed for its SPL; and this may account in part for the anomalous results.

Table 1.9-10 Summary of impact ranges comparing the single pulse auditory injury ranges predicted using the dB_{ht} criteria (Nedwell *et al*, 2007) and the M-weighted SEL (Southall *et al*, 2007) criteria

dB_{ht} (Nedwell *et al*, 2007)		M-weighted SELs (Southall *et al*, 2007)	
Species	**Single pulse auditory injury range (130 dB_{ht})**	**Equivalent M-weighting group**	**Single pulse auditory injury range**
Bottlenose Dolphin	290 m	Mid Frequency Cetacean	10 m
Harbour Porpoise	560 m	High Frequency Cetacean	7 m
Harbour Seal	120 m	Pinnipeds (in water)	130 m

1.9.4 Estimated Ranges at Which Traumatic Hearing Damage may Occur for Multiple Pulses

1.9.4.1 dB_{ht} Cumulative Noise Dose for Fleeing Animal Scenario

84 An estimate of the minimum safe standoff distances from the piling operation based on the INSPIRE fleeing animal noise dose algorithm have also been made. Each standoff range indicates that if a particular species is closer than that range at the onset of piling, then they are unlikely to be able to flee the area before suffering hearing damage. This is based on a conservative swim speed of 1 metre per second (m/s) and takes into account the accumulated noise dose over a typical piling operation.

85 Figure 1.9-4 shows a detailed plot of the results of this modelling that has been carried out for each of the key species, in this case the figure is shown for species of seal. It can be seen that the 90 dB_{ht} $L_{EP,\,D}$ criteria (illustrated by the dashed line) is met between the 100 and 200 m starting range datasets. This means that if the seal were to be closer to the piling operations than these ranges at the onset of piling it is unlikely to escape the area without receiving a damaging noise dose.

86 Table 1.9-11 below presents the results of this modelling for the other key species of fish and marine mammal. It can be seen from these data that herring and harbour porpoise will need to be at the greatest distance from the piling operation at its onset to avoid suffering hearing damage. If the fleeing animal is beyond the ranges presented in Table 1.9-11 that they are likely to be able to reach a safe distance before receiving an unacceptable noise dose.

Table 1.9-11 Summary of the maximum starting ranges for various marine species using the fleeing animal noise dose model

Marine Species	Maximum Starting Range for Fleeing Animal
Bottlenose Dolphin / Risso's Dolphin	120 m
Harbour Porpoise	1350 m
White-Beaked Dolphin	460 m
Harbour Seal / Grey Seal	190 m
Herring	1750 m
Salmon	1 m
Dab	20 m

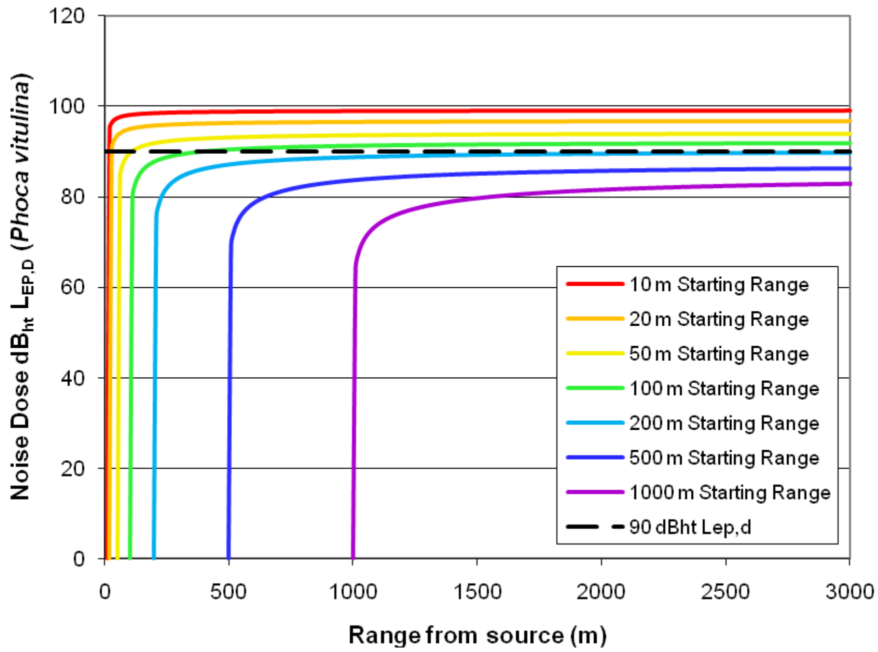

Figure 1.9-4 – Estimated noise dose for a fleeing Harbour Seal or Grey Seal for impact piling of an 8.5 m diameter pile

1.9.4.2 <u>dB$_{ht}$ Cumulative Noise Dose for Stationary Animal Scenario</u>

87 Noise dose modelling has also been carried out for a stationary animal during piling operations. It should be noted that this is considered an unlikely scenario as it implies that the animal makes no attempt to flee the high sound field area. This assessment has been carried out for the harbour seal, and the results can be seen in Figure 1.9-5.

88 It can be seen that the results for the stationary animal modelling give much higher starting ranges than for the fleeing animal modelling, with the starting range for the harbour seal rising from 190 m for a fleeing animal up to almost 1 km for a stationary animal.

89 Further modelling to estimate similar impact ranges for other species has not been carried out for the stationary animal scenario as it is not felt to represent a realistic case. The data presented for the seal is provided to indicate the potential differences in the two scenarios.

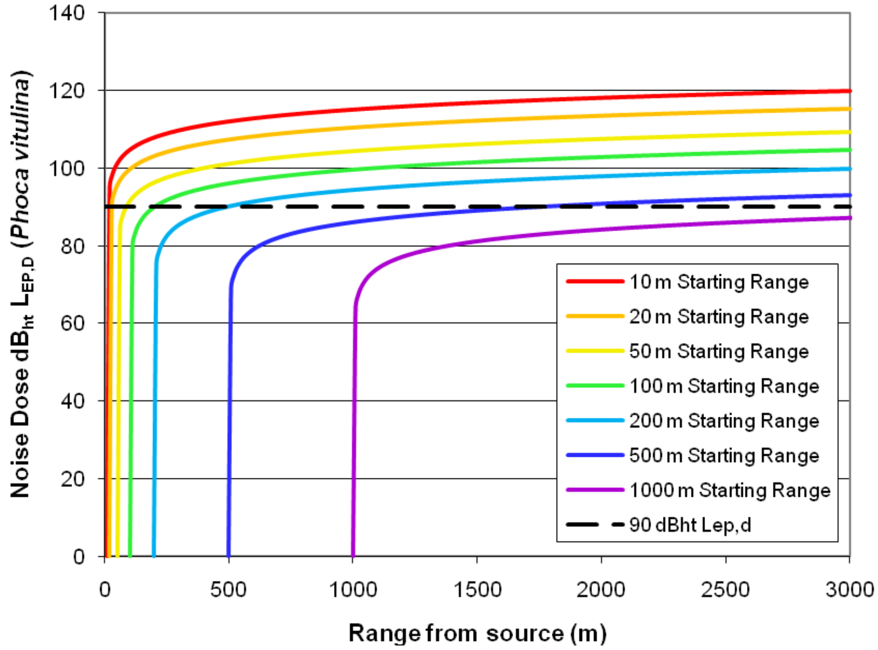

Figure 1.9-5 Estimated noise dose for a stationary Harbour Seal or Grey Seal for impact piling of an 8.5 m diameter pile

1.9.4.3 M-Weighting SEL Multiple Pulses

90 The accumulated exposure to sound for marine mammals has been assessed using the auditory injury criteria proposed by Southall *et al* (2007). This has been done by calculating a standoff range for each marine mammal group, whereby it would safely be able to escape the affected area without receiving a damaging exposure to the sound. Table 1.9-12 shows a summary of these standoff ranges for fleeing animals, assuming a swim speed of 1 m/s. The largest standoff ranges are calculated for the pinnipeds, which, based on the M-weighting criteria are likely to need to be at a range of at least 3.6 km at the onset of piling to avoid a damaging exposure to the sound. Lower standoff ranges are predicted for the three cetacean groups with low frequency cetaceans being the most sensitive to the sound and high frequency cetaceans being the least.

91 Once again, it should be noted that these results do not take into account the mitigating effects of a soft start procedure; these results assume a high blow force at the onset of piling. As long as a soft start procedure is used the effect is likely to be reduced.

92 Figure 1.9-6 shows the calculated multiple pulse M-weighted sound exposure levels for a fleeing high frequency cetacean at various starting ranges, from this it can be seen that if the animal was situated at a range of less than approximately 500 m from the piling operations at the onset of piling it is unlikely to escape the area without receiving a damaging exposure to noise according to the Southall *et al* (2007) criteria. Figure 1.9-7 shows similar data for the high frequency cetacean group; however, this is for a stationary animal during the piling operations. It can be seen that the animal would have to be between 1 and 1.5 km at the onset of piling to avoid a damaging sound exposure level, assuming that it stayed in the same position throughout the entire piling operation. It should be noted that this scenario is considered highly unlikely as marine species are likely to attempt to escape areas where injury is likely to be caused.

Table 1.9-12 Summary of the maximum starting ranges for marine mammal groups before receiving an exposure level that could cause auditory injury, using the multiple pulse criteria from Southall *et al* (2007).

Marine Mammal Group	Maximum Starting Range
Low Frequency Cetaceans	1350 m
Mid Frequency Cetaceans	820 m
High Frequency Cetaceans	650 m
Pinnipeds (in water)	3600 m

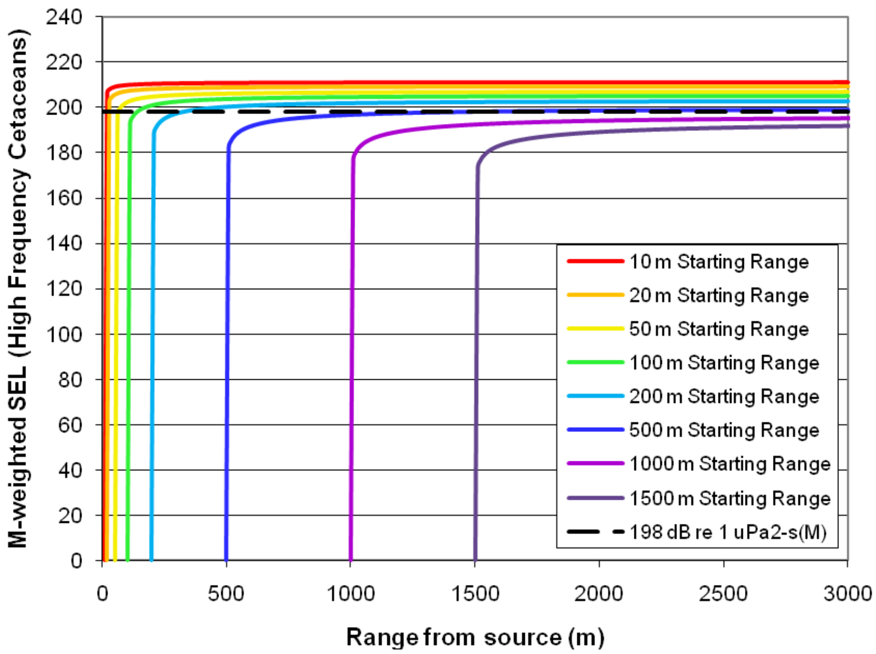

Figure 1.9-6 – Estimated M-weighted Sound Exposure levels from various starting ranges for High Frequency Cetaceans using the multiple pulse criteria from Southall *et al* (2007) for a fleeing animal

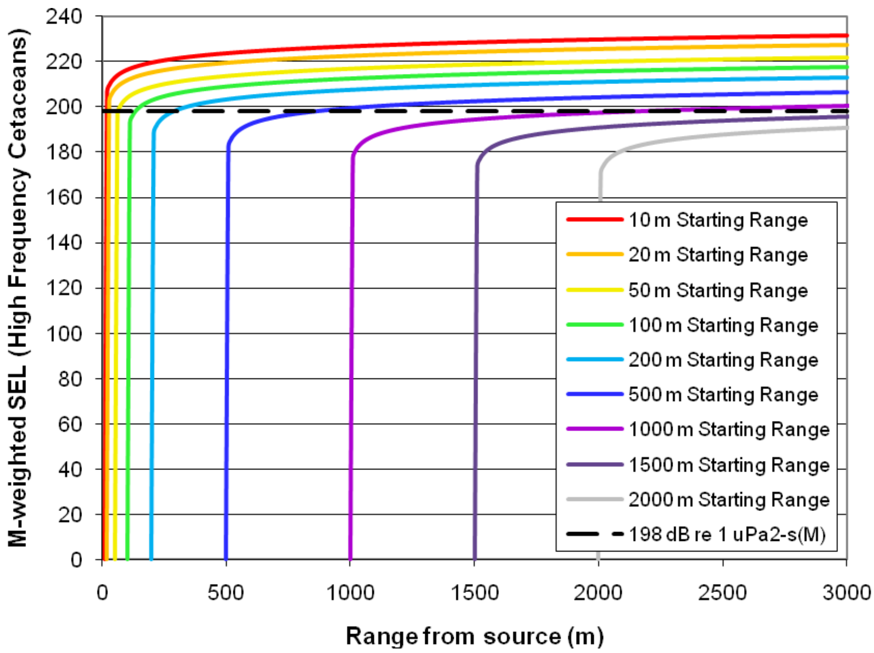

Figure 1.9-7 – Estimated M-weighted Sound Exposure levels from various starting ranges for High Frequency Cetaceans using the multiple pulse criteria from Southall *et al* (2007) for a stationary animal

93 Table 1.9-13 shows a comparison between multiple pulse auditory injury impact ranges for three marine mammals species calculated using the dB_{ht} criteria and the three equivalent M-weighted SEL marine mammal groups.

94 The data indicate that, unlike the single pulse exposure modelling, in some cases the dB_{ht} metric provides the largest estimated range of impact and in some cases the M-weighted SEL metric provides the largest impact range. This discrepancy is result of the different approaches adopted for the two metrics, however, the potential issues with the M-weighting metric have been discussed earlier in this report.

Table 1.9-13 Summary of impact ranges comparing the multiple pulse auditory injury ranges, using the fleeing animal model, predicted using the dB_{ht} criteria (Nedwell *et al*, 2007) and the M-weighted SEL (Southall *et al*, 2007) criteria

dB_{ht} (Nedwell *et al*, 2007)		M-weighted SELs (Southall *et al*, 2007)	
Species	**Multiple pulse auditory injury range (fleeing animal)**	**Equivalent M-weighting group**	**Multiple pulse auditory injury range (fleeing animal)**
Bottlenose Dolphin	120 m	Mid Frequency Cetacean	820 m
Harbour Porpoise	1350 m	High Frequency Cetacean	650 m
Harbour Seal	190 m	Pinnipeds	3600 m

1.9.5 Estimates of Behavioural Impact on Marine Species

1.9.5.1 Peak to Peak dB_{ht}

95 Figures 1.9-4 and 1.9-5 show the results for modelling 8.5 m diameter piles in terms of peak to peak dB_{ht} (*Species*) perceived sound levels for the marine species of interest for a deep water transect and a shallower water transect respectively. The depth profiles for these transects are shown in Figure 1.9-1.

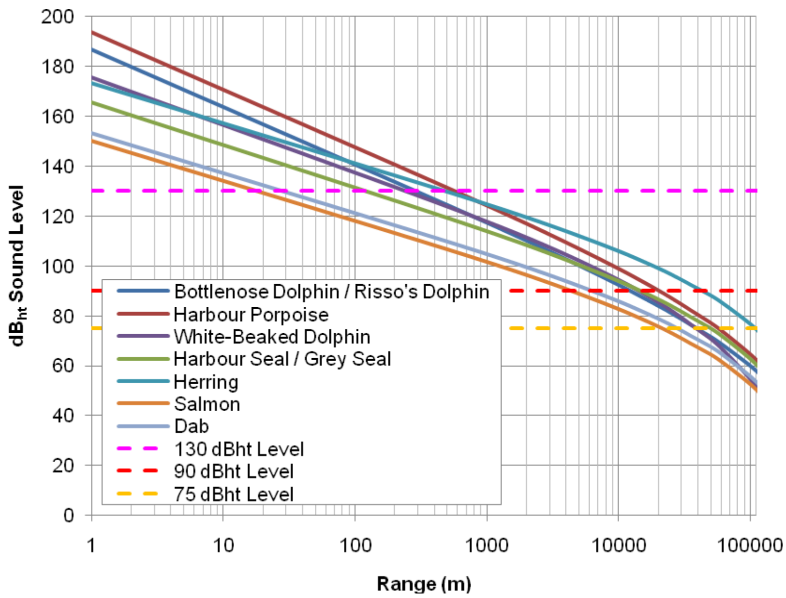

Figure 1.9-8 – Estimated peak to peak dB_{ht} level with range plot of various marine species along a deep water transect (Wind turbine 11, Bearing 060) during the installation of an 8.5 m diameter pile

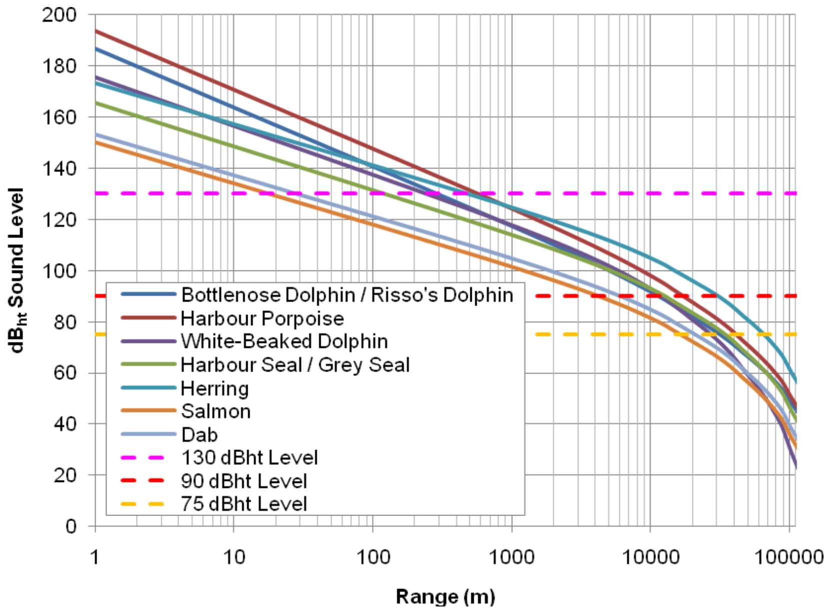

Figure 1.9-9 – Estimated peak to peak dB_{ht} level with range plot of various marine species along a shallow water transect (Wind turbine 11, Bearing 195) during the installation of an 8.5 m diameter pile

96 Table 1.9-14 to 1.9-17 present a comparison of estimated 90 dB_{ht} impact ranges for behavioural response for the species of interest at MHWS. Mean ranges along with the overall range of values are presented for all four wind turbine positions.

97 It can be seen that the largest impact ranges predicted are for herring, where maximum 90 dB_{ht} impact ranges of between 44 and 47 km are predicted. The other key fish species assessed in this study, salmon and dab, have much smaller impact ranges, from between 4.2 and 4.7 km for salmon and between 6.2 and 6.8 km for dab.

98 For species of marine mammal, the largest impact ranges are predicted for the harbour porpoise, which is likely to receive an underwater noise level of $90dB_{ht}$ out to maximum of 22 km from piling operations. The smallest 90 dB_{ht} impact ranges predicted for species of marine mammal is for bottlenose dolphin and Risso's dolphin, which are predicted maximum 90 dB_{ht} impact ranges of between 12 and 13 km.

99 The INSPIRE model calculates impact ranges along transect paths from a selected point, in this case the wind turbine positions, along 180 equally spaced transects (one every 2º). The maximum, minimum and mean ranges from all of these transects are collected in the tables below. It should be noted that the minimum ranges are for transects heading into shallow water, and in most cases, are reaching the coastline before the sound has attenuated to below 90 dB_{ht}. Hence why, for example, all the minimum ranges from Wind turbine 1 are calculated to be 3 km, as this is the minimum distance between the wind turbine position and the coastline. All the predicted received noise for all the key species is still above 90 dB_{ht} at this particular piece of coastline.

100 As the mean values quoted in the tables take into account all of the transects, these apparently shorter impact ranges are also used on the averaging. It is, therefore, suggested that the maximum values quoted and the contour plots presented later are also considered along with these results.

Table 1.9-14 – Summary of the estimated impact ranges for piling an 8.5 m diameter pile at wind turbine position 1 on various marine species

Species	90 dB_{ht} Range	
	Mean	Range of values
Bottlenose Dolphin Risso's Dolphin	8.5 km	3.0 – 13 km
Harbour Porpoise	12 km	3.0 – 21 km
White-Beaked Dolphin	9.3 km	3.0 – 15 km
Harbour Seal Grey Seal	9.6 km	3.0 – 16 km
Herring	22 km	3.0 – 45 km
Salmon	3.9 km	3.0 – 4.4 km
Dab	5.2 km	3.0 – 6.5 km

Table 1.9-15 – Summary of the estimated impact ranges for piling an 8.5 m diameter pile at wind turbine position 3 on various marine species

Species	90 dB_{ht} Range	
	Mean	Range of values
Bottlenose Dolphin Risso's Dolphin	7.9 km	2.3 – 12 km
Harbour Porpoise	11 km	2.3 – 20 km
White-Beaked Dolphin	8.4 km	2.3 – 14 km
Harbour Seal Grey Seal	8.7 km	2.3 – 15 km
Herring	20 km	2.3 – 44 km
Salmon	3.5 km	2.3 – 4.2 km
Dab	4.6 km	2.3 – 6.2 km

Table 1.9-16 – Summary of the estimated impact ranges for piling an 8.5 m diameter pile at wind turbine position 7 on various marine species

Species	90 dB_{ht} Range	
	Mean	Range of values
Bottlenose Dolphin Risso's Dolphin	9.5 km	4.1 – 13 km
Harbour Porpoise	13 km	4.1 – 22 km
White-Beaked Dolphin	10 km	4.1 – 16 km
Harbour Seal Grey Seal	11 km	4.1 – 16 km
Herring	24 km	4.1 – 47 km
Salmon	4.2 km	3.6 – 4.7 km
Dab	5.8 km	4.1 – 6.8 km

Table 1.9-17 – Summary of the estimated impact ranges for piling an 8.5 m diameter pile at wind turbine position 11 on various marine species

Species	90 dB_{ht} Range	
	Mean	Range of values
Bottlenose Dolphin Risso's Dolphin	9.2 km	3.8 – 13 km
Harbour Porpoise	13 km	3.8 – 21 km
White-Beaked Dolphin	10 km	3.8 – 16 km
Harbour Seal Grey Seal	10 km	3.8 – 16 km
Herring	23 km	3.8 – 47 km
Salmon	4.1 km	3.4 – 4.6 km
Dab	5.6 km	3.8 – 6.6 km

101 These results are also presented graphically as contour plots in Figures 1.9-10 to 1.9-16, with each group of images showing the 90 and 75 dB_{ht} impact ranges for each marine species of interest. The 75 dB_{ht} level is a lower behavioural avoidance level which has been used for analysis to show a level of "significant avoidance". At this level, about 85% of individuals will react to noise, although the effect will probably be limited in duration by habituation. In general, the 90dB_{ht} criteria level is thought to represent the most useful measure of behavioural disturbance in this case. It should be noted that the figures for dab and salmon are shown in a larger scale that the contours for the other species, this is so the extents of these smaller impact ranges can be seen in detail.

102 It can be seen from these figures that the maximum impact ranges stretch out to the east and north east of the proposed EOWDC into the deeper water of the North Sea, where, in some places, water depths are in excess of 100 m LAT. The data indicate that, in nearly all cases, the minimum 90 dB_{ht} contours are the same for each pile; this is due to sound levels being above 90 dB_{ht} for these species at the Scottish coastline. Salmon is the exception to this where, on two occasions, Turbine 7 and Turbine 11, noise levels during the

installation of 8.5m diameter piles have dropped below 90 dB_{ht}(*Salmo salar*) before reaching the Scottish coastline to the west.

103 As with the unweighted results it can be seen from these contour plots that the difference between the impact ranges at the four wind turbine sites are similar. The largest impact ranges are estimated for wind turbines 7 and 11; this is due to being situated on the east boundary of the proposed EOWDC, which is closer to the deep water of the North Sea.

1.9.6 Estimates of Behavioural Impact on Marine Species; M-weighted SELs

104 Tables 1.9-18 to 1.9-21 show summaries of the single pulse behavioural impact ranges predicted using the Southall *et al* (2007) criteria. It can be seen that the largest impact ranges are predicted for the Pinnipeds group with behavioural avoidance predicted out to a range of 1.6 km during the installation of an 8.5 m diameter pile. The three cetacean groups predict lower single pulse behavioural impact ranges, ranging from 280 m, for low frequency cetaceans, to 100 m, for high frequency cetaceans.

105 Due to these SEL levels predicting relatively low impact ranges, no maximum and minimum ranges have been included as, at these close ranges, changes in bathymetry do not affect the attenuation of sound significantly, resulting in relatively uniform results.

Table 1.9-18 – Summary of ranges out to which a behavioural avoidance reaction in cetaceans in the low frequency cetaceans group may occur using the Southall *et al* (2007) criteria

Low Frequency Cetaceans	Behavioural Avoidance Range 183 dB re. 1 μPa^2/s (M_{lf})
Wind turbine 1	270 m
Wind turbine 3	260 m
Wind turbine 7	280 m
Wind turbine 11	280 m

Table 1.9-19 – Summary of ranges out to which a behavioural avoidance reaction in cetaceans in the mid frequency cetaceans group may occur using the Southall *et al* (2007) criteria

Mid Frequency Cetaceans	Behavioural Avoidance Range 183 dB re. 1 μPa^2/s (M_{mf})
Wind turbine 1	120 m
Wind turbine 3	110 m
Wind turbine 7	120 m
Wind turbine 11	120 m

Table 1.9-20 – Summary of ranges out to which a behavioural avoidance reaction in cetaceans in the high frequency cetaceans group may occur using the Southall *et al* (2007) criteria

High Frequency Cetaceans	Behavioural Avoidance Range 183 dB re. 1 μPa^2/s (M_{hf})
Wind turbine 1	100 m
Wind turbine 3	100 m
Wind turbine 7	100 m
Wind turbine 11	100 m

Table 1.9-21 – Summary of ranges out to which a behavioural avoidance reaction in pinnipeds (in water) may occur using the Southall *et al* (2007) criteria

Pinnipeds (in water)	Behavioural Avoidance Range 171 dB re. 1 μPa^2/s (M_{pw})
Wind turbine 1	1.6 km
Wind turbine 3	1.5 km
Wind turbine 7	1.6 km
Wind turbine 11	1.6 km

106 Table 1.9-22 presents a comparison between the mean predicted dB_{ht} behavioural avoidance impact ranges and the mean M-weighted SEL behavioural avoidance impact ranges for the equivalent marine mammal groups for modelling undertaken for wind turbine position 1.

107 Once again it can be seen that the impact ranges for dB_{ht} differ substantially from those predicted using the M-weighted SEL criteria. The ranges using the M-weighted SEL criteria are thought to be highly optimistic, and are in conflict with the limited amount of published information currently available. For instance, harbour porpoise have been found to avoid an area around similar pile driving operations out to a distance of 15 km (Tougaard *et al*, 2006).

Table 1.9-22 – Summary of impact ranges comparing the single pulse behavioural avoidance ranges, at wind turbine position 1, predicted using the dB_{ht} criteria (Nedwell *et al*, 2007) and the M-weighted SEL (Southall *et al*, 2007) criteria

dB_{ht} (Nedwell *et al*, 2007)		M-weighted SELs (Southall *et al*, 2007)	
Species	**Mean behavioural avoidance range (90 dB_{ht})**	**Equivalent M-weighting group**	**Mean behavioural avoidance range**
Bottlenose Dolphin	8.5 km	Mid Frequency Cetacean	120 m
Harbour Porpoise	12 km	High Frequency Cetacean	100 m
Harbour Seal	9.6 km	Pinnipeds (in water)	1.6 km

1.10 Summary

108 Subsea noise modelling has been carried out by Subacoustech Environmental Ltd to estimate the potential impact on various species of marine mammal and fish during the installation of 8.5 m diameter piles at the proposed EOWDC. Four modelling locations were chosen to provide a representative overview of potential impact ranges from the impact piling; showing the greatest variation across the site in terms of locations. The modelling has been carried out using the latest version of the INSPIRE acoustic model (version 2.0).

- Data analysed in terms of unweighted levels of underwater noise have indicated that, for impact piling operations of 8.5 m diameter piles, the levels of underwater noise produced are predicted to be of a sufficient level to cause lethality out to a range of 3 m (using the 240 dB re. 1 μPa criteria) and physical injury out to a range of 60 m (using the 220 dB re.1 μPa criteria). Beyond these ranges severe physical effects are not expected to occur based on the assessment criteria used.
- The ranges at which traumatic hearing injury is likely to occur in the selected marine species have been estimated based on the 130 dB_{ht} (*Species*) perceived noise level. The modelled data have indicated that hearing damage may occur out to a maximum of 570 m for the harbour porpoise (the most sensitive marine mammal species to underwater noise) and 480 m for the herring (the most sensitive fish species in terms of sensitivity to underwater noise).
- Modelling to determine the potential ranges of behavioural impact for selected marine species has been carried out in terms of the dB_{ht} (*Species*) specific metric for key species of marine mammal and fish. The data have indicated that herring are likely to perceive levels of underwater noise above 90 dB_{ht} out to the greatest ranges. The maximum ranges out to which the noise is expected to remain above 90 dB_{ht} for this species is between 20 and 24 km during piling of an 8.5 m diameter pile.
- Of the marine mammals considered the perceived levels of underwater noise for harbour porpoise is estimated to remain above the behavioural impact criteria out to the greatest ranges. The maximum strong behavioural avoidance impact ranges for this species are estimated to be between 11 and 13 km for the 8.5 m diameter pile.
- The maximum ranges for all the key species are predicted to be out to the east of the site into the North Sea where the water depths are in excess of 100 m. There is not predicted to be great variation in impact ranges for the four modelling locations.
- Analysis of the modelled data has also been carried out so that an assessment can be made in terms of the M-weighted SEL criteria presented by Southall *et al* (2007). These data have indicated that, for an 8.5 m diameter pile, auditory injury from a single pulse is likely to occur out to a maximum range of 130 m for pinnipeds and 20 m for the most sensitive cetacean species.
- Using the same analytical approach for single pulses a behavioural avoidance response may be expected out to a maximum range of 1.6 km for pinnipeds and 280 m for the most sensitive cetacean species for the proposed piling operations. However, these M-weighted SEL ranges are

thought to be highly optimistic, and are in conflict with published information.

- Analysis for multiple pulses has also been carried out using the dB_{ht} Noise Dose metric and the M-Weighted SEL metric presented by Southall *et al* (2007). The dB_{ht} data indicate that the most sensitive marine mammal species, harbour porpoise, and the most sensitive fish species, herring, would have to be less than 1350 m and 1750 m away respectively from the piling operation respectively at the onset of piling to exceed the 90 dB_{ht} $L_{EP, D}$ criterion. Provided these animals were beyond these ranges at the onset of piling they would not be expected to suffer auditory damage as a result of cumulative noise dose.
- For the multiple pulse criteria for auditory injury proposed by Southall *et al* (2007). The data indicate that the pinnipeds group would have to start at a range of at least 3.6 km from the piling to avoid a damaging sound exposure from the piling noise. The cetacean group most sensitive to piling noise, the low frequency cetaceans, which includes Humpback whales (*Megaptera novaeangliae*) and Minke whale, are predicted to have to start at a range of at least 1350 m from the piling operations to escape the area without receiving a damaging exposure to the noise.
- It should be noted that these ranges for multiple pulses were calculated using the assumption that a high blow force is used at the onset of piling, this is an unlikely scenario and a soft start procedure is likely to result in a reduction to these standoff ranges.

1.11 Appendices

1.11.1 Underwater Sound Measurements

1.11.1.1 Units of Measure

109 The fundamental unit of sound pressure is the Newton per square metre, or Pascal. However, in quantifying underwater acoustic phenomena it is convenient to express the sound pressure (either peak, or Root Mean Square (RMS)) as a Sound Pressure Level (SPL) through the use of a logarithmic scale.

110 There are three reasons for this:

- there is a very wide range of sound pressures measured underwater, from around 0.0000001 Pascal in quiet sea to say 10000000 Pascal for an explosive blast. The use of a logarithmic scale compresses the range so that it can be easily described (in this example, from 0 dB to 260 dB re. 1 µPa (referenced to a sound level of 1 µPa)).
- many of the mechanisms affecting sound underwater cause loss of sound at a constant rate when it is expressed on the dB scale.
- the effects of noise tend to increase in proportion to the SPL rather than the linear level. For instance, a given increase in effect will occur each time the sound is doubled, rather than each time it increases by a given unit of pressure.

111 The Sound Pressure Level, or SPL, is defined as

$$SPL = 20\log\left(\frac{P}{P_{ref}}\right)$$

eqn. 1.11-1.

where P is the sound pressure to be expressed on the scale and P_{ref} is the reference pressure, which for underwater applications is 1 µPa.

1.11.1.2 Peak Level

112 The peak level of the noise is the maximum variation in the acoustic pressure from the ambient level within the measurement period. Peak pressures are often quoted for underwater blast measurements where there is a clear positive peak following detonation.

1.11.1.3 Peak-to-Peak Level

113 The peak-to-peak level is calculated using the maximum variation of the pressure from positive to negative within the wave. Where the wave is symmetrically distributed in positive and negative pressure, the peak-to-peak level will be twice the peak level, and hence 6 dB higher.

1.11.1.4 Root-Mean-Square (RMS) Level

114 For both continuous sound, or sound that varies in level, the RMS is used as an "average" value when calculating the level. The time period over which the averaging is conducted has to be quoted as this will influence the average level. For instance, in the case of a pile strike lasting say a tenth of a second, the mean taken over a tenth of a second will be ten times higher than the mean taken over one second.

1.11.1.5 Source Level

115 Where there is a single, well-defined source of noise, underwater sound pressure measurements may be expressed as dB re 1 µPa @ 1m, which represents the apparent level at a distance of one metre from the source. In fact, since the measurements are usually made at some distance from the source, and extrapolated back to the source, the true level at one metre may be very different from the Source Level. The Source Level may itself be quoted in any of the measures above, for instance, a piling source may be expressed as having a "peak-to-peak Source Level of 200 dB re 1 µPa @ 1 m".

1.11.1.6 Sound Exposure Level

116 The degree by which a noise source affects marine animals may depend on the duration the sound is present above background levels. Sound Exposure Level (SEL) takes into account both the SPL of the sound source and the duration the sound is present in the acoustic environment. Sound Exposure (SE) is defined by the equation:

$$SE = \int_0^T p^2(t)dt$$

eqn. 1.11-2.

where p is the acoustic pressure in pascals, T is the duration of the sound in seconds and t is time.

117 Equation A-2 gives units of pascal squared seconds (Pa^2-s).

118 The SE can be expressed as a deciBel level by using a reference pressure (P_{ref}) and a reference time (T_{ref}) on a logarithmic scale giving Sound Exposure Level (SEL):

$$SEL = 10\log_{10}\left(\frac{\int_0^T p^2(t)dt}{P_{ref}^2 T_{ref}}\right)$$

eqn. 1.11-3.

119 P_{ref} and T_{ref} are typically 1 µPa and 1 second respectively for underwater noise.

120 Equation 3 can also be expressed by:

$$SEL = SPL + 10\log_{10}(T)$$ **eqn. 1.11-4**

where T is the duration of the noise in seconds.

121 Using the reference pressures above Equation 1.11-4 shows that for a sound of 1 second duration the Sound Exposure Level is equal to the Sound Pressure Level as $10\log_{10}(1) = 0$. For a sound of 10 seconds duration the SEL will be 10 dB higher than the SPL, for a sound of 100 seconds duration the SEL will be 20 dB higher than the SPL and so on.

1.11.1.7 Frequency Content

122 To interpret an underwater sound signal for the manner in which it will be heard by an underwater animal, the sound signal in a time history format must be converted into its frequency components. This is because the response of marine species to underwater sound is frequency dependent (see the audiograms in Figures 1.7-1 to 1.7-3). This transformation of the sound is achieved by performing a Power Spectral Density (PSD) analysis of the signal. 'The PSD's (frequency spectra) presented in this report may therefore be regarded as dividing up the total power of the sound into its frequency components, and are presented in decibels (dB) referenced to 1 µPa.

1.11.1.8 The dB_{ht} (Species)

123 Measurement of sound using electronic recording equipment provides an overall linear level of that sound. The level that is obtained depends upon the recording bandwidth and sensitivity of the equipment used. This, however, does not provide an indication of the impact that the sound will have upon a particular fish or marine mammal species. This is of fundamental importance when considering the behavioural impact of underwater sound, as this is associated with the perceived loudness of the sound by the species. Therefore, the same underwater sound will affect marine species in a different manner depending upon the hearing sensitivity of that species.

124 The measurements of noise in this study have therefore also been presented in the form of a dB_{ht} level for the species. This scale incorporates the concept of "loudness" for a species. The metric incorporates hearing ability by referencing the sound to the species' hearing threshold, and hence evaluates the level of sound a species can perceive. In Figure 1.11-1, the same noise spectrum is perceived at a different loudness level depending upon the particular fish or marine mammal receptor. The aspect of the noise that can be heard is represented by the 'hatched' region in each case. The receptors also hear different parts (components) of the noise spectrum. In the case shown, Fish 1 has the poorest hearing (highest threshold) and only hears the noise over a limited low frequency range. Fish 2 has very much better hearing and hears the main dominant components of the noise. Although having the lowest threshold to the sound, the marine mammal only hears the very high components of the noise and so it may be perceived as relatively quiet.

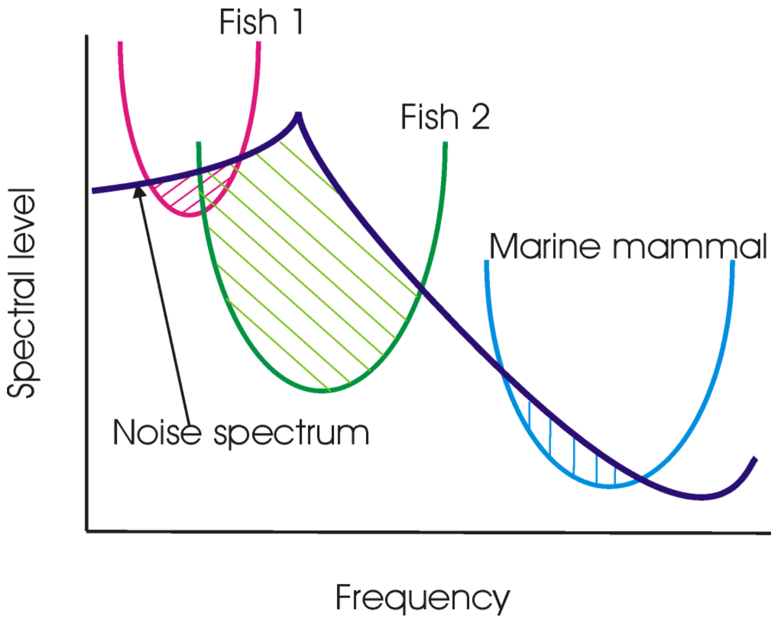

Figure 1.11-1. Illustration of perceived sound level (dBht) for representative fish and marine mammal species.

125 Since any given sound will be perceived differently by different species (since they have differing hearing abilities) the species name must be appended when specifying a level. For instance, the same sound might have a level of 70 dB_{ht} for a cod (*Gaddus morhua*) and 40 dB_{ht} for a salmon (*Salmo salar*).

126 The perceived noise levels of sources measured in dB_{ht} (*Species*) are usually much lower than the un-weighted (linear) levels, both because the sound will contain frequency components that the species cannot detect, and also because most aquatic and marine species have high thresholds of perception to (are relatively insensitive to) sound.

1.11.1.9 <u>M-weighted Sound Exposure Levels</u>

127 Southall *et al*., (2007) proposes the use of generalised frequency weighting functions to filter underwater sound exposure levels to better represent the levels of underwater noise various marine species are likely to be able to hear. The authors group marine mammals into 5 groups, 4 of which are relevant to underwater noise (the fifth is for pinnipeds in air). For each group an approximate frequency range of hearing is proposed based on known audiogram data, where available, or inferred from other information such as auditory morphology. These are summarised in Table 1.11-1 below.

Table 1.11-1 Functional marine mammal groups, their assumed auditory bandwidth of hearing and genera presented in each group (reproduced from Southall *et al* (2007))

Function hearing group	Estimated auditory bandwidth	Genera represented	Example species
Low frequency cetaceans	7 Hz to 22 kHz	*Balaena, Caperea, Eschrichtius, Megaptera, Balaenoptera* (13 species/subspecies)	Grey whale, Right whale, Humpback whale, Minke whale
Mid frequency cetaceans	150 Hz to 160 kHz	*Steno, Sousa, Sotalia, Tursiops, Stenella, Delphinus, Lagenodelphis, Lagenorhynchus, Lissodelphis, Grampus, Peponocephala, Feresa, Pseudorca, Orcinus, Globicephala, Orcaella, Physeter, Delphinapterus, Monodon, Ziphius, Berardius, Tasmacetus, Hyperoodon, Mesoplodon* (57 species/subspecies)	Bottlenose dolphin, striped dolphin, Killer whale, Sperm whale
High frequency cetaceans	200 Hz – 180 kHz	*Phocoena, Neophocaena, Phocoenoides, Platanista, Inia, Kogia, Lipotes, Pontoporia, Cephalorhynchus* (20 species/subspecies)	Harbour porpoise, River dolphins, Hector's dolphin
Pinnipeds (in water)	75 Hz to 75 kHz	*Arctocephalus, Callorhinus, Zalophus, Eumetopias, Neophoca, Phocarctos, Otaria, Erignathus, Phoca, Pusa, Halichoerus, Histriophoca, Pagophilus, Cystophora, Monachus, Mirounga, Leptonychotes, Ommatophoca, Lobodon, Hydrurga,* and *Odobenus* (41 species/subspecies)	Fur seal, Harbour (common) seal, Grey Seal

1.11.1.10 Background Levels

128 Of critical importance in assessing the impact of noise and vibration from an activity is a measure of the ambient noise environment. The pre-existing noise and vibration levels in fast flowing rivers, busy estuaries and coastal waters will be high compared to the levels that are associated with airborne perception by terrestrial animals. As an example, ambient underwater noise in coastal waters measured as a broadband level from 1 Hz to 100 kHz, typically varies from 100 to 130 dB re. 1 µPa.

1.11.1.11 Attenuation of Sound

129 To normalise underwater sound and vibration measurements to a common reference point, levels are normally quoted as Source Levels. As the sound propagates out from the source the level will reduce both as a result of geometric spreading and absorption in the propagation medium. These effects when combined provide a model for the Transmission Loss (TL) of the noise and vibration with range. This means that the received level at range is substantially lower than the Source Level in the immediate vicinity of the activity.

130 The sound level at range from an activity can be described by the expression;

$L(r) = SL – TL$ **eqn. 1.11-5.**

where L(r) is the Sound Pressure Level at distance r from a source (m), SL is the (notional) source level at 1 m from the source, and TL is the transmission loss.

131 The Transmission Loss is frequently described by the equation

$TL = N \log(r) + \alpha r$ **eqn. 1.11-6.**

where r is the distance from the source (m), N is a factor for attenuation due to geometric spreading, and α is a factor for the absorption of sound in water and boundaries (dB.m-1).

132 Using this form of sound transmission loss, the sound level with range L(r) can be described by the expression

$L(r) = SL – N \log(r) - \alpha r$ **eqn. 1.11-7.**

1.11.2 Preliminary subsea noise modelling at the proposed European Offshore Wind Deployment Centre

1.11.2.1 *Introduction*

133 Preliminary underwater noise modelling has been undertaken by Subacoustech Environmental to provide an indication of the likely differences in impact ranges between impact piling different size piles at the proposed EOWDC site.

134 Underwater noise levels have been estimated along one transect using the INSPIRE model (currently version 2.0), a proprietary acoustic propagation modelling program developed by Subacoustech Environmental. INSPIRE has been tested and validated against a large database of measured underwater noise data from previous impact piling operations and calculates absorption and depth-dependent transmission losses. These are used in conjunction with bathymetric data to calculate estimated impact ranges for the underwater noise produced during the proposed impact piling operations.

135 The two options being considered at proposed EOWDC are monopile foundations, using 8.5m diameter piles, and jacket foundations, using four 2.5 m diameter piles. To make this assessment a representative transect has been chosen from turbine position 11, which is in the deepest water (approximately
30 m deep at mean high water springs (MHWS)), at a bearing of 60º, which extends into water that is over 100 m in depth. This particular transect has been chosen to give a “worst case” estimate of the impact ranges for the proposed piling operations at the proposed EOWDC.

136 It should be noted that the INSPIRE model has been developed using the best available underwater noise data, however, the largest pile diameter for which reliable measured data is available is 6.1 m in diameter. Impact range estimates for pile sizes greater than this have been calculated by extrapolation and it is not yet possible to validate the results experimentally.

137 The results of the modelling have been presented here as linear (unweighted) peak to peak sound levels and weighted peak to peak dB_{ht}(*Species*) levels for four species of marine mammal that are of interest in the areas surrounding the proposed EOWDC site; bottlenose dolphin, harbour porpoise, harbour seal and white-beaked dolphin (using the striped dolphin as a surrogate, as currently available information suggests that both species have a similar sensitivity to sound).

1.11.2.2 *Unweighted Results*

138 Figure 1.11-2 illustrates the predicted unweighted peak to peak underwater noise levels, using the INSPIRE model, shown as level against range plots. The results were calculated along one deep water transect of bearing 60º from turbine position 11 estimating the impact of installing an 8.5 m diameter and a 2.5 m diameter pile, these impact ranges are also summarised in Table 1.11-2. It can be seen from these results that the sound is likely to remain at

high levels out to considerably larger distances for the 8.5 m pile when compared to the 2.5 m pile.

139 Table 1.11-3 summarises the unweighted impact ranges using predicted peak underwater noise levels. As the waveform of a pile strike is typically symmetrical about the ambient pressure level (equal high and low pressure excursions) it can be reasonably assumed that the peak pressure level is half of the peak to peak pressure level (a reduction of 6dB). The impact ranges in Table 2 have been calculated by reducing the peak to peak noise levels predicted by the INSPIRE model by 6dB.

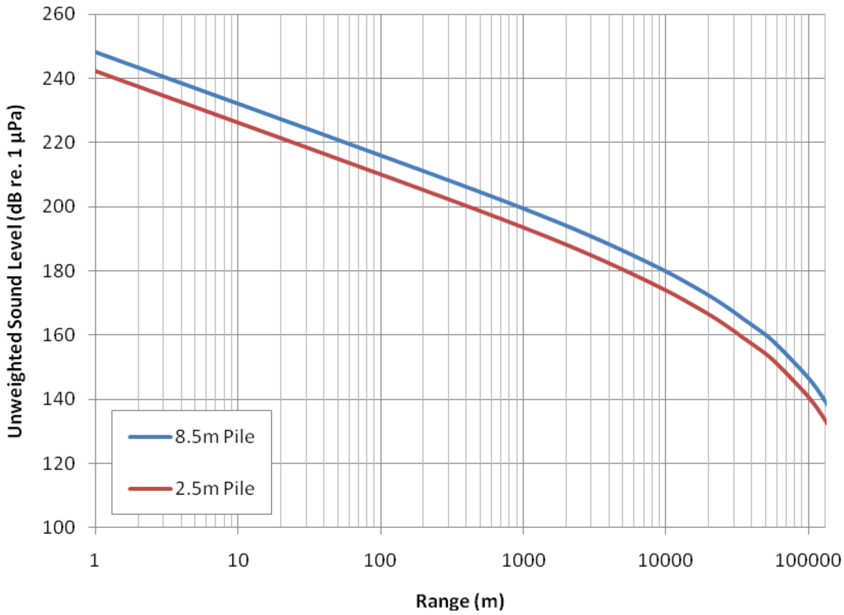

Figure 1.11-2 – Level with range plot for the estimated unweighted peak to peak underwater noise levels at Position 11 for 8.5m and 2.5m diameter piles.

Table 1.11-2 – Summary of the estimated ranges to various unweighted peak to peak underwater noise levels at Position 11 for 8.5 m and 2.5 m diameter piles.

Peak to peak	**8.5 m Diameter Pile**	**2.5 m Diameter Pile**
Range to 200 dB re. 1 µPa	960 m	420 m
Range to 190 dB re. 1 µPa	3.3 km	1.6 km
Range to 180 dB re. 1 µPa	9.9 km	5.3 km
Range to 170 dB re. 1 µPa	24 km	15 km
Range to 160 dB re. 1 µPa	51 km	33 km
Range to 150 dB re. 1 µPa	86 km	64 km

Table 1.11-3 – Summary of the estimated ranges to various unweighted peak underwater noise levels at Position 11 for 8.5 m and 2.5 m diameter piles.

Peak	**8.5 m Diameter Pile**	**2.5 m Diameter Pile**
Range to 200 dB re. 1 µPa	390 m	180 m
Range to 190 dB re. 1 µPa	1.6 km	720 m
Range to 180 dB re. 1 µPa	5.3 km	2.6 km
Range to 170 dB re. 1 µPa	15 km	8.2 km
Range to 160 dB re. 1 µPa	33 km	21 km
Range to 150 dB re. 1 µPa	64 km	44 km

1.11.2.3 dB$_{ht}$(Species) Results

140 The dB$_{ht}$(*Species*) metric (Nedwell *et al.*, 2007) has been developed as a means for quantifying the potential for a behavioural impact on a species in the underwater environment. Since any given sound will be perceived differently by different species (since they have differing hearing abilities) the species name must be appended when specifying a level. For instance, the same sound might have a level of 70 dB$_{ht}$(*Phocoena phocoena*) for harbour porpoise and 40 dB$_{ht}$(*Phoca vitulina*) for harbour seal.

141 Currently, on the basis of a large body of measurements of fish avoidance of noise (Maes *et al,* 2004), and from re-analysis of marine mammal behavioural response to underwater sound, the following assessment criteria was published by the Department of Business, Enterprise and Regulatory Reform (BERR) (Nedwell *et al,* 2007) to assess the potential impact of the underwater noise on marine species:

Table 1.11-4 – Assessment criteria used in this study to assess the potential impact of underwater noise on marine species.

Level in dB$_{ht}$(*Species*)	Effect
90 and above	Strong avoidance reaction by virtually all individuals.
Above 110	Tolerance limit of sound; unbearably loud.
Above 130	Possibility of traumatic hearing damage from single event.

142 In addition, a lower level of 75 dB$_{ht}$ has been used for analysis as a level of “significant avoidance”. At this level, about 85% of individuals will react to the noise, although the effect will probably be limited in duration by habituation.

143 Figures 11.1-3 and 11.1-4 show the results for modelling 8.5 m diameter piles and 2.5 m diameter piles respectively in terms of peak to peak dB$_{ht}$(*Species*) perceived sound levels for the four marine mammals as level with range plots. The levels where traumatic hearing injury (130 dB$_{ht}$), strong behavioural avoidance (90 dB$_{ht}$) and significant behavioural avoidance (75 dB$_{ht}$) may occur in species are also indicated in these figures. The modelling was carried out along the same transect as before at a bearing of 60º from turbine position 11. A summary of these impact ranges is presented in Tables 11.1-5 and 11.1-6.

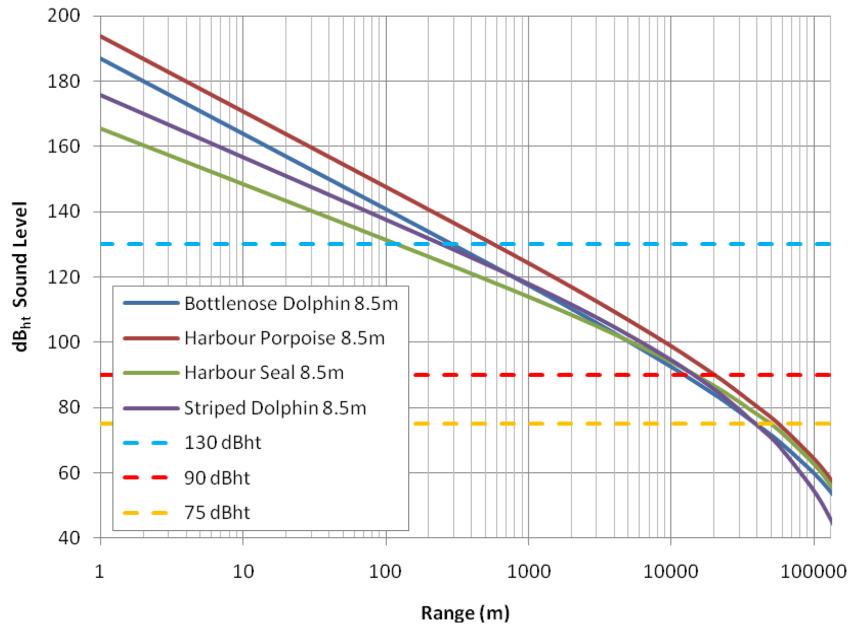

Figure 1.11-3 – Estimated peak to peak dB_{ht} level with range plot for four species of marine mammal during the installation of an 8.5 m diameter pile.

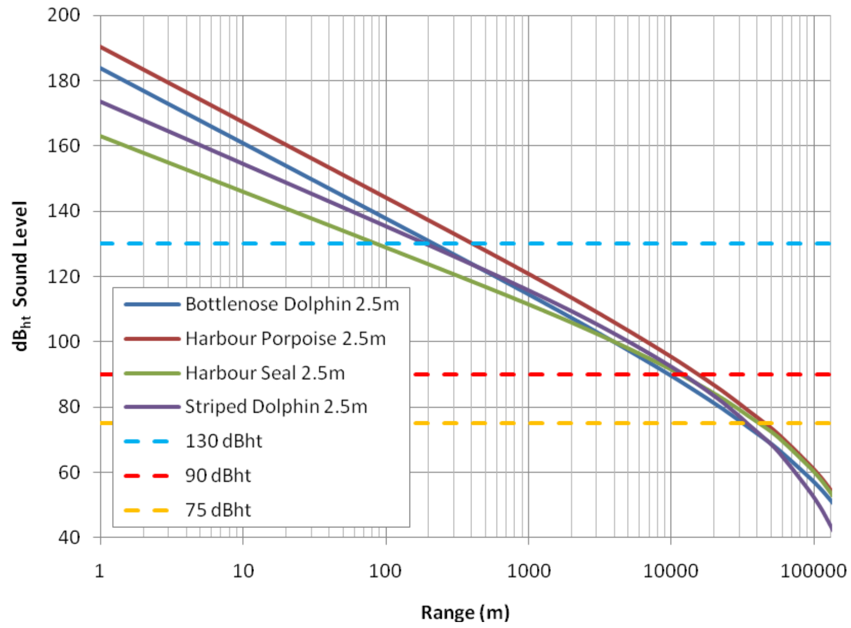

Figure 1.11-4 – Estimated peak to peak dB_{ht} level with range plto for four species of marine ammal during the installation of a 2.5m diameter pile.

Table 11.1-5 – Summary of the estimated impact ranges for piling an 8.5 m diameter pile on various species of marine mammals.

8.5 m Diameter Pile	Range to 130 dB_{ht}	Range to 90 dB_{ht}	Range to 75 dB_{ht}
Bottlenose Dolphin (dB_{ht}(*Tursiops truncatus*))	300 m	12 km	39 km
Harbour Porpoise (dB_{ht}(*Phocoena phocoena*))	570 m	20 km	57 km
Harbour Seal (dB_{ht}(*Phoca vitulina*))	150 m	15 km	50 km
Striped Dolphin (dB_{ht}(*Stenella coeruleoalba*))	270 m	14 km	39 km

Table 11.1-6 – Summary of the estimated impact ranges for piling a 2.5 m diameter pile on various species of marine mammals.

2.5 m Diameter Pile	Range to 130 dB_{ht}	Range to 90 dB_{ht}	Range to 75 dB_{ht}
Bottlenose Dolphin (dB_{ht}(*Tursiops truncatus*))	240 m	10 km	32 km
Harbour Porpoise (dB_{ht}(*Phocoena phocoena*))	420 m	16 km	46 km
Harbour Seal (dB_{ht}(*Phoca vitulina*))	90 m	12 km	42 km
Striped Dolphin (dB_{ht}(*Stenella coeruleoalba*))	210 m	12 km	35 km

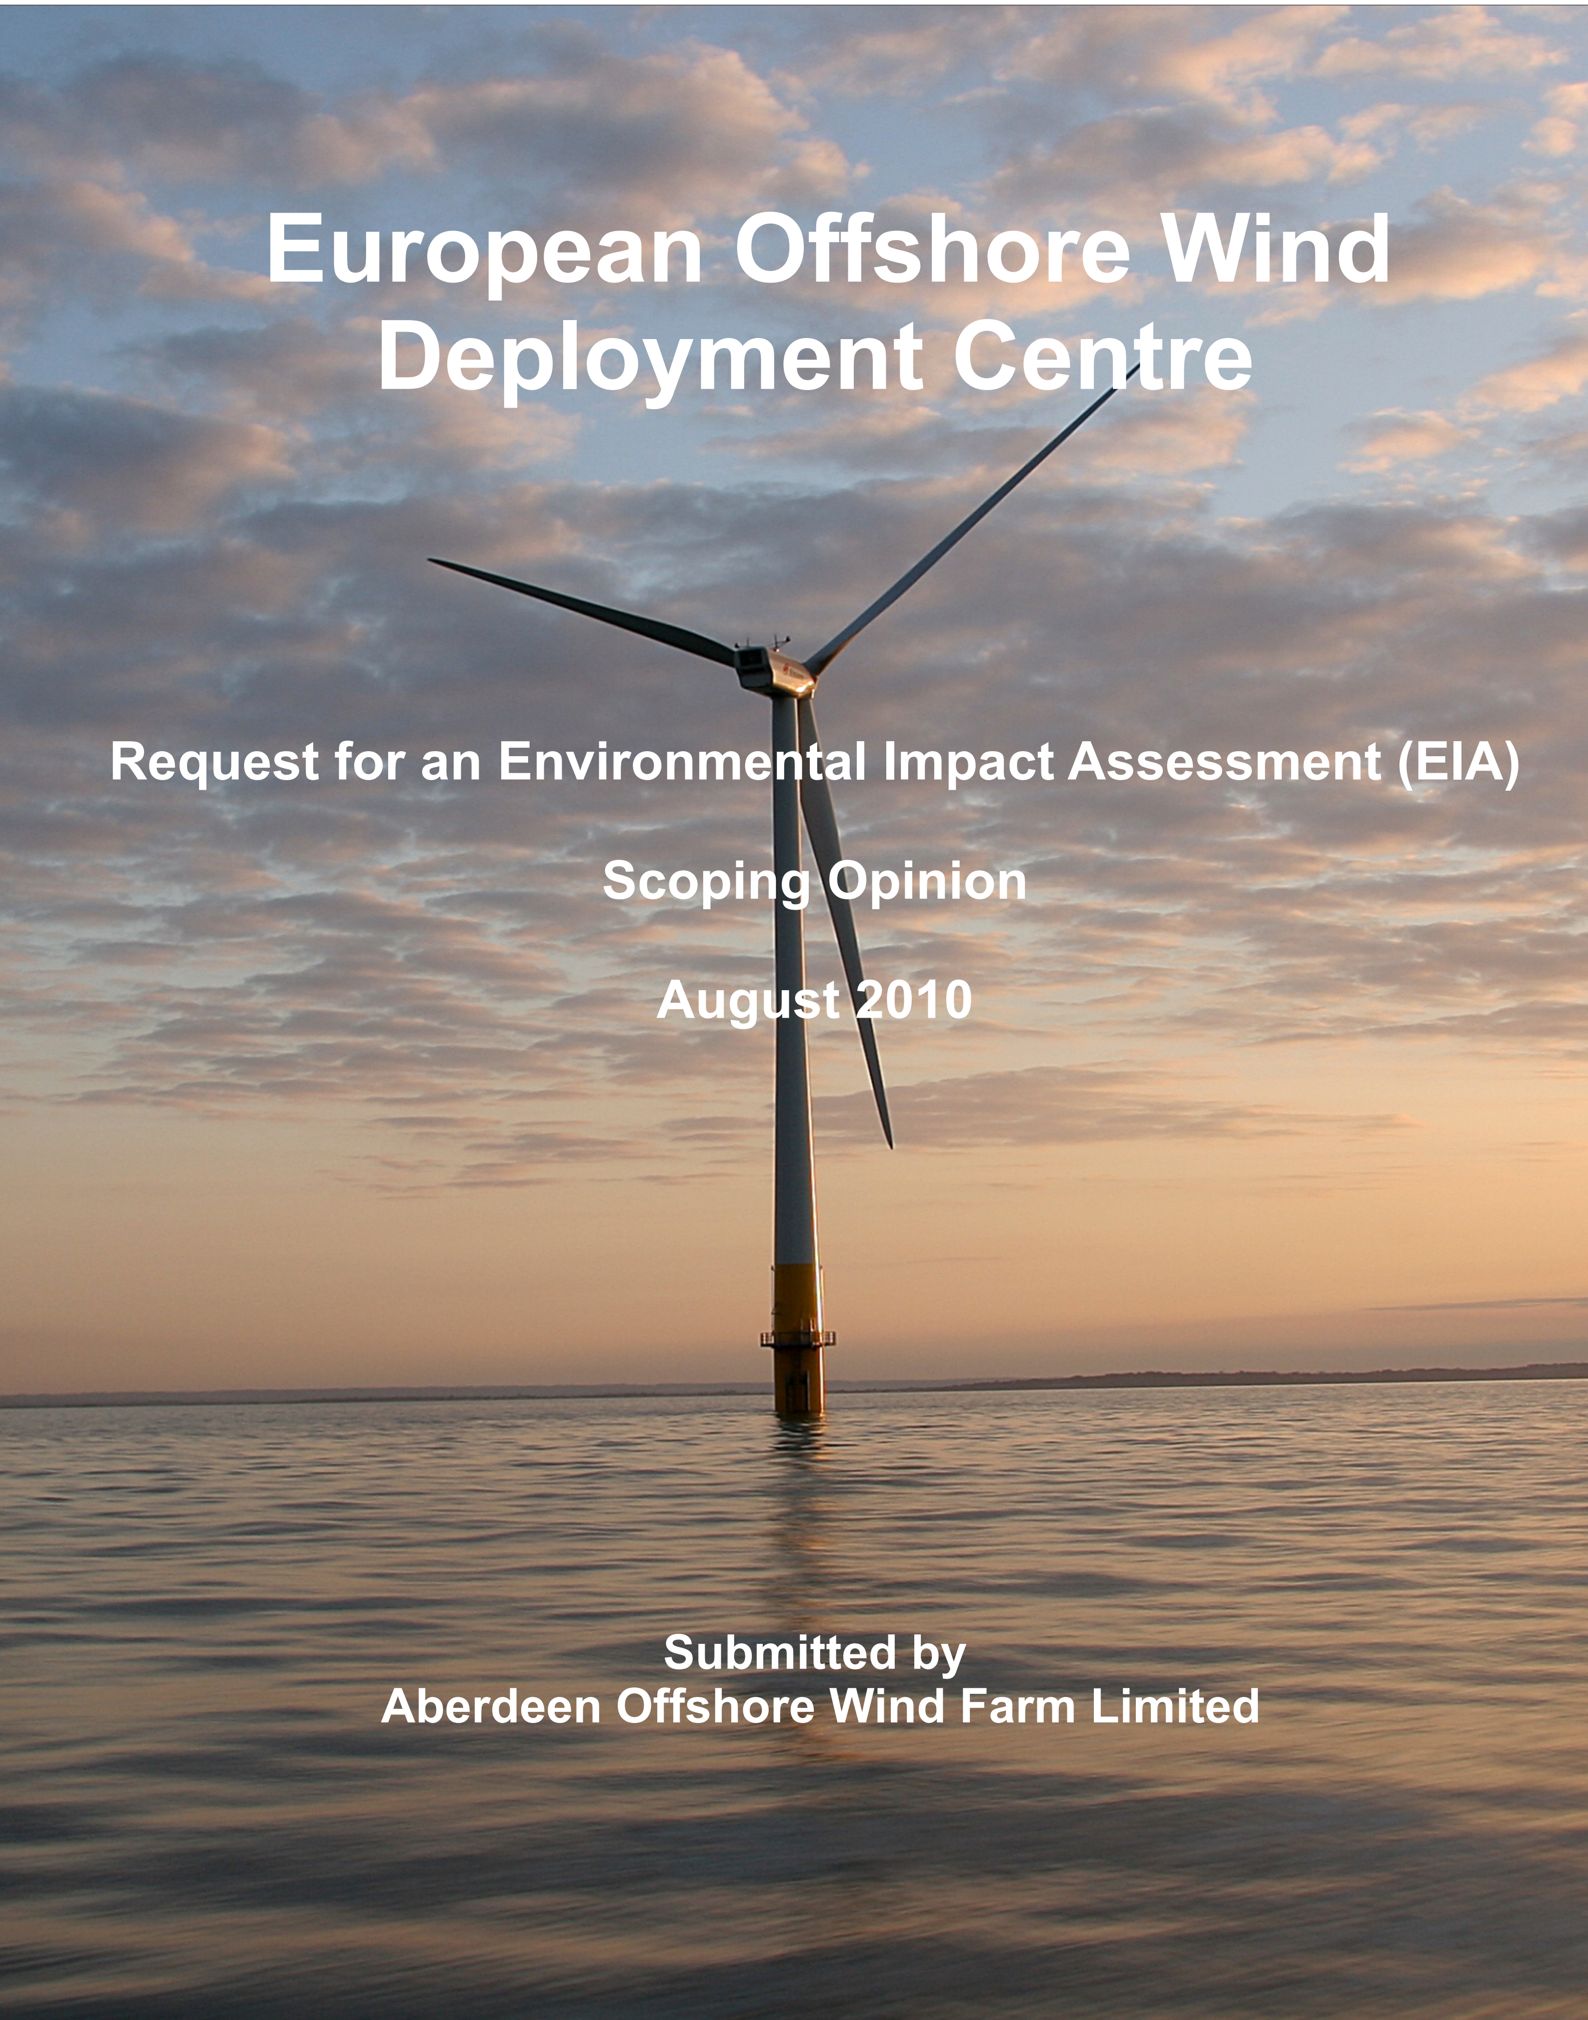
European Offshore Wind Deployment Centre
Environmental Statement

Appendix 4.1: Request for Scoping Opinion 2010

VATTENFALL Technip areg Aberdeen Renewable Energy Group

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy



European Offshore Wind Deployment Centre

Request for an Environmental Impact Assessment (EIA)

Scoping Opinion

August 2010

Submitted by
Aberdeen Offshore Wind Farm Limited

PREFACE

Aberdeen Offshore Wind Farm Limited (AOWFL) is proposing to develop an offshore wind farm and deployment centre off the coast of Aberdeen, known as the European Offshore Wind Deployment Centre (EOWDC).

The proposed project would combine a small commercially operated wind farm with a test and research centre, allowing manufacturers to test “first of run” wind turbines and innovative foundation solutions along with related operation and maintenance access logistics.

The project would also include an Ocean Laboratory which would allow environmental monitoring before, during and after deployments. Environmental data may also be collected through a series of planned surveys.

The site is considered ideal for this purpose as it is close to the city of Aberdeen, a recognised centre of excellence for offshore activities and easily accessible, being approximately 2 to 4.5 km from the shore, and in close proximity to Aberdeen Harbour.

The maximum output, as governed by The Crown Estate lease conditions, is 100 MW which would meet the demand of over 55,300 households, approximately 50 % of the domestic need of the Aberdeen City population.

An application for an agreement for lease from The Crown Estate was submitted as part of the ‘Demonstration Sites’ round in December 2009. In August 2010 AOWFL was awarded an exclusivity agreement for the Aberdeen site.

A Section 36 consent in relation to the European Offshore Wind Deployment Centre, will be applied for within the first quarter of 2011. This timeline is driven by securing and committing 40 million Euros from Europe under the European Energy Programme for Recovery (EEPR).

The project is also likely to require consent under Section 34 of the Coast Protection Act 1949, and a Marine Construction Licence under Section 5 of the Food and Environment Protection Act 1985.

A previous Scoping Report was submitted in 2005. Following detailed consultation the site layout for the project has altered significantly. This document aims to inform stakeholders about the current proposal, the consents required and the planned approach to the Environmental Impact Assessment.

AOWFL welcome your comments on this Scoping Report. Comments should be sent to:

1 INTRODUCTION

1.1 Background Information

1 In 2005 there was an intention to develop a project comprising 33 commercially operating wind turbines off the coast of Aberdeen. However, due to constraints on the layout which became apparent at an early stage, recent rapid developments in technology and the need for further research in key areas, in 2008 the project was developed into its current form and is now known as the European Offshore Wind Deployment Centre (EOWDC) – a small (11 wind turbine) commercially operated wind farm with a test and research facility, including an Ocean Laboratory.

1.2 Project Overview

2 The vision of the project is:

“To deploy new equipment, systems, processes and initiate R&D to improve the competitiveness of Offshore Wind Energy production, whilst generating environmentally sound marketable electricity and to increase the supply chain capabilities in Scotland, the wider UK and Europe.”

3 This project is targeted at both enabling and encouraging increased competition into the European wind turbine supply chain by providing sites for manufacturers both to prove new and innovative solutions and also to allow the acquisition of offshore “hands-on” design, build and operational and maintenance experience, in advance of Round 3.

4 This project will allow “first of run” production wind turbine systems to be operated in the marine environment so that developers, owners and financiers can gain confidence in wind turbine manufacturer’s new machine designs, allowing the development of the supply chain in this area.

5 The project will promote and enable the deployment of pre-production innovative foundations.

6 There will be an Ocean Laboratory that could hold meteorological masts, environmental monitoring equipment and be used for access training. The inclusion of an Ocean Laboratory would allow environmental monitoring before, during and after deployments. Environmental data may also be collected through a series of planned surveys. The environmental effects of the deployment centre could be closely monitored and data collected prior to Round 3 developments being installed.

7 Environmental monitoring would provide stakeholders with information on associated environmental impacts.

8 There is the possibility of novel electrical design through testing grid connection technologies.

1.3 The Developer

9 The project will be developed by Aberdeen Offshore Wind Farm Ltd (“AOWFL”). AOWFL will build, own and operate the project's permanent wind

farm assets. AOWFL is an established legal entity owned by Vattenfall Wind Power Ltd (75 %) and Aberdeen Renewable Energy Group (AREG) (25 %).

1.3.1 Vattenfall Wind Power Ltd (VWPL)

10 Vattenfall Wind Power Ltd's ultimate holding company is Vattenfall AB (publ.), a state owned Swedish energy utility company. It currently operates nearly 570 MW of offshore wind capacity around Europe and has a pipeline of 4,800 MW of offshore wind capacity at various stages of development. Vattenfall are currently constructing Thanet Offshore Wind Farm, located 12 km off the Kent coast. The project consists of 100 wind turbines of 3 MW installed capacity each. Vattenfall are also jointly developing with ScottishPower Renewables, the Round 3 East Anglia zone off the east coast of England which has the potential to provide a capacity of up to 7,200 MW.

1.3.2 Aberdeen Renewable Energy Group (AREG)

11 AREG is an incorporated company representing the interests of over 150 member organisations. Established in 2001, AREG aims to ensure that Aberdeen City and Shire and its businesses play a major role in the energy revolution. AREG has been supported by the Energising Aberdeen Fund of Aberdeen City Council. The Fund represents a £22.25 million investment in the future of Aberdeen over five years by the Scottish Government.

1.4 Aims of this Document

12 AOWFL requests a Scoping Opinion from the Scottish Ministers under Regulation 7 of the Electricity Works (Environmental Impact Assessment) (Scotland) Regulations 2000 specifying the information to be provided in the Environmental Statement (ES) which will accompany the application for a consent under Section 36 of the Electricity Act 1989.

13 A request for a Scoping Opinion was originally made for the scheme in 2005. However there have been considerable changes in both layout and information available on the site since that date so it was suggested and thought highly appropriate that a new Scoping Opinion be requested.

14 AOWFL also requests the Scottish Ministers to procure Scoping Opinions on the basis of the same information under Regulation 4 of the Harbour Works (Environmental Impact Assessment) Regulations 1999 in relation to the intended application for a consent under Section 34 of the Coast Protection Act 1949 and under the provisions of the Food and Environment Protection Act 1985 in relation to the intended application for one or more licences pursuant to Section 5 of that Act.

15 In addition, AOWFL formally notifies the Scottish Ministers under Regulation 8 of the 2000 Regulations described above, that it is intended to submit an application for consent under Section 36 of the 1989 Act for the Aberdeen Offshore Wind Farm and that it is intended to submit an Environmental Statement to accompany this application.

16 In accordance with the above Regulations, this scoping document includes:

- a plan to identify the proposed development site
- a brief description of the nature and purpose of the proposed development and of its possible effects on the environment
- further information as required

17 This document has been prepared with reference to the above Regulations and the Guidance Notes on the Offshore Wind Farm Consents Process issued by Scottish Executive Consents and Emergency Planning Unit.

18 Under Directive 2000/42/EU (the Strategic Environmental Assessment Directive) an environmental assessment is required for plans and programmes in specific sectors, including energy, that sets the framework for development consents for projects listed in the EIA Directive and for those requiring an appropriate assessment under the Habitats or Birds Directives. At present an SEA is being prepared by the Scottish Government in respect of Scottish Territorial Waters, which may impact upon this proposal. We welcome advice from the Scottish Executive on this subject. However we note that the Draft Plan for Offshore Wind Energy in Scottish Territorial Waters confirms "smaller areas that are suitable for test and demonstration sites, including existing sites have been scoped out of the Draft Plan and it's environmental assessment" (Marine Scotland, 2010 paragraph 2.5.3).

1.5 The Need for Offshore Wind Energy

19 Climate change represents one of the greatest environmental threats faced by the world today with far reaching implications for the global environment and economy. Renewable electricity generation is vital for decarbonising the global energy system and hence global climate change mitigation. Wind energy is one of the most competitive technologies in renewable energy. However, large scale implementation offshore, whilst offering potential for significant opportunity to develop vast wind resource capacity, also poses huge challenges, requiring technological innovation, industrial & market development and, in parallel, significant cost reduction to become cost competitive with other forms of energy sources.

20 The UK, and specifically Scotland, has some of the best wind resource in Europe.

21 The Scottish Government aims to achieve a target of 50 % of Scottish demand for electricity from renewable sources by 2020 with a milestone of 31 % by 2011. The Scottish Parliament passed the Scottish Climate Change Act in 2009. It demanded a 42 % cut in greenhouse gas emissions by 2020 and 80 % cuts by 2050, based on a 1990 baseline. The development of Scotland's offshore wind potential will be crucial to the delivery of Scotland's legal obligations on climate change.

22 The rapid development of offshore wind capacity is central to the delivery of the UK's share of the EU target of 20 per cent renewable energy by 2020. The Crown Estate, as the seabed owner, has recently announced proposals to deliver up to 25 GW of new offshore wind farm sites by 2020 through the Round 3 licensing. This is intended to provide a stimulus throughout the EU and to provide an important contribution to both reducing CO_2 emissions and improve security of energy supply to the wider EU. This builds on the 8 GW of offshore wind farm projects currently under development and to be

delivered by Rounds 1 and 2. If successful, the addition of the capacity from Round 3 and the Scottish Territorial Waters Round together with any additional smaller sites, could lead to a potential total of 39.5 GW of offshore wind energy.

23 The scale of the challenge in delivering such a large programme is such that the equipment and services supply chains need to be dramatically enhanced very quickly and efficiently. The central requirement is for live operational experience with validated data, together with an area to deploy novel technologies to gain actual operational hours offshore in a controlled, yet real, environment.

24 The EOWDC focus on proving new technology, processes and operations and improving existing technology, processes and operations. Key objectives will be increasing reliability, efficiency and reducing costs. As such, it will directly contribute to the delivery of not only the UK Round 3 and Scottish Territorial Water Rounds, but also the wider European programme of offshore development.

25 The maximum output, as governed by The Crown Estate lease conditions, is 100 MW, and with a 30 % capacity factor would provide enough capacity to meet the demand of over 55,300 homes, equating to a supply large enough to meet over 50 % of the domestic need of the Aberdeen City population[1]. The 2013 household estimate for Aberdeen is 108,150 (See Appendix 9.1).

1.5.1 Creation of Employment from Wind Energy

26 Estimates vary as to the global job creation potential for wind power (on and offshore). However a middle case scenario suggests 462,000 by 2010 and 1.3 million by 2020 with a potential maximum recognised as 572,000 by 2010 and 2.2 million by 2020 (GWEA, 2008). As Europe is a particularly intensive area for wind development, it is to be expected that the proportion of global employment secured could be significantly higher than implied by the population or land mass and sea area. The European Wind Energy Association estimates that European employment in wind power will increase to almost 330,000 in 2020 and to 375,000 by 2030, 57 % of the latter figure being accounted for by offshore wind (EWEA, 2008).

1.6 Approach to Environmental Impact Assessment

27 The EIA for this project will comprise the following sections:

- Non-Technical Summary
- Introduction
- Legislative Framework
- Project Description
- Physical Environment Baseline Description and Impact Assessment
    - Meteorological Conditions
    - Geology, Bathymetry and Topography

[1] This assumes number of households in Aberdeen was 102,900 in 2008. This is based on the “Household Projections for Scotland 2008-based” from the General Register Office for Scotland (2010).

  - Oceanographic Conditions
  - Sediment and Water Quality
  - Coastal Processes
- Biological Environment Baseline Description and Impact Assessment
  - Marine Ecology
  - Intertidal Ecology
  - Ornithology
  - Bats
  - Marine Mammals
  - Underwater Noise and Vibration
  - Electromagnetic Fields
  - Conservation - to include information to support an Appropriate Assessment if one is required
- Human Environment Baseline Description and Impact Assessment
  - Shipping and Navigation
  - Aviation
  - Ministry of Defence
  - Archaeology
  - Seascape, Landscape and Visual and Cultural Heritage
  - Commercial Fisheries
  - Socio-economics
  - Recreation and Tourism
  - In-Air Noise
  - Energy and Emissions
  - Electromagnetic Interference
  - Other Marine Users
- Summary of Environmental Impact Assessment and Mitigation Measures
- Glossary of Terms
- References
- Supporting Technical Appendices

28 Each Environmental section is likely to comprise the following information:

- Introduction
- Methodology and Guidance
- Baseline Methodology
- Impact Assessment Methodology
- Description of the Baseline Environment
- Impact Assessment – Construction, Operation and Decommissioning
  - Potential Impact
  - Mitigation
  - Residual Impact
  - Monitoring
- Cumulative Impact Assessment
- In-combination Impact Assessment

1.6.1 Impact Assessment Methodology

29 In the case of each impact, the assessment aims to describe the magnitude of effect (ie the change created by an activity in terms of spatial extent, duration and scale) and the sensitivity of each receptor. The combination of the effect and the sensitivity of the receptor are then used to derive the

significance of the impact. The criteria that will be used in general is given below:

1.6.1.1 <u>Spatial Extent of Effect</u>

- a national/international effect
- a regional effect
- a local effect (within 5 km of the site)
- a site-specific effect

1.6.1.2 <u>Duration of Effect</u>

- a long-term/permanent effect (more than 10 years)
- a medium-term effect (existing for 5 to 10 years)
- a short-term effect (existing for 1 to 5 years)
- a temporary effect (existing for less than a year)

1.6.1.3 <u>Scale of Effect</u>

- above accepted standards/guidelines
- within accepted standards/guidelines
- where there are no standards/guidelines available, the impact relative to background conditions

1.6.1.4 <u>Recoverability of the Receptor</u>

- high
- medium
- low or none

1.6.1.5 <u>Importance of the Receptor</u>

- high
- medium
- low

30 The impact significance is then given as *major*, *moderate*, *minor* or *negligible*, see Table 1.1.

TABLE 1.1 Matrix for significance of impact					
	Sensitivity of Receptor				
Magnitude of Effect based on spatial, duration and scale of effect		**Very High**	**High**	**Medium**	**Low**
	Very High	Major	Major	Major	Moderate
	High	Major	Major	Moderate	Minor
	Medium	Major	Moderate	Moderate	Minor
	Low	Moderate	Minor	Minor	Negligible
	Negligible	Minor	Negligible	Negligible	Negligible

1.6.2 Cumulative and In-combination Impact

31 An important part of the EIA process will be to consider cumulative and in-combination impacts.

1.6.2.1 Cumulative Impact

32 Schedule 3 of the Electricity Works EIA (Scotland) Regulations 2000 requires that the potential for *cumulative impact* should be considered and where appropriate, assessed.

33 Cumulative impacts will include, but may not be limited to, impacts that arise from the following existing and reasonably foreseeable development activities:

- other wind farms
- aggregate extraction and dredging
- navigation and shipping
- established fishing activities
- existing and planned construction subsea cables and pipelines
- potential port / harbour development
- oil and gas installations

34 The cumulative assessment will address where predicted impacts of the wind farm construction and operation could interact with impacts from other industry sectors within the same region and impact sensitive receptors. This may be through direct effects or spatially/temporally separated impacts on the same population of a receptor.

1.6.2.2 In-combination Impacts

35 The Conservation (Natural Habitats, & c.) Regulations 1994 (as amended) require that an Appropriate Assessment (AA) must be conducted by a competent authority of the implications for the European site in view of the European sites conservation objectives in respect of any plan or project which is not directly connected with or necessary to the management of the European site for conservation purposes and which is likely to have a significant effect on the European site either alone or *in-combination* with other plans or projects.

36 Therefore the term 'in-combination' will be used when considering the impacts of the proposals with other plans or projects on European sites.

2 PROJECT DESCRIPTION

2.1 Site Location

37 The EOWDC site is located approximately 2 km from the Aberdeenshire coast (see Figure 1). The proposed site comprises an area following the coastline between northern Aberdeen and Balmedie. The lease boundary for development would cover up to 20 km^2.

2.2 Site Selection

38 The EOWDC site location has been determined through a long process of examining the constraints, undertaking consultations, and conducting surveys, studies and assessments.

39 The concept of an offshore wind farm in Aberdeen originated in 2002 following approach by AREG to AMEC Wind Energy. The concept of a Renewable Energy Centre in Aberdeen was discussed and included an onshore wind turbine and a number of offshore wind turbines. AMEC Wind Energy began to look at a layout stretching up the coastline and initial visualisations were carried out by the Macaulay Institute.

40 The joint venture was formed in 2005 in the proportions AMEC 75 % and AREG 25 %. With the sale of AMEC Wind Energy to Vattenfall, the joint venture now comprises Vattenfall Wind Power Ltd 75 % and AREG 25 %. The company has a board of directors drawn from the two constituent organisations.

41 The wind farm layout has undergone a number of iterations from 2004 to 2010 which are described in Table 2.1 and shown on Figures 3, 4 and 5. These layout changes have primarily been a result of consultation with Aberdeen Harbour Board, the aviation industry, the Ministry of Defence and key environmental stakeholders.

42 In 2005, a Scoping Opinion was sought on a wind farm development layout which was located approximately 1 km from the Aberdeenshire coast (See LABER007 Figure 3). This site comprised an area following the coastline between Girdle Ness and Newburgh, with the study area for development covering approximately 26 km^2. It was proposed that the wind turbines would be aligned in two rows either side of the 10 m water depth contour. The wind farm at that time comprised approximately 33, three-bladed wind turbines, with an individual wind turbine capacity of up to 5 MW.

43 The project described in this Scoping Report now comprises 11 wind turbines and an Ocean Laboratory located approximately between 2 and 4.5 km offshore, see Figure 2.

Table 2.1
Site Layout Iterations

Internal Layout Reference	Number of Wind Turbines	Date	Wind Turbine Layout Description
LABER002	18	October 2004	Initial layout (based on 10 m water depth constraint) extended north to Newburgh Bar and increased indicative rotor diameter to 120 m and separation between wind turbines to suit.
LABER007	33	February 2005	Layout followed the coastline between Girdle Ness and Newburgh. Two rows of wind turbines were designed to be aligned either side of the 10 m water depth contour. This is the layout included in the previous Scoping Report 2005.
LABER008	24	September 2005	Similar to LABER007, this layout follows the coastline between Girdle Ness and Newburgh. There are two distinct groups, a northern one and a southern one, with a gap in the middle to accommodate a 4 nm helicopter corridor (Shrub – Balis). Both groups have three columns of wind turbines. Outer wind turbines now in water depths up to 20 m. Not a valid layout, created for discussion only.
LABER011	23	January 2006	Updated aviation constraints (including Bridge of Don alternative route) were used to create this layout along with a water depth limit of 25 m. Layout wind turbines have a 120 m rotor diameter. Not a valid layout, created for discussion only.
LABER012	10	September 2008	Site reduced to 10 wind turbines for MOD re-assessment. From the previous layout, the columns closest and furthest from the shore were both removed (for bird and shipping interests) along with the two northern most wind turbines of the remaining 12 (for Black Dog Rifle Range impact), leaving 10 wind turbines.
LABER015	10	March 2009	Wind turbine locations similar to subset of LABER011. Wind turbine locations differ slightly due to increased separation to accommodate a 126 m rotor diameter. Created with the intention of a 10 wind turbine layout not extending as far south as LABER012, in order to avoid Bridge of Don alternative helicopter corridor constraint.
LABER021	15	September 2009	Layout created based on LABER015. Five wind turbines added in total. Two coastal wind turbines removed, extra row added to south (but outside helicopter constraint) and three wind turbines added as eastern column. One wind turbine added into the Black Dog Rifle Range giving a total of two in this area.
LABER027	12	October 2009	Layout based on new internal agreed list of constraints: - outside existing northern and alternative southern helicopter constraints - within geophysical survey area

Table 2.1
Site Layout Iterations

Internal Layout Reference	**Number of Wind Turbines**	**Date**	**Wind Turbine Layout Description**
			- outside of MoD Black Dog Rifle Range - no closer to coast than layout LABER021. Layout designed to consider multiple rotor diameters of 90 m, 126 m and 150 m so that outer row accommodates largest rotor diameter. The layout was limited by the necessary spacing between wind turbines. Layouts LABER022 to 026 informed this layout through several variations for discussion.
LABER028	11	November 2009	Following a response from the MoD the wind turbine which was located within the MoD Black Dog Firing Range was removed.
LABER032	16	April 2010	Following further consultation with NATS, it became apparent that there is a possibility of moving the northern helicopter route further north allowing room for two more wind turbines at the north of the site. Also three wind turbines were added to the east of the site as the geophysical survey boundary constraint was relaxed due to this expansion to the north. The decision to have wind turbines beyond the geophysical survey boundary was driven by desire to increase distance from Aberdeen Harbour.
LABER033	11	April 2010	The six southernmost wind turbines were removed to increase distance from the harbour and shipping. The entire site was slightly shifted down to accommodate an extra wind turbine to the north of the site such that it doesn't lie within the helicopter constraint.
LABER034	11	April 2010	Entire layout was rotated using northernmost wind turbine as a turning point to align the rows of wind turbines to the proposed realigned helicopter constraint. Layout created for discussion.
LABER037	12	April 2010	New layout based on latest constraints of revised northern helicopter route, MoD Black Dog Rifle Range and maintaining a distance from the harbour similar to LABER036. Layout is a regular grid of 3 rows and 4 columns of wind turbines.
LABER039	11	April 2010	Removed the easternmost wind turbine of LABER037 to increase distance from shipping routes.

2.3 The Project Concept

44 The intent is to install a mix of "first run of production" wind turbines on a mix of conventional and novel foundations with monitoring and instrumentation, both for technical and environmental purposes.

45 By providing this infrastructure relatively close to shore, the EOWDC has a possibility for novel training, logistics and an accreditation centre to enable the efficient and timely deployment for European offshore wind turbines

46 Timely construction of the EOWDC will be conditional on successfully raising of all the funding requirements which include a €40m grant from the EU under the European Energy Programme for Recovery (EEPR).

47 At the heart of the project is the interaction between a research, test and training centre with a small, highly innovative, commercially operated and highly instrumented and monitored offshore wind farm. The technologies deployed on the wind farm will provide supporting income to the EOWDC and will offer potential opportunities for:

- the provision of renewable electricity
- technology “proving” through commercial development and deployment
- logistics and supply chain development and proving
- accreditation and training as commercial offerings, especially Health, Safety and Environmental protection (HS&E)
- commercial R&D, testing and dissemination including:
  - long-term environmental monitoring and improvement
  - University level research
  - community, regional, national and international education

2.4 Proposed Development

48 This section summarises the key aspects of the project design. It should be noted that, in defining the project that will be assessed during the EIA, the “Rochdale Envelope” approach (see section 3.4.1) will be adopted. By adopting this approach, it will be possible to conclude that the environmental impact of the proposed development will be no greater than set out in the Environmental Statement.

49 The key offshore components of the proposed EOWDC are:

- 11 offshore wind turbines and their associated foundations
- subsea cables between the wind turbines
- an export cable for connection to the electricity transmission network
- scour protection around foundations and on inter-array and export subsea cables as required and
- an Ocean Laboratory

50 The key onshore components of the wind farm are likely to be:

- onshore deployment facilities
- the landfall site with associated jointing between the offshore export cable and onshore cable to the onshore substation
- the onshore substation

51 This scoping report deals with the offshore components of the project only. The onshore cables and onshore components will be applied for under the Town and Country Planning Act and will be dealt with under a separate Scoping Report. The level of environmental information required to support

the planning application for the onshore works will be discussed with the relevant authorities.

2.4.1 Wind Turbines

52 The wind turbines will be between 4 and 10 MW. The 4 MW wind turbines will have a maximum hub height of 100 m above LAT and the 10 MW wind turbines will have a maximum hub height of 120 m above LAT. Maximum rotor diameter will be 120 m and 150 m respectively. It should be noted that the exact specifications for the project are yet to be determined as it is a test centre and it is not known yet exactly which wind turbines will be deployed on the site.

TABLE 2.2
Wind Turbine Dimensions for the Minimum and Maximum Size Machines

Wind Turbine Size	Maximum Hub Height above LAT (m)	Maximum Rotor Diameter (m)	Maximum Tip Height above LAT (m)
4 MW	100	120	160
10 MW	120	150	195

53 The Environmental Impact Assessment will be based on a hypothetical machine with a maximum height to tip of 195 m above LAT. The lifetime of the project is dependent upon seabed lease agreements and the current proposal for the length of the lease is 22 years.

2.4.2 Foundations

54 Potential foundation types which will be considered within the EIA are:

- steel monopile
- concrete monopile
- jacket on piles
- tripod on piles
- gravity base structure and
- suction caisson

55 A detailed description of the installation, and decommissioning methods for each foundation type considered will be included within the Environmental Statement.

56 Apart from the different foundation types stated in Table 2.3, the EOWDC may also be used to test new concepts.

57 It is expected that any new foundation concepts which may be proposed for the wind farm site would lie within the project envelope used for the purposes of the EIA.

58 More than one foundation type could be used within this project. For all the foundation options, the foundation structure will extend by approximately 15 to 20 m above mean sea level (MSL) such that the base of the wind turbine tower is clear of the most extreme design wave height.

59 Indicative dimensions, construction materials and a brief description of the expected installation methods for each of the foundation options are outlined in Table 2.3. The indicative dimensions are based on a 5 MW wind turbine size and mid-range water depth but will vary for larger wind turbine sizes.

2.4.3 Ocean Laboratory

60 It is the intention to install an Ocean Laboratory on the wind farm site. This is likely to comprise of meteorological monitoring and other environmental measuring equipment. The Ocean Laboratory structure could also be used for access training. Options for future research and monitoring of the site can be found within the relevant sections of this document. The Ocean Laboratory would be subject to a separate consent application which would be discussed with the relevant consenting authorities. Once the Ocean Laboratory is operational it could be used by research organisations to allow long-term environmental monitoring. Potential locations for the Ocean Laboratory can be seen on Figure 2 as an indicative monitoring location.

2.4.4 Export Cable

61 The potential location of the export cable route is dependent on the location of the onshore substation. An indicative onshore substation location and indicative cable route can also be seen on Figure 2.

Table 2.3
Basic Foundation Types and Information

Type	Indicative Dimensions[1]	Construction Material	Indicative Installation Method
Steel monopile[2]	Up to 7.5 m diameter Pile embedment 30 m plus	Steel pile and transition piece	Pile and transition piece transported to site by installation vessel or barge Pile up-ended by crane and lowered to seabed Pile driven by hammer (sometimes drilled) Transition piece installed by crane and connection grouted Rock dumping scour protection (if required)
Concrete monopile[2]	Up to 8.5 m diameter Pile embedment 30 m plus	Pre-cast reinforced concrete ring elements with steel post-tensioning	Pile and ice cone platform transported to site by installation vessel or barge Pile up-ended by crane and lowered to seabed Pile drilled from inside toe of pile Ice cone platform installed Rock dumping scour protection (if required)
Jacket on piles	Numerous variants are being considered. Typically, lattice structure comprising tubular sections of diameter 0.5 to 1.2 m Approx. 25 m x 25 m footprint at base Pile diameter approx. 1.8 to 2.5 m Pile embedment approx. 30 m – 35 m	Steel jacket and piles	Jacket and piles transported to site by barge Installation template set down on sea bed Piles stabbed and driven Survey of pile levels and adjustment of jacket leg positions Jacket lifted and set down on piles Jacket levelled and pile connections grouted

Table 2.3
Basic Foundation Types and Information

Type	Indicative Dimensions[1]	Construction Material	Indicative Installation Method
Tripod on piles	Typically main column approx. 5.5 m diameter, with 3 No. diagonal braces approx. 4 m diameter Approx. 25 m diameter footprint at base Pile diameter approx. 1.8 to 2.5 m Pile embedment approx. 30 m – 35 m	Steel tripod and piles Concrete tripod variants also being considered	Tripod and piles transported to site by barge Tripod lifted and set-down on mudmats on the seabed by crane Piles stabbed and driven Tripod levelled and pile connections grouted
Gravity base structure	Typically conical tower, approx. 6.5 m diameter at top Approx. 30-40 m diameter footprint at base	Reinforced concrete shell with pumped sand ballast fill	Seabed preparation as necessary GBS transported to site by barge or heavy lift vessel (or floated) GBS lifted by crane (or up-ended) and lowered to seabed Levelling and underbase grouting Ballasting (sand or similar) and further levelling as necessary Rock dumping scour protection (if required)
Suction caisson/bucket	Tower section 5.5 to 6.5 m diameter Approx. 18 m diameter footprint for bottom skirt Skirt embedment approx. 10 m depending of the soil conditions	Primary material is steel	Caisson transported to site by floating Up-ended by crane and lowered to seabed Air deflated in bucket skirt to sink caisson Scour protection (if required)

Notes
1 Initial estimate based on mid-range wind turbine size (5 MW) and mid-range water depth
2 These foundation types are limited to lower end of range of wind turbine sizes and water depths

2.5 Project Construction

2.5.1 Construction Timescales

62 The construction of the proposed project is planned in a phased approach and will be further described in the Environmental Statement but it is likely to be:

- four wind turbines installed in Year 1 (2012)
- seven wind turbines to be installed in Year 3 (2014)

63 Construction in the marine environment is potentially hazardous, and in the interests of safe working the project should be permitted to take advantage of as much construction time in favourable conditions as is possible. Construction activity is expected to continue, subject to site weather conditions, for 24 hours per day until construction is complete.

2.5.2 Construction Infrastructure

64 Key to defining the construction methodologies (and therefore the likely construction activities) will be choices on the following:

- wind turbine selection
- foundation types
- inter-array cables
- port(s) used as the base for the construction phase
- vessels to be used for the offshore construction works

65 Potential options would be addressed during the detailed design and EIA phase. However, as the project is being used to test first of run wind turbine and innovative foundation types, new concepts may become apparent throughout the project development. It is anticipated that these would lie within the project envelope used for the purposes of the EIA.

66 A number of ports exist on the east coast of Scotland and mainland Europe coast that may be suitable for much of the construction and operation activities required for the wind farm project. Part of the detailed project design and logistics planning for the project involves assessing a number of potentially suitable port facilities.

67 In addition to using ports for the construction of the wind farm, consideration will be given to the components of the wind farm being brought directly to the project site from their point of manufacture.

68 Construction compounds and storage facilities will be required at the ports used as the construction base(s).

69 It can be assumed that the key stages associated with the installation of the wind farm are likely to be as follows:

- detailed pre-construction site investigation (eg cone penetration tests, boreholes and high resolution geophysics), subject to a separate consent application process

- foundation installation and associated site preparation
- installation of tower, nacelle, hub and blades of the wind turbine generators
- installation of inter-array transmission cables
- installation of transmission cables to shore and
- construction of the required onshore electrical infrastructure (onshore substation) to link the development to the National Grid transmission system

2.5.2.1 *<u>Foundations</u>*

70 Foundation installation will be one of the first offshore construction activities to take place. Methods of installation for foundations vary significantly depending upon the foundation type selected. Techniques typically employed for foundation installation include:

- pile driving
- pile drilling
- seabed levelling (for gravity base structures)
- ballasting (for gravity base structures) and
- grouted connections (eg for connecting piles to jacket)

2.5.2.2 *<u>Wind Turbines</u>*

71 Following foundation installation, offshore wind turbines will be erected. Commonly, towers and nacelles are pre-erected or erected individually at the site using a crane barge. Blades are subsequently fitted to the tower/nacelle structure as individual components or in a part assembled state.

72 Aviation warning lighting to be fitted to some or all of the wind turbines, as required by the UK Air Navigation Order 2009 which will be designed in consultation with key stakeholders, such as the Civil Aviation Authority (CAA). Additionally, international aviation regulatory documentation requires that the rotor blades, nacelle and upper two thirds of the supporting mast that are deemed to be an aviation obstruction should be painted white, unless otherwise indicated by an aeronautical study.

2.5.2.3 *<u>Inter-Array Cables</u>*

73 The extent to which the various burial techniques are used will be dependent on the result of a detailed seabed survey of the final cable route and associated burial risk assessment process. It is likely that some form of ploughing or jetting, or combination of both, will be used.

74 Rock dumping, frond mats/ grout bags or concrete mattresses may be used to protect the cable ends where they enter wind turbine foundations and may be utilised when ground conditions result in the cable being laid near to or on the surface. It is conceivable that the laying of cable protection may also be necessary after burial, where sections of cables are too shallow or have otherwise become exposed as informed by the post installation inspection or periodic maintenance surveys.

2.5.2.4 Cable and Pipeline Crossings

75 There are two telecommunications cables west of and close to EOWDC and it is therefore possible that crossings may be required. The design of any crossing will be agreed with the cable/pipeline owner/operator to ensure that integrity of all the assets is maintained.

2.5.2.5 Scour Protection

76 Scour can occur around the base of a foundation when seabed sediment is worn away as a result of the flow of water around the structure. A number of options for scour protection could be considered for installation, depending on the final project design process, ground conditions and scour assessments. These could include:

- rock and gravel dumping
- protective aprons
- mattresses and
- flow energy dissipation (frond) devices

77 The installation of scour protection material would be carried out using a ship or barge, for example using an on-board fall pipe system. Alternatively, custom-built vessels equipped with side-dump facilities, grabs or fall pipe with a remotely operated vehicle can also be used.

2.6 Project Operation and Maintenance

78 The operation and control of the wind farm will be managed by a Supervisory Control and Data Acquisition (SCADA) system, connecting each wind turbine to a control room.

79 The current technology of wind turbines will require a major service every 12 months. Periodic visits will also be required in the event the wind turbines experience a fault which cannot be remotely reset. Gearbox oil changes are required every five years. Periodically, large components such as gearboxes and blades may need to be replaced.

80 It is not considered a requirement to have formal safety zones around the wind turbines during operation, but an area may be established around each wind turbine to regulate other users of the sea for safety reasons. The applicants understand that provisions within the Electricity Act 1989 could be revised to allow this. Any safety areas will be proposed only after full consultation with the Maritime and Coastguard Agency (MCA) and Aberdeen Harbour Board.

2.7 Project Decommissioning

81 The design life of the wind turbines and other components of the wind farm are likely to be in the order of 20 to 30 years. If the decision to refurbish or replace the wind turbines is made, then any relevant consents or licences required would be applied for at that time.

82 At the end of the operational life of the wind farm it is anticipated that all structures above the seabed will be completely removed by reverse lay, that is, the reverse construction sequence.

83 The decommissioning plan submitted prior to the construction of the EOWDC will be reviewed and revised as necessary throughout the lifecycle of the project to reflect changing circumstances and regulatory requirements, and to incorporate improvements in knowledge and understanding of the marine environment and advances in technology and working practices.

84 Part 2 of the Energy Act 2004 sets out powers requiring the decommissioning of offshore renewable energy installations and their related equipment. Guidance supporting the Act requires a decommissioning plan to be in place prior to the completion of the construction of an offshore wind farm. As part of the decommissioning plan an assessment on the potential environmental impacts may also be required.

85 The International Maritime Organisation Guidelines (IMO) and Standards for the Removal of Offshore Installations and Structures on the Continental Shelf and in the Exclusive Economic Zone (IMO 1989), set out the minimum global standards to be applied to the removal of offshore installations and structures. The Guidelines and Standards were designed essentially to ensure the safety of navigation and are not intended to preclude a coastal state from imposing more stringent removal requirements.

86 In large part, the UK's approach to decommissioning is governed under the 1992 Convention for the Protection of the Marine Environment of the North East Atlantic (OSPAR Convention). Agreement on the regime to be applied to the decommissioning of offshore installations in the Convention area was reached at a meeting of the OSPAR Commission in July 1998 (OSPAR 98/3). The UK's acceptance of OSPAR Decision 98/3 means that the UK will apply the provisions of that instrument when considering the decommissioning of offshore installations rather than the standards and guidelines laid down by the IMO. However, certain aspects of the IMO Guidelines and Standards are still relevant. These are:

- any disused installation or structure, or part thereof, which projects above the surface of the sea should be adequately maintained
- an unobstructed water column of at least 55 m must be provided above the remains of any partially removed installation to ensure safety of navigation
- the position, surveyed depth and dimensions of any installation not entirely removed should be indicated on nautical charts and any remains, where necessary, properly marked with aids to navigation
- the person responsible for maintaining any aids to navigation and for monitoring the condition of any remaining material should be identified
- the liability for meeting any claims for damages which may arise in the future should be clear
- on or after 1 January 1998, no installation or structure should be placed on any continental shelf or in any exclusive economic zone unless the design and construction of the installation or structure is such that entire removal upon abandonment or permanent disuse would be feasible

87 Under the terms of Decision 98/3, which entered into force on 9 February 1999, there is a prohibition on the dumping and leaving wholly or partly in

place offshore installations. The topsides of all installations must be returned to shore. All installations with a jacket weight less than 10,000 tonnes must be completely removed for re-use, recycling or final disposal on land.

3 LEGISLATIVE FRAMEWORK

3.1 The Crown Estate Lease

88 A developer must obtain a site lease from The Crown Estate (TCE) prior to installing a renewable energy device in the marine environment. The Crown Estate owns much of the foreshore and seabed from Low Water out to 12 nautical miles (nm).

89 A Strategic Environmental Assessment (SEA) is currently being prepared by Marine Scotland on behalf of the Scottish Government to assess offshore wind energy within Scottish Territorial Waters to ensure that environmental considerations are incorporated within the decision-making process and that ultimately offshore wind energy development is sustainable. Until the results of the SEA have been finalised by Marine Scotland, developers will be offered an exclusivity agreement with TCE. In the event that the results of the SEA do not rule out prospective development of the proposed site, TCE will proceed to the negotiation of an Agreement for Lease with the developer. AOWFL was awarded an exclusivity agreement with TCE for the Aberdeen site in August 2010. As noted earlier, the Draft Plan for Offshore Wind Energy in Scottish Territorial Waters confirms, “smaller areas that are suitable for test and demonstration sites, including existing sites, have been scoped out of the Draft Plan and its environmental assessment (Marine Scotland, 2010 paragraph 2.5.3). The implications of this for the EOWDC will be discussed with TCE.

90 The Agreement for Lease will contain an option (subject to the fulfilment of all conditions including statutory consents) for the developer to call for the grant of an agreed form lease. The lease will provide the right for the construction, siting and occupation of an area for the purpose of placing structures on, or passing cables over Crown Estate land.

3.2 Marine Licensing

91 On 1 April 2010, Marine Scotland - Licensing Operations Team (MS-LOT) became responsible for a range of statutory controls in waters adjacent to Scotland. Until the new marine licensing regime comes into effect (which is discussed further below), Marine Scotland is responsible for dealing with consent applications.

3.2.1 Current Statutory Regime

92 Under the current statutory regime, the following consents, licences and permits are likely to be required for the project:

3.2.1.1 <u>Marine Permissions</u>

- Section 36 Electricity Act 1989 consent from the Scottish Ministers for the offshore electricity generating station
- Section 36A Electricity Act 1989 declaration will be required to extinguish public rights of navigation

- A licence under the Food and Environment Protection Act 1985 will be required for placing materials in the sea
- A consent under the Coast Protection Act 1949 will be required for placing cables within the water

93 As stated there are presently no offshore works (ie the wind farm and indicative export cable route) within the limits Of the Harbour Board and therefore a works licence will not be required from the Ports and Harbour Authority.

94 In addition, depending upon the characteristics of the site when further investigatory work has been undertaken, the following consent/licences may also be required: wildlife consents, a CAR licence, a licence regarding wrecks, scheduled monument consent, safety zones etc. These will be applied for if necessary.

3.2.1.2 Terrestrial Permissions

95 As noted earlier, this Scoping Report only deals with the offshore element, however for completeness, the following terrestrial permissions would be required:

- an application for the onshore section of the cable route would be made under Section 37 Electricity Act 1989 with a declaration that planning permission be deemed to be granted (if it is for overhead cables)
- a separate planning application under the Town and Country Planning (Scotland) Act 1997 would be required for the onshore substation and any underground cables

3.2.1.3 Other Consents/Licences

- European Protected Species licence under the Habitats Regulations 1994 (as amended) (EPS) (if required)
- Decommissioning Plan Approved by the Department for Energy and Climate Change (DECC)

3.3 Future Statutory Regime

96 The marine consenting regime in Scotland is undergoing change. On 10 March 2010, the Marine (Scotland) Act 2010 received Royal Assent. The Act introduces a framework for the sustainable management of seas around Scotland. This requires marine plans to be produced and be compatible with terrestrial plans to deliver integrated coastal zone management. It is estimated that the marine plans will take approximately two years to produce. In terms of the consenting process, applications for consent under Section 36 of the Electricity Act 1989 and a new marine licence together with any wildlife consents that may be required will all be considered together. Part of the Marine (Scotland) Act came into effect on 1 July 2010 and there will be a phased implementation thereafter. The timing of the coming into effect of the Act will affect whether the applications for consent for the proposal will be made under the statutory regime outlined above or under the Marine

(Scotland) Act. For the terrestrial consents, the process will remain as outlined above under the current statutory regime.

3.4 Environmental Impact Assessment

97 The Environmental Impact Assessment Directive (97/11/EC) requires an EIA to be carried out in support of an application for development consent for categories of project listed in the Directive at Annexes I and II.

98 Offshore wind farm developments are listed in Annex II as 'installations for the harnessing of wind power for energy production (wind farms)'. The EIA Directive has been transposed into UK legislation through various 'EIA Regulations', generally in the form of secondary legislation associated with existing consent provisions.

99 The Electricity Works (Environmental Impact Assessment)(Scotland) Regulations 2000 (“the EIA Regulations”) apply Council Directive 85/337/EEC as amended by Council Directive 97/11/EC to the Electricity Act 1989. The EIA Regulations relate to the assessment of the environmental impact of applications for consent to construct, extend or operate a power station or install or keep installed overhead electricity lines under Sections 36 and 37 of the Act.

100 Under the EIA Regulations, all Section 36 developments, which are considered likely to have significant effects on the environment must be the subject of an EIA, and an Environmental Statement (ES) must therefore be submitted with the Section 36 application.

101 The EIA Directive has not been directly applied under FEPA regulations but there are existing provisions within the Act requiring developers to provide information equivalent to a formal Environmental Statement.

3.4.1 Scope of Environmental Impact Assessment (EIA)

102 Large projects such as an offshore wind farm need to obtain a certain degree of flexibility when applying for consents. AOWFL will submit an application including EIA, which is based on the best design and layout information available to the project when making the applications, involving an assessment allowing for different types of wind turbines and foundations.

103 As not all the details of the proposed development will be known to AOWFL at the time that the application is submitted, when assessing the wind farm, a worst case approach will be taken, according to the principles described as the “Rochdale envelope”. What is considered to be the worst case could be different depending on the receiving environment affected (eg birds, shipping & navigation etc) and the activity undertaken (construction/decommissioning or operation). Where possible, the Environmental Statement will contain a detailed project description. However, when this is not possible, the Environmental Statement will provide a clear rationale for all parameters of the Rochdale Envelope.

3.5 Appropriate Assessment

104 Where the possibility of a likely significant effect on a European offshore marine site and/or a European site cannot be excluded and the plan or project is not directly connected with or necessary to the management of the European site for conservation purposes, a competent authority must undertake an Appropriate Assessment (AA) before deciding to undertake or give any consent, permission or other authorisation for a plan in accordance with the Habitats Directive.

105 For information on Statutory Designations see Section 5.9 Statutory Designations and Conservation.

4 PHYSICAL ENVIRONMENT

4.1 Meteorological Conditions

4.1.1 Introduction

106 Information on the meteorological conditions is required to inform the design of wind farm projects. This section outlines the baseline data collected to date.

4.1.1.1 *Project Reports*

- Prevailing (2009) Aberdeen Offshore Wind Farm: Analysis of LIDAR Data (00028-001-R: 7 October 2009).

4.1.2 Baseline Information

107 The North Sea climate is characterised by large variations in wind direction and speed, a high level of cloud cover and relatively high precipitation (OSPAR, 2000; DTI, 2004). The local climate along the north-east coast is dependent to a large extent on the shelter from winds from the north and west. Predominant winds are from the south and west. Wind strengths along this stretch of coast are variable and generally affected by local topography.

108 Mean annual rainfall in the central North Sea is 400 – 600 mm (OSPAR 2000; DTI, 2004). Coastal fog ("haar") is common during spring and summer along the east coast of Scotland, with up to 14 days per month recorded in exceptional years (North Sea Pilot, 1997; DTI, 2004).

109 Wind data have been recorded at an onshore location nearby the EOWDC site using Natural Power's ZephIR remote sensing LIDAR (Light Detection And Ranging) device.

110 Wind data were recorded by the LIDAR for a period of approximately two and half months from 31 October 2008 to 22 January 2009. A summary of the LIDAR measurements is presented in Table 4.1.

TABLE 4.1
Summary of LIDAR Measurements

Measurement device	Natural Power ZephIR
Location	OS Grid Reference 395024 810254
Monitoring period	31 October 2008 to 22 January 2009
Wind speed measurement heights*	27 m, 70 m, 90 m, 125 m, 153 m
Data recorded	Horizontal and vertical wind speed, wind direction, turbulence, temperature, pressure, humidity.
Configuration	Cloud correction turned on

* Note: 1 m added to the LIDAR measurement heights to account for height of device

111 In addition to the LIDAR data, the following data from the Dyce Meteorological Station are also available:

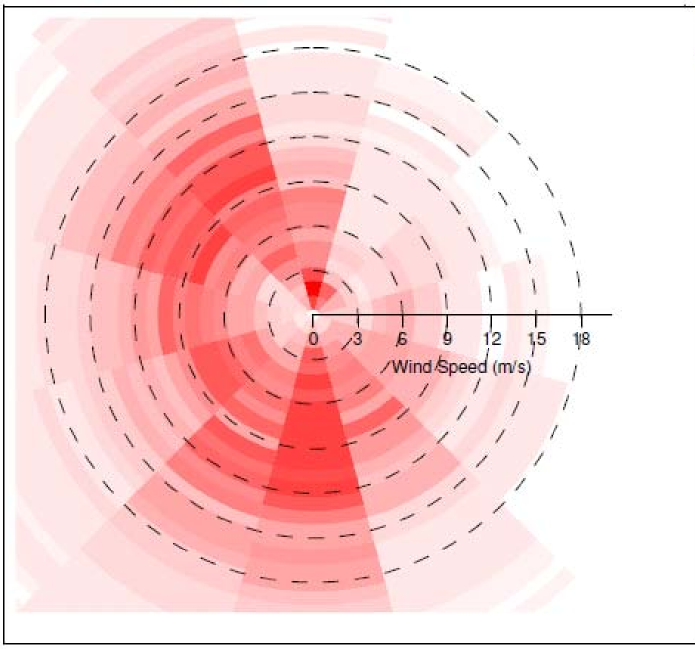
- hourly data from 1 November 2008 to 31 January 2009

- wind speed and direction data collected from January 2001 to January 2009

112 Correlations of the concurrent wind speed at Dyce and the LIDAR using hourly, daily and weekly averaging periods were conducted and the daily correlation used to derive the long-term mean wind speed of 8.74 m/s at a height of 90 m (Prevailing, 2009).

113 Data from the Dyce site has been used to derive the long-term site wind rose using a Measure-Correlate-Predict methodology. The Dyce wind rose was scaled to the predicted long-term mean wind speed of 8.74 m/s at 90 m at the LIDAR location. The resultant wind rose is shown in Diagram 4.1.

Diagram 4.1 Estimated long-term wind rose at the LIDAR location at 90 m



Sector	Probability
0	9.1%
30	2.8%
60	2.0%
90	2.4%
120	4.4%
150	8.4%
180	17.9%
210	12.2%
240	8.8%
270	7.9%
300	10.6%
330	13.4%

114 The meteorological conditions for the EOWDC area are summarised in Table 4.2.

TABLE 4.2
Meteorological conditions at EOWDC area

Meteorological Conditions	EOWDC area
Long-term wind speed*	8.7 m/s
Predominate wind speed – summer**	4.6 m/s
Predominate wind speed – winter**	5.2 m/s
Prevailing wind direction – summer**	South
Prevailing wind direction – winter*	South
Air temperature – annual average+	4.6 – 11.2 ^{o}C
Days of air frost – annual average+	53.6
Hours of sunshine – annual average+	1409
Rainfall – annual average+	816.3 mm
Days of rainfall ≥1mm – annual average+	134.2

*Long-term wind speed predicted at 90 m above ground level for LIDAR location (Prevailing report). Further offshore data collection would clarify this figure

115 More detailed analysis of wind and meteorological data for the area will be conducted as part of the EIA for the EOWDC site.

4.1.3 EOWDC Future Research and Monitoring

116 Options for future wind are currently being discussed within the project.

117 It will be essential to monitor meteorological conditions throughout the life-span of the project to enable comparison between the wind dataset and the operational performance data.

4.2 Oceanographic Conditions

4.2.1 Introduction

118 This section outlines the baseline data collected to date with respect to oceanographic conditions. The information will be used in the coastal process modelling of the wind farm to assess the environmental impact.

4.2.1.1 Project Reports

- EMU Ltd. (2008a) Aberdeen Wind Farm Oceanographic Survey. Report No. 08/J/1/01/1138/0749. February 2008.

4.2.2 Baseline Information

119 EMU Ltd conducted an oceanographic survey in Aberdeen Bay in 2007/2008. Wave, tide, current and suspended solids were monitored within the previously proposed site area for 45 days, subsequently extended to 90 days, at the location shown on Figure 9.

120 A seabed mounted acoustic profiler (Nortek Acoustic Wave and Current, AWAC) was deployed, which is capable of recording current profiles, tidal heights, directional wave data and acoustic backscatter (ABS) profiles (see Plate 4.1). In addition, the frame was equipped with an environmental sonde comprising optical backscatter (OBS), salinity and temperature sensors. The ABS and OBS data were used to ascertain the suspended sediment load in combination with water samples analysed for total suspended solids (EMU Ltd, 2008a).

Plate 4.1 AWAC Seabed Frame

121 The AWAC was onsite from 12 September 2007 to 13 February 2008. During the course of this survey, the following main results were obtained:

- the tidal regime is characteristic of a standing oscillation. A standing oscillation tide is characterised by the occurrence of slack water at mid-tide. It appears as a phase difference between tidal and tidal current principal harmonic of approximately 6-7 hours, which indicates that high water and low water coincide with the periods of strongest currents
- the currents are tidally dominated with a semi-diurnal pattern, showing an expected spring-neap cycle
- the current peaks at the surface, reducing towards the seabed
- the current appears to be flowing parallel to the coast in a north-east/ south-west direction
- the dominant wave direction is south-east whereas the larger events are from due east during the survey period
- the largest recorded wave peaked at 5.5 m significant wave height. This coincided with a large storm event (1 to 5 January 2008) with a wave direction from the east. Other storm events were recorded throughout the deployment period, but none as energetic or sustained
- in general, wave periods appear to fluctuate between 4 s and 12 s, indicating that then energy recorded is both locally generated sea waves and remotely generated swell from the east
- the water samples collected returned suspended sediment values in the range of 6 mg/l to 29 mg/l. Variations in suspended solid concentration (SSC) values over time appear to show a correlation to physical forcing (waves and currents). A high SCC value throughout the water column coincided with the large storm event at the beginning of January 2008

122 Table 4.3 summarises the main statistical parameters for each data type collected during the survey period.

TABLE 4.3
Oceanography Survey (AWAC) Summary Statistics

Data Type		Maximum	Minimum	Mean	Standard deviation
Tidal Data	Height to LAT	4.675	-0.101	2.37594	0.98152
	Residual height	0.777	-0.791	0.00000	0.17809
Suspended Solid	OBS (mg/l)	1768.39 *	0.00	28.53	104.92
	ABS 2 (mg/l)	43.12	0.12720	20.67	7.97

	Peak spreading angle (°T)	40.5	0.8	24.1	10.0

4.2.3 EOWDC Future Research and Monitoring

123 Potential effects of both individual structures and a collection of structures on the physical oceanographic characteristics of the area and the potential resulting impact on coastal processes are discussed in Section 4.3 Coastal Processes.

4.3 Coastal Processes

4.3.1 Introduction

124 This section will outline the key coastal process issues which influence the form and function of the local coastal environment. At this stage a brief overview is offered in relation to the relationships between the wave, tidal and sediment regimes which will be described in further detail through the EIA phase.

4.3.2 Baseline Information

125 Aberdeen Bay is on the east coast of Scotland. It is characterised by dune backed sandy beaches which are fully exposed to the wave climate of the North Sea. The coastline adopts a crenulated bay formation whereby a sandy embayment has formed between Girdle Ness and the River Don in the south, and Collieston in the north. Offshore, the seabed bathymetry is relatively featureless forming a sloping ramp of sandy sediment. The exception to this is a narrow ridge of unknown origin situated in the region between the offshore and littoral zones; it is possible that this ridge affords some protection to the coast from wave action.

126 In the context of the overall hydrodynamic regime, tidal currents in the littoral zone are relatively weak and existing modelling studies (ABPmer, 2006) have noted that tidal currents alone are insufficient to mobilise beach sediment. Because of this it is likely that sediment transport in the nearshore area is predominantly due to wave action. Waves recorded within the vicinity of the development show that the most common wave direction is from the south-east although waves are also common from the sector between south-east and the north-east (Emu, 2008a). The south-east wave direction results in a net northerly direction of littoral transport as evidenced by the numerous small streams along the embayment that have been deflected to the north due to sediment deposition at their mouths. However, the southerly orientation of a spit across the mouth of the River Ythan at the northerly extent of the bay shows the potential for a locally net southerly littoral transport in this part of the bay. Three main rivers intersect with the coast within Aberdeen Bay namely (south to north) the Dee, the Don and the Ythan. Transport processes will be locally more complex at the mouths of the rivers Don and Ythan due to the interaction of waves, tides and freshwater flows (Halcrow Crouch, 1999).

127 Further offshore tidal processes become more important and sediment transport in the offshore zone is likely to be tidally dominant (Kenyon and Cooper, 2004). Based on regional scale BGS mapping the seabed sediment within the proposed wind farm site is generalised as predominantly sand with some gravel present further offshore, just outside the site. Net regional sediment transport direction has previously been shown to be in a northerly direction towards a bedload convergence zone which lies offshore from Rattray Head (DTI, 2004). Rates of transport are however reported to be low (HR Wallingford, 1997). Isolated areas of sand waves have also been reported in the area.

128 For the site itself, the following sections identify the currently available data and proposed additional data collection.

129 **Bathymetric data:** The principal source of bathymetry data for the EOWDC site is a swath bathymetry survey undertaken by Emu Ltd in September 2007 (Emu Ltd, 2008b). Additional surveys are also planned to cover those parts of the new site outwith the previously surveyed area.

130 In addition to the project specific bathymetric data, data is possibly available from the southern part of Aberdeen Bay collected for the Aberdeen Beach Study. We would need to seek the permission to use these data.

131 Data are also available from the United Kingdom Hydrographic Office (UKHO). The most recent data set is from December 2004, but this only

covers half the proposed model area; the remaining area is covered by data from 1965. SeaZone 'GIS ready' bathymetry data is also available as well as bathymetric survey.

132 Additional datasets, which are planned to be acquired, are the UKHO hydrospatial, digital survey bathymetry, charted raster and charted vector data.

133 Enquiries have also been made to Aberdeen University about the availability of bathymetric survey data, which was collected for the southern part of Aberdeen Bay for the Aberdeen Beach study.

134 **Beach elevation data:** Several datasets have been researched including Light Detection and Ranging (LIDAR), Ordnance Survey Landform Profile (OSLP) and NextMap Digital Surface Model (DSM). The NextMap Digital Surface Model (DSM) was identified as potentially providing a valuable data source for input into the littoral transport modelling. However, due to the potential limitations associated with the above data source and the importance of obtaining an adequate beach profile dataset, the options for undertaking a specific site survey are being considered.

135 Aberdeen University collect beach profile data along the Aberdeen Beach front between the Aberdeen North breakwater and the River Don. This information could be available from the University at a number of selected locations along this part of frontage, which is to the south of the site. There is also the possibility for ABPmer to undertake a survey to collect beach profile data and sediment samples along the foreshore adjacent to the site to inform the littoral drift modelling.

136 **Sediment size data:** This, combined with beach profile data, is a primary input into sediment modelling. Grain size information is available from 14 sediment samples collected by Fisheries Research Services (FRS) in 2006. These are located within the old site boundary and were processed using particle size analysis. Twelve samples were collected by ABPmer in 2003 along the nearshore opposite the Aberdeen Beach defences (near Beach Boulevard) as part of the Aberdeen Beach works. Permission would need to be sought to use this information for the site. The collection of project specific sediment data is planned to fill the data gap that exists within close proximity to the site as part of the offshore and intertidal grab sampling programmes, as discussed under 'Marine Ecology' and 'Intertidal Habitats and Ecology' (Sections 5.1 and 5.2). There is also the possibility for ABPmer to undertake a survey to collect beach profile data and sediment samples along the foreshore adjacent to the site to inform the littoral drift modelling.

137 Additional information identifying the offshore surface sediments is also available from the British Geological Survey (BGS).

138 **Geology:** The surface morphology and subsurface geology within the previously proposed EOWDC area has been characterised through a geophysical survey using sidescan sonar, seismics, magnetometer, AGDS and a video survey (Emu Ltd, 2008b). In addition to the geophysical survey, a desk review of available geotechnical information has also been carried out (Setech, 2009). During this study a review was carried out of BGS boreholes and maps along with the geophysical report to determine the likely subsurface geology. No new boreholes were collected for this survey. Additional

geophysical surveys are planned for the proposed site outwith the previous survey area and the geotechnical desk study updated to cover this area.

139 Additional information identifying the sub-surface geology is also available from the BGS.

140 **Tidal (hydrodynamic) data:** Tidal data for the site were collected by Emu Ltd using an AWAC device (see section 4.2) deployed in the north eastern part of the previous site (this corresponds to the south western part of the new layout area) (Emu Ltd, 2008a). This device collected tidal data between 12/09/2007 and 13/02/2008 and current data between 01/11/2007 and 13/02/2008.

141 The British Oceanographic Data Centre's (BODC) National Tidal and Sea Level Facility (NTSLF) holds data for water levels at a tide gauge maintained at Aberdeen. Water levels at the site are available from 1980 to 2010. The BODC also holds a record of in-situ current meter data at two locations in Aberdeen Bay.

142 **Wave data:** Wave data were collected by Emu Ltd between 01/11/2007 and 13/02/2008 using an AWAC (see section 4.2) deployed in the north eastern part of the previously proposed site (this corresponds to the south western part of the new layout area) (Emu Ltd, 2008a). This dataset details significant wave height, maximum wave height, peak period, zero up crossing period, mean period, significant wave period, total energy, mean coming direction, peak coming direction, mean spreading angle and peak spreading angle.

143 Limited offshore wave data are held within the CEFAS Wavenet system for two locations close to the EOWDC area. The available data was collected over the winter period of 1992 to 1993. Further information may also be available from a Datawell Waverider buoy deployed in Aberdeen Bay from 1 November 2007 to 9 August 2008 and from 24 September 2008 to 1 December 2008. The data recorded during deployment were significant wave height, average (zero crossing) wave period, dominant (peak) wave period and dominant (peak) wave direction. These data should be available through Aberdeen University or Aberdeen City Council.

144 Additional wave data are also available from the Met Office's 'European Wave Model'.

145 **Wind data:** Wind data are available from the two and half month LIDAR deployment and from Aberdeen Airport at Dyce (see section 4.1). Further data collection is planned (see section 4.1).

146 Aberdeen Harbour Board also record wind (and tidal) data at four hourly intervals, but these data will not be available for this project.

147 **Freshwater data:** The Scottish Environmental Protection Agency (SEPA) maintains river gauging stations in the River Dee, the River Don and the River Ythan. There are a number of gauging stations along each of these rivers which record daily mean flows.

148 A selection of the available datasets is shown in Figure 11.

4.3.3 Proposed Scope of Assessment

149 The proposed scope of assessment will make consideration of spatial and temporal scales using the presently available guidance (Defra, CEFAS and DfT, 2004), (OfDPM, 2001), (Defra, 2005), (SNH, 2003) which requires a specific assessment to be made of the following:

4.3.3.1 Baseline Assessment

- coastal processes which maintain the existing system, explanations for past changes and the sensitivity of the system to changes in these processes
- relative importance of high-energy, low-frequency (episodic) events versus low-energy, high-frequency events
- coastal processes controlling morphological change
- identification of sediment sources, pathways and sinks
- identification of the geological, geophysical and geotechnical sediment properties and the depth of any sediment strata within the wind farm site

4.3.3.2 Impact Assessment

- scour around the wind turbine structures and consideration of scour protection
- stability of buried cables under the influence of coastal processes
- scour around any cabling overlying the sediment surface
- effect on the spatial distribution of wave patterns, tidal flows and sedimentation (all near-field) and wave direction and energy (far-field) and any subsequent impacts on littoral transport
- non-linear interaction of waves and currents and the extent of sea bed sediment mobilisation
- sediment mobility and the natural variability of sediment depth across the near-field and the effect on wind turbine foundations and cable burial depth
- effect of cable laying on local levels of suspended sediment
- assessment of the scales and magnitudes of processes controlling sediment transport rates and pathways; and
- assessment of climate change impact on the coastal process regime

150 The baseline, or pre-construction, conditions include a description of the existing coastal process regimes prior to any works on the wind farm site. A consideration of natural changes (ie sea level rise) which may result in changes to the regime over the wind farm's operating period will be included, thus providing context for comparing natural changes against any introduced by the development.

151 Based on the understanding of the sediment and coastal processes occurring within the study area and the relative proximity of the development to the coastline the main concern will be addressing the potential impacts of the wind farm array on coastal processes. This will involve the assessment of any changes to the wave regime and any subsequent changes to rates and / or direction of littoral transport and any resultant changes to the crenulated bay form of the coastline.

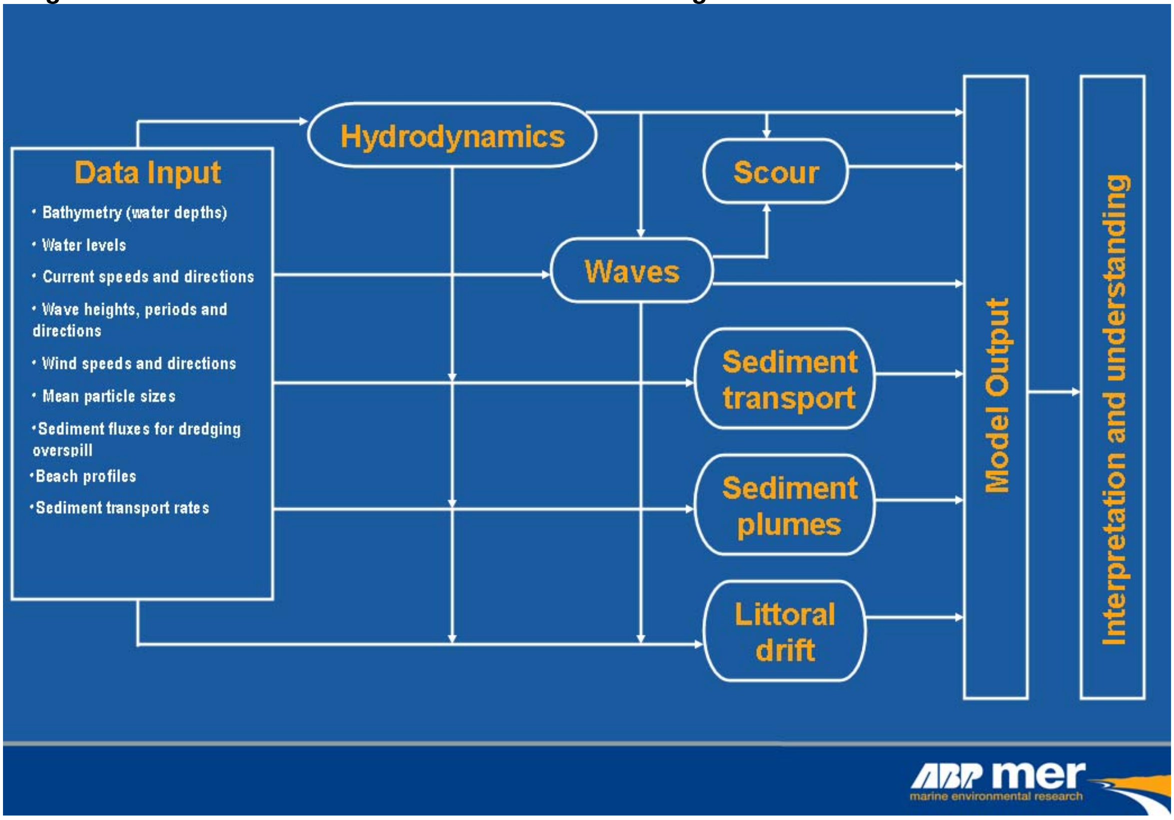
152 The oceanographic and coastal processes investigations will be conducted at different scales including:

- spatial scales:
  - near-field (ie the area within the immediate vicinity of different wind turbines/foundation types, within the wind turbine grid and along the cable route – an indicative near-field area is should on Figure 11); and
  - far-field (ie the wider environment over which effects could potentially occur an indicative far-field area is should on Figure 11)
- temporal scales:
  - baseline (pre-construction phase)
  - construction phase
  - post-construction phase
  - sediment recovery phase (period during which a new equilibrium position is attained with the wind turbines in place)
  - lifetime of the EOWDC array
  - decommissioning phase
  - post-decommissioning phase

153 Coastal process numerical modelling will be undertaken using a range of state of the art computer models which simulate tidal flow and coastal hydraulics, wind and wave, and resultant sediment transport processes. The application of the coastal process models will provide a series of quantified descriptions of changes to the wave, tidal and sediment transport regimes brought about from the proposed site development at a number of scales and representative of a number of stages during the lifecycle of the development. Outputs from the numerical modelling will be used to assess any direct and indirect impacts and provide considerations for potential mitigation and appropriate monitoring requirements (ABPmer, 2008). Diagram 4.1 outlines the modelling process.

154 Diagram 4.1 gives an overview of the modelling process; the effectiveness of modelling is highly dependent on the availability of data sources (as described in the previous section.

Diagram 4.1 Overview of the Coastal Process Modelling Process



4.3.4 Potential Impacts

155 Issues raised during the initial scoping in 2005 and ongoing consultations include the importance of understanding effects of the wind farm on patterns of erosion, deposition and on issues such as longshore drift and coastal morphology, specifically the impacts on foreshore aesthetics and harbour siltation rates. Concerns were raised that there should be no impact on the current erosion tendency of the coastline. Golf clubs have expressed concern regarding the impact on sand dunes and increasing the potential for erosion of some of the fairways and greens. FRS raised the need to consider seasonal changes in oceanic currents and wind forcing in the model. The need to consider other activities which may impact coastal processes, including offshore munitions dumping, the recent coastal defence works and dredging/aggregates removal, was also highlighted. In addition it is recognised that the Aberdeen Beach represents an important recreational resource in terms of surfing and the impacts of the development on this resource should be considered within the context of the coastal processes report (SAS, 2009).

156 Conclusions will be given that highlight the significance of any impact particularly relating to sediment movement, coastal erosion, coastal processes, depth and movement and coastal defences, with reference where appropriate to existing, consented and proposed wind farm development impacts elsewhere in the UK.

4.3.5 Cumulative Assessment

157 Coastal process studies must consider the effects of each wind farm acting cumulatively with other seabed activities. Guidance which exists from Scottish Natural Heritage (SNH) re-enforces that published by Cefas and Defra. Here it was defined that:

- all developments, both known, under consideration and in existence must be considered; and
- all developments within one tidal excursion must be considered.

158 With respect to coastal processes, other developments which are typically considered are dredging and aggregate activities. An initial consideration of other seabed users within the study area, includes:

- offshore munitions dumping. Conventional munitions are dumped within the study area (QinetiQ, 2007; OSPAR, 2005)
- coastal defence works. Coastal defence works are located to the south of the proposed wind farm site towards Aberdeen. Recent works have been carried out to enforce these defences through the installation of rock revetments. Immediately onshore of the wind farm, there are no hard defences installed with the natural dune system providing some protection to the hinterland
- dredging/aggregates. There are currently only two licensed dredge areas in Scotland (Scottish Executive, 2006) and neither is located within the study area. However, there is ongoing maintenance dredging in Aberdeen harbour.

4.3.6 Mitigation

159 Best practice procedures during construction and operation would be followed to minimise effects on coastal processes, seabed and water movements. Measures relating to coastal processes may include the installation of appropriate scour protection.

4.3.7 EOWDC Future Research and Monitoring

160 Potential effects of both individual structures and a collection of structures on the physical oceanographic characteristics of the area and the potential resulting impact on coastal process can be studied in a number of ways.

161 Possible options include an environmental station and additional array of buoys within the EOWDC research area and beyond which could be used to determine the oceanographic and coastal processes which maintain the existing system in the area before construction and any potential effects during and after construction, including:

- physical factors – temperature and salinity to ensure that any changes are the result of changes to physical processes e.g. location of tidal front due to fluid movement, rather than an external force, such as heavy run-off
- physical processes, such as effects on tidal movements/fluid dynamics leading to potential scouring/deposition, turbidity, etc.

- Effect on sediment transport of the area and comparison with sediment transport models
- scour around the different wind turbine structures / foundation types and cable routes. Effectiveness of different scour protection methods, including the potential impacts of scour and scour protection methods on benthic ecology (see reef effects Section 5.1)
- effect on the spatial distribution of wave patterns, tidal flows, sedimentation, wave direction and energy
- interaction of waves and currents and the extent of seabed sediment mobilisation
- sediment mobility and the natural variability of sediment depth at different distances from the wind turbine(s) and the effect of different wind turbine foundations and cable burial depth

4.4 Geology and Seabed Characteristics

4.4.1 Introduction

162 A review of the offshore sediments and geology in Aberdeen Bay indicates that the seabed sediments are defined as non-solid sediments laid down on the seabed by the actions of the sea during the early Holocene. The sediments in this region reflect its glacial history and hydrodynamic regime. There is little input of sediment from land most being derived from peat deposits. The sediments off Aberdeen consist predominantly of sand and slightly gravelly sand (DTI, 2004).

163 Below the seabed, Pleistocene deposits off the Aberdeenshire coast varies from soft red-brown, grey-brown and pink-grey muds to compact grey clays with scattered pebbles that probably indicate glacial tills. The soft muds probably date from late Devensian to Early Flandrian and were most likely deposited during the retreat of the last ice sheet. Seabed sediments mostly conceal bedrock in the area. The underlying bedrock along the coast between Aberdeen and Stonehaven comprises sandstones, conglomerates, mudstones and cherts.

164 Forvie is designated as a geological conservation statutory review site, this is a non statutory designation which reflects the areas earth science interest in relation to coastal geomorphology.

165 Surveys to obtain bathymetric, seabed and sub-bottom data are critical to the project, providing a basis for the foundation design work, and informing the coastal process modelling and marine ecological and archaeological impact assessments.

4.4.1.1 Project Reports

- EMU Ltd (2008b) Geophysical and Seabed Habitat Assessment of the Proposed Aberdeen Offshore Wind Farm. Report No. 07/J/1/02/1136/0716. February 2008.
- Setech Ltd (2009) Geotechnical Desktop Study. Report No. 8733-0-0. January 2009.

4.4.2 Baseline Information

166 EMU Ltd. was commissioned to undertake geophysical and seabed habitat survey of the previously proposed site (Figure 9). The aim of the survey was to determine and report on the seabed and sub-bottom conditions. The survey involved swath bathymetry, sidescan sonar imaging, shallow seismic profiling, magnetometer survey and use of an Acoustic Ground Discrimination System (AGDS) with video ground-truthing (EMU Ltd, 2008b). The survey was completed using the vessel FPV Morven between 12th and 18th September 2007.

4.4.2.1 Geophysical and Seabed Habitat Assessment Survey Results

167 Paper charts that were produced included the seismic trackplot, contoured and colour shaded bathymetry, sidescan sonar mosaic, seabed features with magnetometer and sidescan targets along with video ground truth information. Sediment isopach charts and geological cross sections are also available. Summary information is shown in Figure 9.

168 **Bathymetry:** At the previously proposed site, the bathymetry from shore, as shown in Figure 9, has an even gradient, deepening with distance offshore. Depths throughout the survey area range from 0.7 m to 29.1 m below Chart Datum and the water depth across the previous site ranges from 8.7 m nearshore to 29.1 m offshore, with a gradual gradient of 1 in 10 to 1 in 20 sloping to the east (EMU Ltd, 2008b).

169 **Seabed sediments:** The seabed sediments at the previously proposed site (as illustrated in Figure 9) are dominated by silty sand, with small patches of glacial till towards shore (and therefore in the area for the cable route). The surface sediments range from 0 m thickness at the shore to 6 m thickness at the offshore limit (EMU Ltd, 2008b).

170 The sidescan sonar data revealed five main seabed types in the survey area:

- silty sand
- exposed consolidated glacial material
- patches of glacial material exposed within seabed depression
- silty sand with patches of finer sediment
- linear ribbons of finer sediment within silty sand

171 The sidescan sonar data do not show any significant man-made debris or wrecks. Several trawl scars were noted and there were small amounts of debris including what appears to be a chain. Smaller debris may exist which cannot be resolved from the side scan or magnetometer data (EMU Ltd, 2008b).

172 **Geology and geomorphology:** Beneath the seabed sediments, there is glacial till comprising fine to coarse sand with possible areas of gravel and cobbles. The bedrock is Devonian Old Red Sandstone and increases in depth below seabed from 5 m at the shore to 30 m at the offshore boundary, being between 18 m and 25 m for most of the site. The depths and geology are therefore suitable for a range of foundations, including monopiles (EMU Ltd, 2008b).

173 **Magnetometer data:** The total magnetic field intensity chart for the survey area is dominated by large positive anomalies to the north of the survey area. These anomalies are thought to be the result of submerged geological features, possibly re-worked local material, with the high magnetic signature indicating the presence of remnant igneous material in the fabric of the till deposit. In total, 59 magnetic targets have been identified and plotted on a seabed features chart (EMU Ltd, 2008b).

174 **Video survey:** The objective of the video survey was to provide ground truth habitat identification for each of the seabed types identified from the sidescan sonar and AGDS surveys. Most of the area surveyed was silty to fine-medium sand with occasional patches of shelly fragments (EMU Ltd, 2008b).

4.4.2.2 <u>Geotechnical Study Results</u>

175 Setech (Geotechnical Engineers) Ltd. conducted a geotechnical desk study to determine anticipated soil conditions, in order to facilitate the options for foundation design, at the previously proposed site. The study used data available from the British Geological Survey (BGS) including borehole data and geological surveys, information held by Vattenfall and the Setech database.

176 The study indicated that it is likely that the site is covered by a veneer of silty Holocene Sand underlain by soft to very stiff clays with occasional sand and gravel lens of the Wee Bankie Formation. The base of Wee Bankie Formation ranges in depth from approximately 5 m BSL inshore to 22 m BSL (below seabed level), to the western extent of the previous wind farm lease boundary. Wee Bankie is likely to be underlain by Devonian Old Red Sandstone.

4.4.3 Proposed Scope of Assessment

177 Geophysical and geotechnical information currently available will be collated and assessed. An additional geophysical survey will be undertaken to assess the ground conditions in the area of the proposed site that is being taken forward in the Environmental Statement, which has seven out of the 11 wind turbines that lie outwith the previous geophysical survey area.

178 Following the recommendations by Setech (2009), a full site investigation will be undertaken to obtain site specific data on soil conditions. This would confirm the potential strength parameters of the Wee Bankie Formation, and would also verify the bedrock composition, competency and strength as an addition to the geophysical survey and this desktop study. This survey will be conducted as part of the pre-construction survey.

179 The information from geophysical and geotechnical surveys and studies will be used to assess the potential impact of the wind farm on the seabed and substrata, determine the options for foundation design and other engineering aspects of the site, and provide information for other studies, including coastal processes modelling and marine ecology. The potential impacts of the proposal on the hydrogeology (ground water / aquifers) will be investigated if considered appropriate.

4.4.4 Possible Constraints

180 From a foundation perspective, the Setech (2009) study anticipates that the soils do not pose any unusual impacts on likely foundation options.

181 Water depth has a direct effect on the required support structure height, weight of steel and fabrication cost, as well as associated costs for transport to site, and installation. However, the depth ranges at the proposed site are unlikely to pose any constraints to the proposed development.

182 There is no evidence at this stage to suggest that shallow gas will be present at the proposed site.

183 The UK is an area of low seismicity and the risk to offshore structures is considered to be correspondingly low.

184 The seabed across the proposed EOWDC area appears to be free from significant natural seabed features and from the data sources available no environmentally sensitive habitats have been reported (EMU Ltd, 2008b).

185 The Dee Valley Fault strikes diagonally across Aberdeen Harbour, however it is unlikely to affect ground conditions below the wind farm area (Setech, 2009).

4.4.5 Potential Impacts

186 The Setech (2009) study anticipates that the main issues, regarding soil conditions and foundation options, are likely to be scour in the sand, and the possibility / probability that a drill out will be required if a monopile foundation option is used due to the presence of shallow rockhead.

187 Offshore wind farm construction would not alter the geology of the site other than in localised areas directly impacted by the installation of wind turbine foundations. This is dependent upon the method of foundation chosen, effect will vary between piled foundation and gravity based structures. It is anticipated that during decommissioning, foundations would be removed to below the seabed surface.

188 Offshore wind farm construction is judged not to have a significant effect on the geomorphological features of the seabed.

4.5 Sediment and Water Quality

4.5.1 Introduction

189 The main factors affecting water quality, and in turn marine organisms, are contaminant levels (organic pollutants and metals) and levels of suspended sediments. In this area, nutrient inputs, predominantly from run-off from agricultural land, are also altering the biology of local enclosed waters such as the Ythan Estuary to the north of the proposed site.

190 Any changes to water quality as a result of the development of the wind farm, eg disturbance of polluted sediments and/or the re-suspension of sediment

during construction, have the potential to affect plankton, benthos, fish, birds and marine mammals.

191 Recreational use will also be considered here. The coast along Aberdeen and Aberdeenshire has a number of bathing waters identified under EC Bathing Water Directive (76/160/EEC) shown on Figure 12.

4.5.1.1 Project Reports

- Titan Environmental Survey (TES) Ltd (2008a) Marine Ecology - Review of Baseline Information. Report CS0208/R2/V2. May 2008.

192 Data are also available from the Fisheries Research Services (FRS) which collected sediment samples and analysed the levels of contaminants in Aberdeen Bay in 2006 (FRS, 2006).

4.5.2 Baseline Information

193 Data were collected by FRS in April 2006 to assess the level of contaminants in the sediments in Aberdeen Bay. Figure 9 indicates the location of the FRS samples.

194 **Hydrocarbons:** Levels of PAHs (polyaromatic hydrocarbons) in the FRS sediment samples from Aberdeen Bay were near or below background concentrations. The exception to this was levels of Phenanthrene, Anthracene and Pyrene at one site which were 5, 8 and 6 times higher than OSPAR's Background Assessment Criteria[2] respectively.

195 **Metals:** The results of the FRS survey indicate that metal concentrations were similar within all samples analysed. The average concentrations across all sites are presented in Table 4.4.

TABLE 4.4
Average metal concentrations in Aberdeen Bay

Metal	**As**	**Cd**	**Cr**	**Cu**	**Hg**	**Ni**	**Pb**	**Zn**
Concentration in mg/kg dry weight	4.717	BDL	15.693	3.081	0.079	7.385	7.146	21.716

BDL=Below Detection limits
Source: FRS (2006), TES (2008a)

196 These average concentrations are all below OSPAR Background Concentrations (BC), i.e. those expected in the North East Atlantic if certain industrial developments had not happened, with the exception of mercury concentrations (0.08 mg/kg dry weight) which are slightly above the BC of 0.05 mg/kg. Mercury is on OSPARs list of Chemicals for Priority Action.

197 **Sewage and faecal coliforms:** Overall water quality in the vicinity of Aberdeen is good given the presence of sewage outfalls for trade and domestic effluent. Table 4.5 provides details of the sewage outfalls in the vicinity of Aberdeen.

[2] Background Assessment Criteria (BACs) are statistical tools defined in relation to Background Concentrations to enable testing of whether mean observed concentrations can be considered to be near background concentrations.

TABLE 4.5 **Sewage outfalls in the vicinity of Aberdeen**	
Activity	**Description**

Source: TES (2008a)

198 **Bathing waters:** Various bathing waters have been designated on the east coast of Scotland. The EC Bathing Waters Directive (76/160/EEC) requires monitoring of microbial indicators of faecal contamination (faecal coliform, total coliform and faecal streptococci) during the bathing season. Two main bathing waters have been identified near the proposed EOWDC development area: Aberdeen – Ballroom and Balmedie Country Park. The water quality of these bathing waters has been generally good for the past few years (2005-2007). In 2008 and 2010, Balmedie was designated as MCS Recommended (reaching the highest UK standard for bathing water quality). Aberdeen reached the guideline standard in 2010 and was given a basic pass in 2008. Water quality was poor at both beaches in 2009, Balmedie achieving a basic pass and Aberdeen failing to reach European minimum standards (MCS, 2010).

199 The Ythan estuary and the lower River Don are designated as Sensitive Areas on account of eutrophication (possibly due to run-off from agricultural land). Nutrient inputs to the Ythan estuary are at such a level that the then Scottish Office (now the Scottish Government) proposed its designation as Scotland's first Nitrate Vulnerable Zone under the EC Nitrates Directive (91/676/EEC) in 1994. Increasing weed cover (*Enteromorpha intestinalis*) in the estuary has led to a change in benthic community, with increases in the opportunistic polychaete species *Capitella capitata* noted in the 1980s (TES, 2008a).

200 **Naturally Occurring Radioactive Material (NORM):** Since 1982 offshore oil and gas equipment contaminated with low specific activity (LSA) scale or Naturally Occurring Radioactive Material (NORM) has been cleaned at an industrial site in Aberdeen Harbour. The main discharges from the offshore equipment are radium-226 and radium-228 and lead-210 and polodium-210. The contaminated wastes are discharged into Aberdeen Bay via an outfall pipe. Consequently, there is the potential that the seabed could be contaminated in Aberdeen Bay and that this could be disturbed during the construction of the proposed EOWDC.

201 Surveys undertaken near the outfall in Aberdeen Bay have not found any elevated levels of contamination in the sediments further than 50 m from the point of discharge (CEFAS, 2009). The results from NORM monitoring previously undertaken in Aberdeen Bay will be used in the Environmental Statement, but it is not thought to be of significant concern.

4.5.3 Proposed Scope of Assessment

202 Further literature reviews and detailed consultation will be undertaken in order to collate and assess existing data.

203 Sediment contaminant levels will be assessed during the benthic survey (see Section 5.1 Marine Ecology).

4.5.4 Potential Impacts

204 Potential impacts due to the development of the proposed EOWDC that may require further investigation include:

- discharges of contaminants from the construction vessels affecting water quality
- disturbance of contaminated sediment (if revealed to be present) leading to deterioration in water quality and mortality of plankton and benthos
- release of fines during construction leading to increased turbidity potentially altering planktonic growth and smothering benthic fauna

4.5.5 Cumulative Assessment

205 Data on sediment contaminants within Aberdeen Bay suggests that impacts associated with disturbance and dispersion of contaminated sediments are unlikely. The potential for cumulative impacts associated with an increase in fines during construction will be reviewed within the coastal processes assessment.

4.5.6 Mitigation

206 Implementing the following measures can mitigate potential impacts:

- adherence to MARPOL regulations which set out requirements to establish Pollution Action Plans to control pollution incidents
- good working practices to be adopted throughout the construction to prevent pollution incidents; and
- adherence to the required legislation for the use of paints and biocides

5 BIOLOGICAL ENVIRONMENT

5.1 Marine Ecology

5.1.1 Introduction

207 The North Sea is a complex and productive ecosystem, which supports important populations of fish, seabirds and marine mammals.

208 Plankton and primary productivity play a fundamental role in the food chain, providing food for the benthos and fish. Benthic communities, comprising species which live either within the seabed sediment (infauna) or on its surface (epifauna), feed off the plankton, and detritus (decomposing biogenic material), in turn providing food for larger invertebrate predators, fish and birds.

5.1.1.1 Project Reports

- Titan Environmental Survey (TES) Ltd (2008a) Marine Ecology - Review of Baseline Information. Report CS0208/R2/V2. May 2008.
- EMU Ltd (2008b) Geophysical and Seabed Habitat Assessment of the Proposed Aberdeen Offshore Wind Farm. Report No. 07/J/1/02/1136/0716. February 2008.
- Titan Environmental Survey (TES) Ltd (2008b) Marine Benthic Sampling Proposal. Report CS0208/D1/V1. May 2008.
- GoBe (2010) Review of Proposed Benthic Ecology Sampling

209 In addition, data are available from the Fisheries Research Services (FRS) from their plankton sampling off Stonehaven (FRS, 2010) and video surveys and epifaunal trawls within Aberdeen Bay (FRS, 2006).

5.1.2 Baseline Information

5.1.2.1 Plankton and Primary Productivity

210 Weekly sampling for hydrographic parameters, concentrations of inorganic chemical nutrients and the abundance of phytoplankton and zooplankton species has been carried out 5 km offshore from Stonehaven since January 1997. The objective of the sampling programme is to establish a monitoring base for assessing the status of the Scottish coastal waters ecosystem and responses to climate change (ICES, 2006; FRS, 2010).

211 The biological data show significant differences across seasons and years. The water column at the Stonehaven sampling site remains well mixed throughout much of the year, except in late summer and autumn when surface heating and settled weather often cause temporary thermoclines to appear. The seasonal minimum temperature generally occurs in the last week of February/first week of March.

212 Water movement in the area is generally southerly with quite strong tidal currents. In late summer and through autumn of most years, water with a high Atlantic Ocean content passes down the Scottish east coast. These

influxes often bring oceanic species, for example, the chaetognath *Sagitta serratodentata* and the siphonophore *Muggiea atlantica* are indicators of this oceanic influence.

213 The seasonal pattern of plankton production is clearly evident in the data collected so far, as is the variability among years in its extent. Nutrient data also show strong seasonal cycles but interannual variability.

214 Data are regularly processed in the FRS MLA database, and some of these data are displayed on the MLA website (FRS, 2010) and published in periodic reports.

5.1.2.2 <u>Benthic Habitats</u>

215 Geophysical data from the surveys of the previously proposed Aberdeen Offshore Wind Farm site boundary show that the area is relatively uniform, comprising predominantly silty sand with patches of finer sediment (Figure 10). Further offshore in the south-east corner of the area surveyed there is an area of linear ribbons of finer sand within the silty sand (TES, 2008a).

216 Two main biotope types were found in the surveys: SS.SSa.CMuSa and SS.SSa.CCS (Figure 10).

- SS.SCS.CCS: Circalittoral coarse sediment: Tide-swept circalittoral coarse sands, gravel and shingle generally in depths of over 15-20 m. This habitat may be found in tidal channels of marine inlets, along exposed coasts and offshore. This habitat, as with shallower coarse sediments, may be characterised by robust infaunal polychaetes, mobile crustacea and bivalves.
- SS.SSa.CMuSa: Circalittoral muddy sand: Circalittoral non-cohesive muddy sands with the silt content of the substratum typically ranging from 5 % to 20 %. This habitat is generally found in water depths of over 15-20 m and supports animal-dominated communities characterised by a wide variety of polychaetes, bivalves and echinoderms.

217 Data from Stephen (1922) from a group of inshore samples from around Aberdeen (20 – 40 m depth) and a transect of eight stations extending offshore in a north-westerly direction to the 100 m contour, show a community characterised by the presence of *Ophiura affinis* and *Echinocyamus pusillus*. Stephen (1922) concluded that there was large-scale geographic similarity in the offshore fauna and that it was less abundant than the inshore fauna.

218 McIntyre (1958) described the benthos of the east coast fishing grounds with reference to surveys of Aberdeen Bay. He found the benthic fauna to be dominated by lamellibranchs and polychaetes with *Abra alba*, *Tellina fabula*, *Nucula turgida* and *Ensis* sp. The polychaetes *Lanice conchilega*, *Sigalion mathildae*, *Notomastus latericeus* and *Nephtys* spp were also dominant.

219 The geophysical data show that the nature of the sediments offshore is relatively homogenous and it is expected that the planned surveys will give very similar results to those of McIntyre (1958) despite the lapse of 50 years.

220 Data from FRS summarising the epifauna trawls undertaken on the 7th of April 2006 in Aberdeen Bay (FRS, 2006) are presented in Table 5.1.

TABLE 5.1 Species collected in epifauna trawls of Aberdeen Bay			
	Haul 1	**Haul 2**	**Haul 3**
Haul duration	**20 min**	**20 min**	**23 min**
Start and end coordinates	57º12.690N 2º00.320W57º11.800N 2º00.740W	57º11.970N 2º01.430W57º11.070N 2º00.980W	57º11.170N 2º02.660W57º12.230N 2º02.380W
Depth	25m	19m	12m
Species:			
Common dab	13	13	2
Long rough dab	1	3	/
Plaice	26	29	10
Flounder	1	/	1
Pandalus	1	/	1
Asterias	17	8	/
Echinoderm	2	3	1
Brittle stars	180	50	20
Dead men's fingers	/	1	/
Pipe fish	/	1	4

221 Analysis of video footage collected by FRS during the same survey shows that the surveyed area is a seemingly barren fine grained sand bank containing no weed and no apparent life except for *Ophiura* sp and *Asterias*. Brittle stars were more abundant in the deeper part of the surveyed area (Run 1 – 25 m) whereas *Asterias* are more abundant in Run 1. There was evidence of an *Echinocardium* community due to the presence of empty tests in Runs 2 and 3 (FRS, 2006). Locations of the video runs are indicated in Figure 10.

222 None of the surveys to date have identified species which are of concern from a conservation perspective eg *Sabellaria* reefs and *Modiolus* beds within the general application area. Known seagrass beds on the east coast of Scotland are to the south of Aberdeen. Broken *Sabellaria* tubes were noted by Stephen (between 1922 and 1925) off the north east coast of Aberdeenshire, however these probably originated from masses growing near Rattray Head (Stephen, 1933, 1934).

5.1.3 Proposed Scope of Assessment

223 Further literature reviews and detailed consultation will be undertaken in order to collate and assess existing data.

224 The proposed wind farm lies close to a known front. Modelling will be undertaken, as part of the Coastal Processes modelling (Section 4.3.3) to assess the impacts of the proposed EOWDC on this front.

225 Site specific benthic grab and trawl surveys will be conducted to provide more detailed and current baseline information in order to undertake an impact assessment for the proposed EOWDC development. From a review of available data, the benthic communities in the area are likely to comprise typical and common infaunal invertebrate species of no particular conservation significance.

226 The survey will aim to provide information on habitat type and community structure in the area within which the wind turbines will be placed and the wider area which may be affected by the development. The survey will also form the baseline for future post-construction surveys and, as such, comparable control sites have been included in the survey design.

227 From the detailed geophysical data, it is evident that the habitat in and around the proposed development site is relatively homogenous. Therefore, a relatively low intensity of sampling is proposed to ground truth the habitat types present.

228 All survey data, desk studies and additional information for benthic habitats will be collated and assessed as apart of the EIA process.

229 Benthic surveys will be undertaken in accordance with recommended guidance and in consultation with Marine Scotland.

230 The proposed sampling approach is as follows:

- benthic samples at approximately 19 sites, with single grab samples (no replicates) collected at each site:
  - two sites shall be located within a single cable corridor
  - eight sites shall be within the wind turbine area
  - five sites shall be in the tidal ellipse (outside of the wind farm area) but extending from the edge of the wind turbine array and along the tidal axis
  - four sites shall be inshore of the array (between the 5 to 10 m contour)
  - replicates to be agreed with Marine Scotland
- a total of six single beam trawls of which:
  - three within the wind turbine area
  - two within the secondary impact area (one north and one south)
  - one within the cable route area

231 The beam trawls will be undertaken using a scientific beam trawl with beam width of 2 m, comprised of 20 mm mesh (knot to knot), and a 5 mm liner into the cod-end.

5.1.4 Potential Impacts

232 The planktonic community in the vicinity of the proposed EOWDC development is typical of the area and has the capacity to recover quickly due to the continual exchange of individuals with surrounding waters. Any impacts associated with the proposed EOWDC development are likely to be small in comparison with natural variations and it is proposed that impacts on plankton populations are scoped out of the EIA for this site.

233 Potential impacts on benthic habitats, which will be considered in detail in the Environmental Impact Assessment (EIA), include:

- loss of seabed habitat due to the addition of wind turbine foundations and scour protection
- loss of and disturbance to benthic habitats due to long term changes in sediment transport rates altering seabed sediment types

- release of contaminants from the seabed and contaminant discharge from construction vessels
- disturbance due to increased sediment suspension and deposition. Fine sediments could be brought into suspension during the installation works which could result in the smothering of sessile organisms. Given the relatively coarse nature of the sediments likely to be encountered across the site, it is not expected that increases in suspended sediment concentrations would be significant relative to background levels
- underwater noise and vibration which may affect the behaviour of benthic species
- electromagnetic effects from inter array and export cables which may affect the physiology or behaviours of benthic species
- provision of new habitat due to the presence of wind turbine foundations and scour protection (if required). Small and localised increases in biodiversity could be expected as species that are not regularly found in sandy / muddy environments may be able to establish themselves on the foundation structures

5.1.5 Cumulative Assessment

234 Potential impacts on plankton and marine benthos are likely to be short term and to be site specific. As a result, interactions with other activities are not anticipated and it is proposed that cumulative impacts on plankton and marine benthos are scoped out of the EIA for this site.

5.1.6 Mitigation

235 Implementing the following measures can mitigate potential impacts:

- MARPOL regulations set out requirements to establish Pollution Action Plans to control pollution incidents
- good working practices will be adopted throughout the construction to prevent pollution incidents / spillage of excavated material (if required)
- construction techniques will be used that minimise the amount of fines released into the marine environment
- the required legislation will be adhered to for the use of paints and biocides
- if the site surveys reveal any biologically sensitive areas, micrositing of foundations / cabling may be employed (on the basis of available information, this is considered unlikely)
- scour would be mitigated (as required) through the implementation of appropriate scour protection as agreed with the consenting authorities. The foundations and associated scour would introduce new surfaces for benthic colonisation

5.1.7 EOWDC Future Research and Monitoring

236 Monitoring of seabed communities would be undertaken before and after construction in order to identify any potential long term effects.

5.1.7.1 Further Research Opportunity: Reef Effect

237 The development of arrays of wind turbines at offshore locations may lead to medium-term changes in the "marine ecology" of the whole area of a site. Currents may be subtly altered, sedimentation changed, new surfaces for marine organisms introduced and, crucially, the patterns and amount of commercial fishing activity may change. The presence of hard structures will locally promote marine growth , fish and other marine organisms will in turn be attracted to these structures. The marine organisms that are associated with the turbines are likely to be composed of different species and abundances in comparison to the seabed community that existed previously and, with time, could become typical of a reef like community with encrusting epifauna. If fishing activities, particularly bottom trawling, are reduced or ceases within the wind farm footprint, then this provides an opportunity to study on a small scale potential reef effects. It has been hypothesised that, offshore wind farm sites have the potential to become large "reef complexes", with each of the turbine support structures acting as a reef module. Depending on the spacing between turbines, and, crucially, the fisheries management regime that is agreed for the site, not only would the area immediately around each wind turbine, in time, become a small reef, but the spaces between turbines might also benefit from reduced fishing pressure.

238 Artificial reefs have long been used as part of fisheries management programmes. On a local scale, they can enhance fishing success, or increase fish populations, or support fish breeding and recruitment. Marine organisms within these areas can still be actively "harvested" by sustainable techniques, or they can be left alone to act as sanctuaries and breeding grounds for fish and shellfish that could eventually disperse into the wider population.

239 The beneficial "side-effect" of wind turbine arrays as artificial reefs is poorly understood and the proposed EOWDC could provide an ideal site for a multi-disciplinary study, for the following reasons:

- Aberdeen, and its Universities and Research Institutes and government agencies, has a long and distinguished history of research into commercial fishing and aquaculture. It is well-placed to develop, implement, manage and report on a study of the effects of wind turbine arrays as reefs, and on the implications of the creation of large arrays on existing and future commercial fishing operations and the management of fish stocks
- the site has an established baseline of information, and this could be appropriately enhanced, and control sites established, before construction of the wind farm
- the site is already a multi-user environment, and changes to the status of the area and the management of the site will have to be made. The recognition that the wind farm is also an artificial reef, of benefit to other users of the sea, would be an additional catalyst for imaginative planning and management of the area, perhaps under the umbrella of a broad spectrum of stakeholder groups including fishermen

240 Specific reef study work that could be done at the site, in addition to some of the associated or complimentary studies noted elsewhere in this submission, and the studies on commercial fisheries noted below, could include the following;

- monitoring the change in condition, “health”, biodiversity and contaminant burden of the seabed and benthos (epifaunal and infauna)
- monitoring the change in numbers and species richness of fish and shellfish in and around the site
- monitoring changes in the health/quality of individuals, and the population profile and reproductive potential of populations, of commercial fish and shellfish in and around the area
- conducting trials of “sustainable” fishing methods, such as creeling and long-lining, in and around the area.

5.2 Intertidal Habitats and Ecology

5.2.1 Introduction

241 The intertidal substrate close to the proposed site is mostly sand, however, the sandy foreshore from Aberdeen to the Ythan Estuary is interrupted by a few rock platforms around Blackdog Rock. There are also rock platforms and boulders/loose rock to the south of Aberdeen (south of the Dee river) and to the North of the Ythan Estuary.

5.2.1.1 Project Reports

- Titan Environmental Survey (TES) Ltd (2008a) Marine Ecology - Review of Baseline Information. Report CS0208/R2/V2. May 2008.
- Titan Environmental Survey (TES) Ltd (2008b) Marine Benthic Sampling Proposal. Report CS0208/D1/V1. May 2008.
- GoBe (2010) Review of Proposed Benthic Ecology Sampling.

5.2.2 Baseline Information

242 **Rocky littoral and sublittoral on the east coast:** The macro alga of the rocky outcrops of north eastern Scotland were surveyed by Wilkinson (1975) who found 80 species not previously recorded from the area, including the first British record of the brown algae *Sorapion Kjelmanii* (Bennett and McLeod, 1998). Early records by Jack (1890) provided information on the marine algae of the rocky shores in the vicinity of Arbroath.

243 A large number of common and widespread species in the east coast of Scotland such as chitons, gastropods and bivalves have been recorded from many habitats along the coast. On rocky shores chitons (*Lepidochitona* sp. and *Acanthochitona sp.*), gastropods such as *Nucella lapillus*, *Patella aspera*, *P. vulgata*, *Margarites helicinus*, and several species of *Littorina* and *nudibranchs* (*Onchidoris* spp., *Archidoris*, *Facelina*, *Aeolidia*) were present. There was a large gastropod fauna including *Helcion pellucidum*, several species of Lacuna and some pyramidellids that were associated with Fucus fronds and *laminarian stipes* (Eleftheriou *et al.*, 2004).

244 **Sedimentary shores on the east coast:** The fauna of the Aberdeenshire and Angus beaches is characteristically dominated by haustorid amphipods (*Haustorius arenarius* and *Bathyporeia pelagica*) and in some cases the spionid polychaete *Nerine* (*Scolelepis*) *cirratulus* (Hart, 1971). In a rare study on the vertical and horizontal distribution of the meiofauna of the sandy

sediments at Collieston Beach, north of Aberdeen, a restricted fauna with a patchy distribution due to the local differences in the variation of the grades of sediment has been found (Seaton, 1975).

245 **Ythan Estuary:** The Ythan estuary is a small meso-tidal bar-built estuary (Davidson *et al.*, 1991) lying approximately half way between Peterhead and Aberdeen on the east coast of Scotland.

246 The faunal community of the estuary has been well studied, the amphipod *Corophium volutator*, with the gastropod mollusc *Hydrobia ulvae*, the polychaete *Nereis* (now Hediste) diversicolor and the bivalve *Macoma balthica* being widely distributed. Species such as the cockle *Cerastoderma edule*, the gastropod *Littorina littorea*, the shore crab *Carcinus maenas* and the mussel, *Mytilus edulis* exhibit more localised distributions (Bennett and McLeod, 1998). Increasing weed cover (*Enteromorpha intestinalis*) has led to increases in the opportunistic polychaete species *Capitella capitata* in the 1980s.

5.2.3 Proposed Scope of Assessment

247 Once the location of the cable landfall is known, further literature reviews and detailed consultation will be undertaken in order to collate and assess existing data and ascertain the need for further site specific surveys.

248 If surveys are required, samples would be collected from sites along the beach at high, mid and low water. In order to collect a sufficient number of animals in what is likely to be a sparsely populated area, each sample would cover an area of 0.1 m^2 to a depth of 15 cm.

5.2.4 Potential Impacts

249 Potential impacts on intertidal habitats, which will be considered in detail in the Environmental Impact Assessment (EIA), include:

- substrate loss, physical disturbance and abrasion from cable laying
- smothering of benthos from increases in sediment suspension and deposition
- heating effects

5.2.5 Cumulative Assessment

250 Other shore based activities will be reviewed and assessed at the time of the Environmental Statement compilation. However, from the information available to date, cumulative impacts are not expected.

5.2.6 Mitigation

251 Mitigation could include:

- careful siting of the cables to avoid sensitive areas
- use of appropriate cable laying tools to minimise disturbance
- burial of export cables to reduce potential heating and EMF effects

5.3 Fish, Shellfish and Elasmobranchs

5.3.1 Introduction

252 The fish ecology of any site is an important consideration during offshore wind farm development, the fish communities forming a fundamental part of the part marine ecosystem and providing stock for commercial and recreational fisheries.

253 The northern North Sea is important for its fish stocks and the commercial fisheries it supports; fishing is important to local communities and to the economy of coastal regions (see Section 6.6).

5.3.1.1 Project Reports

- Titan Environmental Survey (TES) Ltd (2008a) Marine Ecology - Review of Baseline Information. Report CS0208/R2/V2. May 2008.
- Brown & May Marine Ltd (2008) Aberdeen Offshore Wind Farm – salmon and sea trout preliminary baseline assessment. August 2008.
- Brown & May Marine Ltd (2008) Aberdeen Offshore Wind Farm – commercial fishing aspect. August 2008.

5.3.2 Baseline Information

254 The SEA 5 area supports a range of fish and shellfish species, including spawning grounds. A number of fish species found in the SEA 5 area have been included on the OSPAR Initial List of Threatened and/or Declining Species, including cod (*Gadus morhua*), common skate (*Raja batis*), spotted ray (*Raja montagui*), basking shark (*Cetorhinus maximus*), common sturgeon (*Acipenser sturio*), allis shad (*Alosa alosa*), sea lamprey (*Petromyzon marinus*) and salmon (*Salmo salar*). A number of rivers within the SEA 5 area support internationally important numbers of salmon and sea lamprey (Chapman, 2004).

255 The offshore area around Aberdeen supports a range of fish and shellfish species. Offshore fish communities are dominated by haddock (*Melanogrammus aeglefinus*), whiting (*Merlangius merlangus*) and cod, with saithe (*Pollachius virens*) and Norway pout (*Trisopterus* sp.) being associated with deeper waters. Migratory species such as herring (*Clupea harengus*) and mackerel (*Scomber scombrus*) are found throughout the area, although their distribution is seasonal. Sandeels (*Ammodytes marinus*) are also abundant and their distribution is closely associated with well-oxygenated, medium to coarse sand.

5.3.2.1 Spawning and Nursery Grounds

256 Data from Coull *et al.* (1998) show that the offshore area off north-east Scotland contains spawning grounds for cod, herring, lemon sole (*Microstomus kitt*), Norway lobster (*Nephrops norvegicus*), Norway pout, saithe, sandeel, sprat (*Sprattus sprattus*) and whiting (Diagram 5.1), as well as nursery grounds for whiting, saithe, lemon sole, sprat, plaice (*Pleuronectes platessa*) and sandeel, *Nephrops* and haddock (Diagram 5.2).

257 The proposed EOWDC site coincides with potential spawning grounds used by herring (May to August, with peak spawning period in May and June), lemon sole (February to June, with peak spawning period between April and May), sandeels (November to February) and scallops (*Pecten maximus*) (August/September and April/May) and nursery areas for lemon sole, sprat, saithe, plaice and sandeel.

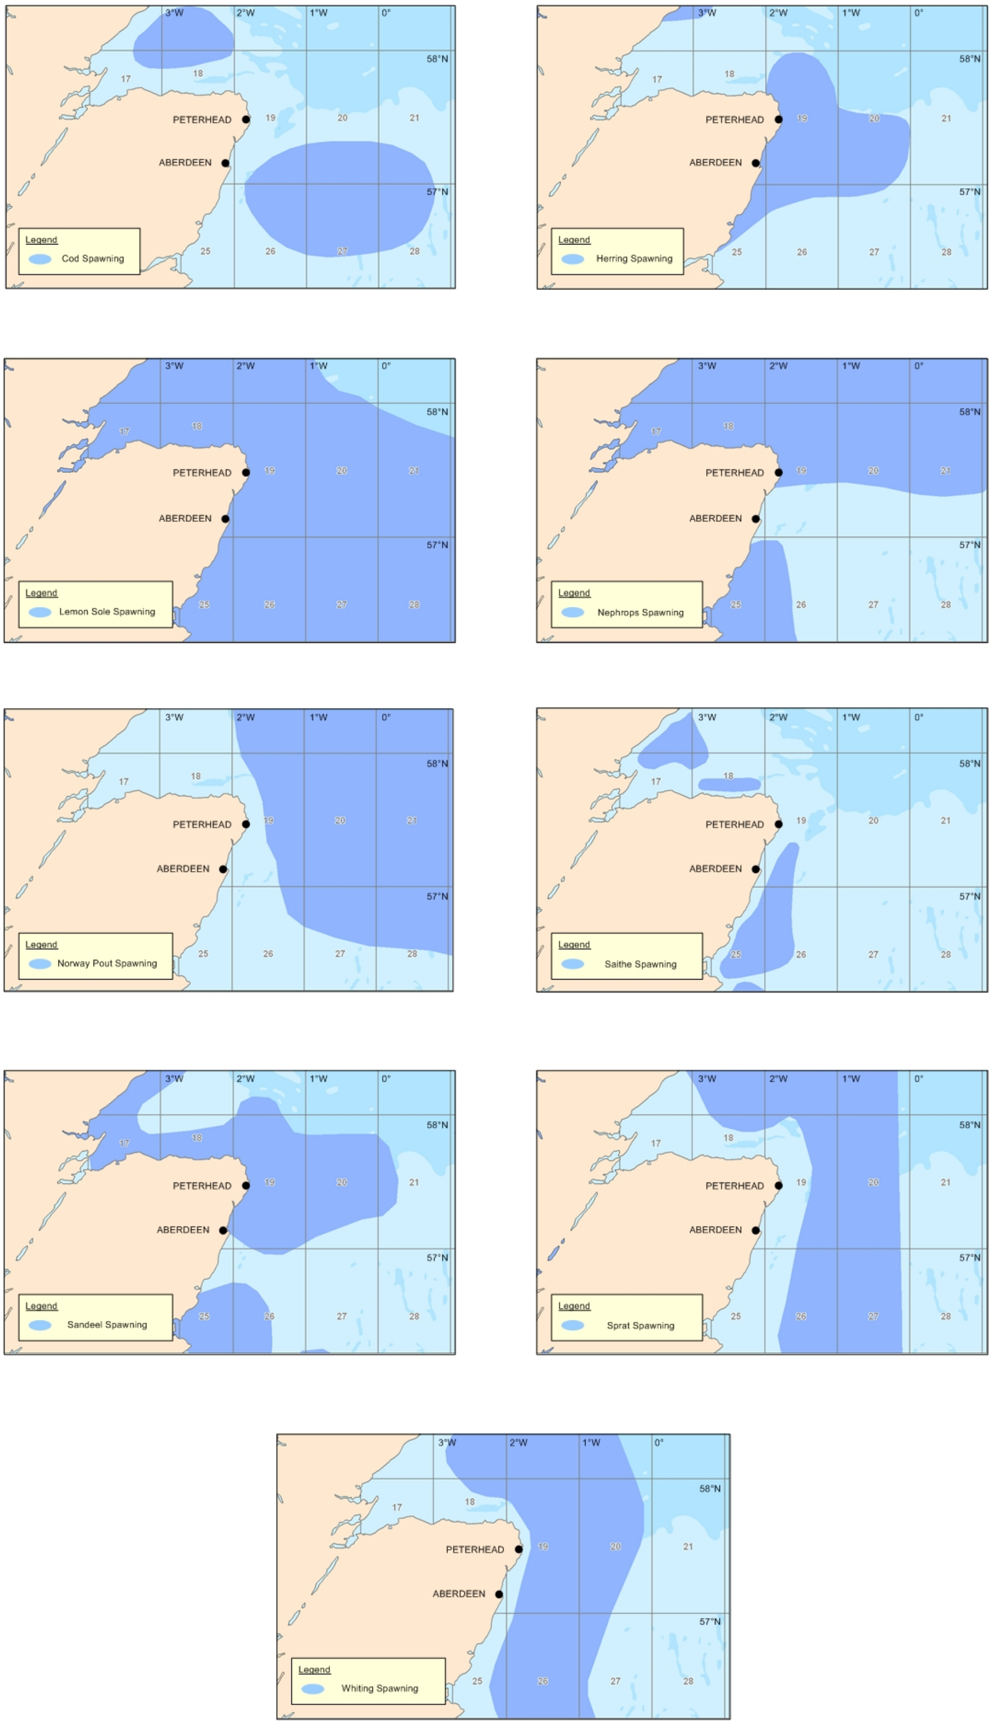
258 Spawning grounds are dynamic features of fish life history and are rarely fixed in one location from year to year. Although some fish species exhibit the same broad patterns of distribution from one year or season to the next, others show a large degree of variability. For sediment spawners, not all suitable sediment areas might be used in every year and areas used will depend on the size of the spawning stock. Therefore, the information provided in Diagram 5.1 represents the widest known distribution given current knowledge and should not be seen as a rigid, unchanging description of presence or absence. Spawning times represent the generally accepted maximum duration of spawning. In addition, fish may spawn earlier or later in the season in response to environmental change (Coull *et al.*, 1998).

259 In the North Sea, sub-populations of herring (*Clupea harengus*) spawn at different times and localised groups of herring can be found spawning in almost any month. At present there are three major populations of herring in the North Sea. These ‘races’ are mixed for the majority of the year, but separate during the breeding season when each race migrates to its own spawning grounds (Daan *et al.*, 1990). In the area off the north-east coast of Scotland, herring spawn during August to September. Spawning normally takes place in relatively shallow water, at depths of approximately 15-40 m.

260 Lemon sole are distributed throughout the central and northern North Sea and are pelagic spawners. Little is known about its spawning habits, and it is thought that Lemon sole spawns throughout its range (CEFAS, 2001).

261 There are five species of sandeel in the North Sea, though the majority of commercial landings are of *Ammodytes marinus* (CEFAS, 2001). Sandeel eggs are demersal, and are laid in sticky clumps on sandy substrates. On hatching, the larvae become planktonic, resulting in a potentially wide distribution (CEFAS, 2001).

262 The locations of nursery areas can change from year to year depending on factors such as water temperature or the availability of food. It is therefore difficult to define the limits of nurseries precisely and, as with the spawning locations the maps in Diagram 5.2 give an indication of the likely positions of juvenile concentrations and represent the widest known distribution, rather than a definitive description of the limits of all nursery grounds (Coull *et al.*, 1998).



Source: Coull *et al.* (1998)

Diagram 5.1 Fish spawning grounds off north-east Scotland

Diagram 5.2 Fish Nursery Areas off north-east Scotland
Source: Coull *et al.* (1998)

5.3.2.2 Shellfish

263 Shellfish species known to occur off Aberdeen include European lobster (*Homarus gammarus*), edible crab (*Cancer pagurus*), velvet swimming crab (*Necora puber*), shore crab (*Carcinus maenus*), giant scallops, cockle (*Cerastoderma edule*), mussels (*Mytilus edulis*), whelks (*Buccinum undatum*) and periwinkles (Littorina sp.).

264 The Norway lobster (*Nephrops norvegicus*) is by far the most important shellfish species exploited in Scottish waters. Norway lobsters are located in areas of soft mud or muddy sand in which they excavate and inhabit burrows. There are known spawning grounds to the north and south of Aberdeen Bay.

5.3.2.3 Cephalopods

265 Cephalopods (including cuttlefish, squid and octopus) are a prey item for a number of marine top predators such as fish, birds and marine mammals (Stowasser *et al.*, 2004). Evidence exists that fishing pressure has changed ecological conditions and shifts in community structures have occurred with cephalopod stocks slowly replacing predatory fish stocks (Caddy and Rodhouse, 1998).

266 Oceanic inflows from the Atlantic, coupled with the numerous shallow inshore habitats, make the northern North Sea a region of greater cephalopod diversity and abundance than the southern North Sea. Among the most frequently recorded species are: the long-finned squids, *Alloteuthis subulata* and *Loligo forbesii*; the short finned squid, *Todaropsis sagittatus*, *G. fabricii* and *Onychoteuthis banksii*; *the bobtail squids*, *Rossia macrosoma*, *Sepietta atlantica* and *Sepietta oweniana* and the octopus, *Eledone cirrhosa* (Hastie, Pierce and Wang 2008).

5.3.2.4 Non-commercial Species

267 The number of exploited and non-exploited fish species from coastal areas of SEA 5 was estimated by Potts and Swaby 1993 (cited by Swaby and Potts 1996, 1997a, b, c). Information on the distribution and abundance of non-commercial species comes from records made during routine groundfish surveys, landings data, historical records as well as scientific studies. The most abundant species found in near surface surveys in areas from Aberdeen to off Shetland were rocklings (*Gadidae*), members of the herring family (*Clupeidae*) and three-spined sticklebacks (*Gasterosteus aculeatus*) (Hislop 1979, cited by Swaby and Potts 1996). In summer and autumn, there is a large population of the sand goby (*Pomatoschistus minutus*) in the Ythan Estuary (NESBiodiversity, 2007).

5.3.2.5 Diadromous and freshwater species

268 There are several species that migrate between fresh and salt waters (diadromous species). These include the Atlantic salmon (*Salmo salar*), sea trout (*Salmo trutta*), sea lamprey (*Petromyzon marinus*), river lamprey (*Lampetra fluviatilis*), eel (*Anguilla anguilla*), twaite shad (*Alosa fallax*) and allis shad (*Alosa alosa*) (Barne *et al.*, 1996; DTI, 2004). Atlantic salmon, river

and sea lamprey, twaite shad and allis shad are listed as protected species in Annex II of the EU Habitats Directive.

269 In addition to salmon and sea trout, the North East Scotland region has records of all seven British marine and estuarine species protected under national, European and international legislation. However, these records tend to be individual records of the lamprey and sea lamprey, allis and twaite shads, and sturgeon. These species are considered threatened in the UK and European waters.

270 There are no designated SAC sites in the vicinity of the proposed EOWDC for sea lamprey, river lamprey, allis shad and twaite shad (JNCC, 2010).

Salmonids

271 Salmonids (salmon and sea trout) spawn in freshwater and migrate to the sea to mature. On the North Sea coast, salmon rivers are concentrated in the north and northeast Scotland. Trout tend to have a more westerly distribution. Around the North East of Scotland region, the Deveron, Ugie, Ythan, Don, Dee and Bervie are the main rivers that are known to contain populations of salmon and sea trout. Smaller rivers and tributaries may also contain populations (Barne *et al.*, 1996).

272 The river Dee has been designated as an SAC for its populations of Atlantic salmon. The River Dee supports a high-quality Atlantic salmon population and contributes to a significant proportion of the Scottish salmon resource. In recent years it has contributed about 4 or 5 % of all salmon caught in Scotland (JNCC, 2010).

273 As a result of various environmental pressures, the numbers of both species, salmon and sea trout, have declined in recent years leading to increased concerns over fish stocks. International and national legislation, as well as a number of management initiatives have been introduced in an effort to halt declines and improve stocks.

274 Salmon and sea trout are of particular importance in this area with the Rivers Dee and Don having salmon and trout fisheries. In Scotland, the management of the salmon fishery is entrusted to District Salmon Fishery Boards (DSFBs) whose responsibilities include the protection and improvement of the salmon fisheries within their districts. The two Salmon Fishery Districts in the immediate vicinity of the proposed development are the Dee and Don Boards.

275 All Scottish salmon fisheries are closed for a minimum of 168 days a year for spawning. The actual dates may vary but are usually from late August to mid February. Salmon spawning periods vary between rivers and are thought to be influenced by water temperature and day length. Hatching generally occurs in spring. The length of time young salmon stay in a river varies considerably and is dependent upon water temperature and food availability. With transition into smolts (the stage between a parr and a grilse when a salmon first migrates from fresh water to the sea), fish normally leave rivers between February and June to commence their northward migration. Young fish however spend some time at the river mouth, acclimatising to the transition from fresh to salt water; observations on the River Dee have noted that this takes around three weeks, during which time the smolts are vulnerable to predation. Salmon return to their native rivers throughout the year, with districts recording different peak periods. Generally, returning

grilse (young salmon returning to freshwater after the sea) peak in June and continue until October. As with smolts, returning salmon and grilse are known to congregate around the river entrances.

276 Sea trout spawning generally occurs between mid October and January. Parr (young salmon and trout in the first two years of life) destined to become smolts leave the river slightly later than salmon, but migration is again over by mid-June. Adult sea trout return to their native rivers in May and this may continue in some areas until October. Sea trout are also known to congregate at river mouths.

Freshwater Pearl Mussel

277 The freshwater pearl mussel (*Margaritifera margaritifera*) is a rare and threatened species which is listed in Annex II of the EU Habitats Directive. The life cycle of the freshwater pearl mussel is closely linked to that of salmonids fish, therefore any potential impacts on salmonids may have implications for freshwater pearl mussels.

278 Freshwater pearl mussels inhabit cool, well-oxygenated soft water free of pollution or turbidity in fast-flowing rivers and streams with healthy salmon populations. The mussels spend their larval stage attached to the gills of salmonid fishes, attaching themselves during mid to late summer and then dropping off the following spring to settle in the riverbed gravel where they grow to adulthood (JNCC, 2009).

279 The freshwater pearl mussel is a primary reason for the selection of the River Dee SAC, along with Atlantic salmon and otter (JNCC, 2010). The River Dee supports a functional population of freshwater pearl mussel and mussels have been recorded from a location approximately 30 km from the river source to approximately 6-7 km upstream of its mouth. Juveniles make up approximately 30 % of the recorded population, among the highest proportions recorded in Scotland. This indicates that the population is recruiting strongly and is one of the most important in the UK (JNCC, 2010).

5.3.2.6 <u>*Elasmobranchs*</u>

Basking Shark

280 The basking shark (*Cetorhinus maximus*) is listed as ‘vulnerable’ on the IUCN Red List of Threatened Species and in Appendix II of CITES. The species is also listed on the Wildlife and Countryside Act (1981), Schedule 5. The distribution of basking sharks in British waters is predominantly along the west coast of the British Isles, with peak sightings occurring in May to August (MCS, 2005). Studies conducted by the Marine Conservation Society indicate an increase in the numbers of basking sharks sighted in British waters, with a 65 % increase in Scottish waters between 2001 and 2004. The majority of sightings are from the west coast of Scotland; however, there has been an increase in basking shark sightings on the Scottish east coast since 1999.

281 The basking shark is the world's second largest fish species, with a circum-global distribution in warm-temperate to boreal seas. Little is known about many aspects of the life history and biology of basking sharks, including how their distribution may be related to broader scale changes of the marine environment.

282 Reference to data from the Wildlife Trusts' basking shark study shows that there have been no basking shark sightings close to Aberdeen as their usual distribution follows the west coast of Britain. However, a basking shark was observed during a boat survey of the wind farm site on the 16th November 2007 (IECS, pers. comm.).

Other Shark and Ray Species

283 Porbeagle sharks (*Lamna nasus*) are found throughout the North Atlantic, with the largest population in UK waters found to the north of Scotland. Recorded sightings of porbeagle sharks within the North Sea have generally occurred offshore in the central North Sea, between May and September (JNCC, 2010).

5.3.2.7 *<u>Threatened and Protected Species</u>*

284 A number of fish species present in the area have been included in the OSPAR Initial List of Threatened and/or Declining Species and Habitats. These include cod (*Gadus morhua*), common skate (*Dipoturus batus*), basking shark (*Cetorhinus maximus*), allis shad (*Alosa alosa*), sea lamprey (*Petromyzon marinus*) and salmon (*Salmo salar*). A number of fish species, including the Atlantic salmon (*Salmo salar*), river and sea lamprey (*Lampetra fluviatilis* and *Petromyzon marinus*), twaite shad (*Alosa fallax*), allis shad (*Alosa alosa*) and freshwater pearl mussel (*Margaritifera margaritifera*) are listed on Annex II of the Habitats Directive (92/43/EEC). Several fish species are also protected in UK waters under Schedule 5 of The Wildlife and Countryside Act, 1981 including the sturgeon (*Acipenser sturio*), allis shad (*Alosa alosa*), twaite shad (*Alosa fallax*) and basking shark (*Cetorhinus maximus*). The basking shark has also been given protection by the Convention on International Trade in Endangered Species (CITES).

5.3.3 Proposed Scope of Assessment

285 In order to investigate the potential effects on fish including salmon and sea trout, shellfish and elasmobranches in the area, extensive consultation and a desk study will be undertaken. This will include liaison with:

- The District Salmon Fishery Boards (DSFBs)
- Aberdeen University
- Scottish Sea Fisheries Committees (SFCs)
- The Scottish Fishermen's Federation (SFF)
- Local fishermens organisations
- Marine Scotland
- SNH
- JNCC

5.3.4 Potential Impacts

286 Potential impacts to be considered within the Environmental Impact Assessment (EIA) will include:

- loss of spawning and nursery grounds due to the installation of foundations and cables

- disturbance to benthic and pelagic habitats due to an increase in sediment suspension and deposition
- remobilisation of contaminants from seabed disturbance / release of contaminants from vessels leading to a reduction in water quality
- noise and vibration which could affect fish and shellfish behaviour
- electro-magnetic fields which could affect fish and shellfish physiology and behaviour
- introduction of new habitat which could have positive impacts on fish and shellfish species
- disruption of shoaling and migration patterns

5.3.5 Cumulative Assessment

287 Relevant activities to be considered within the cumulative assessment include shipping, fishing and oil and gas exploration.

5.3.6 Mitigation

288 Possible mitigation measures to reduce and minimise potential impacts on fish and other species include:

- choice of foundation type and installation method
- timing of construction to avoid key spawning and/or migration periods
- use of a soft start to piling operations
- careful siting of wind turbines and cable routes
- contaminant management

5.3.7 EOWDC Future Research and Monitoring

5.3.7.1 <u>*Migratory Fish*</u>

289 The effects of buried electricity cables on migrating fish remain unclear and further work on this would be valuable. The impacts of construction (eg underwater noise) are also unclear. The site lies in the vicinity of the Rivers Dee and Don, two of Scotland's great salmon rivers. The city's universities and research institutes have a long history of researching the population dynamics, migration, life history and behaviours of salmonid fish. The EOWDC would therefore be a good location for further studies on this important topic. Subjects that could be studied could include:

- potential effects from noise and turbidity on life cycles and movements of migratory fish
- assessment of noise reduction mitigation measures and techniques
- EMF effects on migrating populations – establish migrating routes (salmon highway)
- benefits of various mitigation methods to eliminate or reduce impacts on salmon

5.4 Birds

5.4.1 Introduction

290 The assessment of EOWDC on the ornithological resource of the area entails identifying the species that use the area, and the extent to which the value of the overall ornithological resource of the area could be altered both directly, for example through increased mortality as a consequence of wind turbine collision, or indirectly, for example through changes to prey.

291 Aberdeen Bay is recognised as supporting a wide variety of avian species that are present throughout the year or only during winter or summer months. Although the bay itself is not a designated site it has been considered, as a possible Special Protected Area (SPA) for the concentrations of sea ducks and divers in the inshore area.

292 Many seabird colonies along the Scottish east coast have been afforded protection status under the EU “Birds” Directive as SPAs for the species breeding there and the numbers they support (JNCC, 2010). Seven Special Protection Areas (SPAs), located within the daily flight distance of their qualifying species, were identified as relevant to the development (Table 5.2 & Figure 6). The requirement for evidence based assessments of the potential impacts on the SPA interests has been identified as the most important requirement in the EIA and AA process.

293 This section outlines the bird surveys undertaken to date, which have included radar, boat-based surveys and vantage point counts, and discusses the boat-survey programme that is planned for 2010-2011. The interim results for the surveys carried out so far are presented along with the analysis planned for the impact assessment stage.

5.4.2 Baseline Information

294 The north-east coast of Scotland supports a wide variety of avian species and offers a variety of habitats from sea cliffs to sand dunes. A number of designated sites are located in the region, although all are outwith the proposed development area. The Ythan Estuary and Sands of Forvie is the protected site in closest proximity and is particularly important for a range of species, including pink-footed goose, common eider, cormorant, common scoter and terns (common, Sandwich and little). The Buchan Ness and Collieston coast SPA along with the Fowsheugh SPA are important sites for seabird assemblages containing more than 20,000 birds with Fowsheugh also being an SPA interest feature for breeding guillemots and kittiwakes.

295 Full species accounts of seabirds and waterbirds that are present in the Aberdeen Bay area will be provided in the Environmental Statement. The following information provides summary information of the main species present in the area.

296 Large numbers of shorebirds and waterfowl also use North Sea coastal waters and shores, particularly in winter (DTI, 2001). Divers, grebes and seaduck are primarily inshore species typically wintering in sandy bays or estuaries, although some prefer rocky shorelines. Some species are resident while others are winter visitors to Britain. Scotland is particularly important for these species, with Shetland, Orkney, the Moray Firth and the Aberdeenshire

coast rated of prime importance for divers, grebes and seaduck for all months of the year (Barton & Pollack, 2004a).

297 Tern colonies occur on the Ythan, Loch of Strathbeg and Spey Bay. Common terns also breed along the rivers of Dee and Don. The Sandwich tern colony on the Ythan is the largest in Scotland and holds more than half the Scottish breeding population. There are also smaller colonies of common, Arctic and little terns, and also a black-headed gull colony. Terns are present in the area during spring, summer and autumn with particular concentrations along the north east coast during the breeding season. All four species are listed on Annex 1 of the EU Birds Directive. Breeding populations of Sandwich tern, common tern and little tern are an interest feature of the Ythan Estuary, Sands of Forvie and Meikle Loch SPA.

298 Daily feeding movements of cormorants and shags have been recorded passing Peterhead throughout the year (Innes, 1991) and occur throughout the Aberdeen Bay area. The shag forms part of the Buchan Ness to Collieston Coast SPA seabird assemblage interest feature.

299 Gannets are present throughout the year. At Peterhead, gannets are scarcest in the winter, but numbers present increase significantly in the spring from April onwards, peaking in May (Innes, 1991). They are observed to feed and fly along the north east coast with movements to and from their breeding colony at Troupe Head SPA and possibly the Bass Rock which is part of the Forth Islands SPA.

300 Gulls occur throughout the year. At Peterhead, black-headed, common, herring and great black-backed gulls pass along the north-east coast throughout the year (Innes 1994). Lesser black-backed gulls are regularly recorded between of March and September (Innes, 1994). Little gulls are relatively scarce but have been recorded in every month, with most sightings between June and November (Innes, 1994). Detailed counts of common gulls on the Ythan Estuary during the 1980s showed that numbers peaked in October and November, thereafter declining until return passage in the spring (Wernham *et al.* 2002). Kittiwakes pass along the north-east coast throughout the year and observations at Peterhead indicate that they are less frequent during the winter compared to the summer months (Innes, 1994). Kittiwake and herring gull form part of the Buchan Ness to Collieston Coast SPA seabird assemblage interest feature.

301 Fulmar breeding numbers in North-East Scotland have steadily increased in recent decades with increases along Banff and Buchan of 136 %; Gordon 26 %; City of Aberdeen 241 %; and Kincardine and Deeside 167 % all between 1969 and 2000 (Mitchell *et al.*, 2004). At Peterhead, fulmars pass along the north-east coast throughout the year, but are scarcest in winter (Innes, 1992). Fulmar form part of the Buchan Ness to Collieston Coast SPA seabird assemblage interest feature.

302 Auks (guillemots, razorbills, puffin) are present throughout the year with peaks in spring and autumn and numbers tend to be lower during the winter months. Auks leave colonies in the early morning to forage offshore and return in the evening.

303 Three species of diver are known to be present along the north east coast of Scotland: red-throated diver, black-throated diver and great northern diver. Of these, red-throated divers are by far the most abundant. The

Aberdeenshire coast regularly holds nationally-important numbers of red-throated diver (Barton & Pollack, 2004a). Numbers are highest during late autumn, winter and early spring with peak passages during April-May and October. All three species are listed on Annex 1 of the EU Birds Directive.

304 Seaduck (including eider, common scoter, velvet scoter and long-tailed duck) are likely to be present throughout the year. Eider forms part of the Ythan Estuary, Sands of Forvie and Meikle Loch SPA seabird assemblage interest feature. Eider are found in nationally important numbers from Donmouth to the Ythan Estuary. The Aberdeenshire coast also regularly holds nationally-important numbers of common scoter; numbers of eider and common scoter tend to peak in late summer (Barton & Pollack, 2004a).

305 There are major concentrations of waders associated with the Ythan Estuary. In winter many species of wader are present in the estuary, including turnstone, purple sandpiper, knot, redshank, lapwing and golden plover. There is some movement of waders, both north and south, close to shore throughout the year. Redshank and lapwing form part of the Ythan Estuary, Sands of Forvie and Meikle Loch SPA seabird assemblage interest feature.

306 Manx shearwaters are present in North East Scotland from late spring, throughout the summer and autumn. During a ten-year study of seabird movements at Peterhead, Manx shearwater passage began in April, peaked in June-July and continued through to early November (Innes, 1992). Sooty shearwaters are a scarce autumn passage migrant in North East Scotland usually seen from mid-July to mid-November. Most birds recorded are heading north with peak numbers in August and September (Innes, 1992). Manx and sooty shearwaters are thought to come closer to shore when visibility is poor. Storm and Leach's Petrels are rarely recorded in North East Scotland except from between July and September when they are frequently caught and ringed along coast. They are rarely seen during the day except during very poor stormy weather when small numbers are occasionally recorded offshore.

307 Skuas are present offshore during summer months. Great skuas occur from April with numbers increasing throughout the summer until August before dropping off towards late October/early November (Innes, 1993). Great skuas are regularly sighted at Fowlsheugh SPA. The passage of Arctic skua is generally from the April to November, with peak numbers in late summer (Innes, 1993). Pomarine skuas and to a lesser extent, long-tailed skuas are regular, but uncommon late summer-autumn passage migrants in the north-east of Scotland (Innes, 1993).

308 Apart from the resident mute swan, Swans and Geese are primarily winter visitors to north-east Scotland, arriving in autumn and spending the winter feeding on agricultural land or saltmarshes. North-east Scotland is a particularly important wintering and passage area for these species. Five species of swans and geese (whooper swan, mute swan, pink-footed goose, greylag goose and barnacle goose) occur in internationally-important numbers at coastal sites along the east coast of Scotland, (Barton & Pollack, 2004b).

309 Whooper swans have been observed over the sea during October to December. Whooper swan is listed on Annex 1 of the EU Birds Directive. Greylag, barnacle, pink-footed, white-fronted and Brent geese are present

from September through the winter until they return to breeding grounds in March and April. Greenland white-fronted goose and barnacle goose are listed on Annex 1 of the EU Birds Directive. The wintering population of pink-footed goose is an interest feature of the Ythan Estuary, Sands of Forvie and Meikle Loch SPA. The Loch of Strathbeg is internationally important for whooper swans, pink-footed geese and barnacle geese from the Svalbard breeding population in autumn and winter. Several inland sites also hold significant numbers of Swans and Geese during the winter.

TABLE 5.2
SPA and their qualifying interest features in the vicinity of Aberdeen Bay

Site	SPA interest feature breeding	SPA interest feature non-breeding
Ythan Estuary, Sands of Forvie and Meikle Loch SPA (also Ramsar site)	Common Tern Little Tern Sandwich Tern	Pink-footed Goose Waterfowl assemblage, including Eider, Redshank and Lapwing.
Loch of Skene SPA (also Ramsar site)	-	Whooper Swan Greylag Goose
Fowlsheugh SPA	Kittiwake Guillemot Seabird assemblage including Fulmar, Herring Gull and Razorbill	-
Buchan Ness to Collieston Coast SPA	Seabird assemblage, including Fulmar, Shag, Kittiwake, Herring Gull and Guillemot	
Loch of Strathbeg SPA (also Ramsar site)	Sandwich Tern	Barnacle Goose Greylag Goose Pink-footed Goose Whooper Swan Waterfowl assemblage including Teal
Troup, Pennan and Lion's Heads SPA	Guillemot Seabird assemblage including Fulmar, Herring Gull, Kittiwake and Razorbill	-
Forth Islands SPA (includes Bass Rock)	Gannet Shag Lesser Black-backed Gull Roseate Tern Arctic Tern Common Tern Sandwich Tern Puffin Seabird assemblage including Cormorant, Herring Gull Kittiwake, Razorbill and Guillemot	
Aberdeen Bay potential coastal or marine SPA	[not stated by SNH]	[not stated by SNH]

5.4.3 Proposed Scope of Assessment

310 A comprehensive programme of surveys and studies have been undertaken and are underway for the EOWDC site in order to provide baseline data for use in the environmental impact assessment and to help inform any appropriate assessments should they be required. To date, surveys have included land based vantage point surveys, boat based surveys, and radar surveys.

311 The survey programme aims to provide data and supplement the existing information for the EOWDC site, and determine:

- the general importance of the area for birds, including the distribution and abundance of birds and densities of the birds in the area for use in population estimates
- the behaviour of birds and their use of the site for example, for feeding, resting or passage
- the flight height of birds for use in assessments of collision risk with wind turbines
- bird behavioural responses to ship-based survey vessel to gauge the extent to which counts can be influenced by avoidance responses of flushed birds
- the evidence for the site being located on any spring or autumn migratory flight route and occurrence of significant numbers of migrants

5.4.3.1 Vantage Point Bird Surveys

312 Shore-based vantage point bird surveys were conducted for two hours weekly at Blackdog and Donmouth and fortnightly at Drums and Balmedie covering a distance of up to 2 km from shore. These surveys were conducted between April 2006 and March 2008 (two years completed). The surveys gave good coverage of the inshore areas of the bay which were not accessible by boat due to shallow water depth. However, due to the distance offshore of the proposed wind turbines it was not possible to accurately survey out to the revised proposed location. The detection arc possible from each vantage point surveyed, in relation to the wind farm survey area is presented in Figure 7.

TABLE 5.3
Totals and mean numbers per hour of principal species recorded in Aberdeen Bay for the four six-month periods summer 2006, winter 2006-2007, summer 2007 and winter 2007-2008.

Species	Summer 2006	Winter 2006-2007	Summer 2007	Winter 2007-2008
Red-throated Diver	567 (5.7)	226 (3.0)	435 (4.3)	272 (2.5)
Fulmar	852 (8.6)	25 (0.3)	898 (8.8)	24 (0.2)
Gannet	4492 (45.4)	165 (2.2)	4352 (42.7)	713 (6.4)
Manx Shearwater	186 (1.9)	1 (0.01)	49 (0.5)	7 (0.1)
Sooty Shearwater	12 (0.1)	0 (0.0)	10 (0.1)	5 (0.05)
Cormorant	418 (4.2)	248 (3.3)	446 (4.4)	424 (3.8)
Shag	46 (0.5)	66 (0.9)	43 (0.4)	35 (0.3)
Eider	885 (8.9)	355 (4.7)	780 (7.7)	877 (7.9)
Common Scoter	2798 (28.3)	297 (4.0)	4665 (45.7)	1159 (10.4)
Velvet Scoter	41 (0.4)	7 (0.1)	16 (0.2)	16 (0.1)
Red-breasted Merganser	44 (0.4)	53 (0.7)	45 (0.4)	97 (0.9)
Curlew	50 (0.5)	199 (2.7)	181 (1.8)	92 (0.8)
Oystercatcher	34 (0.3)	147 (2.0)	190 (1.9)	62 (0.6)
Guillemot	5635 (56.9)	1495 (19.9)	3151 (30.9)	628 (5.7)
Razorbill	91 (0.9)	113 (1.5)	198 (1.9)	56 (0.5)
Puffin	22 (0.2)	1 (0.01)	54 (0.5)	4 (0.04)
undiff. auks	1145 (11.6)	1324 (17.7)	3354 (32.9)	838 (7.6)
Great Skua	109 (1.1)	3 (0.04)	110 (1.1)	2 (0.02)
Arctic Skua	69 (0.7)	0 (0.0)	164 (1.6)	6 (0.05)
Black-headed Gull	143 (1.4)	638 (8.5)	684 (6.7)	912 (8.2)
Common Gull	1256 (12.7)	3419 (45.6)	1215 (11.9)	3024 (27.2)
Herring Gull	6158 (62.2)	4112 (54.8)	8099 (79.4)	6737 (60.7)
Lesser Black-backed Gull	19 (0.2)	3 (0.04)	50 (0.5)	19 (0.2)
Great Black-backed Gull	360 (3.6)	178 (2.4)	232 (2.3)	367 (3.3)
Kittiwake	6429 (64.9)	67 (0.9)	4127 (40.5)	124 (1.1)
undiff. gulls	4001 (40.4)	924 (12.3)	3845 (37.7)	786 (7.1)
Sandwich Tern	2536 (25.6)	1 (0.01)	4561 (44.7)	1 (0.01)
Common Tern	1720 (17.4)	0 (0.0)	105 (1.0)	0 (0.0)
Arctic Tern	359 (3.6)	0 (0.0)	2678 (26.3)	14 (0.1)
'commic' terns	*2079 (21.0)*	*0 (0.0)*	*2783 (27.3)*	*14 (0.1)*
Little Tern	6 (0.1)	0 (0.0)	11 (0.1)	0 (0.0)
undiff. terns	70 (0.7)	0 (0.0)	1186 (11.6)	0 (0.0)

313 The vantage point surveys primarily collected data on flying birds (ie species, numbers, direction of flight, distance from shore and height), although some information on birds on the surface was noted, along with marine mammals. Weather conditions, including wind direction and sea state was also recorded for each of the surveys.

314 Vantage point surveys are very useful in establishing the bird species frequenting and passing through Aberdeen Bay and can detect the large variations in numbers for some species that have been recorded between consecutive seasons (Table 5.3). The results of the vantage point surveys are useful in providing evidence for the main passage of birds along the shorefront and the flight height of these birds. This information has been used to modify the original wind turbine layout and position it further offshore away from the main areas used by birds.

315 No further vantage point surveys are planned as they are not suitable for accurately detecting birds at the revised wind farm location.

5.4.3.2 *Boat Based Surveys*

316 Boat based surveys following the methodology of Camphuysen *et al.* (2004), were carried out monthly between February 2007 and April 2008. There has been a gap in survey coverage since April 2008. To date, boat based surveys have covered a period of 15 months, which is recognised to be below the recommended two years of survey coverage advised by SNH. For the months May to January there has only been one months worth of boat based survey data (Table 5.4). Following the recommendations of a gap analysis on the existing survey data, and advice from statutory consultees, an additional boat based survey programme has been designed. Further surveys started in August 2010 and will continue for at least 12 months, or more prior to construction.

✓Survey took place

317 The original boat based survey transect design, followed the statutory advice provided by JNCC and SNH and consisted of a survey area including the wind farm plus a buffer zone and control site to the north of wind farm site. The total survey area was 101.6 km^2. The boat survey track, wind farm and study site and control areas are shown on Figure 8.

318 Data obtained from all the surveys will be used to assess the importance of the site for all species, especially those likely to be from SPAs. The data will also be used to help determine the risk and significance of potential impacts and identify possible mitigation measures. A summary of the initial boat based survey results for the main species of interest is shown in Table 5.5 and brief conclusions are provided. The impact assessment section expands upon the further analysis that is planned for the complete survey dataset.

TABLE 5.5
Summary accounts of key bird species detected in the surveys in Aberdeen Bay. The three main risks to birds which are collision, displacement and barrier effects are shown with each species being assigned a low, medium or high score. Species that are highlighted in red are qualifying species of SPAs.

	Species	Comments	Risks		
			Collision	**Barrier**	**Displacement**
Auks	Guillemot	Population was estimated at over 1,000 individuals within the wind farm survey area in summer with a peak of 1,161 (95 % confidence limits 796 - 1,692) individuals in July and lower than the control area 2,419 (1812-3231). The numbers of common guillemot declines during the winter with birds dispersing further offshore. Population estimates produced were larger in the control survey area during the breeding and post breeding season, but smaller in the winter in comparison to the wind farm survey area. Birds were evenly distributed with marginally more observations in waters <20 m. One out of 243 recorded flights was above 25 m.	Low	Low	Moderate
	Razorbill	Increase in abundance occurred during the summer months. Post-breeding surveys in July, August and September featured the largest numbers of birds Peak count in wind farm area of 273 in August 2007. Up to 378 in control area (August 2007). Sightings were evenly distributed between shallow and deeper areas. Only a few individuals were detected in the survey areas during winter. All flights recorded below 25 m.	Low	Low	Moderate
	Unidentified Guillemot / Razorbill	Some common guillemot and razorbill were not identified to a species level, and as such, sightings were grouped into an unidentified common guillemot/razorbill category. The peak count from boat surveys was made in July within the control survey area, and reached 1,431 birds.	Low	Low	Moderate
	Atlantic Puffin	Increase in numbers during summer months. Peak population estimate of 285 (95 % confidence limits 172-471) birds in September (control area). Majority of birds were found in deeper waters >20 m. No sightings in winter months (Dec-Apr). Sightings were relatively scarce within the wind turbine footprint and wind farm survey area. No birds were detected flying above 15 m.	Low	Low	Moderate
	Little Auk	The little auk is an overwinter visitor to the North East coast, a total of 6 little auks were detected during the boat based surveys during the winter months.	Low	Low	Low
Terns	Common Tern	Common terns were present in the survey areas between May and	Low	Low	Moderate

		September. Populations were much lower in the wind farm survey area than in the control survey area. Numbers peaked in July with a maximum population 55 birds in the wind farm survey area and 264 birds in the control survey area. 93 % of the common terns recorded in transect were actively foraging (shallow plunging). No birds were recorded in the wind turbine footprint. Foraging concentrations were found in the south-west corner of the wind farm survey area and off the Ythan Estuary. No birds recorded flying above 25 m.			
	Arctic Tern	The Sands of Forvie support a breeding population of 76 pairs (Mitchell *et al.,* 2004). Only three Arctic terns were recorded in the control survey area during the July survey.	Low	Low	Low
	Common/Arctic Tern	A total of 29 birds classed as 'commic' tern were observed from May to September. 20 % of the individuals were recorded foraging 'in transect'.	Low	Low	Low
	Sandwich Tern	Very few birds were recorded in the ship-based survey areas. Based on extrapolation of overall density, the maximum counts were of only five birds in the wind farm survey and 21 birds in the control survey area. Majority of sightings were in close proximity to the shore in shallow waters <20 m. No birds were recorded in the wind turbine footprint. No birds recorded flying above 25 m.	Low	Low	Low
Gulls	Common Gull	The largest counts of were recorded during the winter period, producing a population estimate of 239 individuals in March in the wind farm survey area and 235 individuals in the control survey area. Estimated population sizes within the wind farm site were larger from September to February. The majority of common gulls were present in the southern part of the wind farm survey area during winter. There was a net reduction in April following the departure of birds to their main breeding ground, however, although, a small population breed in Aberdeen city, numbers were almost absent from the area during summer. The majority of birds (66 %) were observed flying below 25 m.	Moderate	Low	Low
	Herring Gull	Within the wind farm survey area, the population size was estimated to be of 417 birds in June and 456 in July. Outside the late breeding and post breeding period, monthly population estimates were very low, and the species was absent from this area in April and May. A similar pattern was observed within the control survey area, although estimated populations were very low during the breeding season. Low numbers of counts were	Moderate	Low	Low

		observed between November to May. In contrast, during the post breeding season, large concentrations occurred in the south-west corner of the wind farm site close to Aberdeen Harbour, but also around the cliffs of Collieston within the control survey area. The majority of birds (52.8 %) were observed flying above 25 m.			
	Great Blacked Gull	Great black-backed gulls were present in Aberdeen Bay all year round. Within the wind farm survey area, numbers of birds recorded in transect peaked in June, resulting in a population estimate of 123 individuals. Monthly population estimates in the control survey area were lower. Bird sightings are dispersed across the site, but small concentrations were found between the Ythan Estuary and the cliffs of Collieston, as well as the southern transects of the wind farm survey area. The majority of birds (56%) were observed flying above 25 m.	Moderate	Low	Low
	Black Legged Kittiwake	Population estimates were at their highest during the late breeding season and their lowest during the winter. Within the wind farm survey area, a population of 1,092 black-legged kittiwakes was estimated in July. Distance sampling produced similar population estimates in the control survey area with a total of 810 individuals in July (95% confidence limits on distance estimate: 405 - 1,620). Outside the breeding season the species is essentially oceanic, and low numbers were recorded from November to March. Distribution of black-legged kittiwake to be patchy during the late breeding season, but with large flocks present (single flock of up 130 individuals). This is possibly linked to the distribution of the kittiwake's main prey items across the survey area, i.e. small pelagic shoaling fish, such as sandeels, sprats and young herring. By contrast, sightings in winter consisted of one or two individuals scattered across the ship-based survey area. Majority (61.6 %) of birds were flying below 25 m, with birds observed flying upto 100 m.	Moderate	Low	Low
	Black Headed Gull	In the North Sea, black-headed gulls occur at sea only during migration periods. In the winter, black-headed gulls can be found in inshore tidal waters with a preference for bays and estuaries with sandy and muddy beaches . Eight of the nine sightings recorded during the survey programme were made in November - all in the inshore short legs between the main transects.	Low	Low	Low
	Lesser Black	Lesser black-backed gulls breed in colonies along the coast and at some	Low	Low	Low

	backed Gull	inland sites in Britain and Ireland. Only two sightings of lesser black-backed gull were made during the survey programme. Both were in June within the wind farm survey area.			
Skuas	Great Skua	Great skuas were recorded from July to September, with peak numbers in August (74 % of the sightings occurred in August). Great skuas were recorded in lower numbers than Arctic skuas. Sightings indicate a concentration of birds in the north-east part of the control survey area. 25 % of birds were observed flying within wind turbine height.	Low	Low	Low
	Arctic Skua	Arctic skuas were present in the survey areas from June to November. Peak passage occurred in November with a total of 23 birds. Several kleptoparasitic attempts were recorded during the surveys on terns, black-legged kittiwakes and common gull. Arctic skuas were more abundant and widely distributed in the control survey area than in the wind farm survey area. The majority of observations (83 %) were observed flying below 25 m.	Low	Low	Low
	Long-tailed Skua	One long-tailed skua was seen in June. The species is a passage migrant to the UK, breeding in the high Arctic.	Low	Low	Low
Cormorants	European Shag	Present in low numbers from between February 2007 and January 2008 with fewer sightings during the winter. Sightings were scattered across the ship-based seabird survey area. No birds were detected in the wind turbine footprint and majority of sightings occurred in shallow < 20 m waters. All birds were detected flying below 10 m.	Low	Low	Low
	Great Cormorant	Present all year around in Aberdeen Bay, but with lowest numbers in May and greatest numbers in September and October. Estimated population sizes indicates the control area to support the largest population, with up to 20 individuals in September. The distribution of sightings from February 2007 to January 2008 indicates the species to prefer shallow waters with the species rarely occurring in water exceeding the 20 m depth contour line. Concentrations were found in shallow waters from the Ythan estuary to the cliffs of Collieston. All birds were detected flying below 25 m.	Low	Low	Low
Gannets, Shearwaters, Fulmars	Northern Gannet	Population estimates were the highest during the breeding season in the wind farm and control survey areas with 45 birds and 62 birds, respectively in August. Outwith the breeding season, estimated populations using the site were low and the species was almost absent during the winter period. Population estimates are mainly derived from birds seen in flight ('in	Moderate	Low	Low

		transect' at the time of snapshot), which suggest that the species passes through the site rather than stopping to forage. The distribution maps indicate the sightings to be scattered across the boat survey areas during the breeding season, but occurring mainly in the deepest water of the survey areas during the post breeding season. The majority of birds (82 %) were observed flying below 25 m.			
	Manx Shearwater	During the first year of surveys, the sightings of Manx shearwater began in May, peaked in September and continued through to early November. Of a total of 22 individuals recorded during the May to November period, 90 % were recorded in flight, mainly in a northerly direction. This suggests that Manx shearwater spent most of the time passing through the area without stopping and foraging. No birds were observed flying above 10 m.	Low	Low	Low
	Sooty Shearwater	Only one individual was recorded flying north in October. Although breeding only in the Southern Ocean, sooty shearwaters disperse widely outwith the breeding season and regularly reach the North Atlantic. Sooty shearwaters are a scarce autumn passage migrant in north-east Scotland usually seen from July to mid November.	Low	Low	Low
	Northern Fulmar	With the exception of February (16 individuals), northern fulmar population estimates using the wind farm survey area were very low in comparison to the control survey area. Sightings were dispersed in water deeper than 20 m with small concentrations observed around the cliffs of Collieston, where the species nests. No birds were observed flying above 10 m.	Low	Low	Low
Seaducks	Common Scoter	Only a few sightings were recorded 'in transect' as the majority of birds were recorded between the 'short legs' and the coast in the shallowest water, and therefore outside the 300m band transect. As a result, population estimates are very low in the wind farm and the control survey areas, despite large flocks being present between Donmouth and Balmedie, in particular around Blackdog. Counts outside transect included a single flock of up to 1,200 common scoters in July 2007. During winter, low numbers of common scoters remained between Donmouth and Balmedie. Only 3 % of birds were observed flying within wind turbine height (25-100 m).	Low	Moderate	Moderate
	Common Eider	Common eiders were present in both the control and wind farm sites throughout most of the year, but in very low numbers, with only a total of 53 individuals recorded 'in transect' between February 2007 and January	Low	Moderate	Low

		2008. As the result the population size estimated by extrapolation of overall density was very low in the ship-based survey areas. Common eiders were mainly distributed in inshore shallow waters, between the short legs and the coast, and thus not shown in as these were outside transects. Only a few individuals were seen in water exceeding 10 m depth. It is noteworthy that maximum counts outside the survey area were made in August (450 birds) and September (450 birds), both around Blackdog. No birds were observed flying above 25 m.			
	Velvet Scoter	Three sightings of velvet scoter were made during the survey programme totalling 14 birds. The two sightings in February (two individuals) and July (five individuals) were associated with a flock of common scoter. The seven individuals sighted in early November at dawn were presumably birds on migration as the birds were noted to fly in a south-westerly direction. Velvet scoters passed along the north-east coast through the year, with a notable increase during the spring before numbers dropped off in the summer and peaked again in late autumn. No birds were observed flying above 15 m.	Low	Low	Low
	Long-tailed Duck	The surveys did not identify the presence of a flock within the wind farm survey area, although occasional sightings close to the beach were an indication of the preference of this species for the shallowest areas. A total of 14 birds were recorded in ship-based survey areas in April, October and November. All sightings related to birds flying parallel to the coast (flock of up to four individuals), in a northerly or southerly direction. No birds were observed flying above 15 m.	Low	Low	Low
Wildfowl	Red-breasted Merganser	Only one red-breasted merganser was recorded in March at the mouth of the river Don. Red-breasted mergansers are recorded in small numbers throughout the year in Aberdeen Bay.	Low	Low	Low
Divers	Red-throated Diver	Red-throated divers were present throughout the year in Aberdeen Bay. The greatest usage was noted to occur in spring and winter within the wind farm survey area. The peak in May probably reflected movement of divers heading to northern Scottish breeding sites or to Scandinavia, whilst the increase in winter months indicated the presence of wintering a population in Aberdeen Bay. A total of 88 birds were estimated to be using the wind farm survey area during the passage period in May whilst an estimated 55 birds were present in January. Population estimates were much lower in	Low	Low	Moderate

		the control survey area, particularly during the winter months. Distribution maps indicate that red-throated divers exhibit a preference for water shallower than 20m, but with concentrations observed on the ‘short legs’ around the 5 to 10m depth contour line. No birds were observed flying above 25 m.			
	Unidentified divers	A total of six unidentified black-throated/red-throated diver were seen in both survey areas, mainly birds in flight or taking off from the sea surface at great distances.	Low	Low	Moderate

319 Seaducks (including common scoter and common eider) exhibited a very near-shore distribution, with concentrations observed in water depths of less than 5 m, and thus in low abundance in the wind farm site itself where water depths are greater. Red-throated divers were recorded within both the proposed development area and control survey areas. The species had a less concentrated near-shore distribution than that of the seaducks, but were found around the 5 to 10 m depth contour line, and thus found in shallower area than the proposed development.

320 Terns were more abundant in the control survey area than in the wind farm survey area. Sandwich, common and Arctic terns exhibited a preference for shallow waters adjacent to the Sands of Forvie colonies.

321 Gulls were numerous during the survey programme, with black-legged kittiwake and herring gull primarily recorded during the summer months (June and July) and mew (common) gull present during the winter period. Black-legged kittiwake exhibited no particular concentration of usage within, or adjacent to, the proposed project, although the control survey area was potentially one of the preferred areas for this species.

322 Common guillemots were widespread within the wind farm survey area, but with the largest foraging aggregations found in the control survey area during the post-breeding period. A general north-south flight line was observed through the wind farm survey area, although flight movements across the survey area were undertaken below 15 m.

5.4.3.3 <u>Boat Based Surveys 2010 – 2011</u>

323 AOWFL has contracted SMRU Ltd to provide further boat surveys which will be combined to cover marine mammals and birds. The new survey design is a gradient type approach and is different to the BACI type design that was surveyed in 2007 and 2008.

324 The 2010 surveys commenced in August and will be conducted monthly over two days. The surveys will extend the survey coverage and will follow a different type of transect pattern to that used in the original survey to allow the continual collection of data during line turns (Figure 8). SNH and JNCC were consulted upon the new survey transect design and surveying schedule.

325 The survey area has been extended to cover three survey strata

- i) extending northwards, covering both the wind farm, buffer and control areas surveyed in the previous surveys
- ii) extending eastwards further offshore
- iii) a southwards stratum

326 The total survey area is 339 km^2. This gradient approach allows potential displacement of birds to be assessed once the wind farm is operational. One 2-day survey will be conducted per month, initially for a 12 month period, with at least three months of data available for inclusion in the EIA and Environmental Statement, in addition to the previous data collect for the site. The boat surveys will continue after the submission of the Environmental Statement until 12 months of data have been collected, giving two years of data for the site. The intention is to then continue the surveys before, during and after construction, using the same transect design.

327 Standardised survey methods (as described in Camphuysen *et al.* 2004) will be used to allow comparison with previous boat-based surveys. Seabird observers will be experienced and ESAS trained and survey effort will be restricted to sea states of 4 or less. The data collected will allow density estimates to be created for the survey area and the data will provide a repeatable baseline from which to monitor throughout the wind farm installation. Data collected from previous surveys once fully analysed will contribute to the new dataset and be analysed in conjunction with it.

5.4.3.4 Radar Surveys

328 Radar studies provide data on flight height and bird movements for bird species in the area. Radar also provides a way of assessing bird movement during the hours of darkness and in adverse weather conditions, such as haar. The areas of Aberdeen Bay surveyed using radar are illustrated on Figure 7. The following radar surveys have been conducted:

- Autumn 2005: two 5-day surveys were conducted at Drums (24 – 29 October 2005) and Easter Hatton (29 October – 3 November 2005).
- Spring 2007: 10-day survey conducted at Blackdog (11-27 April 2007).
- Spring 2010: 6-day survey conducted at Blackdog (24-29th April 2010).

329 The results of the Autumn 2005 study indicated that the majority (>95 %) of flight movements were outside the proposed wind farm footprint but flight transits were detected up to 5000 m offshore, with the majority of movements being within 3000 m. Flight altitude was predominantly low (<50 m) at both the Drums site and the Easter Hatton site. The study indicated a high degree of interchange between birds along the whole coastline from Ythan Estuary south to Drums, Balmedie and Blackdog.

330 The results of the Spring 2007 study conducted at Blackdog supported the results of the previous radar study in that the majority of flight activity (90.9 %) was within 1.4 km of the shore. The majority of flight altitudes were below 40 m and from the visual observations by ornithologists the flight heights for most species of seaduck and diver observed was <30 m. Due to the spring migration a considerable northern bias to flight movements was detected.

331 Night activity was of a similar magnitude to daytime bird movement activity levels. Activity levels during Haar conditions did not alter for species within the fast speed classes, (seaduck, divers, auks,) but was much reduced for slow speed class species, notably gulls.

332 During periods identified from the radar tracks as having low migrational activity there were still numbers of tracks recorded within the wind farm footprint. This would indicate that the wind farm area is used by local birds either for foraging or transit, a pattern also repeated in the visual observation results

333 The spring 2010 radar study was designed to target the spring migration of geese. Very few geese were recorded during the survey undertaken in April and it may have missed the main migration period or, it is possible that the offshore area is not frequently used by migrating geese. Studies undertaken at constructed offshore and onshore wind farms have reported a very high avoidance rates by geese with collisions with wind turbines being extremely

unusual. AOWFL are not planning to commission any further radar studies that will specifically target geese.

5.4.3.5 Aerial Surveys

334 After careful consideration, aerial surveys were not considered appropriate for this development due to the size of the site and its proximity to land and helicopter flight paths. No aerial surveys are planned as part of the EIA process.

5.4.4 Predicted Impacts

335 A preliminary analysis of all ornithological data was undertaken in order to assess the potential impacts of the original proposal for a 23 wind turbine wind farm on the sensitive species identified above. Impacts assessed were: collision risk, disturbance / displacement, barrier effects, and habitat loss. From the initial analysis of the data it was recognised that bird movement was primarily within the inshore section close to the coast, this was confirmed from the results of the vantage point counts and radar monitoring. This resulted in a redesign of the wind farm layout with wind turbines placed further offshore avoiding the area which appeared to have the highest movement of birds.

336 The impact assessment for the new wind farm area will take into account and assess collision risk, displacement / disturbance, barrier effects, habitat loss and cumulative impacts. In order to analyse the data and to calculate the total population size within the areas survey it is proposed to use distance computer modelling. Modelling the data using distance methods may not produce accurate results where the numbers of observations are very small, which will be the case for many species in Aberdeen Bay. Where this is the case, use of an alternative method is necessary to estimate population size. Where distance sampling was not possible (< 50 different observations), simple extrapolation of the overall sample density will be used to estimate the total numbers of birds in the seabird survey areas. This approach has so far been used to analyse one year’s worth of boat based data and will be extended to include all available monthly survey data at the compilation stage of the Environmental Statement. Initial population estimates of birds in the wind farm survey areas will be generated using distance sampling techniques where possible, and distribution maps of seabird and seaduck sightings will be produced on a seasonal basis.

337 The use of the gradient approach for the 2nd phase of boat based survey work (rather than Treatment – Control) allows distance from the development footprint to be included as a covariate within analyses. This is particularly useful where the level of an impact may be expected to decline with distance or the spatial extent of an impact footprint is unknown. At the Aberdeen site, it may be expected that any negative impact results in displacement of birds away from the development site, with movement along the depth gradient up/ down the coast potentially more likely than offshore displacement (particularly with species like scoter, divers and eider). By extending the survey areas to the north and south of the development site, the potential to detect any such coastal displacement of divers and sea duck is maximised.

338 **Collision risk:** Collision risk to birds transiting through the wind farm area will be assessed using the Band model (Band, 2000) and will incorporate flight

height data collected during the offshore surveys and available literature on flight heights. The collision risk calculations will include all species, with particular attention paid to key species in the wind farm area, red throated diver, common eider and common scoter and terns.

339 **Displacement:** Displacement will be assessed for sensitive receptors with a particular emphasis on the key species red throated diver, common scoter, eider, guillemot and razorbill would be likely to be most sensitive to displacement due to their presence in large aggregations or high numbers on the surface waters of the bay. For species where insufficient information exists to predict likely displacement impacts, a worst case scenario will be applied which uses the assumption that 100 per cent of birds would be displaced from the wind farm and buffer zone and that habituation would not occur. Displacement effects will be considered on a number of scales, temporary displacement during construction and longer term after the installation of the wind farms.

340 **Barrier effects:** The assessment will take into consideration the potential for disruption to flight lines, including migratory flight paths and also daily movement of birds. From the initial analysis of the data it is considered unlikely that a significant barrier effect would arise owing to the orientation of the wind turbines in a north-south direction which is parallel to the predominant flight direction identified by radar and also parallel to the shore line. If appropriate, an energetic model will be applied to bird flight tracts to determine the effect that any deviation to flight lines will have.

341 **Habitat loss:** This will be assessed in its simplest form by calculating the amount of benthic habitat lost by the installation of the wind turbine bases, inter-array cables and export cables. Consideration will also be given to potential change in habitat and indirect effects on prey due to the installation and operation of the wind farm.

5.4.5 Cumulative Assessment

342 The cumulative assessment will follow the latest recommended guidance on CIA published by COWRIE (King *et al.*, 2009). For the assessment purposes, the only consented offshore renewable development for which there are bird data available to use in a cumulative impact assessment is the Beatrice wind farm located in the Moray Firth. The cumulative assessment will therefore be restricted to species that are found off Aberdeen Bay and the Moray Firth. The cumulative assessment will make reference to other renewable developments that are planned for Scottish territorial waters and Round 3 offshore areas, however detailed cumulative assessment is not possible for projects that are at an early stage of data collection and for which no data are available.

5.4.6 EOWDC Future Research and Monitoring

343 AOWFL proposes to monitor the movement of birds around, through and over the wind turbines to determine more accurately the actual influence of the wind turbines on the birds, and the birds' interaction with the wind turbines. Other parameters that could be investigated include studies into mortality of birds through collisions with wind turbine blades. This information would help inform the theoretical mortality estimates produced for collision risk, eg the

SNH bird-collision model. Further discussion on how to best collect this type of post construction data will be held with SNH and other appropriate organisations at a later date. EOWDC could be the focus of pre-construction, construction and post-construction ornithological surveys to determine the actual effects of the wind farm on the bird species of Aberdeen Bay and also validate the predictions made within the Environmental Statement.

344 The studies will include observations by ornithologists during bird boat-based surveys. The proposed Ocean Laboratory on the site could also be used to conduct specific bird investigations from, although the design and the type of equipment on the platform have yet to be ascertained so at this early stage it is not possible to commit to particular types of equipment. Stakeholders are being contacted to discuss potential collaborations and research opportunities that the platform will bring.

5.5 Bats

5.5.1 Introduction

345 It is recognised that bats may be impacted by wind farms; evidence from a number of onshore wind farms has indicated that bats have a higher mortality rate due to wind farms than birds. Although direct collisions with the wind turbines does occur, a higher mortality rate arises from due to barotraumas caused by sudden changes in air pressure causing lethal lung damage.

346 Bats have been recorded foraging around offshore wind farms. Studies undertaken in Sweden to explore potential impacts on migrating bats discovered that non migratory bats also occurred foraging around the wind turbines as far as 10 km from shore (Ahlén *et al.,* 2007).

347 All bats in the UK are fully protected under the Wildlife and Countryside Act and the European Habitats Directive.

5.5.2 Baseline Information

348 Bats in north-east Scotland have been extensively studied with significant research over the years undertaken by the University of Aberdeen.

349 Seven species of bat are known to occur in north-east Scotland of which only two are very common, the other species are either uncommon, rare or very rare (Table 5.6). There is little or no evidence of any regular migration of European bats to or from Scotland.

350 **Common pipistrelle and Soprano pipistrelle** - Due to the similarity of the two species *Soprano pipistrelle* was not discovered until the 1990s but has since been found to be common and widespread throughout the UK, including north-east Scotland. They occur in most habitats but particularly riparian woodland and parkland. They will forage up to 5 km from their roosts and are the most frequently recorded species along the Aberdeenshire coast.

351 **Nathusiu's pipistrelle** - A previous migrant species, it has only been classified as a resident in the UK since 1996. Only one record in north-east

Scotland. Two records from oil platforms suggest that this species may be a very scarce migrant.

352 **Brown long-eared bat** - This species is widespread but less common than the pipistrelles particularly along the coast. Brown long-eared bats roost in old houses and forage within 1.5 km from their roost which are invariably near to thick woodland. Consequently they are scarce along the coast.

353 **Daubenton's bat** - Although widespread in north-east Scotland, Daubenton's bats are closely associated with fresh water and avoid urban habitats. Roosts are in mature deciduous trees and rarely in houses. The species occurs along the Ythan as well as Deeside and Donside. However, it is rare or scarce near the coast.

354 **Natterer'sbat** - Natterer's bats are found throughout most of the British Isles. Recent records have extended its range in Scotland north to the Great Glen fault. This is a very rare bat in north-east Scotland with few records reported. It does forage widely and over a wide variety of habitats including grassland, but it prefers semi-open woodland often coniferous.

355 **Whiskered bat** – Very rare with just one record in north-east Scotland. It is found throughout England and Wales and even in southern Scotland and throughout Ireland.

TABLE 5.6	
Species	**Status**
Common pipistrelle	Very Common
Soprano pipistrelle	Very Common
Nathusiu's pipistrelle	Very Rare
Brown long-eared bat	Uncommon
Daubenton's bat	Uncommon
Natterer's bat	Rare
Whiskered bat	Very Rare

5.5.3 Proposed Scope of Assessment

356 A literature review will provide the major source of information for the Environmental Statement. From the information above there are only two species potentially occurring at the proposed offshore wind farm site should foraging occur at the wind farm. The assessment will also explore the potential for migrating bats to occur within the wind farm location.

5.6 Marine Mammals

5.6.1 Introduction

357 The north east of Scotland is widely recognised as being important for marine mammals and there has been considerable research effort directed towards studying populations and marine mammals in the wider area. The EIA will review and take into account all relevant available information along with the data collected at the site to establish potential impacts associated with the proposed development and determine adequate mitigation measures to implement.

358 Marine mammals are protected under several sections of conservation legislation. All cetacean species are listed in Annex IV of the EC Habitats Directive, which protects them from any deliberate disturbance, particularly during the periods of breeding and migration. In addition, bottlenose dolphins, harbour porpoises, harbour seals, grey seals and otters are also listed in Annex II of the Habitats Directive.

359 This section outlines the marine mammal surveys undertaken to date which have included acoustic monitoring, boat-based surveys and vantage point counts, and the future monitoring that is planned for the site. The interim results for the surveys carried out thus far are presented along with the analysis planned for the impact assessment stage.

- Travers, S., Thomson, S. and Mander, L. (2008). Institute of Estuarine & Coastal Studies, University of Hull. 68pp.Monthly boat based marine mammal survey reports February-April 2008. The Institute of Estuarine & Coastal Studies (IECS).
- Weir, C. (2008). Photo-identification catalogue for bottlenose dolphins (Tursiops truncatus) and other cetacean species off the coast of Aberdeenshire, NE Scotland. Version 1.1 ACC.

5.6.2 Baseline Information

360 The coastal stretch between the Moray Firth and St Andrews contains a population of bottlenose dolphins. In Aberdeen Bay the bottlenose dolphins are semi-resident and are frequently observed at the mouth of the harbour entrance. Other frequently sighted marine mammals include the harbour porpoises (*Phocoena phocoena*), harbour seals (*Phoca vitulina*) and grey seals (*Halchoerus grypus*). In the summer months white-beaked dolphins (*Lagenorhynchus albirostris*) and minke whales (*Balaenoptera acutorostrata*) have been observed further offshore. Records of marine mammal sightings including from stranding records indicate 12 odontocete species, three mysticete species and three pinniped species (Table 5.8).

361 For species such as white-sided dolphins, killer whales, common dolphins, striped dolphins, long-finned pilot whales, sperm whales, humpback whales, fin whales, northern bottlenose whales, Sowerby’s beaked whales and other pinniped species, the area off north-east Scotland is either on the edge of their range or the habitat is unsuitable for them consequently, they are likely to occur only occasionally and then only be a few individuals (Hammond *et al.*, 2004).

362 The proposed wind farm site does not contain any designated sites for marine mammals, but there are a number of SACs, on the east coast of Scotland for

which marine mammals are an interest feature. These sites are the Inner Moray Firth SAC for bottlenose dolphins (*Tursiops truncatus*); Dornoch Firth and Morrich More SAC and the Firth of Tay and Eden Estuary SAC for harbour seals; Faray and Holm of Faray SAC, the Isle of May SAC and Berwickshire and Northumberland Coast SAC for grey seals (*Halichoerus grypus*). For seals there is no evidence linking the SACs further north of Aberdeen Bay with any seals present in Aberdeen. Due to the requirements of the EU Birds and Habitats Directive, assessing potential impacts on SAC interest features is an important component of the EIA process and due consideration will be given to this assessment.

363 Harbour seals are widely distributed along the east coast of Scotland. They are present in the Aberdeen area throughout the year. Their occurrence at the estuaries of the Rivers Dee and Don is seasonal with an increase in numbers during the winter and early spring. Harbour seals use haul-out sites at the Donmouth, at the mouth of the Ythan River and at Catterline. Harbour seals have been observed feeding on salmonids and flatfish at the estuaries of the Rivers Dee and Don, as well as other marine prey species. The pupping period for harbour seals occurs from June to July and moulting occurs from June to September. During these times they spend a higher proportion of their time ashore and in coastal waters. The closest SAC for harbour seals to the wind farm site is in the Firth of Tay.

364 Grey seals are also found along the east coast of Scotland. They are present in the Aberdeen area throughout the year. Grey seals use haul-out sites at the Donmouth, at the mouth of the Ythan River, outside Peterhead harbour, Cruden Bay, Boddom and at Catterline. The most well established colony in the area is at Catterline where up to five pups may be born each year. The pupping period for grey seals occurs from October to November and moulting occurs from February to April. During these times they spend a higher proportion of their time ashore and in coastal waters. Grey seals have been observed feeding on salmonids and flatfish at the estuaries of the Rivers Dee and Don, as well as on other marine prey species. The closest SAC for grey seals to the wind farm site is the Isle of May in the Firth of Forth.

365 The otter (*Lutra lutra*) is a semi-aquatic mammal which occurs in a wide range of ecological conditions including inland freshwater and coastal areas. Otters are one of the primary reasons for the site selection of the River Dee SAC. The Dee is a major east coast Scottish river which flows uninterrupted for approximately 130 km from its upland reached in the high Cairngorms to the North Sea. Surveys have indicated that the otter is found throughout the Dee catchment, from its mouth at Aberdeen to the high-altitude lochs (JNCC, 2008a). Otters are generally limited to coastal waters so any impacts on it would be near the shore. Surveys of the cable landfall and on-shore cable route would be conducted to determine the presence and potential impacts on otters.

366 There is a substantial amount of baseline information that can be used in the EIA. The most applicable reference sources and organisations that hold data are discussed below.

367 A cetacean photo-id catalogue was sponsored by AOWFL based on photographs and surveys previously conducted in the area between May 1999 and June 2007 - the ACC (2008) Aberdeenshire Cetacean Catalogue (ACC). A total of 49 dedicated boat surveys where cetacean photo-

identification images were collected were carried out between Aberdeen and Inverbervie, however dedicated photo-identification data has not been collected evenly over the 1999–2007 period. A total of 1,823 images from 88 cetacean encounters were analysed from the 1 May 1999 to 9 June 2007 period. The identified animals predominantly comprised bottlenose dolphins with some Risso's dolphins, white-beaked dolphins and minke whale. A total of 63 bottlenose dolphins has been identified during this study (ACC, 2008). This reference will be useful in identifying specific animals that are observed in future monitoring effort that can be attributed with other sightings records to help develop our understanding of how animals move within specific areas of the North Sea.

368 An overview of the distribution of cetaceans in north-west European waters is provided by Reid *et al.* (2003) based on data collected by the Seabirds at Sea Team (SAST) of the JNCC, opportunistic sightings from the SeaWatch Foundation and a (Small Cetacean Abundance in the North Sea) SCANS survey conducted in July 1994. Additional information on recorded sightings of marine mammals is also available on UKDMAP (1998).

369 Hammond *et al.* (2004) reviewed and examined the distribution and abundance of marine mammals occurring to the north and east of Scotland as part of the Strategic Environmental Assessment 5 (SEA5).

370 SCANS surveys provide information on the distribution and abundance estimates of cetaceans. The first SCANS survey was conducted in the summer of 1994 and SCANS II in the summer of 2005 (Hammond *et al.*, 2002; SCANS II, 2006).

371 The Joint Nature Conservation Committee (JNCC) conducted aerial surveys of wintering aggregations of seaducks, divers and grebes within Aberdeen Bay between 2003 and 2007. During these surveys observations of bottlenose dolphins and harbour porpoises were recorded incidentally (Söhle *et al.*, 2006; Wilson *et al.*, 2006).

372 Cetacean surveys have been conducted from the bridge of the MV Hascosay ferry between Aberdeen, Orkney and Shetland during daylight hours in summer months (April to September) from 2002 to 2006 (MacLeod *et al.*, 2007).

373 The Scottish Agricultural College (SAC) Veterinary Services at Inverness carry out necropsies on stranded and by-caught cetaceans in Scotland for the DEFRA funded Marine Mammal Stranding Program.

374 Land- and vessel based surveys for marine mammals have been conducted between 1999 and 2005, along the Aberdeenshire coast (between St Cyrus and Collieston, primarily between Stonehaven and Aberdeen) as part of SeaWatch surveys and University of Aberdeen research projects (Canning, 2007; SeaWatch, 2008; Sini *et al.*, 2005; Stockin *et al.*, 2006; Weir & Stockin, 2001, 2002; Weir *et al.*, 2007).

375 Since 1990, research on marine mammals in the Moray Firth has been conducted from the University of Aberdeen's Lighthouse Field Station in Cromarty. There have been numerous reports and peer-reviewed publications produced by the marine mammal research group the Cromarty Lighthouse Field Station and many researchers are involved in current

research projects upon marine mammals, such as the Department of Energy and Climate Change seismic study in the Moray Firth.

376 The Sea Mammal Research Unit (SMRU) conducts surveys for harbour and grey seals to monitor seal populations around the UK. SMRU provides scientific information to the Special Committee on Seals (SCOS) (SCOS, 2008).

377 An initial marine mammal desk study has been conducted to review the available information on marine mammals off north-east Scotland with particular reference to the Aberdeen Bay area, providing information their occurrence, distribution, abundance, movements, diet and seasonal sensitivities, such as calving periods. In addition, the potential impacts associated with offshore wind farm construction and operation, the possible effects on marine mammals and mitigation measures have been reviewed. Summary results of the review that illustrate the predicted seasonal occurrence of marine mammals in Aberdeen Bay are shown in Table 5.8.

5.6.2.1 *Boat Based Surveys*

378 Boat based surveys have been conducted monthly between February 2007 and April 2008. The surveys covered an area that includes the entire wind farm site plus a buffer zone (south to the limit of the shipping lane, 3 km north, 3 km east and up to the 5 m contour line to the west) and a control site immediately to the north (Figure 8).

379 The surveys were conducted over two days (one day for wind farm site and one day for control site) every month. The boat-based survey programme employed standard marine mammal survey techniques used in similar studies. Visual observations of marine mammals were conducted by two marine mammal observers (MMOs) during the surveys. Data collected included species, number, location and activity of marine mammals in the survey area. In addition, marine mammal observations were also made ‘off-transect’ when the boat was steaming to and from the survey areas.

380 The following species were observed during the boat based surveys: harbour porpoise; bottlenose dolphin; minke whale; grey seal and harbour seal. The white-beaked dolphin has only been recorded off-transect. Table 5.7 summarises the observations of marine mammals during monthly boat surveys of wind farm & control survey areas between February 2007 and January 2008 (including observations off transect). In general, the species sightings corroborate well with the existing baseline information for the area.

381 The harbour porpoise was the most commonly sighted marine mammal species. There were at least twice as many harbour porpoise sightings in the control survey area (119 sightings) compared to the wind farm survey area (47 sightings) over the course of the 12 month survey period. Within the wind farm survey area, the peak sighting index for harbour porpoises was during October-November surveys (0.1149 sightings km-1). In the control survey area, the peak sighting index was during October-November and December-January survey groups (0.2365 and 0.2500 sightings km-1 respectively) (Travers *et al.*, 2008).

382 Bottlenose dolphin were the second most commonly sighted species, however the number of sightings was relatively low . An absence of

bottlenose dolphin sightings was noted during February-March, August-September, October-November and December-January month groups (Travers *et al.*, 2008). .

383 A single minke whale was sighted during the 12 months of surveys in July 2007 (Travers *et al.*, 2008).

384 Five sightings of unidentified cetaceans were recorded during the 12 month survey period: three sightings in the wind farm survey area and two in the control survey area (Travers *et al.*, 2008).

385 Seal sightings were recorded in all month groups during the 12 month survey period apart from the April-May and August-September groups. Overall there were more than twice as many seal sightings in the control survey area (25 sightings) compared to the wind farm survey area (10 sightings), with all seal sightings recorded being of individuals (Travers *et al.*, 2008).

386 Harbour porpoise, bottlenose dolphin, seal species and white-beaked dolphin were sighted off-transect during the 12 month survey programme. Bottlenose dolphins occurred at least once off-transect in more than half of the surveys (13 out of 24 surveys). The majority of off-transect bottlenose dolphin sightings have been recorded in the vicinity of the Aberdeen Harbour mouth. Harbour porpoise were observed to a lesser extent than the bottlenose dolphin; being detected in seven out of 24 surveys off-transect. Seals were observed off-transect in one out of 24 surveys. The white-beaked dolphin was recorded during the August 2007 survey trip (Travers *et al.*, 2008).

387 The results of the first year of marine mammal survey will be pooled together with future boat based survey information. To establish the numbers of marine mammal using specific survey areas density and abundance estimates will generated for species detected where sufficient sightings allow this. Based on current sightings rates, this approach is only likely to be possible for the harbour porpoise. The harbour porpoise data could be pooled over all months and the possibility of fitting a detection function explored within the software DISTANCE. If the model fit is adequate, this could be used to generate density and abundance estimates. These estimates would be biased low because the single platform visual method cannot account for sightings missed on the transect line. Distance estimates are preferable to basic encounter rates because they take into account the effects of distance (and other covariates if there are sufficient data) on the sightings process.

5.6.2.2 Towed Acoustic Monitoring (PAM)

388 In conjunction with the boat based surveying PAM data were collected between October 20007 and February 2008. PAM enables the detection of dolphins and porpoises that might not otherwise be observed by the MMOs, for example due to poor visibility. These surveys were designed to optimise the collection of acoustic information on the occurrence of harbour porpoises. From the initial 5 months of acoustic survey effort harbour porpoises were detected every hour for every survey, in both the control and wind farm site. The acoustic data suggests a regular presence of these marine mammals during the months surveyed. Although, no acoustic survey effort occurred in Spring and Summer, from evidence supplied by the visual surveys, it is likely that the harbour porpoises will still be present throughout spring and summer months.

389 Towed acoustic monitoring is taking place for EOWDC as part of the ongoing boat based surveys which started in August 2010.

Table 5.7 Observations of marine mammals during monthly boat surveys of wind farm & control survey areas between February 2007 and January 2008 (including observations off transect) Travers *et al.* (2008)

	Survey Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec

	Not observed

Table 5.8 Summary of the occurrence of marine mammals in the Aberdeen area (based on desk study and all Aberdeen offshore wind farm surveys)

Species	Occurrence	Seasonal Occurrence											
		Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Bottlenose dolphin	**Regular**												
Harbour porpoise	**Regular**												
White-beaked dolphin	**seasonal/regular**												
Minke whale	**seasonal/regular**												
Risso's dolphin	Occasional												
White-sided dolphin	rare/occasional												
Killer whale	rare/occasional												
Common dolphin	rare/occasional												
Striped dolphin	Rare												
Long-finned pilot whale	rare/occasional												
Sperm whale	Rare												
Humpback whale	Rare												
Fin whale	Rare												
Northern bottlenose whale	Rare												
Sowerby's beaked whale	Rare												
Harbour seal	**Regular**												
Grey seal	**Regular**												
Hooded seal	Rare												

Key

- Recorded during AOWF surveys (VP and boat surveys of wind farm and control survey areas, including on & off transect)
- Present in area (sighting and/or stranding based on desk study)
- Potential to be present in area (based on desk study)
- Not recorded

(Sources: Canning, 2007; Hammond *et al.*, 2001, 2002, 2004; Northridge *et al.*, 1995; Reid *et al.*, 2003; SAC, unpublished stranding data; Sabin *et al.*, 2006; Stockin *et al.*,. 2006; Stone, 2003; Travers, *et al.*, 2008; VP survey data; Weir & Stockin, 2001; Weir *et al.*, 2007; Wilson *et al.*, 2004).

5.6.2.3 Future Boat Based Surveys 2010 – 2011

390 Further boat surveys commenced in August 2010. These will be conducted monthly over two days. The surveys involve a new survey area and methodology from the previous boat surveys. The new survey methodology is based on a monitoring approach.

391 Three survey strata will be surveyed each month: i) extending northwards, covering both the wind farm, buffer and control areas surveyed in the previous surveys; ii) extending eastwards further offshore; and iii) a southwards stratum. The total survey area is 339 km^2, comprising three strata: 150.8 km^2 (north), 82.8 km^2 (south) and 105.2 km^2 (offshore).

392 The aim is to conduct one 2-day survey per month, initially for 12 months, with at least four months of these data being included in the EIA and Environmental Statement, in addition to the previous data collected for the site. The boat surveys will continue during the Environmental Statement process for 12 months, giving two years of data for the site. If there are any significant changes to the data presented in the Environmental Statement, these will be submitted as an addendum. The intention is to then to continue the surveys before, during and after construction, using the same transect design but perhaps focusing effort on key periods, for example during the pile installation period where any acoustic disturbance effects to marine mammals may occur.

5.6.2.4 Vantage Point Counts

393 Shore-based vantage point (VP) bird surveys have been conducted at the Donmouth, Blackdog, Balmedie and Drums between April 2006 and March 2008. VP surveys were undertaken at Blackdog and Donmouth (wind farm site) four times per month and fortnightly at Drums and Balmedie (control sites). Although the surveys were designed primarily for birds, the ornithologists also recorded marine mammal sightings up to 3 km from shore. During the two years of VP surveys, bottlenose dolphins were the most frequently observed marine mammal, seen in nine out of 12 months, with absences in June, September and October. Sightings for this species reached a peak in April with 15 sightings over the two survey years. Harbour porpoises were the next most frequently sighted species, seen in all seasons. The grey seal was also seen in all seasons. Only one sighting was made over the two years for the harbour seal and Risso's dolphin (Travers *et al.*, 2008). These data support the general pattern of key marine species frequenting Aberdeen Bay found during the boat-based surveys.

5.6.3 Potential Impacts

394 There are a number of potential impacts to marine mammals associated with the construction, operation and decommissioning of an offshore wind farm, these include (but are not limited to):

- underwater noise disturbance:
  - pile driving
  - other construction operations, eg drilling, rock dumping, dredging

- vessels during surveys, construction, installation and maintenance, including vessel noise, sonar systems and navigational depth sounders
    - seismic surveys
    - Trenching operations to bury sub-sea cables
    - vibration of wind turbines during operation
    - decommissioning operations
    - cumulative noise effects
- construction activities, in addition to noise:
    - increased turbidity
    - increased vessel activity
    - pollution incidents, eg fuel spill if accidental vessel-vessel or vessel-wind turbine collision
- physical presence and operation of wind turbines, in addition to noise
    - creation of artificial reefs
    - loss of seabed area
    - electromagnetic fields from cables
- decommissioning activities

395 The potential effects on marine mammals include:

- risk of physical injury, or temporary auditory hearing effects
- disturbance and displacement
- changes to foraging areas and prey availability
- barrier effects to movements
- increased collision risk with vessels

396 Information collected and evaluated from field and desk studies will be used to identify and predict impacts associated with the proposed development. The potential impacts and effects will be considered individually, and cumulatively, for all species (individuals and populations) using the proposed development site and surrounding areas.

397 The potential impacts from underwater noise, especially during any pile driving operations, have the greatest risk of having a significant effect on marine mammals. In order to assess any possible impacts, detailed modelling of underwater noise levels from different activities will be conducted. The results will help inform ranges from the development at which potential physical injury, such as permanent threshold shifts (PTS) in hearing, could occur and also distances at which the sound levels from construction will be audible to marine mammals. The assessment will cover cumulative noise dose and make recommendations of suitable stand-off distances, see also Section 5.7 Underwater Noise.

398 Consideration will be given to the requirement for a European Protected Species licence, following advice from SNH, to cover the potential risk to any injury or disturbance that may result from the construction of the wind farm.

5.6.4 Cumulative Assessment

399 There is relatively little information on the potential cumulative effects of underwater noise from construction of offshore wind farms and other coastal developments on marine mammals. The approach to the assessment of

cumulative impacts of the development will focus mainly on the noise aspects of the development, but will also cover potential loss of habitat to marine mammals. All other sources of noise that contribute either to the ambient noise level in Aberdeen Bay, or are short term events such as seismic surveys, will be reviewed and considered in relation to potential cumulative effects.

5.6.5 Mitigation

400 There are a number of potential mitigation measures that are available to minimise the risk of causing injury to marine mammals from construction noise, particularly pile driving. AOWFL will apply the results of the noise modelling studies, specifically the ranges at which marine mammals are likely to be at risk from any auditory hearing effects, and incorporate these findings into the mitigation measures.

401 For the piling activity itself, it is envisaged that monitoring both acoustical and visual will be conducted from a platform around the wind turbine and the JNCC piling protocol will be followed, specific aspects of this include:

- establishment of a pre-agreed 'monitored zone' (MZ)
- delay of commencement of piling should marine mammals be detected
- use of soft start procedure for piling operations
- use of Acoustic Mitigation Devices (AMDs) prior to piling start up will be assessed taking into account licensing requirements and current best practice advice issued by SNH

402 Other possible mitigation measures which will be assessed include:

- Timing of operations. The preliminary assessment has not identified any periods as being particularly sensitive, for example no evidence of breeding / calving areas in Aberdeen Bay.
- Use of lower-impact piling techniques, pile sleeves, pile head softening, vibropiling and/or other techniques available at the time of construction.

5.6.6 EOWDC Future Research and Monitoring

5.6.6.1 *C-PODs*

403 AOWFL have purchased 12 C-PODs. These are acoustic monitoring devices used to detect the vocalisations of marine mammals. Continuous acoustic recorders provide valuable information over a long time period. This cannot be achieved by other survey methods and would enable information to be collected during hours of darkness and poor visibility. C-PODs can be used for before, during and after construction monitoring.

404 It is planned to deploy these devices within the wind farm and surrounding area following a gradient approach design where acoustic recorders are also placed in the southerly and northerly extremities of Aberdeen Bay and in deeper waters offshore. SNH have been consulted and provided feedback on the provisional C-POD design layout put forward for the project and will be again consulted before the deployment phase. The impact range and planned distance of C-POD deployment (out to a distance of 35 km) has been

estimated with reference to the current literature (Bailey *et al.*, 2010; Carstensen *et al.*, 2006). The design layout makes an assumption that animals may be dispersed both along the coastline and offshore, and maximises the potential for detecting behavioural responses regardless of response direction (ie offshore or alongshore movements).

405 The use of acoustic devices enables detailed information to be collected about how marine mammals use Aberdeen Bay. This information is useful in terms of collecting further baseline information about general usage of the area, and will also allow an indication of relative abundance of acoustically active cetaceans. However, it is not possible to detect seals or to discriminate between dolphin species (for example bottlenose dolphin and common dolphin).

406 It would be reasonably foreseeable that during the piling phase of construction marine mammals would leave the immediate locality and only return once the piling has ceased. Using the information from C-PODS and other marine mammal studies, further information could be collected to ascertain the responses to underwater noise (for example animals temporarily leaving Aberdeen Bay) and help populate the evidence base for the duration and magnitude of impacts (for example, when marine mammals were shown to return).

407 The long-term effects of the presence of wind turbines on marine mammals are not well understood. It would be valuable to obtain data to determine if marine mammals change their behaviour or utilisation of the area or their feeding patterns or movements as a result of the presence of the wind turbines. A long-term dataset (pre-construction) would ideally be needed to provide a robust evidence base and C-POD deployment pre-construction would contribute to the existing baseline.

5.6.6.2 Ambient Noise Measurements and Validation of Construction Noise Levels

408 Further underwater noise studies are planned including measurements of ambient noise levels and construction noise. These would be useful to validate the predictions made within the impact assessment and also in the analysis of the observations of marine mammals detected visually and acoustically during post construction monitoring.

5.7 Underwater Noise

5.7.1 Introduction

409 The construction of an offshore wind farm is an activity which can generate noise. Impact piling in particular can generate high levels of predominantly low frequency underwater noise that can travel large distances. Other activities that generate underwater noise include vessel movement to and from the construction site.

410 Once operational, the wind farm is expected to generate low levels of underwater noise via the transfer of energy from the moving wind turbine blades into the seabed sediments and water column.

411 AOWFL proposes to conduct a number of noise studies that will be carried out during specific stages of the wind farm. Initial studies, commissioned to support the Environmental Statement, will aim to model and estimate the underwater noise levels generated from construction, specifically piling.

412 The noise predictions in the model will inform other parts of the EIA process notably:

- marine mammals
- fisheries
- commercial fisheries

5.7.2 Baseline Information Overview

413 In order to model sound, it is important to have information on the wind turbine design and piling details (if used) as well as oceanographic information including water depth and seabed conditions. Ambient underwater noise levels are also required. AOWFL are not aware of any underwater noise studies that have been carried out in the Aberdeen area and are proposing to collect ambient noise data within Aberdeen Bay from published reports.

414 Noise modelling will be undertaken to predict the propagation of sound from the piling location along a number of water depth transects. The sound levels that are predicted from the noise modelling can then be assessed against potential impact criteria for marine animals to inform the EIA.

415 The ranges at which hearing injury and temporary threshold shifts in hearing are expected will be estimated using recognised marine mammal impact criteria, such as Southall (2007) and other types of proposed impact thresholds, such as conservative temporary threshold hearing levels proposed by Lucke (2008).

416 Current practice to mitigate impacts to marine mammals from piling is to apply the JNCC piling guidelines which specify that a mitigation zone of 500 m, or higher is used. The mitigation zone is the area within which if a marine mammal is observed prior to starting operations then any commencement must be delayed for at least 30 minutes during which time there must be no observations of marine mammals within the zone. The use of trained MMOs and PAM will reduce the risk of a marine mammal not being detected. Modelling will be able to predict the range at which injury, defined as a Permanent Threshold Shift (PTS) in hearing is expected and this will be used as the basis for setting the mitigation zone. In the likely event that the modelling predicts PTS to be restricted to the immediate vicinity of the pile, a minimum of 500 m will be used as the mitigation zone.

417 The following data sources will be reviewed as part of the EIA process:

- ambient noise recording measurements for the North Sea, for example the DECC funded Moray Firth seismic survey ambient noise measurement programme

5.7.3 Potential Impacts

418 Impacts to marine mammals from noise are covered in Section 5.6 Marine Mammals. Impacts to fish are covered in Section 5.1 Marine Ecology.

5.7.4 Mitigation

419 The mitigation measures for underwater noise will follow the piling protocol as specified in the marine mammal chapter.

5.7.5 EOWDC Future Research and Monitoring

420 Additional noise studies are planned for the construction phase. It is expected that future noise studies will obtain noise measurements at piling locations at a range of distances and use these to provide a breakdown of the spectral levels of sound received to determine sound pressure level and sound exposure level during construction activities. The estimates of sound levels will be particularly useful in validating the noise modelling performed and the assessment of likely impacts on marine fauna made in the Environmental Statement.

421 The scope of work for the future noise studies has yet to be finalised but it is envisaged that underwater noise recording instrumentation will be deployed within the study area to characterise the frequency spectra and levels of sound received.

422 Any future noise studies will be designed to help complement and support the other research activities that are ongoing at the time, such as the acoustic monitoring studies and boat-based survey work.

5.8 Electromagnetic Fields

5.8.1 Introduction

423 The electromagnetic fields (EMF) generated by alternating current (ac), sub-sea power cables have been recognised as an environmental concern since the Round 1 sites were developed. The significance of any likely impact is difficult to quantify due to a lack of information on the type of fields generated by offshore wind farm cables and the effects these have upon marine fauna. Recent research attempted to establish the risk that EMFs pose to the marine environment (Gill, 2008). Although submarine power cables are fully electrically insulated, the fluctuating magnetic field induces a very small electric field in the environment which have the potential to affect fish behaviour. As power cables will be installed as part of the project development for EOWDC, the potential impacts of electromagnetic fields will be assessed in the EIA.

5.8.2 Baseline Information

424 Many fish and a number of other species found in UK waters are potentially capable of responding to anthropogenic sources of electric and magnetic fields. Certain fish species, including common ones such as plaice, are

understood to be both magnetically and electrically sensitive and a range of other species, notably cetaceans and many crustacea, to be magnetically sensitive. Most attention, however, has focused on elasmobranchs (sharks, skates and rays) which have specialist electro-receptive organs and are capable of detecting very small electric fields of around 0.5µV/m (Gill 2005).

425 Potential impacts could result from: *repulsion* effects leading to exclusion of animals from an area of seabed (eg for elasmobranchs in the presence of relatively high electric fields); *attraction* effects, for example, causing elasmobranchs to waste time and energy resources foraging around electric fields mistaken for bioelectric fields of prey organisms; and *disruption* to migrations for magnetically sensitive species such as eels and salmonids that may use the earth's geomagnetic field for navigational cues. The information available on magneto-sensitive species is limited, but it does suggest that potential interactions between EM emissions, of the order likely to be associated with wind farm cables, and a number of UK coastal organisms could occur from the cellular through to the behavioural level.

426 Elasmobranchs have been exposed to similar EMF signals to those generated by power cables (Gill, et al 2008). The results were inconclusive and there was no evidence to suggest any positive or negative effect on elasmobranchs exposed to typical EMF stimuli encountered at an offshore wind farm (Gill, et al 2009). However, it should be noted that the behavioural responses observed in the study are not predictable and appear to be species specific and perhaps individual specific (Gill *et al.*, 2009). It has been recognised that there are inherent difficulties in testing the significance of the EMF and further targeted research is required in order to better develop our understanding of the responses of animals to EMF stimuli.

5.8.3 Proposed Scope of Assessment

427 A literature review will provide a summary of the major sources of information for the EIA. The conclusion of most project-specific environmental impact assessments is that whilst there could be an interaction between marine species and EMF generated by sub-sea cables, it is unlikely to be of any significance at a population level. The assessment for EOWDC is likely to reach the same conclusions as previous offshore wind farms, and will support this by identifying the main species likely to be sensitive to EMF and predicting potential magnitudes of impact. The Cowrie research into EMF will be the primary data source used to support the EIA.

5.9 Statutory Designations and Conservation

428 Although the proposed site does not lie within a designated area, the north-east coast of Scotland does support many sites of national and international importance for wildlife. Table 5.9 presents the designated sites that may be affected by the proposed demonstrator project. These sites are identified on Figure 6.

TABLE 5.9 Designated sites potentially impacted by the proposed EOWDC		
Designation	**Approximate distance from proposed wind farm (km)**	**Citation Information**
Special Areas of Conservation (SACs)	*Convention of Natural Habitats and of Wild Fauna and Flora Directive (92/43/EEC), transposed in the UK through the Conservation (Natural Habitats) Regulations 1994.*	
River Dee SAC	7.5	Presence of Annex II species, Freshwater Pearl Mussel, Atlantic Salmon, Otter
Sands of Forvie SAC	7.2	Annex I habitats, Embryonic shifting dunes, shifting dunes along the shoreline with *Ammophila arenaria*, decalcified fixed dunes with *Empetrum nigrum*, humid dune slacks
Buchan Ness to Collieston SAC	12.2	Annex 1 habitats, vegetated sea cliffs
Moray Firth SAC	150	Annex II Species: Bottlenose dolphin, Annex I Habitats: Sandbanks which at all times are covered by seawater
Special Protection Areas (SPAs) and Ramsar Sites	*Council Directive 79/409/EEC on the Conservation of Wild Birds*	
Ythan Estuary, Sands of Forvie and Meikle Loch Special Protection Area (SPA)	7.2	Qualifying species, pink-footed goose, Sandwich tern, common tern, little tern and waterfowl assemblage including eider, redshank and lapwing
Ythan Estuary and Meikle Loch Ramsar	7.2	Wintering Pink footed geese, breeding sandwich terns Non-breeding waterfowl assemblages
Buchan Ness to Collieston SPA	9.5	Article 4.2: holding in excess of 20,000 seabirds: fulmar, shag, kittiwake, herring gull and guillemot.
Loch of Skene SPA	21	Qualifying species: whooper swan, greylag goose. Article 4.2 waterfowl assemblages: wintering goldeneye, goosander, common gull. Breeding tufted duck
Fowlsheugh SPA	31.1	Qualifying species: kittiwake, guillemot,. Article 4.2 seabird assemblages: fulmar, herring gull and razorbill
Loch of Strathbeg SPA	47.6	Qualifying species: Sandwich tern. Article 4.2 waterfowl assemblages: pink-footed goose, greylag goose, teal and goldeneye.
Troup, Pennan and Lion's Heads SPA	74.3	Article 4.2 seabird assemblages: fulmar, kittiwake, guillemot, herring gull and razorbill.
Forth Islands SPA	124.4	Qualifying species: gannet, shag, lesser black-backed gull, roseate tern, Arctic tern, common tern, Sandwich tern, puffin. Article 4.2 Seabird assemblages: cormorant, herring gull, kittiwake, razorbill and guillemot
National Nature Reserves (NNRs)	*National Parks and Access to the Countryside Act (1949)*	
Forvie NNR	7.2	Sand dune, foreshore, estuarine, spit, dune heath, slacks, rough pasture and cliffs habitat
Sites of Special Scientific Interest (SSSIs)	*Wildlife and Countryside Act (1981/1985)*	
Corby, Lily and Bishops Lochs SSSI	6.7	Wetland sites, aquatic vegetation, wildfowl roost
Foveran Links SSSI	4.8	Mobile foreshore and dunes, interesting

TABLE 5.9 Designated sites potentially impacted by the proposed EOWDC		
Designation	**Approximate distance from proposed wind farm (km)**	**Citation Information**
		vegetation assemblages, migrating birds, moulting and passage sea ducks and divers, and coastal geomorphology
Sands of Forvie and Ythan Estuary SSSI	7.2	Sandwich tern, common tern and little tern
Other Designations	*Ministerial Conference on the Environment (1973); Countryside Act 1968; National Parks and Access to the Countryside Act (1949)*	
Donmouth Local Nature Reserve	5.0	Birds that feed and roost, Grey seals
Balmedie Country Park	2.7	Recreation and leisure interests
Forvie Biogenetic Reserve	7.2	Heathland Interest.

429 There are no other national or local landscape designations such as national scenic areas within the vicinity of the proposal that have the potential to be affected by the proposed project. In pre-scoping consultation, SNH have highlighted, in conjunction with the JNCC, that they are currently in the process of identifying possible marine SPAs. AOWFL will ensure that any relevant changes are addressed within the Environmental Statement.

5.9.1 Conservation Designations

430 A number of protected sites and species in the vicinity of the proposed EOWDC site are designated both internationally and nationally (Table 5.9). The following section provides details of these designations and sites identified of relevance to the proposed project.

5.9.2 Requirement for an Appropriate Assessment

431 Under the Conservation (Natural Habitats, & c.) Regulations (as amended), the relevant Competent Authority (in this case the Scottish Government) must consider the effect of a development on the integrity of a European site. If the development is considered likely to have a significant effect on that site, the competent authority would undertake an Appropriate Assessment using information supplied as part of the EIA process to accurately determine risk to site integrity. Special Areas of Conservation (SACs) or Special Protection Areas (SPAs) constitute a European site.

432 Initial consultation with statutory bodies has indicated that the interaction between the proposed EOWDC and European sites in the wider area would need to be considered as part of the EIA process and that an Appropriate Assessment may be required.

5.9.2.1 International Sites

Ramsar Sites

433 These sites are internationally important wetland sites protecting wildfowl habitat. Ramsar sites are designated under the Convention of Wetlands of

International Importance. The Convention was adopted in Ramsar, Iran, in 1971 and ratified by the UK Government in 1976.

Natura 2000 Sites

434 The two most influential pieces of European legislation relating to nature conservation are the "Habitats" Directive and the "Birds" Directive. The 'Council Directive 92/43/EEC on the conservation of natural habitats and of wild fauna and flora', commonly known as the Habitats Directive, adopted in 1992, complements and amends the 1979 'Council Directive 79/409/EEC on the conservation of wild birds', commonly known as the Birds Directive. . A further Directive *On The Conservation of Wild Birds* (Directive 2009/147/EC) amends the 1979 Directive.

435 The Birds Directive protects all wild birds, their nests, eggs and habitats within the European Community. It gives EU member states the power and responsibility to classify Special Protection Areas (SPAs) to protect birds which are rare or vulnerable in Europe as well as all migratory birds which are regular visitors.

436 The Habitats Directive builds on the Birds Directive by protecting natural habitats and other species of wild plants and animals. Together with the Birds Directive, it underpins a European network of protected areas known as Natura 2000. This network includes SPAs classified under the Birds Directive and Special Areas of Conservation (SAC) under the Habitats Directive.

437 Annexes I and II of the Habitats Directive identify a set of habitats (Annex I) and species (Annex II), which require special conservation measures to be taken by Member States. These lists of habitats and species have been used to define the 'features' of a site which form the basis for designating the site as a SAC. Marine SACs may be put forward for habitats of conservation importance (listed in Annex I to the Habitats Directive) or for species of conservation importance (listed in Annex II) (Table 5.10).

TABLE 5.10
Marine habitats on Annex I and species on Annex II of the Habitats Directive found in UK waters

Annex I Habitats Considered for SAC Selection in UK Offshore Waters	**Species Listed in Annex II Know to Occur in UK Offshore Waters**
Sandbanks which are slightly covered by seawater all the time Reefs (bedrock, biogenic and stony) – Bedrock reefs – made from continuous outcroppings of bedrock which may be of various topographical shape (eg pinnacles, offshore banks) – Stony reefs – these consist of aggregations of boulders and cobbles which may have some finer sediments in interstitial spaces (eg cobble and boulder reefs, iceberg ploughmarks) – Biogenic reefs – formed by cold water corals (eg *Lophelia pertusa*) and the polychaete worm *Sabellaria spinulosa* Submarine structure made by leaking gases Submerged or partially submerged sea caves	Grey seal (*Halichoerus grypus*) Harbour or common seal (*Phoca vitulina*) Bottlenose dolphin (*Tursiops truncatus*) Harbour porpoise (*Phocoena phocoena*)

Source: JNCC (2002, 2010)

Special Protection Areas (SPAs)

Buchan Ness to Collieston SPA

438 Buchan Ness to Collieston Coast SPA is located on the coast of Aberdeenshire in north-east Scotland, approximately 9.5 km from the EOWDC site. It is a 15 km stretch of south-east facing cliff formed of granite, quartzite and other rocks running to the south of Peterhead, interrupted only by the sandy beach of Cruden Bay. The low, broken cliffs (generally less than 50 m high) show many erosion features such as stacks, arches, caves and blowholes. The varied coastal vegetation on the ledges and cliff tops includes maritime heath, grassland and brackish flushes.

439 The site is of importance as a nesting area for a number of seabird species (Gulls and Auks). These birds feed outside the SPA in the nearby waters as well as more distantly. It is the sea bird assemblage of international importance that qualifies Buchan Ness to Collieston as a SPA. The area qualifies under Article 4.2 of the Habitats Directive (79/409/EEC) by regularly supporting at least 20,000 seabirds.

440 During the breeding season, the area regularly supports 95,000 individual seabirds (Count, as at mid-1980s) including: Guillemot (*Uria aalge*), Kittiwake (*Rissa tridactyla*), Herring Gull (*Larus argentatus*), Shag (*Phalacrocorax aristotelis*), Fulmar (*Fulmarus glacialis*).

Ythan Estuary, Sands of Forvie and Meickle Loch SPA

441 The Ythan Estuary, Sands of Forvie and Meikle Loch make up an area of 1016.24 ha. The site comprises the long, narrow estuary of the River Ythan and eutrophic Meikle Loch. At its mouth, the river splits an extensive area of sand dunes with the Forveran Links on the west bank and the Sands of Forvie dune system on the east bank. Extensive mud-flats in the upper reaches of the estuary are replaced by coarser gravels with mussel (*Mytilus edulis*) beds closer to the sea (JNCC, 2010).

442 These varying habitats give rise to a varied substrate including clay, sands and gravel, extensive areas of bare mud, small areas of salt marsh with representative northern salt marsh flora. Small areas of club-rush swamp are associated with the salt marsh. In the upper parts of the estuary there is a reed bed and near the mouth of the estuary there are shifting sand dunes and areas of bare shingle. To the west of the estuary there is a large area of improved grassland.

443 The margins of the estuary are varied with areas of salt marsh, reed bed and poor fen, heath and scrub, coniferous woodland and grassland. Meikle Loch is an important roost site for geese which feed away from the SPA on surrounding farmland in winter. It is a eutrophic loch supporting limited aquatic vegetation. In summer, the coastal habitats of the dunes and estuary provide an important breeding site for three species of tern, whilst in winter the estuary holds large numbers of waders, ducks and geese.

444 The site qualifies under a number of articles of the European Directive. Firstly, the site qualifies under Article 4.1 of the Habitats Directive (79/409/EEC) by supporting populations of European importance of the following species listed on Annex I of the Directive. During the breeding

season it supports common tern (*Sterna hirundo),* 265 pairs representing up to 2.2 % of the breeding population in Great Britain, little tern (*Sterna albifrons*), 41 pairs representing up to 1.7 % of the breeding population in Great Britain and Sandwich tern (*Sterna sandvicensis*), 600 pairs representing up to 4.3 % of the breeding population in Great Britain (Seabird Census Register).

445 This site also qualifies under Article 4.2 of the Directive (79/409/EEC) by supporting populations of European importance of migratory species. Over-winter pink-footed goose (*Anser brachyrhynchus*), 17,213 individuals representing up to 7.7 % of the wintering Eastern Greenland/Iceland/UK population (winter peak means).

446 The site also qualifies under Article 4.2 of the Directive by regularly supporting at least 20,000 waterfowl. Over winter, the area regularly supports 51,265 individual waterfowl including: redshank *Tringa totanus*, lapwing *Vanellus vanellus*, eider *Somateria mollissima*, and pink-footed goose *Anser brachyrhynchus*.

447 The Ythan Estuary and Meikle Loch sites are also designated as a Ramsar wetland site. The justification for this designation are the assemblages of internationally important waterfowl and the species/populations occurring at levels of international importance.

Loch of Strathbeg SPA

448 The Loch of Strathbeg is located in north-eastern lowland coats of Scotland, in Aberdeenshire, inland from Rattray Head and covers an area of 615.93 ha.

449 The SPA provides wintering habitat for a number of important wetland bird species, particularly wildfowl (swans, geese and ducks), and is also an important staging area for migratory wildfowl from Scandinavia and Iceland/Greenland. In summer, coastal parts of the site are an important breeding area for Sandwich tern (*Sterna sandvicensis*), which feed outside the SPA in adjacent marine areas.

450 The site qualifies under Article 4.1 of the Habitats Directive (79/409/EEC) by supporting populations of European importance of species listed on Annex I of the Directive. During the breeding season it supports Sandwich tern (*Sterna sandvicensis*), 530 pairs representing up to 3.8 % of the breeding population in Great Britain. Over winter it supports barnacle goose (*Branta leucopsis*), 226 individuals representing up to 1.9 % of the wintering population in Great Britain and whooper swan (*Cygnus cygnus*), 183 individuals representing up to 3.3 % of the wintering population in Great Britain.

451 This site also qualifies under Article 4.2 of the Directive (79/409/EEC) by supporting populations of European importance of migratory species. Over winter it supports greylag goose (*Anser anser*), 3,325 individuals representing up to 3.3 % of the wintering Iceland/UK/Ireland population, pink-footed goose, (*Anser brachyrhynchus*), 39,924 individuals representing up to 17.7 % of the wintering Eastern Greenland/Iceland/UK population.

452 In addition area qualifies under Article 4.2 of the Directive (79/409/EEC) by regularly supporting at least 20,000 waterfowl and being a wetland of international importance. Over winter, the area regularly supports 49,452

individual waterfowl including: teal (*Anas crecca*), greylag goose, (*Anser anser*), pink-footed goose, (*Anser brachyrhynchus*), barnacle goose, (*Branta leucopsis*), and whooper swan, (*Cygnus Cygnus*).

453 The majority of the site is managed by the Royal Society for the Protection of Birds (RSPB) for conservation and primarily for the SPA interest. Scottish Natural Heritage (SNH) has piloted a Strathbeg Goose Management Scheme to alleviate the conflict between the geese which roost on the loch and the surrounding farms where they feed.

454 The Loch of Strathbeg site is also a designated Ramsar site as the loch constitutes the largest dune slack pool in the UK and the largest water body in the north-east Scottish lowlands, one of the very few naturally eutrophic lochs of the size in the region. The site also qualifies under criterion 5 and 6 with assemblages of international importance, especially peaks in winter, and species/populations occurring at levels of international importance.

Loch of Skene SPA

455 Loch of Skene lies approximately 21 km from the proposed wind farm location.

456 The qualifying species is greylag goose which roost on the loch during the winter. The population of wintering greylag geese on the Loch has declined in recent years as increasing numbers of greylag geese now winter in Orkney.

457 In addition to greylag geese the loch also holds nationally important numbers of goldeneye (*Bucephala clangula*) and goosander (*Mergus merganser*) during the winter and a large roost of common gulls occurs during the winter. During the summer the loch holds 50 to 100 pairs of tufted duck.

Fowlsheugh SPA

458 Fowlsheugh is a 10.15 ha stretch of cliffs to approximately 31.1 km south of the proposed wind farm location. It is an important site for breeding seabirds with up to 145,000 birds present including guillemot, razorbill, kittiwake, fulmar and herring gull. The site is also part of an RSPB reserve.

Troup, Pennan and Lion’s Heads SPA

459 The sea cliffs along Troup, Pennan and Lion’s Head SPA hold internationally and nationally important numbers of seabirds, notably kittiwake, guillemot, fulmar, herring gull and razorbill. There is a seaward extension out to 2 km from the cliffs which are approximately 74.3 km from the project location.

Forth Islands SPA

460 The Forth Islands SPA comprises a series of islands situated in the Firth Forth and include the Bass Rock and the Isle of May. It is a site holding internationally and nationally important seabirds including gannet, fulmar, shag, cormorant, common tern, Sandwich tern, Arctic tern and roseate tern. Three species of auk: puffin, razorbill and guillemot, and three species of gull: herring, lesser black-backed and kittiwake are found there.

Special Ares of Conervation (SACs)

Buchan Ness to Collieston Coast SAC

461 Buchan Ness to Collieston Coast, an area of 207.52 ha, is a designated special area of conservation (SAC). The site includes shingle sea cliffs and islets, bogs marshes, water fringed vegetation and fens as well as heath, scrub, maquis, garrigue, phygrana, humid grassland, and mesophile grassland. Such habitat qualifies the site as an Annex I Habitat, 1230 Vegetated Sea Cliff of the Atlantic and Baltic Coasts.

462 The vegetated cliff slopes support a wide range of coastal vegetation types with an abundance of such local species as Scots lovage (*Ligusticum scoticum*) and roseroot (*Sedum rosea*). In several places the cliff edge retains semi-natural plant communities such as maritime heath, acid peatland and brackish flushes. All these are now rare on the coast of north-east Scotland and this section of coastline contains some of the best remaining examples. Possibly due to the local microclimate and the presence of lime-rich soils, these communities contain several plants which are associated with dry, calcareous grassland, including carline thistle (*Carlina vulgaris*) and cowslip (*Primula veris*). Sea wormwood (*Seriphidium maritimum*) also occurs. The cliffs and offshore stacks support a scattered but considerable colony of cliff-nesting seabirds with bird-influenced vegetation.

Sands of Forvie SAC

463 The Sands of Forvie SAC includes an area of coastal sand dunes, beaches, machair, inland water bodies, sea cliffs, bogs, marshes, water fringed vegetation, fens, heath, scrub, marquis and garrigue, phygrana, humid grassland and mesophile grassland covering an area of approximately 734.05 ha. There are three primary reasons for selecting Sands of Forvie as an SAC. These include the embryonic shifting dunes, shifting dunes along the shoreline with *Ammophila arenaria* (white dunes), decalcified fixed dunes with *Empetrum nigrum* and humid dune slacks.

464 Sands of Forvie is one of only three sites on the east coat of Scotland which represent the northern part of the UK range of embryonic shifting dunes. Sands of Forvie is one of the most geomorphically active dune systems in the UK and as a result the site contains significant representation of dune types associated with shifting sands. Present throughout the site are identifiable zones of lyme-grass (*Leymus arenarius*) and sand couch (*Elytrigia juncea*).

465 In recent years, Terns have bred in much lower numbers owing to predation and the periodic overtopping of the favoured shingle beds by sand. There is growing concern about the effects of eutrophication on the estuary and its flora and fauna. The continuing build up of algal mats has apparently led to a reduction in the populations of invertebrates which are the prey of waterfowl such as redshank and shelduck.

466 The site forms the Forvie National Nature Reserve which is managed for its nature conservation interest under an agreed management plan. The site is also 100 % covered by SSSI designation.

Moray Firth Marine SAC

467 The Moray Firth was designated by Scottish Ministers as a Special Area of Conservation (SAC) on 17 March 2005. The Moray Firth marine SAC has been designated for the species bottlenose dolphin (*Tursiops truncatu*) which is listed on Annex II of the Habitats Directive, as well as for the Annex I habitat 'Sandbanks which are slightly covered by sea water all the time'.

468 The conservation objectives for the Moray Firth marine SAC with regards to bottlenose dolphins are:

- to avoid deterioration of the habitats of the qualifying species (bottlenose dolphin *Tursiops truncatus*) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained and the site makes an appropriate contribution to achieving favourable conservation status for the qualifying interest
- to ensure for the qualifying species that the following are established then maintained in the long-term:
    - population of the species as a viable component of the site
    - distribution of the species within the site
    - distribution and extent of habitats supporting the species
    - structure, function and supporting processes of habitats supporting the species
- no significant disturbance of the species.

469 The conservation objectives ensure that the obligations of the Habitats Directive are met; that is, there should not be deterioration or significant disturbance of the qualifying interest. This will also ensure that the integrity of the site is maintained and that it makes a full contribution to achieving favourable conservation status for its qualifying interests (SNH, 2006).

River Dee SAC

470 The River Dee SAC lies inland from the proposed project and enters the sea at Aberdeen. The river contains three qualifying species otter (*Lutra lutra*), freshwater pearl mussel (*Margaritifera margaritifera*) and Atlantic salmon (*Salmo salar*). The salmon enter the river throughout the year and the freshwater pearly mussel relies upon the salmon for part of its life cycle when it uses the salmon as a host species. Otters are infrequent on the coast and the majority of the otter population found along the Dee is upstream from the river mouth.

5.9.2.2 <u>*National Sites*</u>

Sites of Special Scientific Interest (SSSI)

Corby, Lilly and Bishops Lochs SSSI

471 Corby, Lilly and Bishops Lochs are designated as Sights of Special Scientific Interest under the Wildlife & Countryside Act (1981). The Lochs lie approximately 6.7 km inland from the proposed wind farm location. The lochs contain locally important vegetation and invertebrate populations. The Lochs also use to hold roosting greylag geese but the numbers roosting on the Lochs has reduced in recent years.

Foveran Links SSSI

472 Extensive sand dune systems lie to the north of the proposed development. Up to the Ythan Estuary. The 205 ha Foveran Links SSSI contains plant communities not found elsewhere along the coast and a variety of habitats including, fixed dunes, dune pastures, marshes and heaths.

Sands of Forvie and Ythan Estuary SSSI

473 The Sands of Forvie lie approximately 7.2 km to the north of the proposed wind farm location. The site is also covered by the SAC.

474 It is an extensive area of sand dunes containing a wide range of typical dune habitats and very diverse range of flora. The site holds the UKs largest breeding colony of eider ducks and nationally and internationally important populations of pink-footed geese and other wildfowl and waders.

5.9.2.3 *Local Sites*

Biodiversity

475 Following the 1992 Rio Earth Summit, the UK Biodiversity Action Plan was published in 1994. At the local level, this is implemented through the North East Scotland Local Biodiversity Action Plan (LBAP). LBAP is a partnership of local authorities, environmental, forestry, farming, land and education agencies, businesses and many individuals involved in biodiversity across North East Scotland (Aberdeen, Aberdeenshire and Moray)

476 Most of the North East action for biodiversity is addressed through Habitat Action Plans (HAPs) which incorporate action for associated priority species. These HAPs are grouped under the broader habitat headings of Coastal & Marine; Farmland & Grassland; Woodland; Montane, Heath & Bog; Wetland & Freshwater; and Urban (NESBiodiversity, 2007).

477 The Coastal and Marine Habitat Action Plans (HAPs) are the most relevant for the proposed development. The protection of these coastal and marine habitats is a top priority for North East LBAP and several specific action plans have been developed, including:

- Coastal Sand Dunes and Shingle
- Coastal Cliffs and Heaths [action plan development in progress]
- Marine Habitats [action plan development in progress]
- Estuarine and Intertidal Habitats

478 A number of species has been identified with dedicated North East Action Plans (NESBiodiversity, 2007).

5.9.3 Marine (Scotland) Act 2010

479 The Marine (Scotland) Act (which applies to Scottish territorial waters) introduces new powers relating to functions and activities in the Scottish marine area, including provisions concerning marine plans, licensing of marine activities, the protection of the area and its wildlife including seals, and regulation of sea fisheries. The Act comprises six key elements: the formation of Marine Scotland, a strategic marine planning system, a

streamlined marine licensing system, improved marine nature conservation measures, improved measures for the protection of seals and improved enforcement measures (JNCC, 2010).

480 Marine Scotland will deliver integrated marine management functions relating to marine science and data, planning, policy development and delivery, compliance, monitoring and enforcement, whether fully or executively devolved to Scottish Ministers out to 200 nautical miles; and will work closely with the UK Marine Management Organisation (MMO) established under the UK Marine and Coastal Access Act 2009 (JNCC, 2010).

481 Scottish Marine Protection Areas (MPAs) are a new national designation under the **Marine (Scotland) Act** for inshore waters and the **Marine and Coastal Access Act 2009** for offshore waters. Scottish Ministers have executive devolution of authority for the designation of MPAs for the conservation of important marine biodiversity and geodiversity out to 200 nm.

482 Within the Marine Nature Conservation element, powers in the **Marine (Scotland) Act** enable Scottish Ministers to designate three types of Marine Protected Area (MPA) across Scottish territorial waters: Nature Conservation MPAs; Historic MPAs; and Research/Demonstration MPAs (JNCC, 2010).

483 The Scottish MPA project has been established by Marine Scotland (Scottish Government), Scottish Natural Heritage and the Joint Nature Conservation Committee (JNCC) to identify and recommend MPAs for the conservation of nationally important features of marine biodiversity and geodiversity to Government. Scottish MPAs will be identified using science-based selection criteria, but socio-economic information may be taken into account when selecting between sites of equal scientific merit and to identify likely management issues (Natural England, 2010).

484 The new MPA powers allow Scotland to contribute to the UK's European and International marine conservation commitments, such as those laid out under the Marine Strategy Framework Directive, the OSPAR Convention and the Convention on Biological Diversity (JNCC, 2010) and the government is required by European law to introduce a network of MPAs by the end of 2012 (Natural England, 2010).

6 HUMAN ENVIRONMENT

6.1 Shipping and Navigation

6.1.1 Introduction

485 Aberdeen Harbour is important to the people and the local economy of Aberdeenshire and is one of the main commercial ports in the North of Scotland. Coastal traffic also exists along the Aberdeenshire and East of Scotland coastline. Any wind farm development has the potential to impact navigational practices and as a result careful consideration of the site and wind turbine layout is required to ensure the safety of the marine stakeholders in preserved.

6.1.2 Baseline Information

486 The proposed wind farm is 4 nm to the north of the entrance to Aberdeen Harbour in Aberdeen Bay Area to the north of a newly designated anchorage. Detailed information on annual shipping has been based on the Annual Review for Aberdeen Harbour (2009). Key points are as follows:

- import and exports: 4.54 million tonnes
- vessel arrivals: 7,933
- tonnage of shipping: 24.01 million gross tonnes
- number of passengers: 142,468

487 Three, two-week AIS and radar surveys were carried out to develop an understanding of shipping and navigational practices in proximity to the proposed development site.

488 The surveys were carried out from a site adjacent to Girdle Ness Lighthouse, south of Aberdeen harbour, at co-ordinates 57° 08'.364 North, 002° 02'.916 West, providing good coverage to the North, including Aberdeen Bay and the harbour entrance.

489 4The results from the study indicate that the majority of the shipping passing in closest proximity to the site is destined for Aberdeen Harbour. The majority of vessels are associated with offshore oil and gas industry and the Northlink passenger ferries: Hrossey, Hamnavoe and Hjaltland. Some cargo vessels were also identified using this route. The results from the study also indicated limited fishing and recreational shipping in and around the proposed wind farm site.

490 Figure 13 provides an overview of the proposed wind turbine layout relative to shipping.

6.1.3 Proposed Scope of Assessment

491 The scope of assessment has been based on the following:

- Department for Energy and Climate Change (DECC) Methodology for Assessing the Marine Navigational Safety Risks of Offshore Windfarms (2005)
- Maritime and Coastguard Agency (MCA) Marine Guidance Notice 371 (MGN 371) Offshore Renewable Energy Installations (OREIs) – Guidance on UK Navigational Practice, Safety and Emergency Response Issues

492 Other key guidance and reference materials that will be used in the assessment are listed below:

- Trinity House Lighthouse Service (2008). Guidance based on IALA Recommendation O-139 On The Marking of Man-Made Offshore Structures, 1st Edition
- DECC Guidance Notes on Applying for Safety Zones around Offshore Renewable Energy Installations
- IMO Guidelines for Formal Safety Assessment (FSA)
- Results of the EM Investigations and assessments of marine radar, communications and positioning systems undertaken at the North Hoyle Wind farm by QinetiQ and the MCA
- BWEA, DTI, MCA & PLA (2007). Investigation of Technical and Operational Effects on Marine Radar Close to Kentish Flats Offshore Wind farm
- MCA Marine Guidance Notice 372 (2008). Guidance to Mariners Operating in the Vicinity of UK OREIs

493 The DECC methodology provides a template for preparing a navigation risk assessment. The methodology is centred on risk controls and the feedback from risk controls into risk assessment. It requires a submission that shows that sufficient risk controls are, or will be, in place for the assessed risk to be judged as broadly acceptable or tolerable with further controls or actions. The DECC assessment methodology includes:

- defining a scope and depth of the submission proportionate to the scale of the development and the magnitude of the risk
- estimating the 'base case' level of risk
- estimating the 'future case' level of risk
- creating a hazard log
- defining risk control and creating a risk control log
- predicting 'base case with wind farm' level of risk
- predicting 'future case with wind farm' level of risk

494 The key features of the Marine Safety Navigational Risk Assessment Methodology are risk assessment (supported by appropriate techniques and tools), creating a hazard log, defining the risk controls (in a Risk Control Log) required to achieve a level of risk that is broadly acceptable (or tolerable with controls or actions), and preparing a submission that includes a Claim, based on a reasoned argument, for a positive consent decision.

495 One of the primary tasks of the scope of assessment was key stakeholder consultation. This has been carried out throughout the entire project and is integral to the navigational review. The following organisations have been involved in this process:

- Aberdeen Harbour Board
- Marine Safety Forum
- Aberdeen users
- Northern Lighthouse Board
- Chamber of Shipping
- Fisheries Associations
- RYA and Cruising Association

496 In addition to the three, two week radar surveys which have been carried out, Anatec has access to a year of current AIS survey data for the area which will be used in the assessment.

6.1.4 Potential Impacts

6.1.4.1 *Merchant Shipping*

497 The proposed 11 wind turbine wind farm layout has been determined through ongoing consultation with the Aberdeen Harbour Board and other marine stakeholders associated with this area. It has been designed to minimise the impacts on shipping and to ensure safe vessel operations.

498 The layout is positioned over 4 nm to the north of the north breakwater and inshore of the main route taken by vessels heading between the port and the north, and is well clear from other routes taken by vessels to and from Aberdeen Harbour.

499 Consultation with the Harbour Board, Marine Safety Forum and Ferry Operator has indicated that wind turbines located at the proposed site will not impact their operations significantly. As a result the proposed development is unlikely to have significant navigational impacts providing reasonable mitigation measures are put in place. A hazard workshop is to be carried out with the stakeholders to ensure their views are considered and the mitigations put in place are adequate.

6.1.4.2 *Fishing Vessels*

500 Fishing vessels are also exposed to collision risks (and radar interference) in the same way as merchant ships. In addition, if fishing within the site, there would be a risk of collision and subsea cable interaction. Also if fishing activity is displaced to outside the site during construction and/or operation, this could influence the rate of vessel-to-vessel encounters and hence the collision risk.

501 A review of the survey data and information gathered over the course of this project indicated that fishing vessel activities in this area is very limited and therefore the potential impacts are considered to be very low. Further discussions will be held with the fishing stakeholders to ensure their views are considered and that the mitigation measures put in place are adequate. Figure 14 provides an overview of the proposed wind turbine layout relative to fishing vessels.

6.1.4.3 Recreational Vessels

502 Recreational vessels can pass close to and in some cases between wind turbines, which exposes them to potentially increased collision risk as well as changes in traffic movements in the vicinity. There is also a risk of blade/mast interaction which depends upon the clearance of the rotor blades in different tidal and sea conditions, and the air draught of yachts using the area. The risk can be minimised through adequate clearance height and implementation of an emergency shutdown system of the rotor blades.

503 A review of the survey data and information gathered over the course of this project has shown that recreational vessel activities in this area are very limited and therefore the potential impacts are considered to be negligible. Further discussions will be held with the recreational stakeholders to ensure their views are considered and the mitigation measures put in place are adequate.

6.1.5 Cumulative Assessment

504 The potential impact of the wind farm on vessels associated with all stakeholders eg the oil and gas industry and those associated with dredging activities will be assessed as part of the Navigational Risk Assessment.

505 No other wind farms are proposed for this area so there are no cumulative impacts to be assessed.

6.1.6 Mitigation

506 There are a range of measures that can be applied to mitigate the impacts of a wind farm development (including through site design). MGN 371 lists the following measures to be applied to a particular development as appropriate to the level and type of risk determined during the EIA:

- promulgation of information and warnings through notices to mariners and other appropriate media
- continuous watch by multi-channel VHF, including Digital Selective Calling (DSC)
- safety zones of appropriate configuration, extent and application to specified vessels
- designation of the site as an area to be avoided (ATBA)
- implementation of routeing measures within or near to the development
- monitoring by radar, AIS and / closed circuit television (CCTV) or other agreed means
- appropriate means to notify and provide evidence of the infringement of safety zones or ATBAs
- any other measures and procedures considered appropriate in consultation with stakeholders (including the MCA)
- creation of an Emergency Response Co-operation plan with the relevant Maritime Rescue Co-ordination Centre from construction phase onwards

507 Other mandatory control measures and/or standard industry practice include:

- marking and lighting the site in accordance with General Lighthouse Authority requirements (which will include a system of routine inspection and maintenance of lights and marks)
- MCA standards and procedures for wind turbine generator shut-down in the event of a search and rescue, counter pollution or salvage incident in or around a wind farm
- wind turbine rotor blade tip clearance at a minimum 22 m above Mean High Water Springs
- vessel nominated as guard vessel during construction /decommissioning activities

6.1.7 EOWDC Future Research and Monitoring

508 Navigational Risk Assessment work and projections are based on a sound understanding of shipping patterns and experience of the likely changes to shipping, ie they represent the best estimate. During construction, operation there is excellent opportunity to assess the impacts of the development in more detail and to review the mitigation measures to ensure they are appropriate and adequate. There is a requirement for this review work to be carried out over the lifetime of the development. This will be carried out by the project and is likely to rely on continued AIS monitoring of the development and continued liaison with the port and other marine stakeholders.

6.2 Aviation

6.2.1 Introduction

509 The handling of aviation issues raised by this project has been an area of high priority for the project team. Aberdeen airport serves more than 3 million travellers a year and is the world's busiest commercial heliport, transporting more than 500,000 passengers in support of the North Sea oil and gas industry.

510 An Aviation Working Group was established as early as 2005, and has met since that time (although there have been periods of lesser activity). The group has met four times in 2010 already.

511 The Civil Aviation Authority (CAA) was an early attendee at these meetings, but in recent years they have been content to allow aviation issues – largely operational in nature – to be discussed by National Air Traffic Services (NATS) (Aberdeen) and BAA (Aberdeen).

512 These meetings have also been attended by the three helicopter companies operating out of Aberdeen airport – Bond, Bristows and CHC Scotia. Also in attendance has been Oil and Gas UK, the main client for their helicopter operations.

6.2.2 Baseline Information

513 No new data has been required in relation to flight movements. Existing data are available to assess the impacts of the wind farm on aviation activities.

514 The presence of helicopter traffic is the most significant aviation issue, the previously proposed wind farm location site assumed that helicopters could fly over the wind turbines. However, following early consultation with the relevant authorities it was identified that in certain weather conditions the helicopters may descend to 1000 feet (or lower), while the tip height of the wind turbines could be in the region of 520 feet. This would breach the minimum clearance limit required for helicopter safety and consequently the wind farm layout has been amended to account for the helicopter corridors. This was a major revision to the wind farm layout, and has dominated all subsequent layout considerations.

6.2.3 Proposed Scope of Assessment

515 The assessment will address all aspects of the potential impact of the wind farm on aviation activities at Aberdeen airport. This may include the following issues:

- as part of the agreement on the final layout of the wind farm, it has been agreed that the northern helicopter route into Aberdeen could be moved to the north, thereby allowing greater clearance between the wind farm and Aberdeen Harbour entrance. The route change is shown in Figure 15. The change will be brought about by applying for an Air Space Change
- the proposed layout is within 10 km of the secondary radar facility at Aberdeen airport and as such it has been necessary to assess the potential impacts of the wind farm on this function. AOWFL has commissioned a study from QinetiQ and the report has been passed to NATS. The report shows that although there may be potentially significant effects there are a number of technical solutions available to solve them. Ongoing consultation with NATS will determine the most efficient and effective technical solution to this issue
- the presence of the wind farm will require some minor changes to helicopter procedures in the event of encountering problems during take-off and landing phases at Aberdeen which may be exacerbated in icy conditions.
- in favourable weather, Aberdeen airport enjoys a relaxation on the carrying of alternate aerodrome helicopter fuel as a result of this “coastal status”. It will be necessary for the project to confirm with the CAA that the wind farm would not prejudice such status. Informal indications are that based on the revised plans the coastal status should be maintained

6.2.4 Potential Impacts

516 The potential impacts of the project on the aviation sector around Aberdeen should be minimal. The effects of the issues listed above are expected to be:

- one minor change to air route maps (and related documents), with associated amendments to procedures, and training requirements
- the construction of a technical solution to the secondary radar issue – possibly a supplementary secondary radar, although a multilateration system using an array of approximately 4 static antenna may prove as effective and less expensive. This system would also need to be “patched in” to the new Perwinnes radar equipment serving Aberdeen airport

- some amendments to the emergency procedures of helicopter companies
- it is likely there will be no change to Aberdeen's "coastal status"

6.2.5 Cumulative Impact

517 Discussions are ongoing with NATS as to whether any of the above issues have any relevance to other wind farms under development in the Aberdeenshire area.

6.2.6 Mitigation

518 In view of the small nature of these impacts, it is believed that the measures described above will be sufficient to mitigate their effects on aviation safety and security.

519 The implementation of these measures will be the subject of ongoing monitoring by the Aviation Working Group, thereby ensuring that the objectives of minimal impact are sustained.

6.2.7 EOWDC Future Research and Monitoring

520 Consultation with CAA, NATS, BAA and the helicopter operators will be ongoing on the research issues that could be addressed by the deployment centre.

6.3 Ministry of Defence

6.3.1 Introduction

521 Consultation with the MoD has been ongoing since 2005. Two principal issues have been dealt with:

- any effect of the wind farm on the operability of the defence radar installation at Peterhead
- any effect of the wind farm on the Black Dog firing range – a small-arms firing range on the coast nearby, but with an associated exclusion zone at sea during firing

522 Liaison with MoD has been constructive, with several meetings being held at Defence Estates, and one at an RAF base in the north of England to discuss the radar interference issue.

6.3.2 Baseline Information

523 In matters of national security, the MoD is the sole holder of the relevant detail to make the assessment of the acceptability of our project on their activities.

6.3.3 Proposed Scope of Assessment

524 An assessment on the potential for interference to radar has been undertaken by the MoD including a number of radar interference trials. During consultation with the MoD, initial objections on the grounds of radar interference have subsequently changed.

525 On the Black Dog Firing range, the MoD has consistently stated that no wind turbines should be placed within the safety exclusion zone at sea.

6.3.4 Potential Impacts

526 The potential impacts of the project on MoD interests should therefore be minimal. The effects of the issues listed above are expected to be:

- confirmation from MoD that a layout of 10 wind turbines close to the current layout is acceptable in terms of radar interference has been received. AOWFL has applied to MoD for confirmation that the current layout of 11 wind turbines is acceptable
- while there will be no wind turbines within the firing range exclusion zone, there will be a need for project vessels to enter the area for the purposes of surveying, construction, operations and maintenance. It will therefore be necessary to agree access provisions with the MoD

6.3.5 Cumulative Impact

527 Cumulative impact between our project and other projects in respects of MoD issues are not anticipated.

6.3.6 Mitigation

528 It is expected that the effect of the project on the military activities described above will be minimal.

529 Operational procedures will be agreed with MoD to allow vessel access to the firing range exclusion zone for project activities during the lifetime of the project.

530 The implementation of these measures will be the subject of ongoing monitoring and communication with MoD Defence Estates in Birmingham, thereby ensuring that the objectives of minimal impact are sustained.

6.3.7 EOWDC Future Research and Monitoring

531 Consultation with the MoD on the research issues that could be addressed by deployment centre will be ongoing.

6.4 Archaeology

6.4.1 Introduction

532 An archaeological desk-based assessment of the proposed EOWDC has been carried out.

533 The aim of the archaeological assessment was to inform the overall environmental assessment of the impacts of the scheme and its associated onshore and offshore infrastructure on the historic environment and archaeology of the area.

6.4.2 Baseline Information

534 The desk-based assessment has focused upon two areas of potential archaeological interest. Firstly, the potential for the survival of submerged prehistoric archaeology, which could manifest itself in the form of either sites or landscapes dating from the Palaeolithic to the Mesolithic periods and is closely related to sea level changes. Secondly, the assessment has focussed on the potential for the presence of maritime archaeology, ie the potential for the presence of ship and boat remains and debris linked to human use of the sea from the Mesolithic to the 20th century.

535 The report concluded that potential for the presence of formerly terrestrial prehistoric archaeology exists within the survey area, but that there is currently insufficient detailed information available concerning the shallow geology and sediments to enable the presence of such archaeology to be proved. Therefore, it is currently not possible to determine potentially significant impacts nor identify suitable mitigation. The report therefore recommends that there should be an archaeological assessment of seismic and geotechnical data produced for the scheme and that there should be archaeological input in geophysical and geotechnical survey planning.

536 The report identified a total of 16 United Kingdom Hydrographic Office (UKHO) charted wreck or obstruction records in the survey area. Known wrecks are predominantly 20th century losses and include a number of steam trawlers and locally built vessels. In addition, coarse analysis of maritime records for the Aberdeen area contained within the National Monuments Record of Scotland (NMRS) database indicates that there are over 200 known vessel losses that could have occurred within the study area or in its vicinity. These known losses date from the medieval period to the 20th century but are predominantly of the Industrial period (AD 1700-1900). This loss record is likely to be unrepresentative of losses from earlier periods due to a lack of wreck reporting prior to the mid-18th century. Several of these known losses appear to be located within the study area, although their precise position is unknown.

537 The relatively dense concentration of loss records in or in the vicinity of the survey area reflects the importance of the port of Aberdeen since at least the medieval period. Loss descriptions contained in the NMRS database and other secondary sources, together with reports submitted to UKHO suggest that losses occurring within the survey area are either clustered around Aberdeen Harbour entrance or along and very close to the shore to the north.

Available wreck descriptions suggest that those charted wrecks located along the shore to the north are largely broken up.

6.4.3 Proposed Scope of Assessment

538 The desk-based assessment of the proposed project has demonstrated that the potential exists for the presence of submerged prehistoric archaeological deposits in the study area. However insufficient data are available about the shallow geology of the study area to determine the level of this potential and how extensive any archaeological deposits are likely to be.

539 The data derived from the geophysical survey will be subject to archaeological assessment and the potential for submerged prehistoric archaeology within the reassessed study area.

540 In addition, the archaeological assessment and analysis of any geotechnical data collected during the development of the wind farm also has the potential to provide information about the presence of submerged prehistoric archaeological deposits in the study area.

541 Analysis of both the charted wrecks and recorded losses for the vicinity of Aberdeen indicates that there is a high potential for the presence of maritime sites within the survey area. Several sites charted by the United Kingdom Hydrographic Office in the study area and buffer zone are of some archaeological importance, but not all are identified and their current extent and condition are unknown.

542 Analysis of available evidence about loss location and likely causal factors suggests that a significant proportion of the losses recorded may have occurred in the vicinity of the study area. Coupled with the relatively few charted wrecks, this suggests that there is high potential for known, but uncharted wrecks to be present in the wind farm development area.

543 Data obtained during the forthcoming geophysical survey for the scheme will be subject to archaeological assessment to determine the condition, character and extent of known sites within the study area and whether there is any evidence for the presence of other, currently uncharted wrecks in the area.

544 Geophysical data will be assessed for features and deposits of archaeological significance. Side scan sonar data will be reviewed to confirm the location and character of known wrecks and to identify previously unrecorded features of anthropogenic origin on the seabed. A review of the magnetometer data will identify further anomalies of anthropogenic origin and assist in confirming identification as anthropogenic of anomalies seen on the side scan sonar.

545 A proportion of the sub bottom profiler data will be reviewed to identify paleo-geographic features, for example paleo-channels and peat horizons and these will be traced through the data with a view to establishing the paleo-landscape during periods of possible hominid occupation.

546 The multi-beam/swathe bathymetry data review will provide vertical datum for the sub bottom interpretation, will aid in the identification of paleo-geographic features and help establish a baseline against which sea level change can be

assessed and will provide additional information on wreck sites identified from the side scan sonar and desk based assessment.

547 The geophysical data will be reviewed and interpreted in order to characterise key units, features and sites, to create an integrated gazetteer.

548 The EIA will include an impact assessment that, if appropriate identifies potential exclusion zones, highlight awareness of risk factors to facilitate project planning, and identify areas, which may require avoidance or mitigation.

6.4.4 Potential Impacts

549 There is potential for damage to occur during pre-construction seabed preparation, wind farm construction, cable laying and intrusive geotechnical survey to:

- submerged prehistoric archaeological sites and finds on the seabed
- wrecks that could potentially date from the later Mesolithic through to the present day
- submerged prehistoric sites and finds and submerged topographic features and deposits that contain palaeo-environmental evidence

550 Potential damage may also occur where local changes in sediment movement caused by the new structures results in scour which may result in heritage assets (wrecks, submerged prehistoric archaeological sites, and archaeological finds) being exposed or undermined. As heritage assets underwater have usually survived as a result of achieving a broadly stable equilibrium with their immediate environment, changes in this environment may trigger renewed degradation as a result of alterations in the physical, chemical and biological processes that the asset is subject to.

551 Archaeological sites identified may require protection from:

- cable burial
- foundation installation
- scour protection
- anchoring
- construction vessel movement
- decommissioning activities

6.4.5 Cumulative Assessment

552 Activities that will potentially have to be considered in relation to cumulative and in-combination impact assessment are:

- aggregate extraction and dredging
- subsea cables and pipelines
- oil and gas infrastructure and operations

553 The main impacts envisaged are movements of sediment and changes in sediment regime deriving from the construction of the wind farm or the construction or operation of the above activities in the proximity of the wind farm and potentially affecting the archaeological study area.

554 Wrecks are site specific so operations in other areas are not likely to affect wreck sites in the project area. If wreck sites are known they will be avoided so that no cumulative effects arise.

6.5 Seascape, Landscape and Visual Effects

6.5.1 Introduction

555 Consideration of landscape, seascape and visual impacts arising from the EOWDC will form an integral part of the EIA process. Initial consultation on the methodology for the Seascape, Landscape and Visual Impact Assessment (SLVIA) with Scottish Natural Heritage (SNH), Aberdeenshire Council (AC) and Aberdeen City Council (ACC) has already taken place and decisions agreed on the approach, which is discussed below.

6.5.2 Baseline Information

556 Defining the baseline character and visual amenity of the study area has been recently discussed with SNH, ACC & AC. The proposed wind farm deployment centre consists of 11 wind turbines anticipated to be of different types/heights, and lies approximately 2.2 km at its closest point from the coastline. Aberdeen City centre lies approximately 8 km south-west of the wind turbines, with its northern suburbs approximately 4.5 km from the nearest wind turbine. Balmedie is the closest settlement to the wind farm, at approximately 3 km from the nearest wind turbine, although there are individual properties which lie closer. A 35 km radius study area and a 50 km cumulative study area were requested by SNH, ACC & AC with the intention that they can be refined down depending on distance/specific areas and the likelihood of significant effects. Due to the close proximity of the offshore wind turbines to the coast the study area will include Aberdeen City, most of Aberdeenshire and limited areas within Moray.

6.5.2.1 <u>Landscape and Seascape Character</u>

557 The landscape character of Aberdeen and Aberdeenshire has been comprehensively documented in the SNH landscape character assessments which were completed in 1996 and 1998 respectively. Given the time elapsed since these were published there will have been changes in the landscape and therefore desk and field work for the SLVIA will take this into consideration when assessing the baseline character of the study area. One of the main changes to the landscape over the last 15 years has been the introduction of wind turbines which are now part of the landscape character of a number of areas in Aberdeenshire.

558 The coastline and sea within the study area has been defined as one national seascape unit (Area 4 – North East Coast) by the SNH commissioned report ‘An assessment of the sensitivity and capacity of the Scottish Seascape in relation to wind farms’ (Scott *et al.*, 2005). Regional seascape units will be established during the assessment through desk and field work. Documents such as SNH’s ‘Beaches of Scotland’ report series will also provide additional baseline information.

559 National landscape designations within 15 km of the site include two Historic Gardens and Designed Landscapes; Duthie Park and Pitmedden Gardens. Local landscape designations include the coastal 'Areas of Landscape Significance' which extend from Balmedie to Peterhead, and beyond, along the north coast of Aberdeenshire.

6.5.2.2 *Visual Amenity*

560 There are a variety of visual receptors within the study area but the key receptors are:

- residents of Balmedie, Aberdeen and its suburbs, and residents of smaller villages and isolated dwellings along the coast and inland (within approximately 5 km of the site)
- recreational users of the foreshore and in particular Balmedie Country Park, Forvie NNR, Foveran Links SSSI and Aberdeen Beach
- the development is also likely to be visible from a number of key transport routes including, ferries to and from Aberdeen, certain air-routes into Aberdeen Airport, and roads such as the A90

561 The representative viewpoints to be used to establish the effects on key visual receptors were discussed and agreed with the consultees. Although this was done on a previous layout and not the layout taken forward here in this Scoping Report it is thought that these viewpoints still represent good coverage of the site layout. Whilst the exact locations may yet be refined during the assessment, it was agreed that the viewpoints listed in Table 6.1 covered all the key receptors across the study area. The Aberdeen City viewpoints are to be confirmed following more detailed desk and field work.

TABLE 6.1
Representative Viewpoint Locations

	Location	**Grid Reference**
1	Public local road near Murcar Golf Course	NJ 956 123
2	Aberdeen Beach	NJ 954 069

17-20	Aberdeen city centre viewpoints - to be confirmed	

6.5.3 Proposed Scope of Assessment

562 A full Seascape and Landscape Visual Impact Assessment (SLVIA) will be undertaken for the Aberdeen Offshore Wind Deployment Centre in close

consultation with statutory stakeholders (eg SNH, AC & ACC). Consultation has already taken place which has confirmed study areas, methodology and initial viewpoints.

563 Relevant good practice guidance on landscape, seascape and cumulative assessment will be used. Examples of such guidance are provided below;

- Maritime Ireland/Wales Interreg 1994 – 1999 Guidance 'Guide to Best Practice in Seascape Assessment', (GSA), published in March 2001
- Guidelines for Landscape and Visual Impact Assessment, Institute of Environmental Management and Assessment (IEMA) and the Landscape Institute's (2nd edition 2002);
- Visual representation of Wind Farms Best Practice Guidance, Scottish Natural Heritage (2007);
- The Guidance on the Assessment of the Impact of Offshore Wind Farms – DTI (2005)
- Cumulative Effects of Wind Farms, SNH (2005)

564 The SLVIA process will be undertaken as follows:

565 The baseline study establishes the relevant landscape planning policy context, the scope of the assessment and the key landscape receptors. It includes the following key activities, some of which have already been undertaken with the statutory consultees:

- a desk study of relevant current national, regional and local planning policy for the study area
- agreement of the main study area radius with the local planning authority and SNH
- a desk study of nationally and locally designated landscapes for the study area
- a desk study of existing landscape character assessments for the study area, at national, regional and local level
- draft Zone of Theoretical Visibility (ZTV) studies to assist in identifying potential viewpoints and indicate the potential visibility of the proposed wind farm, and therefore scope of receptors likely to be affected (An example ZTV can be found as Figure 16, this is based on a maximum tip height of 195 m (above LAT) for all 11 wind turbines)
- the identification of and agreement upon, through consultation, the number and location of representative viewpoints within the study area.
- identification of the range of other visual receptors (public rights of way, settlements and residential properties) within the study area.
- site visits to become familiar with the study area and to identify viewpoints and receptors

566 During this stage, the scheme design may not yet have been finalised and there will be a degree of iteration between this stage (particularly in respect of preparing ZTV studies and consequent changes to likely effects on receptors) whilst the design is finalised.

567 The assessment of effects includes further desk and site based work, covering the following key activities:

- the preparation of ZTVs based on the identified and agreed worst case wind turbine layout for the offshore development

- the preparation of computer generated wireframes showing the proposed development from the agreed representative viewpoints
- an assessment of the magnitude and significance of effects upon the seascape character, landscape designations and the existing visual environment within the study area arising from the proposed development during construction, operational and decommissioning stages
- the production of photomontages from a selection of the agreed viewpoints showing the anticipated view following construction of the proposed wind deployment centre

568 A cumulative assessment of the EOWDC in relation to onshore wind farms, as well as any other relevant developments within the study area will be part of the assessment.

6.5.4 Potential Impacts

6.5.4.1 During Construction

569 Potential landscape and visual effects during construction may include the following:

- the visual impact of active, brightly coloured marine construction plant equipment such as the cranes that will be used to construct and erect the wind turbines, and already constructed wind turbines on site over the construction programme
- the visual effects associated with increased vessel movements in the area as plant, materials and personnel are moved to and from site
- the visual effects of lighting during the construction period. Lighting will be required at sea (wind turbine construction and cable installation) if there is a 24 hour construction programme. The extent of the impact will depend upon elements of the weather and types of lighting used

6.5.4.2 During Operation

570 The potential operational impacts of the extension of the EOWDC may include the following;

- the seascape, landscape and visual effects of the operating wind farm upon sensitive receptors
- the visual effects of increased vessel movements as a result of operation and maintenance activities.
- a change in the landscape or seascape character as a result of the wind turbine structures

571 Due to the proximity of the proposed wind deployment centre to the coast and a large city, the assessment of potential effects on the landscape, seascape and visual amenity of the area is an integral part of the EIA.

572 Particular consideration will need to be given to any character and visual amenity effects that might arise as a result of the anticipated different wind turbine types/heights (Example wireframes can be found as Figures 17 and 18 and these show two different viewpoints with layouts comprising two

different wind turbine heights. Wind turbines 1 to 6 with a tip height of 160 m (above LAT) and wind turbines 7 to 11 with a tip height of 195 m (above LAT).

6.5.4.3 <u>During Decommissioning</u>

573 Impacts arising during the decommissioning are expected to be similar to those experienced during the construction phase. There would be a temporary impact from the activities on site to remove structures, but this would be of relatively short duration.

6.5.5 Cumulative Assessment

574 Consideration will be given to cumulative character and visual effects with other wind farm developments or other relevant structures within 50 km of this proposal that are either operational, consented or formally lodged in the planning/consent process. At the time of writing there are no other offshore wind farms in the area but over 15 operational/consented onshore wind farms within the wider study area and at least a further 10 wind farms in the planning process. Further consultation with SNH will take place to agree an approach to assessing the cumulative effects of the offshore wind farm with the large number of onshore wind farms. This is also anticipated to include a review of which other wind farm developments should be included within the assessment, the scope of the cumulative assessment and the final extent of the study area.

575 Potential cumulative effects may include the following:

- cumulative effects upon seascape/landscape character arising from combined, successive or sequential views from sensitive receptors. This could result where a receptor may experience the presence of other existing and planned wind farm developments in conjunction with the Aberdeen Offshore Wind Deployment Centre
- cumulative effects upon seascape/landscape character arising from the Aberdeen Offshore Wind Deployment Centre when viewed in combination with other structures on land and in the North Sea.

6.5.6 Mitigation

576 Embedded mitigation measures will include the distance that the wind deployment centre is located from sensitive receptors. Also, the choice of colour for the wind turbines will mitigate any landscape and visual impacts.

577 The wind turbines will be temporary in nature (due to maximum lease duration of 22 years) with no anticipated lasting visual effects following completion of decommissioning.

6.5.7 Cultural Heritage Assessment

578 A cultural heritage assessment will be carried out in consultation with Historic Scotland and Scottish Natural Heritage to assess the potential impact on the setting of sites of national or greater significance (eg Scheduled Monuments, Listed Buildings). The locations of Scheduled Monuments and Listed Buildings in the area can be seen on Figure 12.

579 Where significant impacts are predicted, wireframes and photomontages would be produced and assessed.

580 A report on the results of the desk-based survey will be incorporated into the Environmental Statement.

6.6 Commercial Fisheries

6.6.1 Introduction

581 Until the mid 1950s, Aberdeen was Scotland's main fishing port, however, due to the rapid expansion of oil interests in the North Sea, which allowed fishermen to diversify into oil-based work, and the general downturn in the fishing industry, there is now only one fish quay. Although the market now handles significantly reduced quantities of fish, some vessels registered to other ports still land into Aberdeen. A number of fish processing plants remain in Aberdeen with fish brought by road from other ports.

6.6.2 Baseline Information

582 Aberdeen offshore wind farm is located across the boundaries of 2 ICES rectangles, 43E7 and 43E8.

583 ICES rectangle 43E7 has significantly lower landings values than other ICES rectangles in the region, although this is largely due to its small sea area. Within this rectangle, demersal trawling for *Nephrops* and whitefish is the principal method undertaken, followed by scallop dredging by mechanical dredge. Creel fishing is also deployed in inshore areas.

584 Within ICES Rectangle 43E8, there is demersal trawling and mechanical dredging, the majority of which is by the over 10 m fleet. Vessels employing these methods will target whitefish and *Nephrops*, and scallops respectively. There are low levels of pelagic activity by foreign vessels in this rectangle. Creel fishing also takes place, undertaken almost exclusively by the under 10 m fleet.

6.6.2.1 Whitefish

585 The offshore area around Aberdeen supports a range of commercially important fish species. Offshore fish communities are dominated by haddock (*Melanogrammus aeglefinus*), whiting (*Merlangius merlangus*) and cod (*Gadus morhua*), with saithe (*Pollachius virens*) and Norway pout (*Trisopterus* sp.) being associated with deeper waters. Migratory species such as herring (*Clupea harengus*) and mackerel (*Scomber scombrus*) are found throughout the area, although their distribution is seasonal.

6.6.2.2 Shellfish

586 Shellfish species that are commercially important within the Aberdeen fishing areas include the following:

- European lobster, *Homarus gammarus*

- Edible crab, *Cancer pagurus*
- Velvet swimming crab, *Necora puber*
- Shore crab, *Carcinus maenus*
- Giant scallop, *Pecten maximus*
- Cockle, *Cerastoderma edule*
- Mussel, *Mytilus edulus*
- Whelk, *Buccinum undatum*
- Periwinkle, *Littorina littorea*

587 The Norway lobster (*Nephrops* sp.) is by far the most important shellfish species exploited in Scottish waters. Norway lobsters are located in areas of soft mud or muddy sand in which they excavate and inhabit burrows; however known spawning grounds are to the north and south of Aberdeen Bay.

588 In coastal waters, a baited creel fishery exploits four species, the European lobster, edible crab, velvet swimming crab and to a lesser extent, the shore crab (Chapman, 2004). The edible crab is fished all round the coast of Scotland, mostly on inshore grounds over-lapping with the European lobster but occasionally in deeper water away from the coast. The main landing ports in the North Sea are Aberdeen, Fraserburgh, Wick and in the Orkney and Shetland Islands (Chapman, 2004).

589 Four species of bivalve mollusc are exploited in the SEA5 zone, of which the giant scallop is by far the most important. The main fisheries are located around Orkney and Shetland, in the Moray Firth and off the east coast of Scotland, with most of the landings taken within these zones.

590 Gastropod molluscs are represented by two species, the common whelk and the periwinkle. Some fishing for whelks takes place around the whole Scottish coast, though mostly in the North Sea and the Northern Isles. Winkles are inter-tidal in distribution and are harvested by hand at low tide.

6.6.2.3 *Cephalopods*

591 The commercial importance of cephalopods is of relatively recent, but growing, importance (Boyle and Pierce, 1994). Evidence exists that fishing pressure has changed ecological conditions and shifts in community structures have occurred with cephalopod stocks slowly replacing predatory fish stocks (Caddy and Rodhouse, 1998).

592 Several species of cephalopod have been recorded off north-east Scotland. The main commercial species in Scottish waters is the long-finned squid *Loligo forbesi* (Boyle and Pierce, 1994; Pierce *et al.*, 1994a,b, 1998; Stowasser *et al.*, 2004). Since 1995, annual UK landings of loliginid squid have ranged between 1600 and 3200 tonnes, making the UK the second most important fishery nation for loliginid squid within the ICES region after France.

593 Other cephalopod species of commercial interest, present in North Sea area, are the squid species (*Todarodes sagittatus*), (*Todaropsis eblanae*), (*Alloteuthis subulata*) and the octopus (*Eledone cirrhosa*) though in much smaller numbers (Stowasser *et al.*, 2004).

6.6.2.4 *Diadromous and Freshwater Species*

Salmonids

594 Salmon and sea trout are of particular importance in this area with the Rivers Dee and Don having salmon and trout fisheries. In Scotland, the management of the salmon fishery is entrusted to District Salmon Fishery Boards (DSFBs) whose responsibilities include the protection and improvement of the salmon fisheries within their districts. The two salmon Fishery Districts in the immediate vicinity of the proposed development are the Dee and Don Boards.

595 All Scottish salmon fisheries are closed for a minimum of 168 days a year for spawning. The actual dates may vary but are usually from late August to mid February. Salmon spawning periods vary between rivers and are thought to be influenced by water temperature and day length. Sea trout spawning generally occurs between mid October and January.

6.6.3 Proposed Scope of Assessment

596 The principal data sources to be used for the baseline assessment will be:

- Marine Scotland (an executive agency of the Scottish Government)
- The Scottish Executive Environment and Rural Affairs Department (SEERAD)
- International Council for the Exploration of the Sea (ICES)
- Fisheries Research Services (FRS)
- Scottish Fisheries Protection Agency (SFPA)
- The Scottish Fishermen's Federation (SFF)

597 Consultation with local fishermen began in 2007, and was principally undertaken by the Scottish Fishermen's Federation (SFF). The SFF represents approximately 90 % of Scottish fishermen. Those consulted include:

- Scottish Fishermen's Federation (SFF)
- Scottish Inshore Whitefish Producers

598 Consultation with commercial fishermen will continue throughout the development of the project. Liaison with fisheries organisations will primarily be via the contractor of the assessment.

599 A baseline report was completed for commercial fisheries in 2008. For the purposes of the EIA, this report will be reviewed and updated to include more recent information and to cover the revised site layout and cable corridor.

600 The information within the baseline assessment is expected to include:

- review of the types of commercial and traditional fisheries (including shell fisheries) in the area (eg methods/gear used, season, duration, etc.)
- review of the types of salmon and sea trout fishing in the area (eg methods/gear used, season, duration, etc.)
- review of the location of fishing grounds for commercial fisheries and salmon and sea trout (type and season)

- the location and season of spawning and nursery areas of commercial species
- update of fishing activity in and adjacent to the wind farm site (eg fishing effort, number of vessels)
- update of identification of local and foreign vessels using the area (eg size, type, operating ranges, port, nationality)
- update of fish catch and landings data for commercial fisheries and salmon and sea trout (value and amount)
- update on any known fish farms planned for the future in the area
- any hereditary rights to particular fishing grounds in the area and the legal implications of such rights
- review of fishing and angling in the surrounding rivers, the importance of these rivers, eg economic value and potential impacts associated with the wind farm development

601 Full use will be made of information from the Fisheries Statistics Unit including fisheries surveillance information, landings and fishing effort data and registered vessel lists. These data will be supplemented through discussions with local fishermen.

6.6.4 Potential Impacts

602 The following aspects are identified by CEFAS in the Defra (2004) guidelines as requiring addressing in the impact assessment.

- Presence of seabed obstacles
- Impacts on commercially exploited species
- Increased steaming times to fishing grounds
- Safety issues for fishing vessels
- Complete loss of, or restricted access to traditional fishing grounds
- Interference with fisheries activities
- Any other concerns raised by local fishermen and fishermen's organisations

603 Table 6.2 presents the impacts as identified within the impact assessment for the previous site layout. Impacts of the site now proposed are not expected to differ significantly. All aspects are assessed for construction/decommissioning and construction respectively.

TABLE 6.2 Impact Assessment for previous layout								
Environmental effect	**Description of feature(s)/people affected (receptors)**	**Spatial extent**	**Duration**	**Magnitude**	**Probability of effect occurring**	**Significance level**	**Mitigation measures and rationale**	**Significance level after mitigation**
Construction and Decommissioning								
Damage to fishing gears by presence of seabed debris	Potting vessels Demersal trawlers	Local	Temporary	Low to High	Uncertain	Negligible to Major if damage occurred	Contractors obligations and standard offshore practices would prevent, or in the case of accidental incidents, remove dropped objects	Negligible
Adverse Impacts on Commercially Exploited Species	Fish and shellfish	Local	Temporary	Low	Uncertain	Minor	Use of appropriate engineering techniques, eg soft start piling Low sensitivity of principal target species	Minor
Safety issues for fishing vessels (collision with construction vessels)	All vessels	Local	Temporary	High	Unlikely	Negligible to Major if collision occurred	Implementation and adherence to standard offshore safety procedures Involvement of the SFF for liaison and information distribution	Negligible

Increased steaming times to fishing grounds	All vessels	Local Local	Temporary Temporary	Low Low	Likely Unlikely	Minor Negligible	Transitory, short term exclusion areas around construction activities within the site Limited numbers of potentially impacted vessels Low probability of a significant number of steaming routes likely to be affected	Negligible, possibly minor for locally based potters
Complete loss or restricted access to traditional fishing grounds	All vessels	Site-specific	Temporary	Low	Certain	Minor Negligible	Transitory, short term exclusion areas around relatively small areas of sea Limited numbers of potentially impacted vessels Use of local vessels for wind farm related work	Negligible to minor
Interference to fishing activities (from construction vessels)	All vessels	Site-specific	Temporary	Low	Unlikely	Negligible	Construction vessels using existing shipping routes Fishermen’s representatives	Negligible
Restriction of access during laying of export cables	All vessels	Site-specific	Temporary	Low	Certain	Negligible, possible minor for some vessels	Short duration and small transitory area of exclusion Limited numbers of potentially affected vessels	Negligible, possibly minor for some vessels

Operational Phase								
Damage to fishing gear by presence of seabed debris	All vessels	Local	Temporary	Low to High	Uncertain	Minor to Major if damage occurred	Contractors obligations and standard offshore practices should have removed objects Any scour protection rock placement would be adjacent to wind turbine bases	Negligible
Adverse impacts on Commercially Exploited Species	All vessels	Local	Permanent	Low	Unlikely	Negligible	Scour protection will likely offer additional habitat for species by providing shelter and nursery grounds	Negligible to beneficial
Safety issues for fishing vessels (collision with wind turbines)	All vessels	Site-specific	Permanent	High	Unlikely	Minor to Major if collision occurred	Implementation and adherence to standard offshore safety procedures	Negligible
Increased steaming times to fishing grounds	All vessels	Local/ Regional	Permanent	Low	Unlikely	Negligible	Potential for fishing vessels to steam through the site in favourable conditions Limited numbers of potentially impacted vessels Low probability of a significant number of steaming routes likely to be affected	Negligible

Complete loss or restricted access to traditional fishing grounds	All vessels	Local	Permanent	Low	Unlikely	Negligible	Potential for potting gear to be deployed within the operational site Low numbers of other vessels likely to be potentially affected	Negligible to beneficial
Interference to fishing (avoidance of/collision with maintenance vessels)	All vessels	Local	Temporary	Low	Unlikely	Negligible	Maintenance vessels using existing shipping routes Fishermen's representatives	Negligible
Damage to fishing gear/vessels from exposed cables	All vessels	Local	Temporary	High	Unlikely	Minor to Major	Cable burial to a certain depth depth. Implementation and adherence to standard offshore safety procedures Cable route surveys Temporary exclusion zones until issues are rectified	Negligible to Minor

6.6.5 Cumulative Assessment

604 At present there are no offshore wind farms applying for consent off the coast of north-east Scotland. However, there are two proposed wind farms in the Moray Firth which could potentially have a cumulative impact on fisheries.

605 Other elements that could realistically contribute to cumulative impacts are:

- commercial shipping movements
- aggregate dredging
- offshore oil and gas installations
- introduction of protected marine areas

6.6.6 Mitigation

606 Mitigation measures are presented in Table 6.2 and will be further investigated.

6.7 Socioeconomics

6.7.1 Introduction

607 Offshore wind farms offer the potential for significant positive socioeconomic benefits, through job creation locally and nationally, during both the construction and operational phases of the project. In addition to job creation, the proposed development can have positive socioeconomic impacts on a national scale. The generation of renewable energy is essential in assisting the Scottish Government's goal of generating 50 % of Scotland's energy from renewable sources by 2020 (Scottish Government, 2010) and the UK Government's target of 15 % of energy from renewable sources by 2020 (DECC, 2010). Furthermore, wind farms can contribute to achieving long-term sustainable development of the Scottish Economy.

6.7.2 Baseline Information

608 Baseline information should identify key population, employment and economic data. Aberdeen has a total population of 210,400 as reported in 2009. It has an extensive existing offshore skills base generated by the oil and gas industry and between 2007 and 2008 the city had the highest GDP growth rate in Scotland (Aberdeen City Council, 2010).

609 Baseline information at both the regional and national level should be recognized, identifying specific socioeconomic impacts caused by offshore wind farms within particular regions as well as the impacts to Scotland (and the UK) as a whole. The following study areas are suggested:

- inner study area: Aberdeen and Aberdeenshire, the development will pose direct socioeconomic impacts to this area (discussed in section 6.7.4)

- wider study area: Other parts of Scotland. Possible impacts on other areas where potential suppliers and contractors exist should also be identified
- potential national impacts, such as offshore wind farms' potential to assist in national climate change commitments, could be considered at the high level

610 Local communication links including harbours, ports and links to manufacturing and assembly sites should be identified as the development of local infrastructure can result in economic benefits. Furthermore, the identification of local construction and suppliers is also of relevance as the use of local companies will lead to further positive socioeconomic impacts.

6.7.3 Proposed Scope of Assessment

611 The position and performance of Aberdeen's economy and its prospects for the future will be reviewed. This will include information on area, population, economic activity, employment and education and skills. Data on the socioeconomic impacts of existing offshore wind farms will be collated in consultation with relevant organisations, eg Aberdeen City Council and Aberdeenshire Council, the local fishing community via the Fisheries Liaison Officer (FLO), local communities and local groups such as Community Planning in Aberdeen, and via public exhibitions. The potential for job creation and local training opportunities will be assessed. Local communication links, including port facilities, will be assessed for their suitability for construction and operation activities.

612 The following data sources will be reviewed as part of the EIA process:

- The Crown Estate (2008) Socio-Economic Indicators of Marine-Related Activities in the UK Economy
- Scottish Government General Register Office for Scotland (2006) Scottish Economic Statistics

6.7.4 Potential Impacts

613 The economic impact of the project would be most significant during the construction phase, however potential benefits over the lifespan of the wind farm would also be assessed.

614 Potential impacts on socioeconomics, both positive and negative, which will be investigated are:

- construction (may also occur during decommissioning)
  - increased employment in construction and supporting industries Construction jobs relate to both construction of the wind farm itself and onshore facilities, including substation civil and electrical works.
  - increased expenditure through supply of goods and services required to develop the wind farm
  - change in population structure and consequent impacts on infrastructure requirements. The potential use of specialist contractors from out with the area could result in increased use of local accommodation and service industries.

    - academic research opportunities
- operation
    - increased employment, both local and further a field, due to maintenance and operation
    - change in population structure and consequent impacts on infrastructure requirements
    - academic research opportunities
- power generation
    - the development will result in a localised power generation consequently, less power will be wasted in transmission over long distances
    - the supply of site generated power will reduce the requirement to buy power from commercial utility companies, thus reducing fuel bills
- indirect benefits
    - improved marketing of Aberdeen as a 'green' city, leading to potential inward investments in new technologies
    - re-circulation of increased income

615 In 2009 approximately 5000 people were unemployed in the Aberdeen and Aberdeenshire area (Aberdeen City Council, 2010), in. The resultant positive socioeconomic effects of the development could alleviate unemployment.

616 Construction, operation and maintenance of the EOWDC will require both on and offshore local, national and international contractors. Thus, although the focus here has been on local socioeconomic impacts, the development will result in socioeconomic impacts in a wider sense.

617 Offshore wind farms also generate potential socioeconomic impacts on tourism, both beneficial and adverse. Impacts on tourism and commercial fisheries are dealt with in sections 6.6 and 6.8.

618 The visual impacts and mitigation methods are discussed in section 6.5 of this report.

6.7.5 Cumulative Assessment

619 The assessment of impacts would be undertaken on a site specific and cumulative basis to include the proposed project in addition to proposed other developments.

620 The development's impacts on other offshore operations, including oil and gas installations, shall also be addressed.

6.7.6 Mitigation

621 The majority of socioeconomic impacts on the area will be beneficial, thus ways to enhance such impacts must be explored. This may include:

- use of local port facilities where possible
- use of local vessels for survey and guard work where possible
- use of local employment base for both construction, operation and maintenance

- consideration of employment and training for operations and maintenance work
- use of locally manufactured supplies

622 The emphasis here is on focusing on local socioeconomic opportunities, thus consultation with local stakeholders is essential.

6.7.7 EOWDC Future Research and Monitoring

623 Monitoring will be proposed to ensure the implementation and effectiveness of the mitigation.

6.8 Recreation and Tourism

6.8.1 Introduction

624 Tourism is important to the local economy of Aberdeen, in 2008 tourism expenditure in the city was over £300 million (Aberdeen City and Shire Economic Future, 2010). The physical appearance of near shore wind farms means that visual impacts can be important and is of particular relevance to the tourism and recreation industry. Consequently, a detailed assessment of potential impacts would be required. Consultation with relevant organisations will continue throughout the project.

625 In 2005 and 2006 there were two road show events taking an exhibition to libraries, town halls and village halls along the stretch of coast. The events were open to all and were publicised in advance. The road shows proved a very successful means of engaging the public over the wind farm project and reaction was on the whole supportive. Meetings have also been held at earlier stages with both Royal Aberdeen and Murcar golf courses to inform about the project.

6.8.2 Baseline Information

626 Baseline information will identify key tourism data, including Aberdeen's most popular and profitable tourism features and if such features will be impacted by the offshore wind farm.

627 Visit Scotland statistics show that during 2008 UK residents made 1.30 million tourism trips to Aberdeen spending £242 million. Visitors from overseas took 0.25 million trips and spent £90 million in the area. Tourism related employment accounts for 8 per cent of jobs in the area (Visit Scotland, 2008).

628 In addition to summertime recreational boating, the beach adjacent to the area is used by local people for bird watching/nature walks etc.

629 SNH commissioned a review of marine and coastal recreation in Scotland (Land Use Consultants, 2006) which indicates that the most popular specialist activities on the Scottish coastline are walking, sea fishing, sailing, kayaking, canoeing, and wildlife and bird watching.

630 According to Visit Scotland (2008) the top visitor attractions in the Aberdeen and Grampian area are as follows:

- David Welch Winter Gardens, Aberdeen
- Aden Country Park, Mintlaw
- Aberdeen Art Gallery, Aberdeen
- Aberdeen Maritime Museum, Aberdeen
- WDCS Wildlife Centre, Spey Bay
- Provost Skene's House, Aberdeen
- Crathes Castle, Banchory
- Logie Steading Visitor Centre, Forres
- Loch Muick & Lochnagar Wildlife Reserve, by Ballater
- Aberdeen Arts Centre, Aberdeen

631 Coastal golf courses are also popular sites for recreation. There are currently two close-by golf courses situated along the shoreline of northern Aberdeen and further courses are planned.

632 Visual impacts are of particular relevance with regard to tourism and recreation. The geographical extent of the visual impacts of the wind farm will be identified using a ZTV map (discussed in section 6.5) which will be undertaken as part of the SLVIA. Sites that are of particular importance with regards to tourism and the extent to which such sites will be visually impacted will be identified.

633 Aberdeen's tourism resources' dependence on visual features will be identified. The extent to which each resource (eg restaurant views, foot paths, view points etc.) is dependent on the surrounding land/seascape will be identified and the visual impacts the wind farms determined.

6.8.3 Proposed Scope of Assessment

634 The EIA will include an assessment of the tourism sector in Aberdeen focussing on coastal tourism.

635 The following data sources will be referred to during the EIA process:

- Glasgow Caledonian University (2007) Economic Impact of Wind Farms on Scottish Tourism
- Scottish Renewables and the British Wind Energy Association (2002) Tourist Attitudes Towards Wind Farms
- Ladenburg *et al.*, (2006) Socioeconomic Effects: Positive Attitudes in Local Communities
- Land Use Consultants (2006) Review of Marine and Coastal Recreation F05AA608

636 Consultation with Aberdeen City Council and Aberdeenshire Council, Visit Scotland, local recreational groups.

6.8.4 Potential Impacts

637 The development is located 2 km from the coast and will follow the coastline from northern Aberdeen to Balmedie, visually impacting the seascape of the area. According to Glasgow Caledonian University's (2007) study the economic impact of wind farms onScottish tourism is relatively small. This

study was based on the impacts of onshore wind farms, however, the same basic principles can be applied to offshore wind farms.

638 Glasgow Caledonian University's study focused on four case study areas in Scotland, concluding that three quarters of tourists surveyed felt that wind farms had a positive or neutral impact on the landscape. Of the 380 tourists surveyed 39 % were positive about wind farms, 36 % had no opinion and 25 % were negative. Within the minority that were negative about wind farms, only a very small group changed their opinions about revisiting Scotland. The likelihood of those surveyed intentions to return showed that wind farms have very little impact. Three visual situations were required to determine the likelihood of return:

- those having actually seen a wind farm
- respondents were shown photos of an area before and after construction of a wind farm
- respondents were shown a photo montage of an area with an existing wind farm with illustrations of how the landscape would look if the wind farm was extended

639 In all cases the vast majority, 93-99 %, suggested that the experience of seeing a wind farm would have no effect. In addition the presence of wind farms increased the likelihood of some tourists to return to the case study areas and Scotland as a whole.

640 A number of the top visitor attractions, outlined in section 6.8.2, will be completely unaffected by the wind farm. Therefore the wind farm's economic impacts on tourism should be negligible.

641 The potential impacts on Tourism and Recreation which will be investigated are:

- construction (may also occur during decommissioning)
  - visual impacts
  - temporary disruption of offshore tourism and recreation
- operation
  - visual impacts
  - site access for offshore tourism and recreation
  - marine navigational safety
  - offshore wind farms can also present tourism potentials. Many boat operators offer tours of offshore wind farms.

642 Locally, the development may also impact bird watching, during both construction and operation.

6.8.5 Cumulative Assessment

643 The need to assess tourism and recreational impacts cumulatively will be discussed with relevant consultees.

6.8.6 Mitigation

644 A desk study and consultation will be undertaken to gain the views of the local tourist industry, and potentially consider ways of benefiting it.

645 The majority of impacts on tourism will be visual. As such, the mitigation methods outlined in section 6.5 should be considered. In addition, the wind farm may attract tourists. Of the 380 tourists surveyed by Glasgow Caledonian University 48 % agreed with the statement 'I like to see wind farms.' Thus potential ways to use wind farms as a tourist attraction, such as locally run boat trips, will be explored.

6.9 In-Air Noise

6.9.1 Introduction

646 Construction activities, such as wind turbine installation and the associated vessel movements, have the potential to generate airborne noise. The acoustic impacts during construction and operation will be assessed following the former Department of Trade and Industry's (DTI) best practice guidelines. Preliminary noise predictions have been carried out for close-by dwellings, golf course club houses, close coastal points, Balmedie Ranger Station and more. According to these calculations background noise levels will generally be below 35 dB(A).

6.9.2 Baseline Information

647 Aberdeen has a total population of 210,400 as reported in 2009. The proposed wind farm is located 2-4 km from shore north of Aberdeen City. Sensitive receptors to in-air acoustic impacts will include local residents, businesses and tourists. There are beaches and two golf courses along the coastline.

648 Local levels of background ambient noise will be used in the modelling for airborne noise levels during construction and operation.

6.9.3 Proposed Scope of Assessment

649 A detailed baseline noise survey will be conducted at representative locations onshore following consultation with Aberdeen City Council and Aberdeenshire Council with the following proposed outputs:

- identification and agreement on the location of the nearest sensitive receptors
- agreement of noise limits for each receptor with Aberdeen City Council and Aberdeenshire Council
- prediction of noise levels received at each receptor using a recognised computer model that implements the calculation method specified in ISO 9613: Acoustics – Attenuation of sound during propagation outdoors (ISO, 1996)
- comparison of predicted levels with agreed noise limits

650 Advice will be sought on whether measurements of background noise levels will be necessary.

6.9.4 Potential Impacts

651 Potential impacts on in-air noise which will be investigated are:

- construction (may also apply during decommissioning)
  - impacts on recreational users of the area
  - noise disturbance to residential populations
- operation
  - operational noise from wind turbines

6.9.5 Cumulative Assessment

652 If required, a cumulative assessment would be completed.

6.9.6 Mitigation

653 Noise during construction could be managed by the implementation of a site construction policy and, as far as is possible, minimising vessel traffic levels at the construction site.

6.10 Energy and Emissions

6.10.1 Introduction

654 In their Annual Statement (DECC 2010), DECC reports that it is likely that demand for electricity will double over the coming forty years, as a result of the need to electrify large parts of the heat and transport sectors. Further, for the UK to meet its obligations on reducing emissions of greenhouse gases, the electricity being consumed will need to be almost exclusively from low carbon sources. In the first quarter of 2010 nearly 80 % of the UK's electricity was generated by burning gas and coal. This needs to change and, as the Statement sets out, offshore wind will be crucial to delivering the UK's renewable and low carbon targets.

655 This project will be a small, but important, part of delivering a reduction in greenhouse gas emissions due to the displacement of fossil fuel use. Quantification of this will however depend on assumptions regarding the nature of the generating capacity it replaces and will be addressed in the EIA.

6.10.2 Baseline Information

656 The construction and operation of EOWDC would not significantly increase the overall CO_2, SO_x, NO_x and other pollutants within the project site area.

6.10.3 Proposed Scope of Assessment

657 The EIA will consider the current electricity generation mix and assess what greenhouse gas savings could be made. No further assessment is proposed.

6.10.4 Potential Impacts

658 Potential impacts during construction and decommissioning would be addressed through standard mitigation techniques, which are to be agreed as part of an Environmental Management Plan (EMP) for the construction phase. Potential impacts from vessels used during maintenance of the wind turbines may arise during the operation of the wind farm.

6.10.5 Cumulative Impacts

659 Cumulative impact between our project and other projects in respects of energy and emissions issues are not anticipated.

6.11 Electromagnetic Interference

6.11.1 Introduction

660 Provided careful attention is paid to siting, wind turbines should not cause any significant problems due to electromagnetic interference. Wind farms have the potential to cause adverse effects on communication systems which use electromagnetic waves as the transmission medium (for example, television, radio or microwave links).

6.11.2 Baseline Information

6.11.2.1 Television Reception

661 An on-line tool to estimate potential television interference provided by the BBC indicates that no households would be affected.

6.11.2.2 Microwave and Other Telecommunications

662 Contact was made with Ofcom regarding the proposal and information on the site centre and the radius of the development was submitted.

663 Ofcom responded that there are currently no fixed link ends within or fixed paths that cross the site in respect of microwaves.

664 For scanning telemetry the information was passed to both the Joint Radio Company (JRC) and Atkins Ltd both of whom responded with no objection to the proposal.

6.11.3 Proposed Scope of Assessment

665 Relevant organisations will be contacted again prior to consent if necessary.

6.11.4 Potential Impacts

666 Wind turbines can cause electromagnetic interference (EMI) by two means:

- physical interference
- electrical interference

6.11.5 Mitigation

667 If there are any impacts to television signals there are several solutions available that which have been used successfully at other wind farms, for example realigning aerials, fitting better aerials or the use of a digital service.

6.12 Other Marine Users

668 This section of the Environmental Statement will consider other marine users in the area that could be potentially affected by the development. Other marine users are shown on Figure 12.

669 It is likely to consider the following activities:

- existing subsea cables and pipelines
- oil and gas installations
- marine dredging areas and disposal sites
- salmon fisheries
- unexploded ordnance

6.12.1.1 Existing Cables and Pipelines

670 There are two telecommunications cables west of and close to EOWDC and it is therefore possible that crossings may be required. The design of any crossing will be agreed with the cable/pipeline owner/operator to ensure that integrity of all the assets is maintained.

6.12.1.2 Oil and Gas Installations

671 There are currently no oil and gas fields in the area of the proposed development nor is there any related infrastructure. The closest pipelines are gas pipelines entering into St Fergus Gas Terminal, north of Peterhead. Consequently, there will no impact on oil and gas installations from the proposed project.

6.12.1.3 Dredging and Disposal site

672 There are currently only two licensed dredge areas in Scotland (Scottish Executive, 2006) neither are located within the study area. Ongoing dredging activities occur in Aberdeen harbour. The quantity of dredged material and the disposal sites are to be confirmed and will be addressed within the ES.

673 There is a disused explosive dumping ground approximately 6.4 km from the project site.

6.12.1.4 Salmon Fisheries

674 There are a number of salmon fisheries along the coast between the river Don and the Ythan Estuary (Figure 12). No wind turbines are proposed within these areas, however, consultation will take place with the associated Fishery boards.

6.12.1.5 Unexploded Ordnance

675 There is a potential for unexploded ordnance to be the found on the wind farm site and in the surrounding area. There was a study commissioned by the project in 2007 (Bactec, 2007) to look at the risk of unexploded ordnance. A further study will be commissioned due to the change in site location.

6.12.2 Proposed Assessment

676 The effect of the wind farm on the above will be considered in the individual impact assessments previously discussed in this document.

7 CONSULTATIONS

677 The information provided in this document is designed to help consultees and stakeholders comment on the assessment approach outlined, raise other issues of perceived concern, provide further information and, where necessary, advise on alternative methods of assessment.

678 Below is a list of consultees to whom this scoping report has been sent. Suggestions from other bodies of any groups, organisations or individuals not on the list would also be welcome.

List of Statutory Consultees to Marine Scotland
Scottish Natural Heritage (SNH)
Scottish Environment Protection Agency (SEPA)
Aberdeen City Council
Aberdeenshire Council
Fisheries Committee
Association of Salmon Fishery Boards
British Telecom (Radio Network Protection Team)
Civil Aviation Authority (CAA)
Chamber of Shipping
The Crown Estate
Defence Estates
Health and Safety Executive (HSE)
Joint Radio Company (JRC)
Maritime and Coastguard Agency
Marine Safety Forum
Marine Scotland
NATS
Northern Lighthouse Board (NLB)
Royal Yachting Association
RSPB
Scottish Canoe Association
Scottish Fisherman's Federation
Scottish Fisherman's Organisation

List of other Consultees who will be informed of this report
Aberdeen Harbour Board
Aberdeen International Airport
Associated British Ports (ABP)
Atkins Ltd
Scottish Sub Aqua Club
Aberdeen Chamber of Commerce
COWRIE
DEFRA Marine Consents Unit
East Grampian Coastal Partnership
Scottish Federation of Sea Anglers
Friends of the Earth Scotland
Greenpeace
Joint Nature Conservation Committee (JNCC)
Local Fisherman's Organisations
Local Sailing Clubs
The Moray Firth Partnership
National Grid – Gas Distribution
National Trust For Scotland
Ofcom
Oil and Pipelines Agency
Receiver Of Wreck
Royal National Lifeboat Institution
Scottish Wildlife Trust (SWT)
Scottish and Southern Energy Plc
Scottish Water
Shell
Trinity House
University of Aberdeen
Visit Scotland

9 APPENDIX

9.1 Calculations

Based on RenewableUK's calculation for wind energy statistics 100 MW installed capacity is estimated to produce about 260 GWh electricity per year (100 MW * 0.3 capacity factor * 8760 h/yr = 262,800 MWh ie 263 GWh).

Please note that this assumes a capacity factor of 30 %, however in the offshore environment it is likely to be higher which would give a greater production of electricity. The following is stated by RenewableUK: "This is only an average estimation given that in many places, particularly Scotland and offshore, the wind speeds are higher leading to a greater electricity production per turbine, as power output is a cube of the wind speed." (http://www.bwea.com/edu/calcs.html)

According to RenewableUK an average UK household makes use of 4,700 kWh per year for household electricity. This means that 55,300 households can get their household electricity from EOWDC (260 GWh / 4,700 kWh = 55,319 ie 55,300 households).

Share of households that would have been provided with electricity from the EWODC in 2008: 55,300/102,900[3]= 53 %

Estimated share of households provided with electricity from the EOWDC in 2013: 55,300/108,150 = 51 %

[3] This assumes number of households in Aberdeen was 102,900 in 2008. This is based on the "Household Projections for Scotland 2008-based" from the General Register Office for Scotland (2010).

Fao D. Rodger

Dear Sir

Aberdeen Offshore Windfarm – Scoping Report

I refer to the above matter and your letter dated 20 August 2010. Thank you for the opportunity to comment on the above.

It is unclear what is meant by “onshore deployment facilities” as referred to at para 50. It is noted at para 51 that the report only deals with the offshore elements of the project. It should be noted that separate planning permission will be required for the onshore elements of the project from the relevant planning authority (e.g. substation / transmission lines). Given the integral and essential nature of the onshore elements to the project as a whole, it is recommended that they be considered as part of a robust EIA process for the wider project. This has the benefit of potentially avoiding the need for undertaking a separate EIA, as well as enabling a holistic approach to evaluation of the project impacts. It is recommended that scope of the ES should include consideration of the options for the routing of the cable connection, the location of the substation and related environmental and visual impacts, including the need for mitigation measures such as grounding of cable connections to the grid and provision of landscape measures such as tree planting. You may wish to request a screening opinion regarding the specific onshore elements from the relevant planning authority.

It is suggested that the scope of the ES also be expanded to consider the possible indirect environmental, economic and social benefits of the proposed development to the Aberdeen area resulting form the implementation of a community fund. I would appreciate clarification of what specific mechanism is proposed to ensure that such potential community benefits for the City of Aberdeen may be delivered.

As regards consultees, it is recommended that you include Scottish Enterprise (Grampian), UKOOA and North East Scotland Biological Records Centre (Nesbrec), You may also wish to contact relevant technical specialists within the Council directly (e,g, Aftab Majeed, Environmental Planner; Andrew Gilchrist, Environmental Health and Judith Stones, Archaeologist).

I trust the above comments are of some assistance and look forward to further involvement regarding this project. Should you require any clarification regarding the above, please contact me directly.

Yours faithfully

Robert Forbes
Senior Planning Enforcement Officer

Dear Sir

Response to Scoping Report for European Offshore Wind Deployment Centre

Aberdeen Harbour Board welcomes the development of the European Offshore Wind Deployment Centre off Black Dog and is very interested in becoming involved in providing quayside and other facilities for the Centre's development and ongoing operational phase.

There are, however, several concerns regarding the proposal outlined in the scoping report and these are listed below:

1. Due to the high level of shipping activity both using Aberdeen Harbour and passing traffic it is essential that the location of the EOWDC does not change from that proposed. For the same reason no additional turbines or other structures should be added outside the currently proposed footprint in the future unless it is to the north.

2. The proposed cable run connecting the EOWDC to the shore currently passes through the Maritime and Coastguard Agency designated anchorage. This area is in frequent use and cannot safely be reduced in size. An alternative route for the cables should be located at a safe distance from the anchorage allowing for the possibility of a vessel dragging anchor.

3. Has sufficient information been obtained to establish the route and installation of the electricity cables in respect of the highly mobile seabed which can be subject to re-suspension throughout the tidal cycle or under stormy conditions?

4. Has modelling and monitoring been done on the impact of the turbines on the dynamic seabed? Scour and erosion are possible around the base of the turbine and if this were to increase the material in suspension it could impact on the dredging regime at Aberdeen Harbour and the beach profile of Aberdeen beach.

I trust these concerns are self explanatory, however, should you require further information please do not hesitate to contact me.

Yours sincerely

Colin Parker

Dear David

European Offshore Wind Deployment Centre – EIA scoping report

Thank you for your letter dated 20th August,2010.

We have studied this wind farm proposal with respect to EMC and related problems to BT point-to-point microwave radio links.

The conclusion is that, the Wind farm Project indicated should not cause interference to BT's current and presently planned radio networks.

Therefore BT will not be providing comments on the report

Dear Mr Sutherland

Proposed European Offshore Wind Deployment Centre Wind Turbine Development – Scoping Opinion Comment

Thank you for your recent correspondence relating to the proposed European Offshore Wind Deployment Centre wind turbine development. You sought related Civil Aviation Authority (CAA) comment related to the associated Scoping Report (SR); I trust the following is useful.

As alluded to with the documentation provided, like any wind turbine development, the proposed subject development has the potential to impact upon aviation-related operations; the Department for Trade and Industry (DTI – now the Department for Energy and Climate Change)-sponsored document 'Wind Energy and Aviation Interests' and Civil Air Publication 764 refer[1]. The related need to establish the scale of the potential impact of the European Offshore Wind Deployment Centre development is evident.

Having reviewed the SR and in particular the site in question, I can advise that the development might have a potential impact upon operations associated with Aberdeen Airport and note that the SR indicates ongoing consultation. All parties should be aware that aerodrome safeguarding responsibility rests with the aerodrome licensee. Any related Environmental Statement, or equivalent, would be expected to acknowledge and quantify any potential impact upon the Airport-related operations and, where applicable, detail appropriate mitigation.

Similarly, as will all wind turbine developments of this scale, the Environmental Statement will need to detail the associated viewpoints of both NATS and Ministry of Defence (MoD). To that end, I note the SR also details the ongoing consultation with these organisations and the outcomes of these and any associated mitigations as agreed should be reported in the Environmental Statement.

Not highlighted in the Scoping Report is the issue of Aviation Warning Lighting. The subject wind farm will fall under the requirements of Air Navigation Order 2009 Article 220 and this will need to be acknowledged in the Environmental Statement. Given the intensity of helicopter operations in the area, I consider this to be a significant area.

With respect to Landfall, the Environmental Statement may need to address the impact on aviation of power line routeing between Landfall and the onshore substation(s) if the power lines are a significant height above ground.

[1] These documents are available at http://www.bwea.com/pdf/Wind-Energy-and-aviation-interim-guidelines.pdf and http://www.caa.co.uk/docs/33/Cap764.pdf respectively. Please note that after a full review CAP 764 was re-issued on 12 February 2009.

Telephone 020 7453 6545 Fax 020 453 6565 marks.smailes@caa.co.uk

Additionally, if more generically, all parties should be aware that:

- International aviation regulatory documentation requires that the rotor blades, nacelle and upper 2/3 of the supporting mast of wind turbines that are deemed to be an aviation obstruction should be painted white, unless otherwise indicated by an aeronautical study. It follows that the CAA advice on the colour of wind turbines would align with these international criteria.

- There is a civil aviation requirement in the UK for all structures over 300 feet high to be charted on aviation maps. Should this development progress and the 300 feet height be breached the developers will need to provide details of the development to the Defence Geographic Agency.

- The number of pre-planning enquiries associated with windfarm developments has been significant. It is possible that the proliferation of wind turbines in any particular area might potentially result in difficulties for aviation that a single development would not have generated. It is, therefore, not necessarily the case that, because a generic area was not objected to by the aviation industry, future, similarly located potential developments would receive the same positive response. There is a CAA perceived requirement for a co-ordinated regional wind turbine development plan, aimed at meeting renewable energy priorities, whilst addressing aviation concerns and minimising such proliferation issues. Indeed, this may be an area where the centre may be able to provide some research.

Any associated Environmental Statement should mention and, where applicable, address the issues highlighted above.

Yours sincerely

15th December 2010

Dear Edwina

ELECTRICITY ACT 1989
THE ELECTRICITY WORKS (ENVIRONMENTAL IMPACT ASSESSMENT) (SCOTLAND) REGULATIONS 2000

VATTENFALL AND ABERDEEN RENEWABLE ENERGY GROUP (AREG):
ENVIRONMENTAL IMPACT ASSESSMENT SCOPING DOCUMENT, EUROPEAN OFFSHORE WIND DEPLOYMENT CENTRE (EOWDC), ABERDEEN

Thank you for giving Marine Scotland Licensing Operations Team (MS-LOT) the opportunity to comment on the Environmental Impact Assessment (EIA) Scoping Report. MS-LOT is the licensing authority for the above Act which extends seaward of the mean low water spring mark. The proposal is for a commercially operated windfarm deployment centre which will hold 11 turbines and an ocean laboratory. The EOWDC site is located 2km from the Aberdeenshire coast between Aberdeen in the south and Balmedie in the north, with a lease area of 20km^2. The ocean laboratory will be consented separately.

Recently, offshore wind has focussed on large scale windfarm sites leased by The Crown Estate for Round 3 and Scottish territorial waters. These will involve the installation of a large number of turbines over several years to ensure the UK and Scottish Governments meet their commitments to generating electricity from renewable sources. Issues associated with cumulative and in combination effects of these developments will arise, MS-LOT wishes to have further discussions with the developers on this issue, at a recent meeting EOWDC indicated that a separate document addressing these matters was being drafted. The scoping document clearly states that the developer will apply for Town and Country planning for the onshore works and will not be incorporating any of the onshore infrastructure works into the EIA for the wind farm.

The definition of the ‘Rochdale envelope’ approach described in Section 3.4.1 is consistent with all large offshore wind developments. This allows developers to describe their projects in a hypothetical manner by fully assessing any impacts associated with all technology that may be considered on the site. However, MS-LOT understands that only one technology described within the EIA will be progressed towards commercial deployment. The EOWDC project is proposing to use more than one type of foundation i.e. there are 6 described in the scoping document. Therefore, the ‘Rochdale envelope approach’ should be applied differently; the assessment should include the interactions and cumulative impacts between each different type of foundation. However, if EOWDC do intend using the same foundation base throughout then the standard approach could be adopted. Due to the description of the ‘Rochdale envelope’ approach described above; points 56 – 58, within the scoping document, cannot be considered without the above assessment. Therefore, indicative layouts should be presented within the EIA. MS-LOT are available to discuss this issue in greater detail.

The same is also true for the actual turbine(s), the EIA can be drafted on a hypothetical machine with a maximum height to the tip of 195m above Lowest Astronomical Tide (LAT), the technology going forward on the site has been described as between 4-10MW, the 4MW has a maximum hub height of 100m and the 10MW turbine has a max hub height of 120m above LAT. The final design will dictate the maximum rotor diameter and an assessment should be carried out on the worst case scenario.

At the meeting on the 13/05/2010 (please refer to the minutes), EOWDC were advised by MS-LOT on the inflexibility of the Section 36 consent and that a generic EIA for the site should be undertaken. Separate assessments for each foundation could then be undertaken and inserted as an appendix when developers sign up to use the site. It was understood, by MS-LOT, at the time of the meeting, that each type of foundation chosen would require a separate consent, thus a single Section 36 consent would not cover the whole installation. MS-LOT has subsequently reviewed both the Section 36 legislation and its position in regard to the proposal set out in the scoping document and are of the opinion that a degree of flexibility might exist when considering the consenting strategy. MS-LOT would like to discuss this matter with you early in the New Year .

Inter array cabling

Installation methodologies must be detailed as the FEPA/Marine licence applications require a list of deposits. Point 74.

Construction timelines

Phase 1 – 4 x turbines year 1 (2012)
Phase 2 – 7 x turbines year 3 (2014)

MS-LOT requires a further update on the construction timeline and potential funding constraints, a further meeting should be scheduled to discuss the above information. EOWDC should note that mitigation measures for marine mammals will be included in the conditions and at this stage we warn you that a 24hr working window might not be possible as the Marine Mammal Observer onboard will not be able to identify marine mammals in the dark. However, we can discuss this aspect further and we are prepared to be open minded on the outcome of those discussions.

The scoping document highlighted (point 70) that a major turbine service would be required every 12 months. However, MS-LOT are not aware that the proposed technology is fully understood. Therefore please notify MS-LOT if this assessment is based on historical knowledge, and provide references. It was also stated that ‘gearbox oil changes are required every 5 years’, EOWDC will be required to provide method statements and contingency plans for these operations.

Section 36A

We understood that this does not apply in Scottish waters and therefore there are no provisions through section 36 for safety areas around the turbines, however, recent discussions with colleagues indicate that this situation might have changed. We will report back to you as soon as possible.

3.2 Marine Licensing

- MS-LOT will continue to administer all of the consents after April 2011.
- The Environmental Statement (ES) is the section 36 application.

Appropriate Assessment (AA)

In order for the AA to be carried out by the competent authority the installation technologies would have to be known in order to assess the impacts.

Marine Scotland Science (MSS)

The following comments have been received from MSS colleagues.

The Environmental Impact Assessment (EIA) must informatively and clearly identify the key impacts associated with the EOWDC. Within the EIA all useful sources of existing surveys and studies need to be specified.

Proposed survey techniques

The scoping document appears to have identified the potential key impacts with regard to the development. Useful sources of data from existing surveys and studies have been identified but these may not cover the whole area. However, the proposed combination of video survey and benthic grabs is essential to adequately determine the dominant habitat types and species present in the development area, large epifauna are generally under sampled by grab and trawl sampling.

Marine ecology

The Benthic Habitats Para 216 requires the reference for the biotope names to be inserted. Clarification is required within paragraph 230 as single grabs are now being collected from each position, does this mean that the sampling strategy is now considered randomly stratified; please confirm.

Sedimentary shores on the east coast Para 244: MS-LOT would like to highlight that Collieston beach is bounded by a breakwater/pier and the meiofaunal distributions may reflect this artificial situation. Therefore the sediment and the fauna distributions are localised for this area and may not represent soft sediment shores from the area of interest. Beach profiling to quantify erosion / modification should be considered, and the outcome discussed with MS-LOT prior to any action being taken., The name "*diversicolor*" should be rendered in italics.

Coastal processes

Sedimentation/erosion patterns on Aberdeen Beach are influenced by the presence of coastal structures (near shore rock structures and timber groynes), and beach re-charge. Using beach profiles taken by the University of Aberdeen may not be representative of the ongoing processes at the beach near the development site, and MS –LOT are of the opinion that a local survey would give more confidence in the interpretation of current processes and the potential impact of the development on these processes. In case Aberdeen Offshore Wind Farm Ltd has not yet been in contact with Aberdeen University regarding this data, the Aberdeen Beach project is managed by Ms. Amy Taylor and Prof. T. O'Donoghue at the School of Engineering.

Figure 11: The Ythan estuary is not in the area considered for far-field effects. Should there be significant changes in the sediment mobility in the far-field area, then this could have potentially important effects on the sedimentation/erosion patterns of the estuary. Extending the domain in the first instance, could avoid having to do this at a later stage should sediment mobility become an important issue. Again, we request you consider this point and refer to MS-LOT.

Construction

Details of any noise pollution resulting from any construction activity and any associated potential effects on cetaceans/pinnipeds/fish will be required. Noise assessments should take into consideration background noise, including vibration produced from ships' engines, piling hammers and auguring operations during the construction of turbine foundations. Considerable studies have already been conducted on cetaceans in the Moray Firth area, but the particular cause for concern is the potential additional extensive Round 3 wind farm site to the North of this development.

The proposed development will need to consider, in the first instance through a desk study, potential impacts on migratory fish including salmon (*Salmo salar*), sea trout (*Salmo trutta*), sea lamprey (*Petromyzon marinus*), river lamprey (*Hyperoplus lanceolatus*)and sandeels (*Ammodytes marinus*) during all phases of the project. The potential for offshore renewable projects to impact on migratory fish will vary depending on the design and location of the development in relation to the migration routes of adults and juveniles. Potential impacts may include physical or avoidance reactions at both the individual and population level and there may also be avoidance due to electromagnetic sensitivity at both adult and juvenile stages.

In cases where there is uncertainty over potential impacts it may be necessary for the developer to implement a monitoring strategy to assess the influence on salmonid fish populations. The expected levels of noise production must be identified in the ES and derived by using published literature, decide what impact, if any, this will have on fish movements through the area. Will it result in avoidance of the area and, if so, what does this mean for migrating fish. Please refer to Appendix A and after consideration get in contact to MS-LOT.

Inshore fisheries

From a marine fisheries perspective the following comments are provided on the range of issues and impacts identified. The assessment methodologies are proposed and sources of data identified, indicating any perceived information gaps or inaccuracies.

Section 5.3 Fish, shellfish and elasmobranches

The scoping report adequately identifies fish (commercial and non commercial), shellfish and cephalopod species known to and / or likely to occur in the area and the potential impacts of the development on these species.

Species present include some threatened and/or declining species (on OSPAR list) and UK Biodiversity Action Plan (BAP) priority species. The latter have not however been specifically identified. None of the species are unique to the area. The scoping report includes a recorded observation of a basking shark in the vicinity of the proposed development, basking sharks are protected under Schedule 5 of the Wildlife and Countryside Act thus it is a criminal offence to cause any form of disturbance to them. MS-LOT should be informed if any protected species are recorded on the site.

The report includes some reproductions of spawning and nursery grounds data from the fisheries sensitivity maps (Coull et al 1998). The developers are aware that these represent very broad scale (indicative) distributions and that more detailed and site specific information may be available elsewhere (proposal for desk studies). These maps are in some cases misleading, Nephrops distribution for example is limited by suitable (mud) habitat - both juveniles and adults live in burrows in the mud, emerging to feed and breed. MS – LOT is not aware of any specific spawning or nursery grounds within the site.

The colour reproduction of the maps, particularly the colours of the legend compared to the mapped areas make them very difficult to interpret and, in the case of Fig 5.1, render the maps misleading. If they are to be reproduced in the EIA this should be rectified.

In relation to the underwater noise impacts, MS-LOT note that no specific data will be collected on noise effects (associated with piling / installation). MS-LOT concur with the proposal that the current information is adequate for evaluating impacts of the development on fish.

Studies on possible reef effects are proposed, MS-LOT encourages this approach but recommend that it will require robust baseline information. The potential survey methodology plans should identify both mobile and more sedentary species present for all and/or part of the year. The report states there is already an established 'baseline' of data. If these data are from historic surveys it may require updating or expanding.

It is indicated in Section 5.8 that potential impact of Electromagnetic Fields (EMF) will be assessed as part of the EIA process using the results of the Cowrie studies referenced. Although this is probably adequate, given the relatively limited extent of this development and lack of others in the vicinity (limited potential for cumulative effects) results of other relevant research should be considered.

Section 6.1.4.2 fishing vessels

Few vessels appear to transit this area and restrictions during the construction phase are unlikely to cause particular problems. Discussion with fishing stakeholders about any action required appears to be reasonable.

An assessment of the cumulative impacts of fishing in association with other marine activities in the area should be addressed as indicated.

Section 6.6 commercial fisheries

Sources of 'baseline' information on fishing in the area of the proposed wind array and possible impacts on fishing have been adequately considered in the scoping document. MS-LOT would like to see the updated versions of the earlier reports. MS-LOT concurs that with mitigation residual effects on commercial fishing are likely to be minor / negligible.

MS-LOT note, however, that the area of the proposed development does not coincide with suitable habitat for *Nephrops* - interference with *Nephrops* fishing is therefore unlikely to be a major issue.

Consultation with commercial fishermen has to date been through the Scottish Fishermen's Federation (SFF). Although this is appropriate, and the SFF should continue to be consulted, the developers should be aware that many inshore fishermen in Scotland are non-affiliated i.e.

not members of Associations represented by the SFF. Some form of local consultation should therefore be considered.

Cumulative and in combination effects

A cumulative and in combination impact assessment is also a requirement of the Habitats Regulations Appraisal (HRA) with respect to the designated Special Areas of Conservation (SAC) and Special Protection Areas (SPA) which may be affected. As a result, the cumulative and in combination assessment of impacts on the marine mammals and seabirds of the Moray Firth's European designated sites will be an important consideration within the EIA process. Other cumulative effects, which consider the impacts arising from the proposed EOWDC wind farm in the context of other non wind farm developments (e.g. oil and gas operations) and activities (e.g. the shipping and fishing industries) will also be considered in the course of the EIA. MS-LOT await a document that addresses these aspects and, once it has been reviewed, may wish to update this advice.

Cable route and layout

Marine Scotland would like to emphasise that all developers are required to include maps, 'baseline' data and any details associated with the cable route within their ES as it is incorporated into the overall footprint of the works.

Throughout the document there is reference to Fisheries Research Services (FRS), Marine Scotland, and the Scottish Fisheries Protection Agency (SFPA) as data sources for all 'baseline' assessments. Developers should be aware that as of April 1 2009 - FRS became Marine Scotland Science, SFPA became Marine Scotland Compliance and that Marine Scotland is a Directorate (not an Executive agency) of Scottish Government.

Thank you for consulting with MS-LOT on this matter.

Yours sincerely

Fiona Thompson
Marine Scotland

Appendix A

Scoping comments in relation to information requirements on diadromous fish of freshwater fisheries interest

Offshore renewable developments have the potential to directly and indirectly impact diadromous fish of freshwater fisheries interest including Atlantic salmon, anadromous brown trout (sea trout) and European eel. These species use the coastal areas around Scotland for feeding and migration and are of high economic and / or conservation value. As such they should be considered during the EIA process. Developers should also note that offshore renewable projects have the potential to impact on fish populations at substantial distances from the development site.

In the case of Atlantic salmon information will be required to assess whether there is likely to be any significant effect of developments on rivers which are classified as Special Areas of Conservation (SAC's) for Atlantic salmon under the Habitats Directive. Where there is the potential for significant impact then sufficient information will be required to allow Marine Scotland to carry out an Appropriate Assessment.

In order that Marine Scotland is able to assess the potential impacts of marine renewable devices on diadromous fish and meet legislative requirements the developer should consider the site location (including proximity to sensitive areas), type of device, and the design of any array plus installation methodology. Specifically we request that developers provide information in the following areas:

1. Identify use of the proposed development area by diadromous fish (salmon, sea trout and eels)

a. Which species use the area? Is this for feeding or migration?
b. At what times of year are the areas used?
c. In the case of salmon and sea trout what is the origin / destination of fish using the area?

2. Identify the behaviour of fish in the area

a. What swimming depths do the fish utilise
b. Is there a tendency to swim on or offshore

3. Assess the potential impacts of deployed devices on diadromous fish during deployment, operation and decommissioning phases. Potential impacts could include:

a. Strike
b. Avoidance (including exclusion from particular rivers and subsequent impacts on local populations)
c. Disorientation that could potentially affect behaviour, susceptibility to predation or by-catch, or ability to locate normal feeding grounds or river of origin
d. Delayed migration

4. Consider the potential for cumulative impacts if there are multiple deployments in an area.

5. Assess 1-4 above to determine likely risk.

a. If there are insufficient data to determine use of the development area, these should be obtained

b. If there are insufficient data on the origin / destination of fish using the area then these should be obtained

c. Where it is not possible to obtain site specific data, the developer should make a convincing argument why this is the case and apply appropriate expert judgement based on published information.

6. If there is any remaining doubt as to the potential impacts of a particular development, then the developer should recommend a scientifically robust monitoring strategy to assess any impacts either on stocks as a whole, or on particular rivers as necessary.

Marine Scotland Science has just completed a review of migratory routes for Atlantic salmon, sea trout and eels relevant to Scotland, which should be available in 2011. This will assist the developers in identifying what pre-existing information is available and what supplementary site specific data will be required.

The Scottish Government

EUROPEAN OFFSHORE WIND DEVELOPMENT CENTRE (EOWDC) – ABERDEEN

Scoping Opinion

Contents

THE ELECTRICITY WORKS (ENVIRONMENTAL IMPACT ASSESSMENT) (SCOTLAND) REGULATIONS 2000.

SCOPING OPINION FOR THE PROPOSED SECTION 36 APPLICATION FOR THE EOWDC OFFSHORE WINDFARM, ABERDEEN

1. Introduction

I refer to your letter of requesting a scoping opinion under the Electricity Works (Environmental Impact Assessment) (Scotland) (EIA) Regulations 2000 enclosing a scoping report.

Any proposal to construct or operate an offshore power generation scheme with a capacity in **excess of 1 megawatt** requires Scottish Ministers' consent under section 36 of the Electricity Act 1989.

Schedule 9 of the Act places on the developer a duty to "have regard to the desirability of preserving the natural beauty of the countryside, of conserving flora, fauna and geological and physiological features of special interest and of protecting sites, buildings and objects of architectural, historic or archaeological interest". In addition, the developer is required to give consideration to the Scottish Planning Policy on Renewable Energy other relevant Policy and National Policy Planning Guidance, Planning Advice Notes, the relevant planning authority's Development Plans and any relevant supplementary guidance.

Under the Electricity Works (Environmental Impact Assessment)(Scotland)(EIA) Regulations 2000, Scottish Ministers are required to consider whether any proposal for an offshore device is likely to have a significant effect on the environment. Scottish Ministers have considered your request for an opinion on the proposed content of the Environmental Statement (ES) in accordance with regulations and in formulating this opinion Scottish Ministers have consulted with the relevant organisations.

Please note that the EIA process is vital in generating an understanding of the biological and physical processes that operate in the area and that may be impacted by the proposed offshore wind farm. We would however state that references made within the scoping document with regard to the significance of impacts should not prejudice the outcome of the EIA process.

It is important that any devices to exploit renewable energy sources should be accompanied by a robust assessment of its environmental impacts. The assessment should also consider how any negative environmental impacts could be avoided or minimised, through the use of mitigating technologies or regulatory safeguards, so that the quality and diversity of Scotland's wildlife and natural features are maintained or enhanced. Scottish Ministers welcome the commitment given in the report that the EIA process will identify mitigation measures in order to avoid, minimise or reduce any adverse impacts. Marine Scotland Licensing Operations Team (MS-LOT) would suggest that the range of options considered should be informed by the EIA process in order that these objectives can be achieved. Consultation with the relevant nature conservation agencies is essential and it is advised that this is undertaken as appropriate.

2. Aim of this Scoping Opinion

Scottish Ministers are obliged under the EIA regulations to respond to requests from developers for a scoping opinion on outline design proposals.

The purpose of this document is to provide advice and guidance to developers which have been collated from expert consultees whom the Scottish Government has consulted. It should provide clear advice from consultees and enable developers to address the issues they have identified and address these in the EIA process and the ES associated with the application for section 36 consent.

3. Description of your development

From your submitted information it is understood that Aberdeen Offshore Wind Farm Limited (AOWFL) is proposing construct and operate an offshore wind farm and deployment centre off the coast of Aberdeen. The site will be known as the European Offshore Wind Deployment Centre (EOWDC). The maximum electrical output, as governed by the crown estate lease conditions is 100 Megawatts (MW) the site is located approximately 2 to 4.5km east of Blackdog, Aberdeenshire. The development can accommodate up to 11 turbines with a variety of generating capacities. The turbine layout and size will undergo an iterative design process as the EIA progresses.

4. Land Use Planning

The Scottish Government's planning policies are set out in the National Planning Framework, Scottish Planning Policy, Designing Places and Circulars.

The National Planning Framework is the Scottish Government's Strategy for Scotland's long term spatial development.

Scottish Planning Policy (SPP) is a statement of Scottish Government policy on land use planning and contains:

- the Scottish Government's view of the purpose of planning,
- the core principles for the operation of the system and the objectives for key parts of the system,
- statutory guidance on sustainable development and planning under Section 3E of the Planning etc. (Scotland) Act 2006,
- concise subject planning policies, including the implications for development planning and development management, and
- The Scottish Government's expectations of the intended outcomes of the planning system.

Other land use planning documents which may be relevant to this proposal include:

- PAN 42: Archaeology–Planning Process and Scheduled Monument Procedures
- PAN 45: 2002 Renewable Energy Technologies
- PAN 50: Controlling the Environmental Effects of Surface Mineral Workings
- PAN 51: Planning, Environmental Protection and Regulation
- PAN 56: Planning and Noise
- PAN 58: Environmental Impact Assessment
- PAN 60: Planning for Natural Heritage
- PAN 62: Radio Telecommunications
- PAN 68: Design Statements
- PAN 69: Planning and Building Standards Advice on Flooding
- PAN 75: Planning for Transport
- PAN 79: Water and Drainage
- Marine Guidance Note 371 (M)
- The Highland Structure Plan
- West Highland and Islands Local Plan (WHILP).

5. Natural Heritage

Scottish Natural Heritage (SNH) has produced a service level statement (SLS) for renewable energy consultation. This statement provides information regarding the level of input that can be expected from SNH at various stages of the EIA process. Annex A of the SLS details a list of references, which should be fully considered as part of the EIA process. A copy of the SLS and other vital information can be found on the renewable energy section of their website – www.snh.org.uk

6. General Issues

Economic Benefit

The concept of economic benefit as a material consideration is explicitly confirmed in the consolidated SPP. This fits with the priority of the Scottish Government to grow the Scottish economy and, more particularly, with our published policy statement "Securing a Renewable Future: Scotland's Renewable Energy", and the subsequent reports from the Forum for Renewables Development Scotland (FREDS), all of which highlight the manufacturing potential of the renewables sector. The application should include relevant economic information connected with the project, including the potential number of jobs, and economic activity associated with the procurement, construction operation and decommissioning of the development.

7. Contents of the Environmental Statement (ES)

Format

Developers should be aware that the ES should also be submitted in a user-friendly PDF format which can be placed on the Scottish Government (SG) website. A description of the methodology used in assessing all impacts should be included.

It is considered good practice to set out within the ES the qualifications and experience of all those involved in collating, assessing or presenting technical information.

Non Technical Summary.

This should be written in simple non-technical terms to describe the various options for the proposed development and the mitigation measures against the potential adverse impacts which could result. Within an ES it is important that all mitigating measures should be:

- Clearly stated;
- Fully described with accuracy;
- assessed for their environmental effects;
- assessed for their effectiveness;
- Their implementation should be fully described;
- How commitments will be monitored; and
- If necessary, how they relate to any consents or conditions.

Given that the layout and design are still developing and evolving, the exact nature of the work that is needed to inform the EIA may vary depending on the design choices. The EIA must address this uncertainty so that there is a clear explanation of the potential impact of each of the different scenarios. It should be noted that any changes produced after the ES is submitted may result in the requirement of further environmental assessment and public consultation if deemed to be significant by the licensing authority.

Baseline Assessment and Mitigation

Refer to Annex 1 for consultee comments on specific baseline assessment and mitigation.

8. Archaeology and Cultural Heritage

General Principles

The ES should address the predicted impacts on the historic environment and describe the mitigation proposed to avoid or reduce impacts to a level where they are not significant. Historic environment issues should be taken into consideration from the start of the site selection process and as part of the alternatives considered.

National policy for the historic environment is set out in:

- Scottish Planning Policy *Planning and the Historic Environment at:* http://www.scotland.gov.uk/topics/built-environment/planning/National-planning-policy/themes/historic
- The Scottish Historic Environment Policy (SHEP) sets out Scottish Ministers strategic policies for the historic environment and can be found at: http://www.historic-scotland.gov.uk/index/heritage/policy/shep.htm

Amongst other things, SPP paragraph 110–112, Historic Environment, stresses that scheduled monuments should be preserved *in situ* and within an appropriate setting and states that developments must be managed carefully to preserve listed buildings and their settings to retain and enhance any special architectural or historic features of interest. Consequently, both direct impacts on the resource itself and indirect impact on its setting must be addressed in any EIA undertaken for this proposed development. Further information on setting can be found in the following document: Managing Change in the Historic Environment http://www.historic-scotland.gov.uk/managing-change-consultation-setting.pdf.

Historic Scotland recommend that you engage a suitably qualified archaeological/historic environment consultants to advise on, and undertake, the detailed assessment of impacts on the historic environment and advise on appropriate mitigation strategies.

Baseline Information

Information on the location of all archaeological/historic sites held in the National Monuments Record of Scotland, including the locations and, where appropriate, the extent of scheduled monuments, listed buildings and gardens and designed landscapes can be obtained from www.PASTMAP.org.uk

Data on scheduled monuments, listed buildings and properties in the care of Scottish Ministers can also be downloaded from Historic Scotland's Spatial Data Warehouse at
http://hsewsf.sedsh.gov.uk/pls/htmldb/f?p=500:1:8448412299472048421::NO
For any further information on those data sets and for spatial information on gardens and designed landscapes and World Heritage Sites which are not currently included in Historic Scotland's Spatial Data Warehouse please contact

hsgimanager@scotland.gsi.gov.uk. Historic Scotland are also available to provide any further information on all such sites.

9. Navigation

The ES should include the following details on the possible impact on navigation for both commercial and recreational craft.

- Collision Risk
- Navigational Safety
- Risk Management and Emergency response
- Marking and lighting of Tidal Site and information to mariners
- Effect on small craft navigational and communication equipment
- Weather and risk to recreational craft which lose power and are drifting
- In adverse conditions
- Evaluation of likely squeeze of small craft into routes of larger
- Commercial vessels.
- Visual intrusion and noise

10. Ecology, Biodiversity and Nature Conservation

Refer to Annex 1 for comments from advisors on ecology, biodiversity and nature conservation.

Species

The ES should show that the applicants have taken account of the relevant wildlife legislation and guidance, namely

- Coast Protection Act 1949 section 34
- Council Directives on The Conservation of Natural Habitats and of Wild Flora and Fauna
- Conservation of Wild Birds (commonly known as the Habitats and Birds Directives)
- Wildlife & Countryside Act 1981
- Nature Conservation (Scotland) Act 2004
- Protection of Badgers Act 1992
- 1994 Conservation Regulations
- Scottish Executive Interim Guidance on European Protected Species
- Development Sites and the Planning System and the Scottish Biodiversity Strategy and associated Implementation Plans

In terms of the SG Interim Guidance, applicants must give serious consideration to/recognition of meeting the three fundamental tests set out in this Guidance. **It may be worthwhile for applicants to give consideration to this immediately after the completion of the scoping exercise.**

It needs to be categorically established which species are present on and near the site, and where, before the application is considered for consent. The presence of protected species such as Schedule 1 Birds or European Protected Species must be included and considered as part of the application process, not as an issue which can be considered at a later stage. Any consent given without due consideration to these species may breach European Directives with the possibility of consequential delays or the project being halted by the EC. Likewise the presence of species on Schedules 5 (animals) and 8 (plants) of the Wildlife & Countryside Act 1981 should be considered where there is a potential need for a licence under Section 16 of that Act.

11. Water Environment

Developers are strongly advised to consult with the Scottish Environment Protection Agency (SEPA), at an early stage. SEPA are the regulatory body responsible for the implementation of the Controlled Activities Regulations (CAR), to identify if a CAR licence is necessary and clarify the extent of the information required by SEPA to fully assess any licence application.

All applications (including those made prior to 1 April 2006) made to Scottish Ministers for consent under section 36 of the Electricity Act 1989 to construct and operate a electricity generating station are required to comply with new legislation. In this regard MS-LOT will be advised by SEPA and will have regard to this advice in considering any consent under section 36 of the Electricity Act 1989.

SEPA produces a series of Pollution Prevention Guidelines (PPG), several of which should be fully utilised in preparation of an ES and during project development. These include SEPA's guidance note PPG6: Working at Construction and Demolition Sites, PPG5: Works in, near or liable to affect Watercourses, PPG2 Above ground storage tanks, and others, all of which are available on SEPA's website at http://www.sepa.org.uk/guidance/ppg/index.htm. SEPA would look to see specific principles contained within PPG notes to be incorporated within mitigation measures identified within the ES rather than general reference to adherence to the notes.

Prevention and clean-up measures should also be considered for each of the following stages of the development;

- Construction.
- Operation.
- Decommissioning.

Construction contractors may be unaware of the potential for impacts such as those listed below but, when proper consultation with the local fishery board is encouraged at an early stage, many of these issues can be averted or overcome.

- Increases in silt and sediment loads resulting from construction works.
- Point source pollution incidents during construction.
- Obstruction to upstream and downstream migration both during and after construction.
- Disturbance of spawning beds during construction - timing of works is critical.
- Drainage issues.

- sea bed and land contamination

The ES should identify location of, and protective/mitigation measures in relation to, all private water supplies within the catchments impacted by the scheme, including modifications to site design and layout.

Developers should also be aware of available CIRIA guidance on the control of water pollution from construction sites and environmental good practice (www.ciria.org). Design guidance is also available on river crossings and migratory fish (SE consultation paper, 2000) at http://www.scotland.gov.uk/consultations/transport/rcmf-00.asp.

12. Other Material Issues

Traffic Management

The ES should provide information relating to the preferred route options for delivering equipment etc. via the trunk road network. The EIA should also address access issues, particularly those impacting upon the trunk road network; in particular, potential stress points at junctions, approach roads, borrow pits, bridges, site compound and batching areas etc.

Where potential environmental impacts have been fully investigated but found to be of little or no significance, it is sufficient to validate that part of the assessment by stating in the report:

- the work has been undertaken, e.g. transport assessment;
- what this has shown i.e. what impact if any has been identified, and
- Why it is not significant.

13. General ES Issues

In the application for consent the applicant should confirm whether any proposals made within the ES, e.g. for construction methods, mitigation, or decommissioning, form part of the application for consent.

Consultation

Developers should be aware that the ES should also be submitted in a user-friendly PDF format which can be placed on the SG website. Developers are asked to issue ES directly to consultees. Consultee address lists can be obtained from the Energy Consents Unit. The Energy Consents Unit also requires 8 hardcopies to be submitted for onward distribution.

Where the developer has provided Scottish Ministers with an ES, the developer must publish their proposals in accordance with part 4 of the Environmental Impact Assessment (Scotland) Regulations 2000. Energy consents information and guidance, including the specific details of the adverts to be placed in the press, can be obtained from the Energy Consents website; http://www.scotland.gov.uk/Topics/Business-Industry/Energy/Energy-Consents

Gaelic Language

Where s36 applications are located in areas where Gaelic is spoken, developers are encouraged to adopt best practice by publicising the project details in both English and Gaelic (see also Energy consents website as above).

Ordinance Survey (OS) Mapping Records

Developers are requested at application stage to submit a detailed OS plan showing the site boundary and all turbines, access tracks and onshore supporting infrastructure in a format compatible with the SG's Spatial Data Management Environment (SDME), along with appropriate metadata. The SDME is based around Oracle RDBMS and ESRI ArcSDE and all incoming data should be supplied in ESRI shape file format. The SDME also contains a metadata recording system based on the ISO template within ESRI ArcCatalog (agreed standard used by the SG); all metadata should be provided in this format.

Difficulties in Compiling Additional Information

Developers are encouraged to outline their experiences or practical difficulties encountered when collating/recording additional information supporting the application. An explanation of any necessary information not included in the ES should be provided, complete with an indication of when an addendum will be submitted.

Application and ES

A developer checklist is enclosed with this opinion to assist developers in consideration and collation of the relevant ES information to support their application. In advance of publicising the application, developers should be aware this checklist will be used by the licensing authority in consideration of formal applications.

Consent Timescale and Application Quality

In December 2007, Scottish Ministers announced an aspirational target to process new section 36 applications within a 9 month period, provided a Public Local Inquiry (PLI) is not held. This scoping opinion is specifically designed to improve the quality of advice provided to developers and thus reduce the risk of additional information being requested and subject to further publicity and consultation cycles.

Developers are advised to consider all aspects of this scoping opinion when preparing a formal application to reduce the need to submit further information in support of your application. The consultee comments presented in this opinion are designed to offer an opportunity to consider all material issues relating to the development proposals.

In assessing the quality and suitability of applications, the licensing authority will use the enclosed checklist and scoping opinion in assessment of the application. Developers are encouraged to seek advice on the contents of ES prior to applications being submitted, although this process does not involve a full analysis of the proposals. In the event of an application being void of essential information, the licensing authority reserve the right not to accept the application. Developers are advised not to publicise applications in the local or national press, until their application has been accepted by the licensing authority.

Judicial review

All cases may be subject to judicial review. A judicial review statement should be made available to the public.

Signed
Fiona Thompson

Authorised by the Scottish Ministers to sign in that behalf

Consultee Comments Relating To EOWDC Offshore Windfarm, Aberdeen

The following organisations provided a scoping opinion in relation to the EOWDC Offshore windfarm, Aberdeen

Statutory Consultees

Scottish Natural Heritage (SNH)
Aberdeen City Council
SEPA

Non Statutory Consultees

Marine Scotland
Defence Estates
Health and Safety Executive
RYA Scotland
Marine Safety Forum
Northern Lighthouse Board
Chamber of Shipping
BT Radio Network Protection
Association of Salmon Fishery Boards
Civil Aviation Authority – Airspace
Maritime Coastguard Agency
Joint Radio Company
RSPB
Aberdeen Harbour Board
Transport Scotland
Historic Scotland
Ports and Harbours

SNH Comments

POSITION STATEMENT
In principle, we support the development of marine renewable energy devices where sensitively designed and sited – as set out in SNH Policy Statement 04/01. For this offshore windfarm proposal, we have reviewed the scoping report and our advice is provided in Appendix A, and with respect to Natura sites in Appendices D and E. A summary of the key points is provided below.

Please note the comments in this letter are made without prejudice to any further comments that we may make when consulted on an application for this proposal.

Habitats Regulations

It is important to take into account the range of interests and potential impacts of Natura sites that may need to be considered in relation to regulation 48 of the Conservation (Natural Habitats, &c.) Regulations 1994 as amended, and in particular whether an Appropriate Assessment is required. More detail on the legislative requirements relating to Natura Sites and species is contained in Appendices B and C.

Although data has been collected for some time, this has been for different iterations of the development and when submitted, there will be less than the minimum two years data which we recommend. It is also not clear how much of the data available will relate to the current site and layout. **We strongly recommend** that AOWFL consider in detail how they will prepare the report to inform an Appropriate Assessment, and whether the types and amount of information that will be available to them at the time (both their own data and that from other sources) will be sufficient.

The report to inform an Appropriate Assessment must consider the conservation objectives for each Natura site. We hope that the scoping advice contained within the appendices to this letter and the draft table we provided on 19 January 2009 (for impacts to the Moray Firth and River Dee SACs), provide a useful starting point that AOWFL can develop. We would welcome the opportunity to assist AOWFL by commenting on first a detailed scope of the report to inform an Appropriate Assessment and subsequently a draft. There is a risk that Marine Scotland will not be able to carry out the Appropriate Assessment and draw sufficiently robust conclusions when the application is submitted early next year. A detailed scope would help identify if this is the case and may be used to consider how the consenting process can address this.

Key Points

Some of the key points that we wish to draw out are:

- The layout and footprint of the proposal have changed several times and it is unclear which of the data collected so far, and available from other sources, cover the current footprint and how much data will be available when the application is submitted.
- We do not think that the report covers migrant waterfowl sufficiently. For example, there has only been one radar study that was designed to detect migrant geese and it may have taken place too late to measure anything meaningful. There needs to be more information before we can advise whether this can be dismissed as an important issue.

- Impacts on relevant Annex 1 Birds Directive species (e.g. Common Scoter, Red-throated diver, Black-throated diver etc.) and Annex IV Habitats Directive species (all cetacea) should be specifically identified, including their activity outwith any SPAs. It is unclear whether the additional boat survey will give sufficient data to assess impacts to red-throated diver and common scoter and if not, how this will be addressed.

- We strongly recommend that Aberdeen Offshore Wind Farm Limited consider in detail how they will prepare a report to inform an Appropriate Assessment, and what information will be available to them at the time (both their own data and that from other sources).

- It is important to consider the different ‘sections’ in an integrated way that considers the effect of impacts on one aspect of marine ecology on another, taking into account all relevant factors such as coastal processes.

- Little information is available on the offshore research centre and it is unclear if it is covered in the current scoping report. The report states that the location for this has yet to be decided and it will be subject to a separate consent application. We recommend that a clearer rationale is provided for the research centre and that an application is submitted at the same time as that for the offshore wind deployment centre. This would help inform the overall assessment of the project, as well as providing an opportunity for monitoring protocols to be prepared in advance on any works. More consideration of the timing that application is submitted may be needed if the centre is to be used for research before the windfarm is constructed.

- We would welcome the preparation of research proposals in a construction and post-construction monitoring plan. We recommend that the ES includes an outline of such a plan.

APPENDIX A

SNH's DETAILED ADVICE ON EOWDC SCOPING REPORT

1.6 Approach to EIA

1.6.1 Impact Assessment Methodology

Para 30 – We have raised concerns in meetings about the use of a matrix approach, both for birds and marine mammals and seascape impacts. We encourage a more flexible approach that uses a thorough assessment based on rigorous professional judgement, as this better recognises the complex and unique aspects of the proposal.

1.6.2 Cumulative and In-combination Impact

Actual projects anticipated to be included should be outlined at this stage. We recommend AOWFL consider other east coast windfarm sites such as the 3 STW sites in the Outer Forth and Tay Area (Inch Cape, Neart na Gaoithe and Forth Array), the two Round 3 Zones (Zone 1 and Zone 2) as well as the STW site in the Moray Forth (Beatrice).

2.3 The Project Concept / Consenting Process

Para 46 – We understand that the timing of this proposal is in part driven by the funding requirements of the grant this project will receive from them European Energy Programme for Recovery. In order for us to advise further, for example in relation to the consenting process, it would help to know what those funding requirements are.

2.4 Proposed Development

The report states that there are likely to be onshore deployment facilities, substation and cable which will be dealt with under a separate scoping report. It would be helpful if a timescale was given for when that scoping report and subsequent application will be submitted. Please note for the purposes of the Habitats Regulations Appraisal, the project requires to be assessed as one (please see our comments in Appendix E). We can provide further advice on this aspect once we have received the scope of the report to inform an Appropriate Assessment.

Please note that the landfall is on an erosional soft coastline. Future-proofing the cables and landfall infrastructure is therefore important. It should be ensured that there are no obstructions to net northerly sediment movement within the Bay, otherwise the existing erosion problem on the southern two thirds of Aberdeen Bay (and particularly at Blackdog) may worsen.

Fig 2 (p 161) implies two offshore cables merge into one, to cross the intertidal. The ES should consider if there would be jointing infrastructure where the cables merge as this could create a potential impact in terms of obstruction on a lowering & erosional foreshore.

2.4.1 Wind Turbines

Paras 5, 52 and 56 - It is stated that there may be multiple turbine foundation, tower and turbine designs deployed at the proposed development site. We recommend that if any of these designs depart substantially from the standard foundation (jacket, mono-pile, gravity base), tower (single tubular tower) or turbine (three bladed upwind turbine) designs that the potential for increased or additional impacts from these designs are carefully considered in consultation with us and others. For example lattice design towers may cause attraction to the wind farm and turbine as birds try to roost on the structure. Any turbine with more or fewer blades than the normal three bladed design may result in very different bird collision risk calculations. Floating turbine designs may result in increased underwater collisions for marine mammals and diving birds although there is unlikely to be sufficient depth of water for floating turbines at this site.

We support the idea of trialling new foundations so long as appropriate monitoring is in place to look at and assess the impacts.

2.4.3 Ocean Laboratory

The report states that the location for this has yet to be decided and it will be subject to a separate consent application. It is unclear whether or not it is covered in this scoping report (cf 2.4, paras 49-51) and therefore will be covered within the ES. It would be helpful to have further clarification on this aspect.

2.5 Project Construction

2.5.1 Construction Timescales

Para 62 – We note that 4 turbines are expected to be installed in 2012 and that work will be continuous during construction. Given that these four turbines may have entirely different foundations and thus differing vessel requirements, it will be important that the EIA considers all the possible options of likely numbers and types of vessels on site over the construction period.

2.5.2.3 Inter-Array Cables

Para 74 – Any stabilisation methods for the cables should not interrupt tidal or wave driven currents, otherwise they may have significant onshore implications in terms of sediment movement.

2.5.2.5 Scour Protection

Para 76 – This could be an opportunity to trial different methods which is particularly important if AOWFL wish to investigate artificial reef properties (see comments on 5.1.7.1 below).

4.1 Meteorological Conditions

4.1.2 Baseline Information

Haar is frequent on the north east coastline and the ES should take this into account e.g. increased likelihood of accidents and associated environmental effects of these measures and requirements for foghorns and lighting. The section on wind turbines (2.5.2.2) says that aviation warning lighting will be required but does not mention foghorns.

4.3 Coastal Processes

4.3.2 Baseline Information

Para 125 - 'a narrow ridge of unknown origin situated in the region between the offshore and littoral zones; it is possible that this ridge affords some protection to the coast from wave action.' This should be investigated, it may be the lower limits of former emerged shorelines, representing themselves within the nearshore. This could have implications for the cable-installation approach.

Para 126 - The implications of the wind farm on tidal currents should be considered. Halcrow (working for Aberdeen City Council) established that south-north tidal currents at the southern end of the bay, played an important role in sediment dynamics and beach health. Given the wave shadow effect of a nearshore array (with cables, defences, sour protection etc), and the propensity of erosion on the adjacent coast, it would be prudent to ensure that there are unlikely to be knock-on effects.

4.5 Sediment and Water Quality

4.5.2 Baseline Information

Please consider whether the sampling takes into account any pollution from the nearby contaminated land at Blackdog.

5.1 Marine Ecology

5.1.2.2 Benthic Habitats

Para 230 - We note that the sampling approach set out in the scoping report is different to the recently agreed benthic survey strategy. The ES should report on results obtained from the recently agreed benthic sampling strategy (September 2010).

5.1.7.1 Further research opportunity: reef effect

Para 239 - We agree this would be a good location to study the reef effects of structures and distinguish between (a) perceived benefits through enhanced diversity/productivity and (b) the structures acting simply as fish aggregation devices. This should form part of a post-construction monitoring plan that we would welcome the opportunity either to comment on or become more directly involved in. Careful consideration should be given to what would be required for post construction monitoring.

As mentioned above (2.5.2.5) there is also the opportunity to look at the best methods of scour protection and recovery of the site following cable installation.

5.3 Fish, Shellfish and Elasmobranchs

The benthic section of the report should make appropriate links to fish and shellfish where there are strong habitat associations for particular species. For example, muddy sediment is closely associated with Nephrops and their fishery. The sand and gravelly sand which dominates the area for this proposal is likely to have associations particularly with scallops, but also various flatfish and sandeels (in terms of fisheries species).

5.3.2.1 Spawning and nursery grounds

Para 256 - We are pleased that the report acknowledges the spatial and temporal variability of these areas. The spawning and nursery habitats data provided is from Coull et al (1998). Further and more recent information is/should shortly be available from the Defra Data Layers project.

5.3.2.5 Diadromous and freshwater species

Para 268 - We suggest that sparling should also be considered as a diadromous fish species of conservation importance. Sparling is included in the UK Biodiversity Action Plan Priority Species list. They are found in coastal waters and estuaries and migrate into large clean rivers to spawn. Sparling was previously known to occur in a number of Scottish rivers, but has now disappeared from almost all of these sites.

Para 269 - We note that sturgeon have been recorded which are a European Protected Species and must be considered accordingly in the ES (Please see appendix C).

Para 271 - The scoping report identifies various rivers that are important for salmonids, but does not consider whether the River South Esk SAC, to the south of the proposed site, may be affected. The qualifying interests of the River South Esk SAC are Atlantic salmon and freshwater pearl mussel. A recent review by Marine Scotland Science (Malcolm, I., Godfrey, J. & Youngson, A. In prep. Review of migratory routes and behaviour of Atlantic salmon, sea trout and European eel in Scotland's coastal environment: implications for the development of marine renewables. *Marine Scotland Science draft report*.) summarises available information on the migratory routes and behaviour of Atlantic salmon, sea trout and European eel. Although the report indicates that the dominant direction of travel for Atlantic salmon (1 SW and MSW) on the east coast of Scotland, in the area around Aberdeen, is a northerly direction, there is also some southerly movement, and there is both easterly and westerly movement on the east coast to the north of Aberdeen. The River South Esk should be included in the list of Natura sites that are identified in the report. Please see our advice in Appendix E on HRA scoping.

To the south of the River South Esk, there are three SACs with anadromous fish species as qualifying interests - the River Tay SAC (Atlantic salmon, river lamprey, sea lamprey), River Teith SAC (Atlantic salmon, sea lamprey, river lamprey) and the River Tweed SAC (Atlantic salmon, sea lamprey, river lamprey). These SACs are likely to be sufficiently well removed from the proposed site not to be significantly affected by the development.

There are also several SACs with diadromous fish and freshwater pearl mussel qualifying interests to the north of the development, but they are also likely to be sufficiently well removed from the proposed site not to be significantly affected by the development.

Para 277 - Not all sites containing freshwater pearl mussel are designated as SSSI or SAC. Any populations in non-designated sites in the vicinity of the development should be considered, but only within the ES.

<u>5.3.2.6 Elasmobranchs</u>
Para 282 – Basking Sharks are known to occur along the east coast and we recommend AOWFL look for more recent literature or sighting records to check this. They may wish to liaise with some of the some of the other east coast offshore wind developers who are also undertaking surveys to see if they are reporting similarly low numbers. We recommend that basking sharks are recorded as a feature if observed during any marine mammal or bird surveys. As Basking sharks are protected under Schedule 5 of the Wildlife and Countryside Act, no development licences are currently available.

Para 283 - We would have thought that there were other elasmobranchs in the area worth mentioning, not only basking and porbeagle sharks.

Para 286 - This should include the effects of displacing fishing activity; i.e. impacts on areas where fishing activity moves to and therefore becomes concentrated. Also could be put in wider fisheries management context, by considering efforts of Scottish Government to bring fishing (and other marine activities) within environmental and biological limits.

<u>5.3.4 Potential impacts</u>
The scoping report recognises that the potential impacts of noise, electromagnetic fields and other disturbance on diadromous fish species needs to be evaluated. A draft SNH report (Gill, A.B. & Bartless, M. In prep. Literature review on the potential effects of electromagnetic fields and subsea noise from marine renewable energy developments on Atlantic salmon, sea trout and European eel) considers the current state of knowledge with regard to the potential impacts of noise and electromagnetic fields associated with marine renewable energy, on Atlantic salmon, sea trout and European eel.

The draft report by Marine Scotland Science (referred to above, para 271) considers available information on migratory routes and behaviour of Atlantic salmon, European eel and sea trout in Scotland's coastal environment, and should also be useful.

Para 597 - The Inshore Fisheries Group (IFG) that covers this area is not yet set-up but should be established soon - this will be another appropriate point of contact for consulting local fishermen, in theory including those that are not affiliated with fishermen's associations.

Table 6.2, p133: - (a) displacement effects should be included, (b) some of the conclusions in this table make assumptions. We do not know the impacts much of the time or how effective mitigation measures will be e.g. impacts of electromagnetic fields and underwater noise.

5.4 Birds

The layout and footprint of the proposal have changed several times and it is unclear which of the data collected so far, and available from other sources, cover the current footprint and how much will be available when the ES is prepared and application submitted.

One of the subjects that we have consistently raised is the need to consider impacts to red-throated divers and common scoter. It is unclear whether the additional boat survey will give sufficient data to address this.

We also do not think that the report covers migrant waterfowl sufficiently. There has only been one radar study that was designed to detect migrant geese and it may have been undertaken too late to really measure anything meaningful. There needs to be more information before we can advise whether this can be dismissed as an important issue.

5.4.1 Introduction

Paragraph 291 and Table 5.2 – Please note that the JNCC programme for designating SPAs for inshore aggregations of non-breeding waterbirds is ongoing and Aberdeen bay is still an active Area of Search. For any marine area which does become an SPA the provisions of Article 6 of the Habitats Directive (Reg 48) will apply. Meantime the area should be considered as an important area for birds and the effects of development seen in this context. The obligations of Articles 2 and 3 of the Birds Directive also need to be considered.

Para 291 - Aberdeen bay is also used by birds during the spring and autumn migration periods and potentially by moulting birds. Indeed, para 296 notes the Aberdeenshire coast as important for divers, grebes and seaduck for all months of the year.

Paragraph 292 – it is stated that seven SPAs within “daily flight distance” of the proposed development site were identified as being relevant. It is unclear which foraging distance data was used for which species. We recommend that the distances used for each species considered is stated and those SPAs that may have connectivity to the proposed development site is listed for each species. We recommend that foraging distance data is not used as a hard cut off value, but that those SPAs that are close to the cut off value are included at this stage (Please also see our comments in Appendix D on the HRA process for SPAs).

5.4.1.1 Project Reports

Additional data sources should include all data available such as North East Scotland Bird Survey reports.

5.4.2 Baseline information

We welcome the consideration in paras 294-309. As well as considering where particular species are a feature of interest of an SPA, the ES should also consider where they are a feature of interest of an SSSI. The SSSI, SAC and SPA interests for a designated site are not always the same nor have the same boundary. For example, some SSSIs such as Corby, Bishops and Lily Lochs are not SPAs. Ramsar sites should also be considered.

Paragraph 299 – due to the very long foraging distances of northern gannet it is likely that some of the birds observed are from other breeding colonies. We recommend that at this stage other gannet colonies further north than Troup Head are scoped in (Please also see our comments on Appendix D).

Para 300: Kittiwake and herring gull also form part of the Fowlsheugh SPA interests.

Paragraph 302 – auks make multiple foraging trips per day during breeding, not one single all day foraging trip as stated here. Thus the energetic impacts due to barrier effects may be multiplied.

Paragraph 305 – note that redshank and lapwing are qualifying features of the non-breeding waterfowl assemblage of the Ythan Estuary, Sands of Forvie and Meikle Loch SPA and not the "seabird assemblage interest feature" as stated here.

Table 5.2 – please add black-legged kittiwake to the species covered by Article 4.2 for the Troup, Pennan and Lions Head SPA. Also please add northern fulmar as a qualifying feature of the seabird assemblage of the Forth Islands SPA. Please remove whooper swan as a feature of the Loch of Skene SPA.

5.4.3.1 Vantage Point Surveys

Para 312 – it is unlikely that detectability of many species is very good as far out as 2km. If distances to each bird (or group of birds) was recorded during vantage point watches we recommend that the number birds detected is plotted against distance to estimate the detectability function for each species. For some species it may be necessary to plot age and/or sex separately (e.g. young gannets have more cryptic plumage than adults, or female eider are more cryptic than males). It should then be possible to assess the range at which each species was reliably detected and thus constrain the analysis to those records within this distance. In addition the effects of sea state may influence detectability with increasing distance. We recommend that the detectability functions for each species are compared across different sea states to determine at which sea state the detectability becomes too low to reliably record birds.

Para 314 – flight height data in the near shore area recorded from vantage point may not be a good model for flight heights further from shore and in deeper water. We urge caution in interpreting flight height data recorded by shore based observers. If flight height data recorded from shore is to be used, we recommend that analysis is undertaken to determine if flight heights measured from shore differs significantly from flight heights measured either by boat based observers or from radar.

5.4.3.2 Boat Based Surveys

Table 5.5 – It is unclear how the assessment of collision, barrier and displacement risks was made. These are probably derived from the presentation we received from Vattenfall in September 2008. Our comments on those results are contained in our letter of 10 December 2008. In particular, the assessment needs to consider all sources of data available and be based on a sufficient length of time to give confidence in the results.

Table 5.5 – We recommend that rather than providing some data on flight heights that a frequency plot of flight heights is provided for each species when these data are presented in the ES.

Table 5.5 – It is not clear where the wind farm and control survey areas are as these are not indicated in any figures. It is not clear whether these observations have been adjusted to the current proposed development foot print or whether or whether they

relate to a former iteration. If it is a former iteration it would be helpful to know which one. This also applies to section 5.4.3.4 Radar studies.

5.4.3.3 Boat Based Surveys 2010-2011
Para 326 - It is important that there is sufficient data available to enable Marine Scotland to carry out an Appropriate Assessment. Currently it is unclear whether or not this will be the case.

5.4.3.4 Radar Surveys
Para 329 - Does this refer to the current windfarm footprint or that at the time the radar study was carried out?

Para 333 – It is stated that previous studies have found that "very high avoidance rates by geese" and that collisions being "extremely unusual". There should be reference made to these studies and an indication of where they were undertaken and which species were involved and in what numbers. In order to assess the ability of the conducted radar study to adequately assess the presence and numbers of migrating geese much more information needs to be provided. We recommend that the timing of the deployment of the radar is compared to the known time of passage and numbers of geese recorded at regularly counted sites in the area (e.g. Montrose Basin, Loch of Strathbeg). It will then be possible to show whether the radar was deployed at an appropriate time but should also take into account the variation in goose movements between years. We also recommend that the results of radar ground truthing are included in the ES.

5.4.4 Predicted Impacts
Para 335 – We recommend that the details of the analysis that resulted in the redesign of the turbine layout are included in the ES. Any future analysis of impacts should include indirect effects and disturbance from increased boat traffic for operation and maintenance of the proposed turbines. It should consider all aspects of the turbines such as navigation and aviation warning measures including possible lighting and/or foghorns.

Para 336 – We recommend that for those species where there is insufficient data to apply Distance analysis, plots of the locations and numbers of birds are included, e.g. by varying the size of symbols relative to the number of birds recorded.

Para 338 - The ES should include information on how flight height data was verified.

5.4.6 EOWDC future research and monitoring
Para 343 - We welcome the proposal to continue monitoring during and post-construction and welcome the opportunity to discuss research needs further.

5.6 Marine Mammals
5.6.2.3 Future Boat Based Surveys 2010-2011
Para 392 - From the text it appears that the data presented in the ES will be four months of 'new data' combine with approximately 15 months of 'old data' which didn't cover the same points and used a different method. If it is unclear if this will be sufficient for an assessment and we advise that AOWFL ensure that the mitigation and monitoring of impacts is extremely robust. We also recommend the assessments include as much data as possible, albeit if necessary with some months having less analysis.

5.6.5 Mitigation

There is an opportunity to look at how effective different forms of mitigation are on minimising impacts of installation – noise. This is referred to in 5.7 but not with any detail. As a test centre we recommend that there is a detailed look at underwater noise and robust monitoring of marine mammals (which should include behavioural studies to determine whether behavioural effects are occurring). Ideally we would wish to see a number of readings at various distances from each installation to record noise. This would help gain a better understanding of whether or not various types of mitigation are working or indeed worth doing. We would be happy to meet with AOWFL or their consultants at an early stage to discuss this and try to get the most out of this research.

5.6.6 EOWDC Future Research and Monitoring

C-Pods are now proposed as ''future research' and not for gathering data for the ES. As explained above in the main letter, it is unclear whether there will be enough data for assessing impacts to bottle-nose dolphins both as a feature of the Moray Firth SAC and as EPS, when the ES is submitted. It would be useful to get clarification of what survey protocol will be used for C-Pods, when and where they will be deployed. Please see also our Comments in Appendix E.

5.9 Statutory Designations and Conservation

For comments on Natura sites, please refer to our advice in Appendices D and E on the HRA for SPAs and SACs.

Table 5.9 – This should include the River South Esk SAC, to the south of the proposed site. The qualifying interests of the River South Esk SAC are Atlantic salmon and freshwater pearl mussel. The draft Marine Scotland Science report referred to in our comments above indicates that the dominant direction of travel of Atlantic salmon on the south east coast is a northerly one, but there is also some southerly movement. See comments in Appendix E.

The scoping report does not directly consider Ramsar sites and we recommend these are addressed in the ES.

6.5 Seascape, Landscape and visual effects

In general, it appears that the proposed SLVIA outlined takes due cognisance of our previous scoping comments and discussions at meetings. In particular the report recognises the proximity of major and smaller population centres as sensitive receptors, and gives particular consideration to any effects arising as a result of differing wind turbines devices.

6.5.2 Baseline Information

Para 556 – Given the large height of the turbines, it is important to retain a flexible approach to the study area, increasing it if the ZTVs indicate that visual effects are likely to occur in a wider area.

6.5.2.1 Landscape and Seascape Character

Paras 557 - 558 - As we discussed at a meeting with the developer's consultants on 14th April 2010, it is important to consider how the assessments of seascape, landscape and local landscape character types will fit together to prevent duplication and avoid confusion. We would be happy to provide further advice once AOWFL have developed a methodology for this.

6.5.2.2 Visual Amenity

Para 560 – Recreation users at Donmouth LNR should also be considered.

Para. 561 and Table 6.1 - Representative viewpoint locations. Ideally to inform our input into further discussion on viewpoint locations (over and above that previously agreed), it would be useful to have a comparative ZTV, illustrating the extent of changed visibility occurring between the 2009 layout and the current 2010 layout. This would ensure optimum locations are chosen.

Para. 567 - The photomontages should illustrate a range of conditions - eg. sunrise; turbine lighting (dawn/dusk); the international aviation (2.5.2.2) requirement for the turbines to be painted white and aviation warning lighting; the size of the ocean lab (we appreciate this would be a separate application, but some initial indicators of scale, form etc. would be useful).

We had previously suggested allowing for some fixed photomontage 'boards' on site to engage the public. There is no mention of this in the scoping report (within either of the SLVIA or Recreation and Tourism sections) and we recommend that this is undertaken.

6.5.5 Cumulative Impact

Para. 574 - Further engagement on methods for cumulative impact assessment should include both Aberdeen City and Aberdeenshire councils.

Para 576 – This refers to the choice of colour of turbines being used to mitigate landscape and visual impacts, however, section 2.5.2.2 indicates that much of the turbines should be white.

6.8 Recreation and Tourism

6.8.2 Baseline Information

Paras 626-633 – Surfing is another recreational activity that takes place in Aberdeen and kite surfing at Balmedie. All forms of recreation should be considered in the ES and there should be consultation with relevant user groups.

7. Consultations

Para 678 – we recommend that the Whale and Dolphin Conservation Society (WDCS) are added to the list of other consultees. The WDCS have commented on marine mammal survey methods for this proposal and interim reports.

APPENDIX B

HABITATS & BIRDS DIRECTIVES, & HABITATS REGULATIONS

Paragraphs 434-436 of the scoping report outline the Habitats and Birds Directives. The Habitats Directive is transposed into domestic law in Scotland by the 'Conservation (Natural Habitats, &c.) Regulations 1994' which came into force on 30 October 1994 – usually called simply the Habitats Regulations. Several amendments have been made to the Habitats Regulations since they came into force.

The Habitats Regulations apply to the inshore zone, and the rules for the protection of marine Natura sites and marine European protected species (EPS) apply here exactly as they do on land.

Habitats Regulations Appraisal

Where a plan or project could affect a Natura site, the Habitats Regulations require the competent authority – the authority with the power to undertake or grant consent, permission or other authorisation for the plan or project in question – to consider the provisions of regulation 48. This means that the competent authority has a duty to:

- determine whether the proposal is directly connected with or necessary to site management for conservation; and, if not,

- determine whether the proposal is likely to have a significant effect on the site either individually or in combination with other plans or projects; and, if so, then

- make an appropriate assessment of the implications (of the proposal) for the site in view of that site's conservation objectives.

This process is now commonly referred to as **Habitats Regulations Appraisal** (HRA). HRA applies to any plan or project which has the potential to affect the qualifying interests of a Natura site, even when those interests may be at some distance from that site.

The competent authority, with advice from SNH, decides whether an appropriate assessment is necessary and carries it out if so. It is the applicant who is usually required to provide the information to inform the assessment. Appropriate assessment focuses exclusively on the qualifying interests of the Natura site affected and their conservation objectives. A plan or project can only be consented if it can be ascertained that it will not adversely affect the integrity of a Natura site (subject to regulation 49 considerations).

Further Information and Advice on HRA

In this scoping response we provide tailored advice for HRA in respect of birds that are qualifying interests of SPAs, and marine mammals, habitats and fish that are qualifying interests of SACs:

- Appendix D – SNH Advice on Habitats Regulations Appraisal for SPAs
- Appendix E – SNH Advice on Habitats Regulations Appraisal for SACs

In respect of this, further information on the qualifying interests and the conservation objectives for each relevant Natura site is available from SNH's Sitelink database.

For further advice on the HRA process please see SNH's website, including the leaflet on "Natura sites and the Habitats Regulations" which provides a helpful summary. Some of the key concepts are explained in the European Commission's guidance on Article 6 of the Habitats Directive. Revised guidance updating the Scottish Office Circular 6/1995[38] on the implementation of the Habitats and Birds Directive in Scotland was produced in June 2000. This sets out current Government policy relating to Natura sites.

APPENDIX C

EUROPEAN PROTECTED SPECIES

Certain species are listed on Annex IV of the Habitats Directive as species of European Community interest and in need of strict protection. The protective measures required are outlined in Articles 12 to 16 of the Directive. The species listed on Annex IV whose natural range includes any area in the UK are called ‘European protected species’.

SNH is the statutory nature conservation body who provides advice on EPS in respect of the Habitats Regulations in Scotland, including Scottish Territorial Waters. A summary of the legal requirements for EPS is as follows:

The Conservation (Natural Habitats, &c.) Regulations 1994 as amended. (Known as the ‘Habitats Regulations’.) Protection of certain wild animals 39. (1) It is an offence – (a) deliberately or recklessly to capture, injure or kill a wild animal of a European protected species; (b) deliberately or recklessly – i. to harass a wild animal or group of wild animals of a European protected species; ii. to disturb such an animal while it is occupying a structure or place which it uses for shelter or protection; iii. to disturb such an animal while it is rearing or otherwise caring for its young; iv. to obstruct access to a breeding site or resting place of such an animal, or otherwise to deny the animal use of the breeding site or resting place; v. to disturb such an animal in a manner that is, or in circumstances which are, likely to significantly affect the local distribution or abundance of the species to which it belongs; vi. disturb such an animal in a manner that is, or in circumstances which are, likely to impair its ability to survive, breed or reproduce, or rear or otherwise care for its young; or vii. to disturb such an animal while it is migrating or hibernating; (c) deliberately or recklessly to take or destroy the eggs of such an animal; or (d) to damage or destroy a breeding site or resting place of such an animal. (2) Subject to the provisions of this Part, it is an offence to deliberately or recklessly disturb any dolphin, porpoise or whale (cetacean).

Scottish Government has also provided guidance on the 2007 amendments addressing EPS – Explanatory guidance for species related activities.

EPS Licences

Licences may be given authorising activities that could affect EPS which would otherwise be illegal under the Habitats Regulations. For Scottish Territorial Waters these licences will be issued either by Scottish Government or by SNH depending on the reason for the licence request. Licences are only issued under very strict conditions as set out in regulations 44 and 45 of the Habitats Regulations.

As highlighted in Scottish Government Interim Guidance, three tests must be satisfied before the licensing authority can issue a licence under Regulation 44(2) of the Conservation (Natural Habitats &c.) Regulations 1994 (as amended) to permit otherwise prohibited acts. An application for a licence will fail unless all of the three tests are satisfied. The three tests involve the following considerations:

Test 1 - The licence application must demonstrably relate to one of the purposes specified in Regulation 44(2) (as amended). For development proposals, the relevant purpose is likely to be Regulation 44(2)(e) for which Scottish Government is currently the licensing authority. This regulation states that licences may be granted by Scottish Government only for the purpose of "preserving public health or public safety or other imperative reasons of overriding public interest including those of a social or economic nature and beneficial consequences of primary importance for the environment."

Test 2 - Regulation 44(3)(a) states that a licence may not be granted unless the licensing authority (Scottish Government) is satisfied "that there is no satisfactory alternative".

Test 3 - Regulation 44(3)(b) states that a licence cannot be issued unless the licensing authority (Scottish Government) is satisfied that the action proposed "will not be detrimental to the maintenance of the population of the species concerned at a favourable conservation status in their natural range" (The licensing authority will, however, seek the expert advice of SNH on this matter).

Consideration of European protected species must be included as part of the application process, not as an issue to be dealt with at a later stage. Any consent given without due consideration to these species is likely to breach European Directives with the possibility of consequential delays or the project being halted by the EC.

APPENDIX D

EOWDC: HABITATS REGULATIONS APPRAISAL (HRA) – SPECIAL PROTECTION AREAS

Introduction

In the following advice for HRA we set out the three steps that need to be considered in order to determine whether or not the European offshore Wind deployment Centre proposal is likely to have a significant effect on the qualifying interests of SPAs, and any possible adverse impact on site integrity – Appendix B provides more detail on the legislative framework. It is the competent authority (most likely Marine Scotland) who will carry out the HRA, based on our advice and using information and data collated by the developer.

Under HRA, the potential impacts of the EOWDC offshore windfarm proposal will need to be considered alone (all aspects of the proposal i.e. including onshore deployment facilities, substation, cable and offshore research station) and in combination with other plans and projects. It needs to be considered in combination with the Scottish Round 3 zones as well as the following proposed Scottish territorial water sites (Neart na Gaoithe, Inch Cape, Forth Array and Beatrice) and with other types of industry and activity in and around Aberdeen bay and harbour.

Special Protection Areas for inclusion in HRA

We would welcome the opportunity to discuss the scope of HRA with AOWFL (as noted in this response) and we recommend that the following SPAs are considered for individual and also for cumulative assessments:

Troup, Pennan and Lion’s Heads SPA
Forth Islands SPA
Fowlsheugh SPA
Buchan Ness to Collieston Coast SPA
Ythan Estuary, Sands of Forvie and Meikle Loch SPA
Loch of Strathbeg SPA
Loch of Skene SPA
Montrose Basin SPA

Please see also our comments in Appendix A, para 299 recommending that gannet colonies further north than Troup Head are also scoped in at this stage (eg Fair Isle).

Advice for HRA in respect of SPA qualifying interests

The steps of the process are as follows and our advice is tailored to consideration of this offshore windfarm:

Step 1: **Is the proposal directly connected with or necessary for the conservation management of the SPAs?**

The EOWDC proposal is not directly connected with or necessary for the conservation management of any of the SPAs listed above.

Step 2: **Is the proposal likely to have a significant effect on the qualifying interests of the SPAs either alone or in combination with other plans or projects?**

This step acts as a screening stage: it removes from the HRA those proposals (plans or projects) which clearly have no connectivity to SPA qualifying interests or where it is very obvious that the proposal will not undermine the conservation objectives for these interests, despite a connection. When this screening step is undertaken at an early stage in the development process, it usually means that it takes the form of a desk-based appraisal. We advise that this is kept broad so that potentially significant impacts are not missed out, or discounted too early, in any HRA (or EIA).

The SPA bird interests being considered in respect of offshore windfarms are wide-ranging – many seabirds make long foraging trips, especially during the breeding season, and there are also migratory species to consider such as geese and swans. This means that offshore windfarm proposals may be ‘connected to’ SPAs at much greater distances than what has so far been experienced in respect of onshore development. Although connectivity is thus established the fact that the proposal is located further away from the designated sites means that direct impacts are less likely on qualifying species while they are within the SPA.

Expert agreement over species sensitivity should help to identify those SPA qualifying interests for which the conservation objectives are unlikely to be undermined by offshore windfarm development, despite any possible connection (e.g. SPA qualifiers which are recorded within a proposed windfarm site but where their flight behaviour and / or foraging ecology means that the windfarm will not have a likely significant effect).

Determination of ‘likely significant effect’ is not just a record of presence or absence of bird species at an offshore windfarm site, but also involves a judgement as to whether any of the SPA conservation objectives might be undermined. Such judgement is based on a simple consideration of the importance of the area in question for the relevant species. Complex data analysis should not be required at this stage. For example; How many birds have been recorded? What are they using the area for? Is this the only area that they can use for this particular activity? Understanding the behavioural ecology of the species, and the characteristics and context of the proposed windfarm site, will help in determining whether there are likely significant effects. There are three possible conclusions for this step of HRA:

a) The likely impacts are such that there is clear potential for the conservation objectives to be undermined – conclude likely significant effect.

b) The likely impacts are so minimal (either because the affected area is not of sufficient value for the birds concerned or because the risk to them is so small) that the conservation objectives will not be undermined – conclude no likely significant effect.

c) There is doubt about the scale of the likely impacts in terms of the conservation objectives – conclude likely significant effect.

<u>Step 3</u>: Can it be ascertained that the proposal will not adversely affect the integrity of the SPA, either alone or in combination with other plans or projects?

This stage of HRA is termed appropriate assessment, and it is undertaken by the competent authority based on information supplied by the developer, with advice provided by SNH. Appropriate assessment considers the implications of the proposed development for the conservation objectives of the qualifying interests for which a likely significant effect has been determined. These conservation objectives follow a standard format requiring protection of the qualifying bird interests and protection of the habitat in the SPA which supports them.

Conservation objectives for SPA bird species

To ensure that site integrity is maintained by: (i) Avoiding deterioration of the habitats of the qualifying species. (ii) Avoiding significant disturbance to the qualifying species. To ensure for the qualifying species that the following are maintained in the long term: (iii) Population of the bird species as a viable component of the SPA. (iv) Distribution of the bird species within the SPA. (v) Distribution and extent of habitats supporting the species. (vi) Structure, function and supporting processes of habitats supporting the species. **repeat of (ii)** No significant disturbance of the species.

It is important to recognise that the conservation objectives primarily offer site-based protection and that some of them will not directly apply to species when they are outwith the boundaries of the SPA. This is particularly true of objectives **(i), (v)** and **(vi)** which relate to the supporting habitats within the SPA.

Objective **(iii)** however – maintenance of the population of the bird species as a viable component of the SPA – will be relevant in most cases because:

It encompasses direct impacts to the species, such as significant disturbance to qualifying bird interests when they're outwith the SPA.

It addresses indirect impacts such as the degradation or loss of supporting habitats which are outwith the SPA but which help to maintain the population of the bird species of the SPA in the long-term.

Finally, in rare circumstances, it is possible that factors / events outside site boundaries may have the capacity to affect the long term distribution of bird species within the SPA – see objective **(iv)**.

--

Issues to consider under appropriate assessment

The **key question** in any appropriate assessment for the EOWDC windfarm proposal is whether it can be ascertained that this proposal, alone or in combination, will not adversely affect the population of any qualifying bird species as a viable component of the SPAs under consideration.

In considering this matter, we refer to the helpful summary of the main risks of offshore windfarm development to birds provided in Langston 2010. In addition, there may be further issues to consider if the proposal is likely to affect the conservation objectives that relate to bird species while they're in an SPA or to the habitats in the SPA that support them.

- Will the offshore wind proposal(s) cause a deterioration in the habitats of any of the SPAs? NB. *This question relates specifically to the habitats in the SPAs that support the bird interests.*

- Will the offshore wind proposal(s) cause any significant disturbance to bird interests while they're in any of the SPAs?
  N.B. *See the previous discussion in respect of disturbance outside an SPA.*

- Will the offshore wind proposal(s) alter the distribution of the birds within any of the SPAs?

- Will the offshore wind proposal(s) affect the distribution and extent of the habitats (that support the bird species) in any of the SPAs?

- Will the offshore wind proposal(s) in any way affect the structure, function and supporting processes of habitats in any of the SPAs? NB. Those habitats which support the bird species.

We highlight that these questions will be applicable to the habitats which support bird interests in any new SPAs designated for inshore and / or offshore aggregations of seabirds – please see JNCC's website for potential areas of search, including Aberdeen Bay.

As noted above, we hope to further discuss these various aspects with AOWFL once a scope for the HRA has been provided

APPENDIX E

EOWDC: HABITATS REGULATIONS APPRAISAL – SPECIAL AREAS OF CONSERVATION

Introduction

In the following advice for Habitats Regulations Appraisal (HRA) we set out the three steps that need to be considered in order to determine whether or not the EOWDC windfarm proposal is likely to have a significant effect on the qualifying interests of Special Areas of Conservation, and any possible adverse impact on the site integrity of SACs – Appendix B provides more detail on the legislative framework. It is the competent authority (most likely Marine Scotland) who will carry out the HRA, based on our advice and using information and data collated by the developer.

Under HRA, the potential impacts of the EOWDC proposal will need to be considered alone (all aspects of the proposal i.e. including onshore deployment facilities, substation, cable and offshore research station) and in combination with other plans and projects. It needs to be considered in combination with the Round 3 development and with other types of industry and activity in the Moray Firth. We therefore recommend that the Beatrice and Round 3 developers collaborate on the assessment of cumulative impacts and we would welcome discussion of this matter and, preferably, a joint meeting between the developers, Marine Scotland and ourselves (SNH and JNCC).

For those SAC qualifying interests that are also European protected species (such as bottlenose dolphin) please see Appendix C for our advice in respect of their EPS status and for EPS licensing arrangements. The advice that we give below solely relates to their consideration as an SAC qualifying interest and how the HRA process therefore applies.

Special Areas of Conservation for Inclusion in HRA

We advise that the applicant will need to consider the following SACs. Further information, including their conservation objectives, is available from http://www.snh.org.uk/snhi/.

SACs designated for marine mammals:

- Moray Firth SAC - designated for bottlenose dolphin (Tursiops truncatus) and for subtidal sandbank habitat.

SACs designated for fish of conservation concern:

- River Dee SAC - designated for Atlantic salmon, freshwater pearl mussel and otter.
- River South Esk SAC - designated for Atlantic Salmon and freshwater pearl mussel (Please see our comments in Appendix A, para 271).

SNH advice for HRA in respect of Special Areas of Conservation

The steps of the process are as follows; our advice is tailored to consideration of this offshore windfarm proposal:

<u>Step 1</u>: Is the proposal directly connected with or necessary for the conservation management of the SACs?

The EOWDC proposal is not directly connected with or necessary for the conservation management of the South-East Islay Skerries SAC.

Step 2: Is the proposal likely to have a significant effect on the qualifying interests of the SACs either alone or in combination with other plans or projects?

This step acts as a screening stage: it removes from the HRA those proposals which clearly have no connectivity to SAC qualifying interests or where it is very obvious that the proposal will not undermine the conservation objectives for these interests, despite a connection. When this screening step is undertaken at an early stage in the development process, it usually means that it takes the form of a desk-based appraisal.

In respect of the above SACs, we identify that the EOWDC may have connectivity to the following qualifying interests, which will therefore require further consideration under HRA. While a desk-based review is helpful for this screening step, this part of the HRA will only be fully completed when the windfarm proposal has been further progressed – when survey work and analyses have been completed, and when the location of / construction methods for windfarm infrastructure, including onshore elements, has been finalised.

There are three possible conclusions to this step of HRA:

a) The likely impacts are such that there is clear potential for the conservation objectives to be undermined – conclude likely significant effect.

b) The likely impacts are so minimal that the conservation objectives will not be undermined – conclude no likely significant effect.

c) There is doubt about the scale of the likely impacts in terms of the conservation objectives – conclude likely significant effect.

However, we are not yet in a position to present a definite conclusion for this step, so we provide a **summary of our current advice** for each qualifying interest.

Marine and coastal habitats of the Moray Firth.
We do not consider any aspect of the offshore wind deployment centre will have an impact on the habitat qualifying interest of the Moray Firth SAC

Summary of our current advice: no likely significant effect.

- **Bottlenose dolphins of the Moray Firth SAC.**

  While the EOWDC proposal is located approximately 140 km from the Moray Firth SAC, the dolphins are not confined to this SAC and will range more widely within the Firth and beyond. Observations around the area of Aberdeen Harbour have confirmed sighting of individual dolphins from the Moray Firth SAC. Construction (and other) noise arising from the proposal is likely to extend beyond the windfarm footprint and may overlap with dolphin use of the surrounding environment. Boat movements, cable-laying and other construction activity may give rise to disturbance. There may also be impacts to the prey species of dolphin – either from the placement of infrastructure or due to noise. We therefore advise that there is potential for the proposal to have likely significant effects on bottlenose dolphins and we discuss below (under step 3) the issues that we think need to be considered.

It would be beneficial for applicants to collaborate on this issue with other offshore wind developers as appropriate assessment of the cumulative impacts on bottlenose dolphins is likely to be required in combination. Joint discussion and co-ordination of survey and monitoring proposals, mitigation proposals and construction time-tabling would be helpful.

Summary of our current advice: likely significant effect, so impacts (including cumulative) will need to be considered in appropriate assessment (see step 3).

- **Atlantic salmon** as a qualifying interest of the Rivers Dee and South Esk SACs.

  We recognise that there is a significant data / research gap on this issue, and that very little is known about salmon movements – adults and post-smolts – around the Scottish coastline. Marine Scotland have analysed historic tagging data and should be issuing a report soon, however, it is likely that this report will highlight further research requirements.

  We recommend that the applicant assumes all individuals are SAC salmon, and considers the effects on these fish from construction and operational noise / vibration, as well as any other types of disturbance. Mitigation could include timing restrictions on construction work / noisy activities in order to avoid any significant disturbance to migrating salmon, or disruption of their (as yet unknown) migratory routes.

  Onshore infrastructure and / or any required upgrades to roads or bridges may need to be considered under HRA if the work is likely to affect any of these freshwater SACs.

  Summary of our current advice: likely significant effect in relation to offshore infrastructure; impacts (incl. cumulative) will need to be considered in appropriate assessment (see step 3). Consideration of onshore infrastructure may also be required.

- **Freshwater pearl mussels** – qualifying interests of the Rivers Dee and South Esk SACs

  Atlantic salmon (and other salmonids) are integral to the life cycle of freshwater pearl mussel (FWPM), therefore any impacts to Atlantic salmon that prevent them from returning to their natal rivers may have a resulting effect on FWPM populations. While we consider this matter needs discussion in any appropriate assessment we do not identify any survey or research requirements. The impacts are indirect, dependent on the impacts the proposal may have on Atlantic salmon.

  Onshore infrastructure and / or any required upgrades to roads or bridges may need consideration in respect of HRA if the work is likely to affect any of these freshwater SACs.

  Summary of our current advice: likely significant effect, so indirect impacts will need to be considered in appropriate assessment as part of the assessment of any direct impacts on Atlantic salmon (see step 3).

- **Otters of the River Dee SAC**.

  The River Dee SAC is located too far away from the EOWDC proposal for there not to be any likelihood of significant effects on otters there, presuming that no onshore infrastructure is proposed in proximity to this SAC.

  Summary of our current advice: no likely significant effect, although this may need review depending on the proposed location of onshore infrastructure

<u>**Step 3**</u>: Can it be ascertained that the proposal will not adversely affect the integrity of the SAC, either alone or in combination with other plans or projects?

This stage of HRA is termed appropriate assessment, and it is undertaken by the competent authority based on information supplied by the developer, with advice provided by SNH. Appropriate assessment considers the implications of the proposed development for the conservation objectives of the qualifying interests for which a likely significant effect has been determined. We discuss this below for each of the qualifying interests listed above.

Advice for appropriate assessment in respect of bottlenose dolphin of the Moray Firth SAC

The conservation objectives for bottlenose dolphin are: (i) to avoid deterioration of the habitats of bottlenose dolphin or (ii) significant disturbance to bottlenose dolphin, thus ensuring that the integrity of the Moray Firth SAC is maintained and that the site makes an appropriate contribution to achieving favourable conservation status for each of the qualifying features. And to ensure for bottlenose dolphin that the following are established then maintained in the long term: **(iii)** Population of bottlenose dolphin as a viable component of the site. **(iv)** Distribution of bottlenose dolphin within site. **(v)** Distribution and extent of habitats supporting bottlenose dolphin. **(vi)** Structure, function and supporting processes of habitats supporting bottlenose dolphin. **repeat of (ii)** No significant disturbance of bottlenose

Based on these conservation objectives the following questions may need to be addressed:

- Will the proposal cause significant disturbance to bottlenose dolphin while they are outwith the SAC such that the viability of this SAC population is affected?

- Will the proposal in any way affect the population viability of the bottlenose dolphins of the Moray Firth SAC?

The last question encompasses the indirect impacts that a windfarm development could have – such as the degradation or loss of supporting habitats or feeding grounds which are outwith the SAC but which help to maintain the population of bottlenose dolphins in the SAC in the long-term. The risk of impacts, and how many of these questions may need answered, will become clearer when the development process is further advanced and construction methods, location of cable routes, choice of port, and other aspects are finalised. It is possible that onshore elements of infrastructure will need to be considered as well as those offshore.

We advise that noise impact assessment is likely to be an important part of assessing any direct disturbance to bottlenose dolphin, including their potential displacement from feeding grounds and other supporting habitats. While we consider that the construction phase may give rise greatest risk of disturbance, we do highlight that impacts during the operational phase also need to be considered, as well as any repowering and decommissioning work. It will also be important for the applicant to consider impacts on prey species.

We highlight that cumulative impacts are a key concern and we consider that collaboration between other offshore wind applicants on noise impact assessment is likely to be helpful, along with discussion / co-ordination of mitigation proposals and construction time-tabling.

Ongoing Liaison

As noted above, SNH will continue to liaise with the west coast developers in respect of this HRA process. It may be helpful for the developers to collaborate in order to address cumulative impacts on common (harbour) seals and their mitigation.

Advice for appropriate assessment in respect of Atlantic salmon & freshwater pearl mussel

The SAC conservation objectives for Atlantic salmon and freshwater pearl mussel (where appropriate) are: **(i)** to avoid deterioration of the habitats of the qualifying species or **(ii)** significant disturbance to them, thus ensuring that the integrity of the SACs are maintained and that they make an appropriate contribution to achieving favourable conservation status for each species.

And to ensure for each species that the following are maintained in the long term:

(iii) Population of the species, including range of genetic types for salmon, as a viable component of the SACs.

(iv) Distribution of the species within sites.

(v) Distribution and extent of habitats supporting each species.

(vi) Structure, function and supporting processes of habitats supporting each species.

repeat of (ii) No significant disturbance of the species.

And for freshwater pearl mussel in particular, to ensure that the following are maintained in the long term:

(vii) Distribution and viability of freshwater pearl mussel host species

(viii) Structure, function and supporting processes of habitats supporting freshwater pearl mussel host species

In respect of the offshore elements of infrastructure, appropriate assessment will focus on conservation objective (iii) – the population viability of Atlantic salmon – considered for the Rivers Dee and South Esk SACs.

There would not be any impacts to supporting habitats in any freshwater SACs arising from offshore infrastructure, however, the placement of onshore infrastructure – including any road / bridge upgrades – may need further consideration. We will be able to give further advice when the applicant presents more information on this aspect.

So the main impacts to Atlantic salmon would arise when the fish are outwith the freshwater SACs, on migration. An adverse impact on site integrity could arise if individuals are significantly disturbed / their behaviour altered / displaced from their migratory routes such that it affects the population viability of the species. The applicant may also need to consider whether the proposal could in any way act as a barrier to salmon movements, whether it might prevent any salmon from accessing the freshwater SACs, in particular the River Dee SAC.

Noise impact assessment is likely to be a key part of any overall appropriate assessment, and all phases of the development should be considered – construction, operation, repowering and decommissioning.

As discussed above, the applicant also needs to consider the potential (indirect) impacts to freshwater pearl mussel (FWPM) arising from offshore infrastructure. This will be a desk-based appraisal following on from the assessment of impacts to Atlantic salmon. We note that direct impacts to FWPM could arise from the placement of onshore infrastructure if this work takes place close to, or is likely to affect, the River Dee SAC.

Ongoing Liaison
We will continue to review our advice on HRA as this proposal progresses, and as survey work, modelling and other analyses are undertaken. We will discuss any strategic research needs with Marine Scotland and the Crown Estate, particularly those in respect of Atlantic Salmon.

Local Authority – Aberdeen City Council

It is unclear what is meant by “onshore deployment facilities” as referred to at para 50. It is noted at para 51 that the report only deals with the offshore elements of the project. It should be noted that separate planning permission will be required for the onshore elements of the project from the relevant planning authority (e.g. substation / transmission lines). Given the integral and essential nature of the onshore elements to the project as a whole, it is recommended that they be considered as part of a robust EIA process for the wider project. This has the benefit of potentially avoiding the need for undertaking a separate EIA, as well as enabling a holistic approach to evaluation of the project impacts. It is recommended that scope of the ES should include consideration of the options for the routing of the cable connection, the location of the substation and related environmental and visual impacts, including the need for mitigation measures such as grounding of cable connections to the grid and provision of landscape measures such as tree planting. You may wish to request a screening opinion regarding the specific onshore elements from the relevant planning authority.

It is suggested that the scope of the ES also be expanded to consider the possible indirect environmental, economic and social benefits of the proposed development to the Aberdeen area resulting from the implementation of a community fund. I would appreciate clarification of what specific mechanism is proposed to ensure that such potential community benefits for the City of Aberdeen may be delivered.

As regards consultees, it is recommended that you include Scottish Enterprise (Grampian), UKOOA and North East Scotland Biological Records Centre (Nesbrec), You may also wish to contact relevant technical specialists within the Council directly (e.g., Aftab Majeed, Environmental Planner; Andrew Gilchrist, Environmental Health and Judith Stones, Archaeologist).

SEPA

1. Scope of the ES for marine developments

1.1 This project will be developed during a period of fast development of marine policy at national and international levels and this should be addressed with respect to the Marine (Scotland) Act 2010 and Marine Strategy Framework Directive. More information can be found on the Marine Science website at http://www.scotland.gov.uk/Topics/marine/seamanagement.

1.2 From the information submitted we understand the overall project will include both onshore and offshore components including 11 turbines, foundations, cabling, ocean laboratory, and onshore works including landfall and substation. As such, the development will be subject to a range of different consenting regimes. We would encourage you to consider producing a single ES which covers all aspects of the proposed development. This will enable a full assessment of the potential effects of the development as a whole, rather than assessing certain details of the development individually.

2. Site layout and nature of construction for marine developments

2.1 The ES should contain plans giving detailed information on the site layout, including details of all onshore and offshore components such as access tracks, buildings, cabling and marine devices. These plans should be supported by a statement detailing the development, as well as reasons for the choice of site and design of the development. Depending on the types and scale of construction the information below may be required.

2.2 Plans should be included in the ES showing the layout of the devices, cabling routes and associated onshore infrastructure.

2.3 Background information that will help inform the ES process is available from European Marine Energy Centre (EMEC). The EMEC has produced guidelines to assist developers in considering the range and scale of impacts that may result from the testing of devices. These guidelines are available at www.emec.org.uk/index.asp. Generally, if this standard industry guidance is followed for scoping, preparing and undertaking EIA for marine renewables, then we are likely to be satisfied with the standard of assessment.

2.4 There may be a need to address the cumulative effects of devices on coastal processes depending upon density and location with respect to existing renewable and coastal developments.

2.5 The submission should include information on likely timing and duration of the project, possible long-term locational and/or operational impacts and short-term construction impacts.

3. River Basin Management Planning

3.1 Under the Water Environment and Water Services (Scotland) Act 2003, SEPA is responsible for producing and implementing River Basin Management Plans for the Scotland and the Solway Tweed River Basin Districts. River basins comprise all surface waters (including transitional (estuaries) and coastal waters) extending to 3 nautical miles seaward from the Scottish territorial baseline. Any proposed development within these waters must have regard to the requirements of the Water Framework Directive to ensure that all surface water bodies achieve 'Good Ecological Status' and that there is no deterioration in status. The Water Framework Directive requires the consideration of chemical, ecological and hydromorpholgical status. Further information on River Basin Management planning can be found on the SEPA website at www.sepa.org.uk/water/river_basin_planning.aspx. Information on the current status of Scotland's surface waters can be found on the water body data sheets on the the River Basin Management Planning Web Mapping Application available on SEPA's website at (http://213.120.228.231/rbmp/).

3.2 Under section 4, page 57 (baseline data) we would suggest that inclusion of the data held on 'Cruden Bay to Don Estuary' coastal water body should also be included in the baseline dataset. This water body is currently classified at high ecological status – a full datasheet is available at apps.sepa.org.uk/rbmp/pdf/200117.pdf. Any proposed development within these waters must have regard to the requirements of the Water Framework Directive (WFD) to ensure that all surface water bodies achieve 'Good Ecological Status (GES)' and that there is no deterioration in status. The WFD requires the consideration of chemical, ecological and hydromorpholgical status. The ecological status of surface water bodies which may be affected by the proposal should also be considered in section 5, alongside the discussion of protected areas for salmon and freshwater pearl mussel. These can be accessed via the interactive map at www.sepa.org.uk/water/river_basin_planning.aspx.

3.3 The cumulative assessments should consider the proposals alongside any existing coastal development already present within the water bodies in which landfall locations are being considered. EC guidance defines cumulative impacts as "impacts that result from incremental changes caused by other past, present or reasonably foreseeable actions together with the project" (http://ec.europa.eu/environment/eia/eia-studies-and-reports/guidel.pdf).

3.4 Maps should be included in the ES showing the areas of seabed likely to be affected by the footprint of the turbine bases and cabling, and the area of intertidal zone that is likely to be affected by shoreline infrastructure development. To allow for the RBMP classification to be updated and the assessment of cumulative impacts within these water bodies footprint data for the turbines and cabling components of the development should be provided in the ES.

4. Construction Environmental Management Document (CEMD) and pollution prevention

4.1 One of our key interests in relation to major developments is pollution prevention measures during the periods of construction, operation, maintenance, demolition and restoration. The construction phase includes construction of access roads and any other site infrastructure.

4.2 We advise that the applicant, through the EIA process or planning submission, should systematically identify all aspects of site work that might impact upon the environment, potential pollution risks associated with the proposals and identify the principles of preventative measures and mitigation. This will establish a robust Project Environmental Management Process (PEMP) for large scale (eg Major and Environmental Impact Assessment Projects (EIA). A draft Schedule of Mitigation should be produced as part of this process. This should cover all the mitigation measures identified to avoid or minimise environmental effects. Details of the specific issues that we expect to be addressed are available on the Pollution Prevention and Environmental Management section of our website.

4.3 A key issue for us is the timing of works. Therefore, the Schedule of Mitigation should include a timetable of works that takes into account all environmental sensitivities, such as fish spawning, which have been raised by SEPA, SNH or other stakeholders. Timing should also be planned to avoid construction of roads, dewatering of pits and other potentially polluting activities during periods of high rainfall. We can provide useful information such as rainfall and hydrological data through our Access to Information Team.

4.4 A Construction Environmental Management Document (CEMD) is a key management tool to implement the Schedule of Mitigation. We recommend that the principles of the CEMD are set out in the ES drawing together and outlining all the environmental constraints and commitments, proposed pollution prevention measures and mitigation as identified in the ES.

4.5 The CEMD should form the basis of more detailed site specific Construction Environmental Management Plans (CEMPs) which along with detailed method statements may be required by planning condition or, in certain cases, through environmental regulation. This approach provides a useful link between the principles of development which need to be outlined at the early stages of the project and the method statements which are usually produced following award of contract (just before development commences).

4.6 We recommend that the detailed CEMD is submitted for approval to the determining authority at least two months prior to the proposed commencement (or relevant phase) of development to order to provide consultees with sufficient time to assess the information. This document should incorporate detailed pollution prevention and mitigation measures for all construction elements potentially capable of giving rise to pollution during all phases of construction, reinstatement after construction and final site decommissioning. This document should also include any site specific

CEMPs and Construction Method Statements provided by the contractor as required by the planning authority and statutory consultees. The CEMD and CEMP do not negate the need for various licences and consents, e.g. CAR, if required. The requirements from the obtained licences and consents should be included within the final CEMPs.

5. Waste management

5.1 Details of how waste will be minimised at the construction stage should be included in the ES, demonstrating that:

- Construction practices minimise the use of raw materials and maximise the use of secondary aggregates and recycled or renewable materials;
- Waste material generated by the proposal is reduced and re-used or recycled where appropriate on site

5.2 To do this effectively all waste streams and proposals for their management should be identified. Accordingly, we recommend that a site specific site waste management plan is developed to address these points. This is in accordance with the objectives of Scottish Planning Policy and the National Waste Plan which aim to minimise waste production and reduce reliance on landfill for environmental and economic reasons.

5.3 Advice on how to prepare a site waste management plan is available on the NetRegs website and from Envirowise who also provide free advice on resource efficiency. Further advice on the reuse of demolition and excavation materials is available from the Waste and Resources Action Programme. Further guidance can also be found on our website. Information on waste prevention and waste minimisation is available on SEPA's waste minimisation webpage at www.sepa.org.uk/waste/resource_efficiency.aspx.

6. Flood risk

6.1 The onshore components of the development such as the substation may be at risk from coastal flooding. The location of the substation should therefore be assessed for flood risk from all sources in line with Scottish Planning Policy (Paragraphs 196-211). Further information and advice can be sought from the Local Authority technical or engineering services department, Scottish Water and from our website. Our Indicative River & Coastal Flood Map (Scotland) is also available to view online. If a flood risk is identified then a flood risk assessment (FRA) should be carried out following the guidance set out in the Annex to the SEPA Planning Authority flood risk protocol. Our *Technical flood risk guidance for stakeholders* outlines the information we require to be submitted as part of a FRA, and methodologies that may be appropriate for hydrological and hydraulic modelling. Further guidance on assessing flood risk and planning advice can be found at our website.

7. Onshore drainage strategy

7.1 Proposed temporary and long-term foul drainage facilities for workers associated with the onshore component of the development must be described in the ES. Guidance and best practice advice can be found in PPG4 *Disposal of sewage where no mains drainage is available*. We also request the submission of a site drainage strategy, detailing methods for the collection and treatment of all surface water runoff from hard standing areas and roads using sustainable drainage principles, which should be shown on a site plan.

7.2 Surface water drainage arrangements associated with the new substation such as any new access roads and buildings should incorporate the attenuation (where appropriate) and treatment principles of sustainable drainage systems (SUDS). The SUDS treatment train should be followed which uses a logical sequence of SUDS facilities in series allowing run-off to pass through several different SUDS before reaching the receiving waterbody. Further guidance on the design of SUDS systems and appropriate levels of treatment can be found in CIRIA's C697 manual entitled *The SUDS Manual*. Advice can also be found in the SEPA Guidance Note *Planning advice on sustainable drainage systems (SUDS)*. Please refer to the SUDS section of our website for details of regulatory requirements for surface water and SUDS.

8. Marine ecological interests

8.1 A baseline assessment of existing intertidal and subtidal habitats and species should be submitted. This should include any UK Biodiversity Action Plan habitats and species (eg maerl, sea pens, eel grass, horse mussels). Additional information on the UK Biodiversity Action Plan is available at: www.ukbap.org.uk/UKPlans.aspx?ID=35. Developers will then be able to ascertain if they are required to supplement or quantify the available data with in-field surveys.

8.2 We also recommend information be submitted detailing how the development will contribute to sustainable development. Opportunities to enhance marine habitats in line with Water Framework Directive and The Nature Conservation (Scotland) Act 2004 objectives and Scottish Planning Policy guidance should be explored. Examples may include coastal realignment, the incorporation of naturalistic features in the design of shoreline works, or planting with salt tolerant species. These could be used as examples of best practice and demonstration sites under SEPA's Habitat Enhancement Initiative (HEI).

8.3 During the construction phase, it is important that good working practice is adopted and that habitat damage is kept to a minimum and within defined acceptable parameters. These should be controlled through an environmental management plan.

8.4 Advice on designated sites and European Protected Species should be sought from SNH. For marine and transitional Special Areas of Conservation (SAC) and Special Protected Areas (SPA), these are WFD Protected Areas.

Therefore, their objectives are also RBMP objectives. In this case, SNH may contact us for input on the consultation.

9. Coastal Processes

9.1 Coastal processes should be assessed as part of the ES. This should include a baseline assessment to identify the coastal and sedimentary processes operating in the area. The baseline assessment should identify the following features and processes in the environment:

- Sediments (e.g. composition, contaminants and particle size);
- Hydrodynamics (waves and tidal flows);
- Sedimentary environment (e.g. sediment re-suspension, sediment transport pathways, patterns and rates and sediment deposition);
- Sedimentary structures (e.g. protected banks);
- Typical suspended sediment concentrations.

9.2 Developers will then be able to ascertain if they are required to supplement or quantify the available data with in-field surveys and what mitigation measures are required.

9.3 With regard to diagram 4.1 in section 4.3.3.2 the hydrodynamic modelling should be robust and should represent reality as best as possible. Model performance should be checked in order to demonstrate accuracy and should include sensitivity analysis or estimate of errors in order to enable confidence levels to be applied to model results.

9.4 The magnitude and significance of any changes to the natural processes identified in the baseline assessment should be demonstrated in the ES. It would be helpful to see a series of contour plots showing the magnitude and spatial extent of +(ve) and –(ve) changes in current velocities between the 'pre development' and 'post development' scenarios. The assessment should also identify and quantify the relative importance of high energy low frequency events e.g. storm events, versus low energy high frequency processes. Any changes to the existing processes can then be used to infer the extent of any changes to sediment transport processes and potential impacts on the marine ecology.

10. Regulatory advice

10.1 Details of regulatory requirements and good practice advice for the applicant can be found on our website at www.sepa.org.uk/planning.aspx. If you are unable to find the advice you need for a specific regulatory matter, please contact a member of the regulatory team in your local SEPA office at:

Inverdee House, Baxter Street, Torry, Aberdeen, AB11 9QA

Marine Scotland

Recently, offshore wind has focussed on large scale windfarm sites leased by The Crown Estate for Round 3 and Scottish territorial waters. These will involve the installation of a large number of turbines over several years to ensure the UK and Scottish Governments meet their commitments to generating electricity from renewable sources. Issues associated with cumulative and in combination effects of these developments will arise, MS-LOT wishes to have further discussions with the developers on this issue, at a recent meeting EOWDC indicated that a separate document addressing these matters was being drafted. The scoping document clearly states that the developer will apply for Town and Country planning for the onshore works and will not be incorporating any of the onshore infrastructure works into the EIA for the wind farm.

The definition of the 'Rochdale envelope' approach described in Section 3.4.1 is consistent with all large offshore wind developments. This allows developers to describe their projects in a hypothetical manner by fully assessing any impacts associated with all technology that may be considered on the site. However, MS-LOT understands that only one technology described within the EIA will be progressed towards commercial deployment. The EOWDC project is proposing to use more than one type of foundation i.e. there are 6 described in the scoping document. Therefore, the 'Rochdale envelope approach' should be applied differently; the assessment should include the interactions and cumulative impacts between each different type of foundation. However, if EOWDC do intend using the same foundation base throughout then the standard approach could be adopted. Due to the description of the 'Rochdale envelope' approach described above; points 56 – 58, within the scoping document, cannot be considered without the above assessment. Therefore, indicative layouts should be presented within the EIA. MS-LOT are available to discuss this issue in greater detail.

The same is also true for the actual turbine(s), the EIA can be drafted on a hypothetical machine with a maximum height to the tip of 195m above Lowest Astronomical Tide (LAT), the technology going forward on the site has been described as between 4-10MW, the 4MW has a maximum hub height of 100m and the 10MW turbine has a max hub height of 120m above LAT. The final design will dictate the maximum rotor diameter and an assessment should be carried out on the worst case scenario.

At the meeting on the 13/05/2010 (please refer to the minutes), EOWDC were advised by MS-LOT on the inflexibility of the Section 36 consent and that a generic EIA for the site should be undertaken. Separate assessments for each foundation could then be undertaken and inserted as an appendix when developers sign up to use the site. It was understood, by MS-LOT, at the time of the meeting, that each type of foundation chosen would require a separate consent, thus a single Section 36 consent would not cover the whole installation. MS-LOT has subsequently reviewed both the Section 36 legislation and its position in regard to the proposal set out in the scoping document and are of the opinion that a degree of flexibility might exist when considering the consenting strategy. MS-LOT would like to discuss this matter with you early in the New Year .

Inter array cabling

Installation methodologies must be detailed as the FEPA/Marine licence applications require a list of deposits. Point 74.

Construction timelines

Phase 1 – 4 x turbines year 1 (2012)
Phase 2 – 7 x turbines year 3 (2014)

MS-LOT requires a further update on the construction timeline and potential funding constraints, a further meeting should be scheduled to discuss the above information. EOWDC should note that mitigation measures for marine mammals will be included in the conditions and at this stage we warn you that a 24hr working window might not be possible as the Marine Mammal Observer onboard will not be able to identify marine mammals in the dark. However, we can discuss this aspect further and we are prepared to be open minded on the outcome of those discussions.

The scoping document highlighted (point 70) that a major turbine service would be required every 12 months. However, MS-LOT are not aware that the proposed technology is fully understood. Therefore please notify MS-LOT if this assessment is based on historical knowledge, and provide references. It was also stated that 'gearbox oil changes are required every 5 years', EOWDC will be required to provide method statements and contingency plans for these operations.

Section 36A

We understood that this does not apply in Scottish waters and therefore there are no provisions through section 36 for safety areas around the turbines, however, recent discussions with colleagues indicate that this situation might have changed. We will report back to you as soon as possible.

3.2 Marine Licensing

- MS-LOT will continue to administer all of the consents after April 2011.
- The Environmental Statement (ES) is the section 36 application.

Appropriate Assessment (AA)

In order for the AA to be carried out by the competent authority the installation technologies would have to be known in order to assess the impacts.

Marine Scotland Science (MSS)

The following comments have been received from MSS colleagues.

The Environmental Impact Assessment (EIA) must informatively and clearly identify the key impacts associated with the EOWDC. Within the EIA all useful sources of existing surveys and studies need to be specified.

Proposed survey techniques

The scoping document appears to have identified the potential key impacts with regard to the development. Useful sources of data from existing surveys and studies have been identified but these may not cover the whole area. However, the proposed combination of video survey and benthic grabs is essential to adequately determine the dominant habitat types and species present in the development area, large epifauna are generally under sampled by grab and trawl sampling.

Marine ecology

The Benthic Habitats Para 216 requires the reference for the biotope names to be inserted. Clarification is required within paragraph 230 as single grabs are now being collected from each position, does this mean that the sampling strategy is now considered randomly stratified; please confirm.

Sedimentary shores on the east coast Para 244: MS-LOT would like to highlight that Collieston beach is bounded by a breakwater/pier and the meiofaunal distributions may reflect this artificial situation. Therefore the sediment and the fauna distributions are localised for this area and may not represent soft sediment shores from the area of interest. Beach profiling to quantify erosion / modification should be considered, and the outcome discussed with MS-LOT prior to any action being taken., The name "*diversicolor*" should be rendered in italics.

Coastal processes

Sedimentation/erosion patterns on Aberdeen Beach are influenced by the presence of coastal structures (near shore rock structures and timber groynes), and beach re-charge. Using beach profiles taken by the University of Aberdeen may not be representative of the ongoing processes at the beach near the development site, and MS –LOT are of the opinion that a local survey would give more confidence in the interpretation of current processes and the potential impact of the development on these processes. In case Aberdeen Offshore Wind Farm Ltd has not yet been in contact with Aberdeen University regarding this data, the Aberdeen Beach project is managed by Ms. Amy Taylor and Prof. T. O'Donoghue at the School of Engineering.

Figure 11: The Ythan estuary is not in the area considered for far-field effects. Should there be significant changes in the sediment mobility in the far-field area, then this could have potentially important effects on the sedimentation/erosion patterns of the estuary. Extending the domain in the first instance, could avoid having to do this at a later stage should sediment mobility become an important issue. Again, we request you consider this point and refer to MS-LOT.

Construction

Details of any noise pollution resulting from any construction activity and any associated potential effects on cetaceans/pinnipeds/fish will be required. Noise assessments should take into consideration background noise, including vibration produced from ships' engines, piling hammers and auguring operations during the construction of turbine foundations. Considerable studies have already been conducted on cetaceans in the Moray Firth area, but the particular cause for concern is the potential additional extensive Round 3 wind farm site to the North of this development.

The proposed development will need to consider, in the first instance through a desk study, potential impacts on migratory fish including salmon (*Salmo salar*), sea trout (*Salmo trutta*), sea lamprey (*Petromyzon marinus*), river lamprey (*Hyperoplus lanceolatus*)and sandeels (*Ammodytes marinus*) during all phases of the project. The potential for offshore renewable projects to impact on migratory fish will vary depending on the design and location of the development in relation to the migration routes of adults and juveniles. Potential impacts may include physical or avoidance reactions at both the individual and population level and there may also be avoidance due to electromagnetic sensitivity at both adult and juvenile stages.

In cases where there is uncertainty over potential impacts it may be necessary for the developer to implement a monitoring strategy to assess the influence on salmonid fish populations. The expected levels of noise production must be identified in the ES and derived by using published literature, decide what impact, if any, this will have on fish movements through the area. Will it result in avoidance of the area and, if so, what does this mean for migrating fish. Please refer to Appendix A and after consideration get in contact to MS-LOT.

Inshore fisheries

From a marine fisheries perspective the following comments are provided on the range of issues and impacts identified. The assessment methodologies are proposed and sources of data identified, indicating any perceived information gaps or inaccuracies.

Section 5.3 Fish, shellfish and elasmobranches

The scoping report adequately identifies fish (commercial and non commercial), shellfish and cephalopod species known to and / or likely to occur in the area and the potential impacts of the development on these species.

Species present include some threatened and/or declining species (on OSPAR list) and UK Biodiversity Action Plan (BAP) priority species. The latter have not however been specifically identified. None of the species are unique to the area. The scoping report includes a recorded observation of a basking shark in the vicinity of the proposed development, basking sharks are protected under Schedule 5 of the Wildlife and Countryside Act thus it is a criminal offence to cause any form of disturbance to them. MS-LOT should be informed if any protected species are recorded on the site.

The report includes some reproductions of spawning and nursery grounds data from the fisheries sensitivity maps (Coull et al 1998). The developers are aware that these represent very broad scale (indicative) distributions and that more detailed and site specific information may be available elsewhere (proposal for desk studies). These maps are in some cases misleading, Nephrops distribution for example is limited by suitable (mud) habitat - both juveniles and adults live in burrows in the mud, emerging to feed and breed. MS – LOT is not aware of any specific spawning or nursery grounds within the site.

The colour reproduction of the maps, particularly the colours of the legend compared to the mapped areas make them very difficult to interpret and, in the case of Fig 5.1, render the maps misleading. If they are to be reproduced in the EIA this should be rectified.

In relation to the underwater noise impacts, MS-LOT note that no specific data will be collected on noise effects (associated with piling / installation). MS-LOT concur with the proposal that the current information is adequate for evaluating impacts of the development on fish.

Studies on possible reef effects are proposed, MS-LOT encourages this approach but recommend that it will require robust baseline information. The potential survey methodology plans should identify both mobile and more sedentary species present for all and/or part of the year. The report states there is already an established ‘baseline’ of data. If these data are from historic surveys it may require updating or expanding.

It is indicated in Section 5.8 that potential impact of Electromagnetic Fields (EMF) will be assessed as part of the EIA process using the results of the Cowrie studies referenced. Although this is probably adequate, given the relatively limited extent of this development and lack of others in the vicinity (limited potential for cumulative effects) results of other relevant research should be considered.

Section 6.1.4.2 fishing vessels

Few vessels appear to transit this area and restrictions during the construction phase are unlikely to cause particular problems. Discussion with fishing stakeholders about any action required appears to be reasonable.

An assessment of the cumulative impacts of fishing in association with other marine activities in the area should be addressed as indicated.

Section 6.6 commercial fisheries

Sources of ‘baseline’ information on fishing in the area of the proposed wind array and possible impacts on fishing have been adequately considered in the scoping document. MS-LOT would like to see the updated versions of the earlier reports. MS-LOT concurs that with mitigation residual effects on commercial fishing are likely to be minor / negligible.

MS-LOT note, however, that the area of the proposed development does not coincide with suitable habitat for *Nephrops* - interference with *Nephrops* fishing is therefore unlikely to be a major issue.

Consultation with commercial fishermen has to date been through the Scottish Fishermen’s Federation (SFF). Although this is appropriate, and the SFF should continue to be consulted, the developers should be aware that many inshore fishermen in Scotland are non-affiliated i.e. not members of Associations represented by the SFF. Some form of local consultation should therefore be considered.

Cumulative and in combination effects

A cumulative and in combination impact assessment is also a requirement of the Habitats Regulations Appraisal (HRA) with respect to the designated Special Areas of Conservation (SAC) and Special Protection Areas (SPA) which may be affected. As a result, the cumulative and in combination assessment of impacts on the marine mammals and seabirds of the Moray Firth's European designated sites will be an important consideration within the EIA process. Other cumulative effects, which consider the impacts arising from the proposed EOWDC wind farm in the context of other non wind farm developments (e.g. oil and gas operations) and activities (e.g. the shipping and fishing industries) will also be considered in the course of the EIA. MS-LOT await a document that addresses these aspects and, once it has been reviewed, may wish to update this advice.

Cable route and layout

Marine Scotland would like to emphasise that all developers are required to include maps, 'baseline' data and any details associated with the cable route within their ES as it is incorporated into the overall footprint of the works.

Throughout the document there is reference to Fisheries Research Services (FRS), Marine Scotland, and the Scottish Fisheries Protection Agency (SFPA) as data sources for all 'baseline' assessments. Developers should be aware that as of April 1 2009 - FRS became Marine Scotland Science, SFPA became Marine Scotland Compliance and that Marine Scotland is a Directorate (not an Executive agency) of Scottish Government.

Appendix A

Scoping comments in relation to information requirements on diadromous fish of freshwater fisheries interest

Offshore renewable developments have the potential to directly and indirectly impact diadromous fish of freshwater fisheries interest including Atlantic salmon, anadromous brown trout (sea trout) and European eel. These species use the coastal areas around Scotland for feeding and migration and are of high economic and / or conservation value. As such they should be considered during the EIA process. Developers should also note that offshore renewable projects have the potential to impact on fish populations at substantial distances from the development site.

In the case of Atlantic salmon information will be required to assess whether there is likely to be any significant effect of developments on rivers which are classified as Special Areas of Conservation (SAC's) for Atlantic salmon under the Habitats Directive. Where there is the potential for significant impact then sufficient information will be required to allow Marine Scotland to carry out an Appropriate Assessment.

In order that Marine Scotland is able to assess the potential impacts of marine renewable devices on diadromous fish and meet legislative requirements the developer should consider the site location (including proximity to sensitive areas), type of device, and the design of any array plus installation methodology. Specifically we request that developers provide information in the following areas:

1. Identify use of the proposed development area by diadromous fish (salmon, sea trout and eels)

a. Which species use the area? Is this for feeding or migration?
b. At what times of year are the areas used?
c. In the case of salmon and sea trout what is the origin / destination of fish using the area?

2. Identify the behaviour of fish in the area

a. What swimming depths do the fish utilise
b. Is there a tendency to swim on or offshore

3. Assess the potential impacts of deployed devices on diadromous fish during deployment, operation and decommissioning phases. Potential impacts could include:

a. Strike
b. Avoidance (including exclusion from particular rivers and subsequent impacts on local populations)
c. Disorientation that could potentially affect behaviour, susceptibility to predation or by-catch, or ability to locate normal feeding grounds or river of origin
d. Delayed migration

4. Consider the potential for cumulative impacts if there are multiple deployments in an area.

5. Assess 1-4 above to determine likely risk.

a. If there are insufficient data to determine use of the development area, these should be obtained
b. If there are insufficient data on the origin / destination of fish using the area then these should be obtained
c. Where it is not possible to obtain site specific data, the developer should make a convincing argument why this is the case and apply appropriate expert judgement based on published information.

6. If there is any remaining doubt as to the potential impacts of a particular development, then the developer should recommend a scientifically robust monitoring strategy to assess any impacts either on stocks as a whole, or on particular rivers as necessary.

Marine Scotland Science has just completed a review of migratory routes for Atlantic salmon, sea trout and eels relevant to Scotland, which should be available in 2011. This will assist the developers in identifying what pre-existing information is available and what supplementary site specific data will be required.

Ministry Of Defence

The scheme outlined involves the construction of 11 free standing wind turbines with associated infra-structure. The turbines are expected to be 195 metres to blade tip above ground level.

The principal safeguarding concern of the MOD with respect to the development of wind turbines relates to their potential to create a physical obstruction to air traffic movements and cause interference to Air Traffic Control and Air Defence radar installations.

Consultation by the developer at the pre-planning stage has identified the following concerns:

Air Defence (AD) radar

The turbines will be 26 km from; in line of sight to; and will cause unacceptable interference to the AD radar at Buchan. Following trials carried out in 2005, it has been concluded that wind turbines can affect the probability of detection of aircraft flying over or in the vicinity of wind turbines. Due to this, the RAF would be unable to provide a full air surveillance service in the area of the proposed wind farm.

Accordingly the applicant should take account of MOD aviation and radar operations in completing the EIA particularly in identifying a suitable site for development and the dimensions of the turbines that are to be installed.

It should be noted that this response is based on current levels of wind farm development in the area. If additional wind farms are consented or built prior to this development being submitted for planning consent, our position may change.

Defence Estates Safeguarding wishes to be consulted and notified of the progression of planning applications and submissions relating to this proposal to verify that it will not adversely affect defence interests.

Health and Safety Executive

Environmental Impact Assessments are concerned with projects which are likely to have significant effects on the environment. HSE's principal concerns are the health and safety of people affected by work activities. HSE cannot usefully comment on what information should be included in the environmental statement of the proposed development. However, the environmental statements should not include measures which would conflict with the requirements of the Health and Safety at Work etc Act 1974 and its relevant statutory provisions.

RYA Scotland

In the case of Aberdeen Bay, recreational sailing should be considered under both ‘Shipping and navigation’ and ‘Recreation and tourism’. The approaches to the port of Aberdeen harbour can be very busy with vessels entering and leaving. Many recreational vessels follow an inshore route from the Forth to Peterhead and vice versa, often at night to take advantage of a favourable tidal flow. Only some recreational vessels are equipped with radar and AIS and great care is needed to avoid commercial vessels entering or leaving Aberdeen. Although some recreational vessels will choose to sail further offshore to avoid the development, effective marking and lighting will be essential and needs to be considered from the point of view of recreational craft as well as much larger commercial vessels. There is a further danger of squeezing recreational craft between the commercial shipping routes and the development.

Position on offshore Energy developments attached to email.

Marine Safety Forum

Whilst we are happy with the proposed locations of the wind turbines as agreed with the developer we must comment on the route proposed for the power cabling. The developers must re-route the electricity supply cables to shore well clear of the anchorage. These would present a very great marine hazard if routed as proposed even if trenched.

The Health and Safety Executive have performed studies on pipeline and cable vulnerability which will support our concerns. A vessel (which is legally entitled to use this government approved anchorage) could drag it's anchor in severe weather which in turn could foul and damage the electricity cables putting the vessel, her crew and wind deployment centre in danger.

If the cables were routed directly to shore northward of the anchorage boundaries and then southwards inshore of the western limits to the anchorage boundary then this would not pose a significant risk. We would also like to stress that it is imperative that the proposed eleven turbines are actually located as shown in the plan so as not to impinge on the safety of marine navigation any more than agreed and absolutely necessary. Any future expansions are to be only to the north and not eastwards towards the shipping lanes or southwards into the anchorage area.

Northern Lighthouse Board

With regard to the consultation and the scope of assessment, we would only comment on that part relating to Shipping and Navigational Safety contained within several sections of the consultation document. Notice(s) to Mariners, Radio Navigation Warning and publication in appropriate bulletins will be required stating the nature and timescale of any works carried out in the marine environment relating to this project.

We would advise that any final marking and lighting recommendations will be made in a formal response through the Coast Protection Act 1949: Section 34 consultation process, and will be based on IALA Recommendation O-139. All navigational marking and lighting of the site or its associated marine infrastructure will require the Statutory Sanction of the Northern Lighthouse Board prior to deployment.

We would require the Navigational Risk Assessment to be in accordance with the information given at section 6.1.3 and in line with the requirement of MCA Marine Guidance Notice 371. This should cover all aspects of the site (including cable routes) during construction, operation, maintenance and de-commissioning phases of the project. We welcome the use of a local workshop to ensure all shipping and port interests are consulted.

We can advise that we have noted the charted anchorage and would require the area to be considered within the navigational Risk Assessment already requested above.

Chamber of Shipping

The cable route should remain well clear of the designated anchorage in close proximity. We would also like to state that the developers must ensure that there should be no material change either to the proposed location or the number of the wind turbines as stated on the plan.

BT Network Radio Protection

We have studied this wind farm proposal with respect to EMC and related problems to BT point-to-point microwave radio links.

The conclusion is that, the Wind farm Project indicated should not cause interference to BT’s current and presently planned radio networks.

Therefore BT will not be providing comments on the report

Association of Salmon Fishery Boards

The proposed developments should be conducted in full consultation with the local District Salmon Fishery Boards and Fishery Trusts for these rivers. The boards hold various statutory powers and duties and they will have an interest in the potential effects of offshore installations on migratory salmonids in their marine phase, both during construction and during subsequent operation. The Trusts may have a particular interest in assessing potential impacts and monitoring the interactions between fish and developments such as these. Given that the Dee has SAC status (salmon are a qualifying species), there is a particular need to consider any actions which might impact on this status, even if they are beyond the jurisdictional boundary of the SAC.

We would like to record our own concerns that such developments will have considerable implications and these very often can be conducted without proper regard or understanding of the potential impacts on the fish species and their habitat. Some of the issues and questions we would raise on behalf of our members are itemised below:

Effects arising from construction

- What effect would the construction processes have on fish?
- Physiological and behavioural effects of underwater noise and vibration resulting from construction operations
- Direct effects on fish of water quality changes through suspension of sediment in the water column disturbed during construction
- Indirect effects of water quality changes through effects on food sources available to salmon and sea trout
- Will the effects of noise and mechanical disruption be assessed prior to construction and would on-going monitoring be put in place if the project is approved and completed?

Operational Effects

- Physiological and behavioural effects of underwater noise and vibration resulting from turbine operation
- Are there likely to be electrical or magnetic fields associated with the installation and operation and will these have a discernable effect on salmon?
- Indirect effects on fish of permanent changes in habitat
- Whilst salmon use the Firth as a migration route and are unlikely to remain there for lengthy periods, the habits of sea trout are rather different and this species will use the firth more extensively as a feeding area before migration into freshwater systems. Accordingly there may be a risk of more prolonged interaction with sea trout in relation to the turbines.

Civil Aviation Authority - Airspace

As alluded to with the documentation provided, like any wind turbine development, the proposed subject development has the potential to impact upon aviation-related operations; the Department for Trade and Industry (DTI – now the Department for Energy and Climate Change)-sponsored document 'Wind Energy and Aviation Interests' and Civil Air Publication 764 refer. The related need to establish the scale of the potential impact of the European Offshore Wind Deployment Centre development is evident.

Having reviewed the SR and in particular the site in question, I can advise that the development might have a potential impact upon operations associated with Aberdeen Airport and note that the SR indicates ongoing consultation. All parties should be aware that aerodrome safeguarding responsibility rests with the aerodrome licensee. Any related Environmental Statement, or equivalent, would be expected to acknowledge and quantify any potential impact upon the Airport-related operations and, where applicable, detail appropriate mitigation.

Similarly, as will all wind turbine developments of this scale, the Environmental Statement will need to detail the associated viewpoints of both NATS and Ministry of Defence (MoD). To that end, I note the SR also details the ongoing consultation with these organisations and the outcomes of these and any associated mitigations as agreed should be reported in the Environmental Statement.

Not highlighted in the Scoping Report is the issue of Aviation Warning Lighting. The subject wind farm will fall under the requirements of Air Navigation Order 2009 Article 220 and this will need to be acknowledged in the Environmental Statement. Given the intensity of helicopter operations in the area, I consider this to be a significant area.

With respect to Landfall, the Environmental Statement may need to address the impact on aviation of power line routeing between Landfall and the onshore substation(s) if the power lines are a significant height above ground.

Additionally, if more generically, all parties should be aware that:

- International aviation regulatory documentation requires that the rotor blades, nacelle and upper 2/3 of the supporting mast of wind turbines that are deemed to be an aviation obstruction should be painted white, unless otherwise indicated by an aeronautical study. It follows that the CAA advice on the colour of wind turbines would align with these international criteria.

- There is a civil aviation requirement in the UK for all structures over 300 feet high to be charted on aviation maps. Should this development progress and the 300 feet height be breached the developers will need to provide details of the development to the Defence Geographic Agency.

- The number of pre-planning enquiries associated with windfarm developments has been significant. It is possible that the proliferation of wind turbines in any particular area might potentially result in difficulties for aviation that a single development would not have generated. It is, therefore, not necessarily the case that, because a generic area was not objected to by the aviation industry, future, similarly located potential developments would receive the same positive response. There is a CAA perceived requirement for a co-ordinated regional wind turbine development plan, aimed at meeting renewable energy priorities, whilst addressing aviation concerns and minimising such proliferation issues. Indeed, this may be an area where the centre may be able to provide some research.

Any associated Environmental Statement should mention and, where applicable, address the issues highlighted above.

Maritime and Coastguard Agency

The Environmental Statement should supply detail on the possible the impact on navigational issues for both commercial and recreational craft, viz.

Collision Risk
Navigational Safety
Visual intrusion and noise
Risk Management and Emergency response
Marking and lighting of site and information to mariners
Effect on small craft navigational and communication equipment
The risk to drifting recreational craft in adverse weather or tidal conditions
The likely squeeze of small craft into the routes of larger commercial vessels.

Particular reference will need to be made to the impact of the marine traffic associated with the wind farm throughout the lifetime of the project.

A Navigational Risk Assessment will need to be submitted in accordance with MGN 371 (and 372) and the DTI/DfT/MCA Methodology for Assessing Wind farms.

Attention should be paid to cabling routes and burial depth and subject to the traffic volumes an anchor penetration study may be necessary. Any proposed cable route should avoid the recently established anchorage area to the south of the proposal. Close liaison with Aberdeen Harbour Board, and other users, should be maintained.

Reference should be made to any Marine Environmental High Risk Areas (MEHRAS) established on adjacent coastlines.

The Offshore Ocean Laboratory will be required to be marked in accordance with the UK Standard Marking Schedule for Offshore Installations as required by the Northern Lighthouse Board

Any application for the establishment of safety zones during the construction stage will need to be submitted in accordance with the DTI Guidance.

Casualty information from the MAIB and RNLI would also be a good data source, in establishing the risk profile for the area.

Given that the capacity of the individual wind turbine generators have not been decided the principles of the Rochdale envelope should be used in the EIA.

The MCA Shipping Route template distances are based on risks having been identified As Low As Reasonably Practical (ALARP) and evidence to demonstrate this will be expected in the Navigational Risk Assessment.

Developers need to be aware that the radar effects of OWF on ship's radars are an important issue and subject to further discussion within the radar sub group of NOREL The radar effects will need to be assessed on a site specific basis taking into consideration previous reports on the subject available on the MCA website at:

http://www.mcga.gov.uk/c4mca/mcga07-home/shipsandcargoes/mcga-shipsregsandguidance/mcga-windfarms/offshore-renewable_energy_installations.htm

Joint Radio Company

JRC analyses proposals for wind farms on behalf of the UK Fuel & Power Industry. This is to assess their potential to interfere with radio systems operated by utility companies in support of their regulatory operational requirements.

In the case of this proposed wind energy development, JRC does not foresee any potential problems based on known interference scenarios and the data you have provided. However, if any details of the wind farm change, particularly the disposition or scale of any turbine(s), it will be necessary to re-evaluate the proposal.

In making this judgement, JRC has used its best endeavours with the available data, although we recognise that there may be effects which are as yet unknown or inadequately predicted. JRC cannot therefore be held liable if subsequently problems arise that we have not predicted.

It should be noted that this clearance pertains only to the date of its issue. As the use of the spectrum is dynamic, the use of the band is changing on an ongoing basis and consequently, you are advised to seek re-coordination prior to submitting a planning application, as this will negate the possibility of an objection being raised at that time as a consequence of any links assigned between your enquiry and the finalisation of your project.

RSPB

It has always been our contention that there is a high degree of use of the Aberdeen Bay area by many species of bird, including in particular Red-throated Diver. The numbers of this species found so far exceed the revised GB 1% threshold and we believe that at times numbers could be much higher than have been found by the limited sampling offshore so far. Use of the area by some gull species and by auks and Gannets is also high, and the importance of the concentration of moulting and feeding Common Scoters and Eiders close to the shore is also clear. Some of these birds are associated with designated European Protected Sites nearby and further afield. The information presented to date in the Scoping Report and earlier documents supports this assessment. Accordingly, there are numerous important issues to address.

Important issues that should be fully considered in the ES

1. Impact on qualifying interests of existing and potential Special Protection Areas, including distant sites such as Bass Rock and Troup Head.

Aberdeen Bay is under consideration as an SPA for inshore waterbirds. Aberdeen Bay meets stage 1.1 of the UK SPA site selection guidelines for concentrations of

Red-throated Diver (in spring and autumn). If Aberdeen Bay was to be classified as an SPA, other species may be included, such as Eider, Common Scoter and possibly Velvet Scoter.

The need for **Appropriate Assessment** is referred to in Section 5.9.2. Information presented in the Environmental Statement will be used by the Competent Authority in the Appropriate Assessment. This relates to all SPAs and SACs likely to be affected by the development.

2. Determination of bird use of the area: Vantage Point Surveys

We note that no more of these are planned. See our comments below about further data sources. We also recommended previously that it would be useful to position observers on boats moored further out from shore, in the general zone likely to be occupied by the wind turbines and urge that this should be done. Figure 7 shows clearly that the only regular survey technique covering the revised wind farm envelope reliably would be boat surveys. Stationing observers on moored vessels, through some suitable arrangement, would add much useful information. This would be particularly useful for the April/May period in 2011, since this is a time when Red-throated Divers peak in numbers.

3. Determination of bird use of the area: Boat-based Surveys

We accept the revised method, and the further extension to these for at least 12 further months from August 2010 is noted. This information, coupled with earlier surveys, should produce enough baseline information for minimum level of assessment. However, we are still concerned that an application is likely to be made before a full two years of boat-based survey information has been collected. This is not good practice considering the length of time that has elapsed since the initial surveys in 2007-2008; useful data could have been gathered in the interim.

4. Determination of bird use of the area: Radar Surveys

We note the recent further survey period in April 2010. It is clear from previous deployments of radar that a very large number of birds of many species use the bay or fly through it at all times of year, in all weather conditions and throughout the 24-hour period. This activity is concentrated in the near shore area. Previous survey periods have provided only a snapshot of the year and sampled only a proportion of the possible conditions that can be encountered offshore. It is important that there should not be over-reliance on conclusions from limited periods of radar deployment; key movement periods and weather conditions may not be sampled, and records indicate that episodic large movements and short-term usage patterns are characteristic of this offshore environment. We recommend that consideration be given to further deployment to cover periods not yet sampled.

5. Predicted impacts (5.4.4.336)

Since a subjective extrapolation method is being proposed for birds recorded in low densities, it is important to provide further contextual information for this exercise from other North-East Scotland bird data sources (see below).

5.1 Assessment of potential disturbance and displacement
One key issue here is that many of the sea ducks present in summer are moulting and this will influence their behaviour and needs to be taken into account.

5.2 Assessment of potential collision risk
Gannet is a key species for inclusion in collision risk modelling as its flight height is more likely to bring it within the area swept by rotors.

5.3 Assessment of impact of changed hydrodynamic regime on coastal and benthic processes and consequent impact **on location and nature of food sources for offshore birds**. This is touched on in Sections 4.5.1.190 and 5.1.3 and in a slightly different context [reef effect] in 5.1.7.1. It should be explicitly included in the scope of assessment for shellfish and other marine invertebrates in Section 5.3.3 and the assessment proposed in 5.4.4.341 should take account of this, away from the windfarm envelope. We are concerned here about loss of potential feeding resources linked to the seabed, especially for moulting birds. Also of course, there could be changes that increase food availability. Species to consider in particular here are: Red-throated Diver, Common Eider, Common Scoter, Velvet Scoter, all Gull, Tern and Auk species

5.4 Assessment of cumulative and in-combination impacts
All available data sources should be used, including those relevant to the sites proposed offshore from the Angus coast to the south, and the possible floating turbines off Peterhead (to be developed by StatOil).

6. Information sources for birds

These should include all recent records held in the North-East Scotland Bird records database, up to 2010 and 2011. These will include numerous counts of sea duck closer inshore than boat transects can cover, and deal with the period for which there will be no further shore-based vantage point watches by the developer.

7. Mitigation

There appears to be no section on this in the Scoping Report relevant to birds. (It is mentioned in passing in Section 5.4.3.2.318). A full consideration of potential mitigation of adverse effects on birds should be included in the Environmental Statement.

8. Issues to be addressed by the proposed Centre

We welcome the proposed Ocean Laboratory and the intent to use this to monitor environmental issues. Such monitoring should certainly include ornithological aspects, as acknowledged in Section 5.4.6. There are considerable opportunities to treat the environmental aspects of offshore wind development on an equal footing with the technical and engineering aspects. We recommend strongly that if the centre goes ahead, these environmental aspects should be incorporated as core business. A detailed plan should be produced for the development of research and monitoring techniques for all environmental aspects of any test centre developments (including an allocation of the European financial award). RSPB Scotland would be prepared to work with AOWFL and others in taking forward ornithological monitoring and research in connection with a test centre.

If these issues were fully addressed, not only would it allow the potential environmental impacts of the Aberdeen Bay proposal to be assessed properly, but it would also lend credibility to a project which intends to be an international exemplar of good practice for offshore wind development.

Aberdeen Harbour Board

Aberdeen Harbour Board welcomes the development of the European Offshore Wind Deployment Centre off Black Dog and is very interested in becoming involved in providing quayside and other facilities for the Centre's development and ongoing operational phase.

There are, however, several concerns regarding the proposal outlined in the scoping report and these are listed below:

1. Due to the high level of shipping activity both using Aberdeen Harbour and passing traffic it is essential that the location of the EOWDC does not change from that proposed. For the same reason no additional turbines or other structures should be added outside the currently proposed footprint in the future unless it is to the north.

2. The proposed cable run connecting the EOWDC to the shore currently passes through the Maritime and Coastguard Agency designated anchorage. This area is in frequent use and cannot safely be reduced in size. An alternative route for the cables should be located at a safe distance from the anchorage allowing for the possibility of a vessel dragging anchor.

3. Has sufficient information been obtained to establish the route and installation of the electricity cables in respect of the highly mobile seabed which can be subject to re-suspension throughout the tidal cycle or under stormy conditions?

4. Has modelling and monitoring been done on the impact of the turbines on the dynamic seabed? Scour and erosion are possible around the base of the turbine and if this were to increase the material in suspension it could impact on the dredging regime at Aberdeen Harbour and the beach profile of Aberdeen beach.

Transport Scotland

The proposed development represents an intensification of the use of this site however the percentage increase in traffic on the trunk road is such that the proposed development is likely to cause minimal environmental impact on the trunk road network. On this basis TRNMD have no comment to make.

Historic Scotland

Information on the location of all scheduled monuments, listed buildings, gardens and designed landscapes and designated wreck sites can be obtained from www.PASTMAP.org.uk. This is a free, interactive website produced jointly by Historic Scotland and the Royal Commission on the Ancient and Historical Monuments of Scotland which allows anyone with internet access to display and search data on Scotland's historic environment.

The proposed Development

I understand that the proposed offshore elements of the development consists of the following:

- 11 offshore wind turbines and their associated foundations
- Subsea cables between the turbines;
- An export cable for connection to the transmission network;
- An Ocean Laboratory.

The proposed onshore elements of the proposal consists of:

- Onshore deployment facilities
- Onshore substation;
- The landfall connection between offshorw export cable and onshore cable.

The scoping comments below relate to the potential impacts of the offshore aspects of the scheme only (excluding the proposed Ocean Laboratory).

Marine Assets - Potential Impacts

In relation to the submitted search area of the proposed offshore wind farm, I can confirm that there are no designations within our statutory remit located within this identified area. I can also confirm that there are no such designations within the immediate vicinity of the proposed wind farm search area.

I note that the scoping report identifies that there are certain undesignated wrecks within the survey area and that there is a potential for former terrestrial prehistoric archaeology within the subsea survey area. I welcome the proposed approach in terms of incorporating archaeological assessment and input to the geotechnical data and geophysical surveys which shall be undertaken. This is consistent with guidelines set down in 'Historic Environment Guidance for the Offshore Renewable Energy Sector' (Cowrie 2007). The relevant Council Archaeology Services may also wish to comment.

It would be very helpful if the results of all archaeological assessments could be archived through the Royal Commission on the Ancient and Historical Monuments of Scotland.

Terrestrial Assets - Potential Direct Impacts

I understand that the potential direct impacts on terrestrial assets shall be addressed separately. We shall provide further comments at this stage.

Terrestrial Assets - Impact on Setting

In relation to the search area of the proposed offshore wind farm, I can confirm that there are terrestrial assets with a seascape setting, which may be subject to an indirect impact as a result of the proposed offshore turbines. I note that viewpoints are proposed to be taken from Dunnottar Castle (Index no.986) and Torry Battery, battery 130m ESE of Old South Breakwater (Index no. 9215). I would also recommend visualisations to be taken from Hare Cairn, cairn 600m W of Keir (Index no. 3277), Forvie Church and deserted village (site of) (Index no. 7644) and Straloch designed landscape.

I understand that the potential indirect impacts of the proposed onshore works shall be assessed separately. We shall provide further comments at this stage.

Cumulative Impact

We welcome the proposed cumulative assessment and would refer you to the appropriate industry guidance on this matter; Cowrie 2008, ‘Guidance for assessment of Cumulative Impacts on the Historic Environment from Offshore Renewable Energy’.

This can be sourced at:
http://www.offshorewindfarms.co.uk/Assets/4Archaeological%20guidance%20final%20version.pdf)

Our Views on the Principle of this Proposal

Without prejudice and on the basis of the information supplied, we can indicate that while it may be possible to accommodate a wind farm development in this location, there are certain aspects of the proposal which we would require to be assessed. In particular, this relates to the potential impacts on the setting of the assets referred to above.

In terms of assessing marine archaeology, subject to the comments provided above, in our view the proposed methodology for baseline surveys, assessment of impacts and mitigation is considered acceptable.

In terms of assessing the potential impacts on marine archaeology, subject to the comments provided above, in our view the proposed methodology for baseline surveys, assessment of potential impacts and mitigation is considered acceptable.

The relevant Council archaeological and conservation service will be able to provide information and advice on unscheduled archaeology and category B and C(S) listed buildings.

Please refer to the advice contained in our technical guidance note on setting. This documents is available at:

http://www.historic-scotland.gov.uk/managing-change-consultation-setting.pdf

Ports and Harbours

The application must include a full Navigation Risk Assessment in line with MGN 371. Having cables running through an anchorage area would appear to be a risky idea and they would need to be buried to a suitable depth to prevent damage.

Annex 2.

DEVELOPER APPLICATION AND ENVIRONMENTAL STATEMENT CHECKLIST

	Enclosed
1. Developer cover letter and fee cheque	□
2. Copies of ES and associated OS maps	□
3. Copies of Non Technical Summary	□
4. Confidential Bird Annexes	□
5. Draft Adverts	□
6. E Data – CDs, PDFs and SHAPE files	□

Environmental Statement	Enclosed	ES Reference (Section & Page No.)
7. Development Description	□	
8. Planning Policies, Guidance and Agreements	□	
9. Economic Benefits	□	
10. Site Selection and Alternatives	□	
11. Baseline Assessment data – air emissions	□

2 September 2010

Dear Mr Sutherland

MOD SAFEGUARDING: – MOD RADAR AND FLIGHT SAFETY WIND ENERGY SAFEGUARDING INTERESTS

Proposal: Scoping Opinion Request For Proposed Section 36 Application

Location: European Offshore Wind Deployment Centre, Aberdeen

Thank you for consulting the Ministry of Defence (MOD) on the scoping request with respect to the above proposal.

The scheme outlined involves the construction of 11 free standing wind turbines with associated infra-structure. The turbines are expected to be 195 metres to blade tip above ground level.

The principal safeguarding concern of the MOD with respect to the development of wind turbines relates to their potential to create a physical obstruction to air traffic movements and cause interference to Air Traffic Control and Air Defence radar installations.

Consultation by the developer at the pre-planning stage has identified the following concerns:

Air Defence (AD) radar

The turbines will be 26 km from; in line of sight to; and will cause unacceptable interference to the AD radar at Buchan. Following trials carried out in 2005, it has been concluded that wind turbines can affect the probability of detection of aircraft flying over or in the vicinity of wind turbines. Due to this, the RAF would be unable to provide a full air surveillance service in the area of the proposed wind farm.

DEFENCE ESTATES
Delivering Estate Solutions to Defence Needs

Accordingly the applicant should take account of MOD aviation and radar operations in completing the EIA particularly in identifying a suitable site for development and the dimensions of the turbines that are to be installed.

It should be noted that this response is based on current levels of wind farm development in the area. If additional wind farms are consented or built prior to this development being submitted for planning consent, our position may change.

Defence Estates Safeguarding wishes to be consulted and notified of the progression of planning applications and submissions relating to this proposal to verify that it will not adversely affect defence interests.

I hope this adequately explains our position on this matter. If you require further information or would like to discuss this matter further please do not hesitate to contact me.

Yours sincerely

Richard Maisey

4 Jackson's Entry
Holyrood Road
Edinburgh
EH8 8AE

01 September 2010

Dear Mr Rodger

Scoping Document for the Proposed Islay Offshore Wind Farm

Thank you for your correspondence dated 20 August 2010 regarding the Scoping Document Consultation for the proposed Aberdeen Bay wind turbine site development and the intention of **Aberdeen Offshore Windfarm Limited** to deploy up to 11 turbines in test area approximately 2km off the Aberdeenshire coast.

With regard to the consultation and the scope of assessment, we would only comment on that part relating to Shipping and Navigational Safety contained within several sections of the consultation document. Notice(s) to Mariners, Radio Navigation Warning and publication in appropriate bulletins will be required stating the nature and timescale of any works carried out in the marine environment relating to this project.

We would advise that any final marking and lighting recommendations will be made in a formal response through the Coast Protection Act 1949: Section 34 consultation process, and will be based on IALA Recommendation O-139. All navigational marking and lighting of the site or its associated marine infrastructure will require the Statutory Sanction of the Northern Lighthouse Board prior to deployment.

We note that the reference to cable routes and other marine users depicted in the Annex at Fig 2 and Fig 12 do not contain the recently recommended anchorage area within Aberdeen Bay. This should be included in all future documentation.

We would require the Navigational Risk Assessment to be in accordance with the information given at section 6.1.3 and in line with the requirement of MCA Marine Guidance Notice 371. This should cover all aspects of the site (including cable routes) during construction, operation, maintenance and de-commissioning phases of the project. We welcome the use of a local workshop to ensure all shipping and port interests are consulted.

Please advise if we can be of any further assistance, or require clarification any of the above.

I would be obliged if any further communication to the Northern Lighthouse Board can be sent via fax on 0131 220 0235, e-mail to navigation@nlb.org.uk or our postal address, Northern Lighthouse Board, 84 George Street, Edinburgh, EH2 3DA.

David Roger
Senior Development Manager
Vattenfall Windpower Ltd
The Tun Building
4 Jacksons Entry
Holyrood Road
Edinburgh
EH8 8AE

14 February 2011

Dear David,

European Offshore Wind Deployment Centre

The RYA is the national body for all forms of recreational and competitive boating. It represents dinghy and yacht racing, motor and sail cruising, RIBs and sports boats, powerboat racing, windsurfing, inland cruising and personal watercraft. The RYA manages the British sailing team and Great Britain was the top sailing nation at the 2000, 2004 and 2008 Olympic Games.

The RYA is recognised by all government offices as being the negotiating body for the activities it represents. The RYA currently has over 100,000 personal members, the majority of whom choose to go afloat for purely recreational non-competitive pleasure on coastal and inland waters. There are an estimated further 500,000 boat owners nationally who are members of over 1,500 RYA affiliated clubs and class associations.

The RYA also sets and maintains an international standard for recreational boat training through a network of over 2,200 RYA Recognised Training Centres in 20 countries. On average, approximately 160,000 people per year complete RYA training courses. RYA training courses form the basis for the small craft training of lifeboat crews, police officers and the Royal Navy and are also adopted as a template for training in many other countries throughout the world.

There are two RYA publications which are relevant. The first is the '***RYA Position Statement on Offshore Renewable Energy Developments'***, a copy of which is attached. The RYA's concerns regarding recreational boating and offshore energy devices are included in this statement and we would expect these to be addressed in the planning of any marine development.

In addition to the position statement, the RYA has also produced the UK Coastal Atlas of Recreational Boating. The Atlas contains maps of recreational cruising routes, racing and sailing areas as well as locations of RYA affiliated clubs, training centres and also marinas (independent) around the UK. The Atlas is freely available electronically as a PDF file and is also available in GIS format for an annual £600 licence fee from the RYA (contact: emma.stewart@rya.org.uk). Please note that the routes given are those most commonly used and are based on information given by local experts. Passage planning depends on the expected weather, tidal flows, whether the vessel is under sail or power, and many other individual factors. Any increase in storminess during the normal sailing season (April 1 to 31 October) has implications for navigation in these waters.

RYA Scotland, through its network of local experts, will be happy to provide any additional detailed information required for Environmental Statements.

In summary the RYA's concerns with offshore energy developments and recreational boating relate to:

Navigational safety
Collision risk, particularly in adverse weather conditions
Risk management and emergency response, for example in response to units breaking free in a storm
Marking and lighting
Weather
Location
Loss of cruising routes and anchorages
Squeeze into commercial routes
Effect on sailing and racing areas
Cumulative effects both of other similar schemes and also other developments
Visual intrusion and noise
End of life
Dereliction
Decommissioning
Consultation
These are detailed in our position statement, referenced above and attached to this letter.

There can also be positive benefits for marine recreation from the development of marine renewables. These might include provision of onshore infrastructure, marking of underwater hazards and reduction of wave heights by wave devices.

In the case of Aberdeen Bay, recreational sailing should be considered under both 'Shipping and navigation' and 'Recreation and tourism'. The approaches to the port of Aberdeen harbour can be very busy with vessels entering and leaving. Many recreational vessels follow an inshore route from the Forth to Peterhead and vice versa, often at night to take advantage of a favourable tidal flow. Only some recreational vessels are equipped with radar and AIS and great care is needed to avoid commercial vessels entering or leaving Aberdeen. Although some recreational vessels will choose to sail further offshore to avoid the development, effective marking and lighting will be essential and needs to be considered from the point of view of recreational craft as well as much larger commercial vessels. There is a further danger of squeezing recreational craft between the commercial shipping routes and the development.

I hope the above information proves useful. Please do not hesitate to contact RYA Scotland should you have any questions.

Yours aye,

James Stuart
Chief Operating Officer

Dear Andrew

Electricity Act 1989

The Electricity Works (Environmental Impact Assessment) (Scotland) Regulations 2000

Scoping Opinion For The Proposed Section 36 Application For The European Offshore Wind Deployment Centre, Aberdeen

Thank you for consulting SEPA on the scoping opinion for the above development proposal by way of your letter which we received on 30 August 2010. We consider that the following key issues should be addressed in the EIA process:

- River Basin Planning
- Pollution Prevention and Environmental Management
- Coastal Processes

Please note that all of the issues below should be addressed in the Environmental Statement (ES) for the whole project, but there may be opportunities for several of these to be scoped out of detailed consideration for specific aspects or phases. The justification for this approach in relation to specific issues should be set out within the ES.

1. Scope of the ES for marine developments

1.1 This project will be developed during a period of fast development of marine policy at national and international levels and this should be addressed with respect to the Marine (Scotland) Act 2010 and Marine Strategy Framework Directive. More information can be found on the Marine Science website at http://www.scotland.gov.uk/Topics/marine/seamanagement.

1.2 From the information submitted we understand the overall project will include both onshore and offshore components including 11 turbines, foundations, cabling, ocean laboratory, and onshore works including landfall and substation. As such, the development will be subject to a range of different consenting regimes. We would encourage you to consider producing a single ES which covers all aspects of the proposed development. This will enable a full assessment of the potential effects of the development as a whole, rather than assessing certain details of the development individually.

2. Site layout and nature of construction for marine developments

2.1 The ES should contain plans giving detailed information on the site layout, including details of all onshore and offshore components such as access tracks, buildings, cabling and marine devices. These plans should be supported by a statement detailing the development, as well as reasons for the choice of site and design of the development. Depending on the types and scale of construction the information below may be required.

2.2 Plans should be included in the ES showing the layout of the devices, cabling routes and associated onshore infrastructure.

2.3 Background information that will help inform the ES process is available from European Marine Energy Centre (EMEC). The EMEC has produced guidelines to assist developers in considering the range and scale of impacts that may result from the testing of devices. These guidelines are available at www.emec.org.uk/index.asp. Generally, if this standard industry guidance is followed for scoping, preparing and undertaking EIA for marine renewables, then we are likely to be satisfied with the standard of assessment.

2.4 There may be a need to address the cumulative effects of devices on coastal processes depending upon density and location with respect to existing renewable and coastal developments.

2.5 The submission should include information on likely timing and duration of the project, possible long-term locational and/or operational impacts and short-term construction impacts.

3. River Basin Management Planning

3.1 Under the Water Environment and Water Services (Scotland) Act 2003, SEPA is responsible for producing and implementing River Basin Management Plans for the Scotland and the Solway Tweed River Basin Districts. River basins comprise all surface waters (including transitional (estuaries) and coastal waters) extending to 3 nautical miles seaward from the Scottish territorial baseline. Any proposed development within these waters must have regard to the requirements of the Water Framework Directive to ensure that all surface water bodies achieve 'Good Ecological Status' and that there is no deterioration in status. The Water Framework Directive requires the consideration of chemical, ecological and hydromorpholgical status. Further information on River Basin Management planning can be found on the SEPA website at www.sepa.org.uk/water/river_basin_planning.aspx. Information on the current status of Scotland's surface waters can be found on the water body data sheets on the the River Basin Management Planning Web Mapping Application available on SEPA's website at (http://213.120.228.231/rbmp/).

3.2 Under section 4, page 57 (baseline data) we would suggest that inclusion of the data held on 'Cruden Bay to Don Estuary' coastal water body should also be included in the baseline dataset. This water body is currently classified at high ecological status – a full datasheet is available at apps.sepa.org.uk/rbmp/pdf/200117.pdf. Any proposed development within these waters must have regard to the requirements of the Water Framework Directive (WFD) to ensure that all surface water bodies achieve 'Good Ecological Status (GES)' and that there is no deterioration in status. The WFD requires the consideration of chemical, ecological and hydromorpholgical status. The ecological status of surface water bodies which may be affected by the proposal should also be considered in section 5, alongside the discussion of protected areas for salmon and freshwater pearl mussel. These can be accessed via the interactive map at www.sepa.org.uk/water/river_basin_planning.aspx.

3.3 The cumulative assessments should consider the proposals alongside any existing coastal development already present within the water bodies in which landfall locations are being considered. EC guidance defines cumulative impacts as "impacts that result from incremental changes caused by other past, present or reasonably foreseeable actions together with the project" (http://ec.europa.eu/environment/eia/eia-studies-and-reports/guidel.pdf).

3.4 Maps should be included in the ES showing the areas of seabed likely to be affected by the footprint of the turbine bases and cabling, and the area of intertidal zone that is likely to be affected by shoreline infrastructure development. To allow for the RBMP classification to be updated and the assessment of cumulative impacts within these water bodies footprint data for the turbines and cabling components of the development should be provided in the ES.

4. Construction Environmental Management Document (CEMD) and pollution prevention

4.1 One of our key interests in relation to major developments is pollution prevention measures during the periods of construction, operation, maintenance, demolition and restoration. The construction phase includes construction of access roads and any other site infrastructure.

4.2 We advise that the applicant, through the EIA process or planning submission, should systematically identify all aspects of site work that might impact upon the environment, potential pollution risks associated with the proposals and identify the principles of preventative measures and mitigation. This will establish a robust Project Environmental Management Process (PEMP) for large scale (eg Major and Environmental Impact Assessment Projects (EIA). A draft Schedule of Mitigation should be produced as part of this process. This should cover all the mitigation measures identified to avoid or minimise environmental effects. Details of the specific issues that we expect to be addressed are available on the Pollution Prevention and Environmental Management section of our website.

4.3 A key issue for us is the timing of works. Therefore, the Schedule of Mitigation should include a timetable of works that takes into account all environmental sensitivities, such as fish spawning, which have been raised by SEPA, SNH or other stakeholders. Timing should also be planned to avoid construction of roads, dewatering of pits and other potentially polluting activities during periods of high rainfall. We can provide useful information such as rainfall and hydrological data through our Access to Information Team.

4.4 A Construction Environmental Management Document (CEMD) is a key management tool to implement the Schedule of Mitigation. We recommend that the principles of the CEMD are set out in the ES drawing together and outlining all the environmental constraints and commitments, proposed pollution prevention measures and mitigation as identified in the ES.

4.5 The CEMD should form the basis of more detailed site specific Construction Environmental Management Plans (CEMPs) which along with detailed method statements may be required by planning condition or, in certain cases, through environmental regulation. This approach provides a useful link between the principles of development which need to be outlined at the early stages of the project and the method statements which are usually produced following award of contract (just before development commences).

4.6 We recommend that the detailed CEMD is submitted for approval to the determining authority at least two months prior to the proposed commencement (or relevant phase) of development to order to provide consultees with sufficient time to assess the information. This document should incorporate detailed pollution prevention and mitigation measures for all construction elements potentially capable of giving rise to pollution during all phases of construction, reinstatement after construction and final site decommissioning. This document should also include any site specific CEMPs and Construction Method Statements provided by the contractor as required by the planning authority and statutory consultees. The CEMD and CEMP do not negate the need for various licences and consents, e.g. CAR, if required. The requirements from the obtained licences and consents should be included within the final CEMPs.

5. Waste management

5.1 Details of how waste will be minimised at the construction stage should be included in the ES, demonstrating that:

- Construction practices minimise the use of raw materials and maximise the use of secondary aggregates and recycled or renewable materials;

- Waste material generated by the proposal is reduced and re-used or recycled where appropriate on site

5.2 To do this effectively all waste streams and proposals for their management should be identified. Accordingly, we recommend that a site specific site waste management plan is developed to address these points. This is in accordance with the objectives of Scottish Planning Policy and the National Waste Plan which aim to minimise waste production and reduce reliance on landfill for environmental and economic reasons.

5.3 Advice on how to prepare a site waste management plan is available on the NetRegs website and from Envirowise who also provide free advice on resource efficiency. Further advice on the reuse of demolition and excavation materials is available from the Waste and Resources Action Programme. Further guidance can also be found on our website. Information on waste prevention and waste minimisation is available on SEPA's waste minimisation webpage at www.sepa.org.uk/waste/resource_efficiency.aspx.

6. Flood risk

6.1 The onshore components of the development such as the substation may be at risk from coastal flooding. The location of the substation should therefore be assessed for flood risk from all sources in line with Scottish Planning Policy (Paragraphs 196-211). Further information and advice can be sought from the Local Authority technical or engineering services department, Scottish Water and from our website. Our Indicative River & Coastal Flood Map (Scotland) is also available to view online. If a flood risk is identified then a flood

risk assessment (FRA) should be carried out following the guidance set out in the Annex to the SEPA Planning Authority flood risk protocol. Our *Technical flood risk guidance for stakeholders* outlines the information we require to be submitted as part of a FRA, and methodologies that may be appropriate for hydrological and hydraulic modelling. Further guidance on assessing flood risk and planning advice can be found at our website.

7. Onshore drainage strategy

7.1 Proposed temporary and long-term foul drainage facilities for workers associated with the onshore component of the development must be described in the ES. Guidance and best practice advice can be found in PPG4 *Disposal of sewage where no mains drainage is available*. We also request the submission of a site drainage strategy, detailing methods for the collection and treatment of all surface water runoff from hard standing areas and roads using sustainable drainage principles, which should be shown on a site plan.

7.2 Surface water drainage arrangements associated with the new substation such as any new access roads and buildings should incorporate the attenuation (where appropriate) and treatment principles of sustainable drainage systems (SUDS). The SUDS treatment train should be followed which uses a logical sequence of SUDS facilities in series allowing run-off to pass through several different SUDS before reaching the receiving waterbody. Further guidance on the design of SUDS systems and appropriate levels of treatment can be found in CIRIA's C697 manual entitled *The SUDS Manual*. Advice can also be found in the SEPA Guidance Note *Planning advice on sustainable drainage systems (SUDS)*. Please refer to the SUDS section of our website for details of regulatory requirements for surface water and SUDS.

8. Marine ecological interests

8.1 A baseline assessment of existing intertidal and subtidal habitats and species should be submitted. This should include any UK Biodiversity Action Plan habitats and species (eg maerl, sea pens, eel grass, horse mussels). Additional information on the UK Biodiversity Action Plan is available at: www.ukbap.org.uk/UKPlans.aspx?ID=35. Developers will then be able to ascertain if they are required to supplement or quantify the available data with in-field surveys.

8.2 We also recommend information be submitted detailing how the development will contribute to sustainable development. Opportunities to enhance marine habitats in line with Water Framework Directive and The Nature Conservation (Scotland) Act 2004 objectives and Scottish Planning Policy guidance should be explored. Examples may include coastal realignment, the incorporation of naturalistic features in the design of shoreline works, or planting with salt tolerant species. These could be used as examples of best practice and demonstration sites under SEPA's Habitat Enhancement Initiative (HEI).

8.3 During the construction phase, it is important that good working practice is adopted and that habitat damage is kept to a minimum and within defined acceptable parameters. These should be controlled through an environmental management plan.

8.4 Advice on designated sites and European Protected Species should be sought from SNH. For marine and transitional Special Areas of Conservation (SAC) and Special Protected Areas (SPA), these are WFD Protected Areas. Therefore, their objectives are also RBMP objectives. In this case, SNH may contact us for input on the consultation.

9. Coastal Processes

9.1 Coastal processes should be assessed as part of the ES. This should include a baseline assessment to identify the coastal and sedimentary processes operating in the area. The baseline assessment should identify the following features and processes in the environment:

- Sediments (e.g. composition, contaminants and particle size);
- Hydrodynamics (waves and tidal flows);
- Sedimentary environment (e.g. sediment re-suspension, sediment transport pathways, patterns and rates and sediment deposition);
- Sedimentary structures (e.g. protected banks);
- Typical suspended sediment concentrations.

9.2 Developers will then be able to ascertain if they are required to supplement or quantify the available data with in-field surveys and what mitigation measures are required.

9.3 With regard to diagram 4.1 in section 4.3.3.2 the hydrodynamic modelling should be robust and should represent reality as best as possible. Model performance should be checked in order to demonstrate accuracy and should include sensitivity analysis or estimate of errors in order to enable confidence levels to be applied to model results.

9.4 The magnitude and significance of any changes to the natural processes identified in the baseline assessment should be demonstrated in the ES. It would be helpful to see a series of contour plots showing the magnitude and spatial extent of +(ve) and –(ve) changes in current velocities between the ‘pre development’ and ‘post development’ scenarios. The assessment should also identify and quantify the relative importance of high energy low frequency events e.g. storm events, versus low energy high frequency processes. Any changes to the existing processes can then be used to infer the extent of any changes to sediment transport processes and potential impacts on the marine ecology.

10. Regulatory advice

10.1 Details of regulatory requirements and good practice advice for the applicant can be found on our website at www.sepa.org.uk/planning.aspx. If you are unable to find the advice you need for a specific regulatory matter, please contact a member of the regulatory team in your local SEPA office at:

Inverdee House, Baxter Street, Torry, Aberdeen, AB11 9QA

If you have any queries relating to this letter, please contact me by telephone on 01224 266698 or e-mail at planningaberdeen@sepa.org.uk.

Yours faithfully

Our ref: CNS REN WF ABOF

Dear Sir

ELECTRICITY ACT 1989
THE ELECTRICITY WORKS (ENVIRONMENTAL IMPACT ASSESSMENT) (SCOTLAND) REGULATIONS 2000
SCOPING OPINION REQUEST FOR PROPOSED SECTION 36 APPLICATION FOR THE EUROPEAN OFFSHORE WIND DEPLOYMENT CENTRE, ABERDEEN

Thank you for your recent consultation requesting our scoping advice on this proposed offshore windfarm development to be located in Scottish territorial waters north west of Aberdeen, approximately 2km offshore. Our advice incorporates comments from the Joint Nature Conservation Committee (JNCC).

Background

Scoping for this proposal originally took place in 2005, when 33 turbines were being considered and our advice at that time was provided in our letter of 2 August 2005. The proposal has changed in location, scale and layout several times since then. We have been worked with AWOFL and its predecessors over the last five years to help identify the potential natural heritage impacts of the proposal and commented on survey methodologies and interim reports, particularly for birds and marine mammals.

The current proposal is for 11 turbines and an ocean lab with connecting cables and scour protection, 2-4.5km offshore. It is likely an application will be submitted early next year.

There will also be onshore deployment facilities and a substation which will be dealt with by a separate planning application and scoping report.

Consenting Process

We appreciate the complexity of dealing with both terrestrial and marine consenting processes; however we recommend that the onshore grid connection application is submitted simultaneously with the offshore wind deployment centre application. This would allow us to provide advice on all aspects of the proposal and give sufficient regard to potential cumulative impacts to the natural heritage. The application for the offshore research centre should be submitted at the same time for the same reasons, unless there is a need to submit it earlier so that it can be used to gather data before construction of the windfarm.

Given the nature of this proposal as a test centre, we also recommend further discussion about the consenting process. We would be happy to be involved in any such discussions with Marine Scotland and AOWFL to identify the potential options including: phasing of the development, assessment of differing and innovative turbine and / or foundation types, timing and duration of construction and operational activities etc.

Natural Heritage Interests to be Considered

In principle, we support the development of marine renewable energy devices where sensitively designed and sited – as set out in SNH Policy Statement 04/01[1]. For this offshore windfarm proposal, we have reviewed the scoping report and our advice is provided in Appendix A and with respect to Natura sites, in Appendices D and E. A summary of some of the key points is provided below.

Please note that the comments in this letter are made without prejudice to any further comments that we might make when consulted on an application for this proposal.

Habitats Regulations

It is important to take into account the range of interests and potential impacts of Natura sites that may need to be considered in relation to regulation 48 of the Conservation (Natural Habitats, &c.) Regulations 1994 as amended, and in particular whether an Appropriate Assessment is required. More detail on the legislative requirements relating to Natura Sites and species is contained in Appendices B and C.

When submitting this application, AOWFL should include a report to inform the Appropriate Assessment. We welcome the consideration that has been given to this in section 5.9.2 of the scoping report and provide further advice on the Habitats Regulations Appraisal process within Appendices D and E.

Although data has been collected for some time, this has been for different iterations of the development and when submitted, there will be less than the minimum two years data which we recommend. It is also not clear how much of the data available will relate to the current site and layout. We **strongly recommend** that AOWFL consider in detail how they will prepare the report to inform an Appropriate Assessment, and whether the types and amount of information that will be available to them at the time (both their own data and that from other sources) will be sufficient.

The report to inform an Appropriate Assessment must consider the conservation objectives for each Natura site. We hope that the scoping advice contained within the appendices to this letter and the draft table we provided on 19 January 2009 (for impacts to the Moray Firth and

---

[1] Marine Renewable Energy and the Natural Heritage: An Overview and Policy Statement. No. 04/01. (Please note this is currently being revised.)

Available from: http://www.snh.gov.uk/docs/A327477.pdf

River Dee SACs), provide a useful starting point that AOWFL can develop. We would welcome the opportunity to assist AOWFL by commenting on first a detailed scope of the report to inform an Appropriate Assessment and subsequently a draft. There is a risk that Marine Scotland will not be able to carry out the Appropriate Assessment and draw sufficiently robust conclusions when the application is submitted early next year. A detailed scope would help identify if this is the case and may be used to consider how the consenting process can address this.

Key Points

Some of the key points that we wish to draw out are:

- The layout and footprint of the proposal have changed several times and it is unclear which of the data collected so far, and available from other sources, cover the current footprint and how much data will be available when the application is submitted.

- We do not think that the report covers migrant waterfowl sufficiently. For example, there has only been one radar study that was designed to detect migrant geese and it may have taken place too late to measure anything meaningful. There needs to be more information before we can advise whether this can be dismissed as an important issue.

- Impacts on relevant Annex 1 Birds Directive species (e.g. Common Scoter, Red-throated diver, Black-throated diver etc.) and Annex IV Habitats Directive species (all cetacea) should be specifically identified, including their activity outwith any SPAs. It is unclear whether the additional boat survey will give sufficient data to assess impacts to red-throated diver and common scoter and if not, how this will be addressed.

- We strongly recommend that Aberdeen Offshore Wind Farm Limited consider in detail how they will prepare a report to inform an Appropriate Assessment, and what information will be available to them at the time (both their own data and that from other sources).

- It is important to consider the different ‘sections’ in an integrated way that considers the effect of impacts on one aspect of marine ecology on another, taking into account all relevant factors such as coastal processes.

- Little information is available on the offshore research centre and it is unclear if it is covered in the current scoping report. The report states that the location for this has yet to be decided and it will be subject to a separate consent application. We recommend that a clearer rationale is provided for the research centre and that an application is submitted at the same time as that for the offshore wind deployment centre. This would help inform the overall assessment of the project, as well as providing an opportunity for monitoring protocols to be prepared in advance on any works. More consideration of the timing that application is submitted may be needed if the centre is to be used for research before the windfarm is constructed.

- We would welcome the preparation of research proposals in a construction and post-construction monitoring plan. We recommend that the ES includes an outline of such a plan.

Further Information and Advice

We hope this information is helpful and would welcome the opportunity to continue to provide advice to AOWFL by for instance, commenting on survey results before the ES is prepared. We would be grateful if you could copy us into the formal scoping opinion in due course. Please do not hesitate to contact me if I can be of any further assistance.

Yours faithfully

Sue Lawrence
Area Officer – City of Aberdeen and Aberdeenshire Central
Sue.lawrence@snh.gov.uk

cc David Rodger, Vattenfall Wind Power Ltd

APPENDIX A

SNH's DETAILED ADVICE ON EOWDC SCOPING REPORT

1.6 Approach to EIA

1.6.1 Impact Assessment Methodology

Para 30 – We have raised concerns in meetings about the use of a matrix approach, both for birds and marine mammals and seascape impacts. We encourage a more flexible approach that uses a thorough assessment based on rigorous professional judgement, as this better recognises the complex and unique aspects of the proposal.

1.6.2 Cumulative and In-combination Impact

Actual projects anticipated to be included should be outlined at this stage. We recommend AOWFL consider other east coast windfarm sites such as the 3 STW sites in the Outer Forth and Tay Area (Inch Cape, Neart na Gaoithe and Forth Array), the two Round 3 Zones (Zone 1 and Zone 2) as well as the STW site in the Moray Forth (Beatrice).

2.3 The Project Concept / Consenting Process

Para 46 – We understand that the timing of this proposal is in part driven by the funding requirements of the grant this project will receive from them European Energy Programme for Recovery. In order for us to advise further, for example in relation to the consenting process, it would help to know what those funding requirements are.

2.4 Proposed Development

The report states that there are likely to be onshore deployment facilities, substation and cable which will be dealt with under a separate scoping report. It would be helpful if a timescale was given for when that scoping report and subsequent application will be submitted. Please note for the purposes of the Habitats Regulations Appraisal, the project requires to be assessed as one (please see our comments in Appendix E). We can provide further advice on this aspect once we have received the scope of the report to inform an Appropriate Assessment.

Please note that the landfall is on an erosional soft coastline. Future-proofing the cables and landfall infrastructure is therefore important. It should be ensured that there are no obstructions to net northerly sediment movement within the Bay, otherwise the existing erosion problem on the southern two thirds of Aberdeen Bay (and particularly at Blackdog) may worsen.

Fig 2 (p 161) implies two offshore cables merge into one, to cross the intertidal. The ES should consider if there would be jointing infrastructure where the cables merge as this could create a potential impact in terms of obstruction on a lowering & erosional foreshore.

2.4.1 Wind Turbines

Paras 5, 52 and 56 - It is stated that there may be multiple turbine foundation, tower and turbine designs deployed at the proposed development site. We recommend that if any of these designs depart substantially from the standard foundation (jacket, mono-pile, gravity base), tower (single tubular tower) or turbine (three bladed upwind turbine) designs that the potential for increased or additional impacts from these designs are carefully considered in consultation with us and others. For example lattice design towers may cause attraction to the wind farm and turbine as birds try to roost on the structure. Any turbine with more or fewer blades than the normal three bladed design may result in very different bird collision risk calculations. Floating turbine designs may result in increased underwater collisions for marine mammals and diving birds although there is unlikely to be sufficient depth of water for floating turbines at this site.

We support the idea of trialling new foundations so long as appropriate monitoring is in place to look at and assess the impacts.

2.4.3 Ocean Laboratory
The report states that the location for this has yet to be decided and it will be subject to a separate consent application. It is unclear whether or not it is covered in this scoping report (cf 2.4, paras 49-51) and therefore will be covered within the ES. It would be helpful to have further clarification on this aspect.

2.5 Project Construction

2.5.1 Construction Timescales
Para 62 – We note that 4 turbines are expected to be installed in 2012 and that work will be continuous during construction. Given that these four turbines may have entirely different foundations and thus differing vessel requirements, it will be important that the EIA considers all the possible options of likely numbers and types of vessels on site over the construction period.

2.5.2.3 Inter-Array Cables

Para 74 – Any stabilisation methods for the cables should not interrupt tidal or wave driven currents, otherwise they may have significant onshore implications in terms of sediment movement.

2.5.2.5 Scour Protection
Para 76 – This could be an opportunity to trial different methods which is particularly important if AOWFL wish to investigate artificial reef properties (see comments on 5.1.7.1 below).

4.1 Meteorological Conditions

4.1.2 Baseline Information
Haar is frequent on the north east coastline and the ES should take this into account eg increased likelihood of accidents and associated environmental effects of these measures and requirements for foghorns and lighting. The section on wind turbines (2.5.2.2) says that aviation warning lighting will be required but does not mention foghorns.

4.3 Coastal Processes

4.3.2 Baseline Information
Para 125 - 'a narrow ridge of unknown origin situated in the region between the offshore and littoral zones; it is possible that this ridge affords some protection to the coast from wave action.' This should be investigated, it may be the lower limits of former emerged shorelines, representing themselves within the nearshore. This could have implications for the cable-installation approach.

Para 126 - The implications of the wind farm on tidal currents should be considered. Halcrow (working for Aberdeen City Council) established that south-north tidal currents at the southern end of the bay, played an important role in sediment dynamics and beach health. Given the wave shadow effect of a nearshore array (with cables, defences, sour protection etc), and the propensity of erosion on the adjacent coast, it would be prudent to ensure that there are unlikely to be knock-on effects.

4.5 Sediment and Water Quality

4.5.2 Baseline Information

Please consider whether the sampling takes into account any pollution from the nearby contaminated land at Blackdog.

5.1 Marine Ecology

5.1.2.2 Benthic Habitats

Para 230 - We note that the sampling approach set out in the scoping report is different to the recently agreed benthic survey strategy. The ES should report on results obtained from the recently agreed benthic sampling strategy (September 2010).

5.1.7.1 Further research opportunity: reef effect

Para 239 - We agree this would be a good location to study the reef effects of structures and distinguish between (a) perceived benefits through enhanced diversity/productivity and (b) the structures acting simply as fish aggregation devices. This should form part of a post-construction monitoring plan that we would welcome the opportunity either to comment on or become more directly involved in. Careful consideration should be given to what would be required for post construction monitoring.

As mentioned above (2.5.2.5) there is also the opportunity to look at the best methods of scour protection and recovery of the site following cable installation.

5.3 Fish, Shellfish and Elasmobranchs

The benthic section of the report should make appropriate links to fish and shellfish where there are strong habitat associations for particular species. For example, muddy sediment is closely associated with *Nephrops* and their fishery. The sand and gravelly sand which dominates the area for this proposal is likely to have associations particularly with scallops, but also various flatfish and sandeels (in terms of fisheries species).

5.3.2.1 Spawning and nursery grounds

Para 256 - We are pleased that the report acknowledges the spatial and temporal variability of these areas. The spawning and nursery habitats data provided is from Coull *et al* (1998). Further and more recent information is/should shortly be available from the Defra Data Layers project.

5.3.2.5 Diadromous and freshwater species

Para 268 - We suggest that sparling should also be considered as a diadromous fish species of conservation importance. Sparling is included in the UK Biodiversity Action Plan Priority Species list. They are found in coastal waters and estuaries and migrate into large clean rivers to spawn. Sparling was previously known to occur in a number of Scottish rivers, but has now disappeared from almost all of these sites.

Para 269 - We note that sturgeon have been recorded which are a European Protected Species and must be considered accordingly in the ES (Please see appendix C).

Para 271 - The scoping report identifies various rivers that are important for salmonids, but does not consider whether the River South Esk SAC, to the south of the proposed site, may be affected. The qualifying interests of the River South Esk SAC are Atlantic salmon and freshwater pearl mussel. A recent review by Marine Scotland Science (Malcolm, I., Godfrey, J. & Youngson, A. In prep. Review of migratory routes and behaviour of Atlantic salmon, sea trout and European eel in Scotland's coastal environment: implications for the development of marine renewables. *Marine Scotland Science draft report*.) summarises available information on the migratory routes and behaviour of Atlantic salmon, sea trout and European eel. Although the report indicates that the dominant direction of travel for Atlantic salmon (1 SW and MSW) on the east coast of Scotland, in the area around Aberdeen, is a northerly direction, there is also some southerly movement, and there is both easterly and westerly movement on the east coast to the north of Aberdeen. The River South Esk should be included in the list of Natura sites that are identified in the report. Please see our advice in Appendix E on HRA scoping.

To the south of the River South Esk, there are three SACs with anadromous fish species as qualifying interests - the River Tay SAC (Atlantic salmon, river lamprey, sea lamprey), River Teith SAC (Atlantic salmon, sea lamprey, river lamprey) and the River Tweed SAC (Atlantic salmon, sea lamprey, river lamprey). These SACs are likely to be sufficiently well removed from the proposed site not to be significantly affected by the development.

There are also several SACs with diadromous fish and freshwater pearl mussel qualifying interests to the north of the development, but they are also likely to be sufficiently well removed from the proposed site not to be significantly affected by the development.

Para 277 - Not all sites containing freshwater pearl mussel are designated as SSSI or SAC. Any populations in non-designated sites in the vicinity of the development should be considered, but only within the ES.

5.3.2.6 Elasmobranchs

Para 282 – Basking Sharks are known to occur along the east coast and we recommend AOWFL look for more recent literature or sighting records to check this. They may wish to liaise with some of the some of the other east coast offshore wind developers who are also undertaking surveys to see if they are reporting similarly low numbers. We recommend that basking sharks are recorded as a feature if observed during any marine mammal or bird surveys. As Basking sharks are protected under Schedule 5 of the Wildlife and Countryside Act, no development licences are currently available.

Para 283 - We would have thought that there were other elasmobranchs in the area worth mentioning, not only basking and porbeagle sharks.

Para 286 - This should include the effects of displacing fishing activity; i.e. impacts on areas where fishing activity moves to and therefore becomes concentrated. Also could be put in wider fisheries management context, by considering efforts of Scottish Government to bring fishing (and other marine activities) within environmental and biological limits.

5.3.4 Potential impacts

The scoping report recognises that the potential impacts of noise, electromagnetic fields and other disturbance on diadromous fish species needs to be evaluated. A draft SNH report (Gill, A.B. & Bartless, M. In prep. Literature review on the potential effects of electromagnetic fields and subsea noise from marine renewable energy developments on Atlantic salmon, sea trout and European eel) considers the current state of knowledge with regard to the potential impacts of noise and electromagnetic fields associated with marine renewable energy, on Atlantic salmon, sea trout and European eel.

The draft report by Marine Scotland Science (referred to above, para 271) considers available information on migratory routes and behaviour of Atlantic salmon, European eel and sea trout in Scotland's coastal environment, and should also be useful.

Para 597 - The Inshore Fisheries Group (IFG) that covers this area is not yet set-up but should be established soon - this will be another appropriate point of contact for consulting local fishermen, in theory including those that are not affiliated with fishermen's associations.

Table 6.2, p133: - (a) displacement effects should be included, (b) some of the conclusions in this table make assumptions. We do not know the impacts much of the time or how effective mitigation measures will be e.g. impacts of electromagnetic fields and underwater noise.

5.4 Birds

The layout and footprint of the proposal have changed several times and it is unclear which of the data collected so far, and available from other sources, cover the current footprint and how much will be available when the ES is prepared and application submitted.

One of the subjects that we have consistently raised is the need to consider impacts to red-throated divers and common scoter. It is unclear whether the additional boat survey will give sufficient data to address this.

We also do not think that the report covers migrant waterfowl sufficiently. There has only been one radar study that was designed to detect migrant geese and it may have been undertaken too late to really measure anything meaningful. There needs to be more information before we can advise whether this can be dismissed as an important issue.

<u>5.4.1 Introduction</u>

Paragraph 291 and Table 5.2 – Please note that the JNCC programme for designating SPAs for inshore aggregations of non-breeding waterbirds is ongoing and Aberdeen bay is still an active Area of Search. For any marine area which does become an SPA the provisions of Article 6 of the Habitats Directive (Reg 48) will apply. Meantime the area should be considered as an important area for birds and the effects of development seen in this context. The obligations of Articles 2 and 3 of the Birds Directive also need to be considered.

Para 291 - Aberdeen bay is also used by birds during the spring and autumn migration periods and potentially by moulting birds. Indeed, para 296 notes the Aberdeenshire coast as important for divers, grebes and seaduck for all months of the year.

Paragraph 292 – it is stated that seven SPAs within "daily flight distance" of the proposed development site were identified as being relevant. It is unclear which foraging distance data was used for which species. We recommend that the distances used for each species considered is stated and those SPAs that may have connectivity to the proposed development site is listed for each species. We recommend that foraging distance data is not used as a hard cut off value, but that those SPAs that are close to the cut off value are included at this stage (Please also see our comments in Appendix D on the HRA process for SPAs).

<u>5.4.1.1 Project Reports</u>

Additional data sources should include all data available such as North East Scotland Bird Survey reports.

<u>5.4.2 Baseline information</u>

We welcome the consideration in paras 294-309. As well as considering where particular species are a feature of interest of an SPA, the ES should also consider where they are a feature of interest of an SSSI. The SSSI, SAC and SPA interests for a designated site are not always the same nor have the same boundary. For example, some SSSIs such as Corby, Bishops and Lily Lochs are not SPAs. Ramsar sites should also be considered.

Paragraph 299 – due to the very long foraging distances of northern gannet it is likely that some of the birds observed are from other breeding colonies. We recommend that at this stage other gannet colonies further north than Troup Head are scoped in (Please also see our comments on Appendix D).

Para 300: Kittiwake and herring gull also form part of the Fowlsheugh SPA interests.

Paragraph 302 – auks make multiple foraging trips per day during breeding, not one single all day foraging trip as stated here. Thus the energetic impacts due to barrier effects may be multiplied.

Paragraph 305 – note that redshank and lapwing are qualifying features of the non-breeding waterfowl assemblage of the Ythan Estuary, Sands of Forvie and Meikle Loch SPA and not the "seabird assemblage interest feature" as stated here.

Table 5.2 – please add black-legged kittiwake to the species covered by Article 4.2 for the Troup, Pennan and Lions Head SPA. Also please add northern fulmar as a qualifying feature of the seabird assemblage of the Forth Islands SPA. Please remove whooper swan as a feature of the Loch of Skene SPA.

5.4.3.1 Vantage Point Surveys

Para 312 – it is unlikely that detectability of many species is very good as far out as 2km. If distances to each bird (or group of birds) was recorded during vantage point watches we recommend that the number birds detected is plotted against distance to estimate the detectability function for each species. For some species it may be necessary to plot age and/or sex separately (e.g. young gannets have more cryptic plumage than adults, or female eider are more cryptic than males). It should then be possible to assess the range at which each species was reliably detected and thus constrain the analysis to those records within this distance. In addition the effects of sea state may influence detectability with increasing distance. We recommend that the detectability functions for each species are compared across different sea states to determine at which sea state the detectability becomes too low to reliably record birds.

Para 314 – flight height data in the near shore area recorded from vantage point may not be a good model for flight heights further from shore and in deeper water. We urge caution in interpreting flight height data recorded by shore based observers. If flight height data recorded from shore is to be used, we recommend that analysis is undertaken to determine if flight heights measured from shore differs significantly from flight heights measured either by boat based observers or from radar.

5.4.3.2 Boat Based Surveys

Table 5.5 – It is unclear how the assessment of collision, barrier and displacement risks was made. These are probably derived from the presentation we received from Vattenfall in September 2008. Our comments on those results are contained in our letter of 10 December 2008. In particular, the assessment needs to consider all sources of data available and be based on a sufficient length of time to give confidence in the results.

Table 5.5 – We recommend that rather than providing some data on flight heights that a frequency plot of flight heights is provided for each species when these data are presented in the ES.

Table 5.5 – It is not clear where the wind farm and control survey areas are as these are not indicated in any figures. It is not clear whether these observations have been adjusted to the current proposed development foot print or whether or whether they relate to a former iteration. If it is a former iteration it would be helpful to know which one. This also applies to section 5.4.3.4 Radar studies.

5.4.3.3 Boat Based Surveys 2010-2011

Para 326 - It is important that there is sufficient data available to enable Marine Scotland to carry out an Appropriate Assessment. Currently it is unclear whether or not this will be the case.

5.4.3.4 Radar Surveys

Para 329 - Does this refer to the current windfarm footprint or that at the time the radar study was carried out?

Para 333 – It is stated that previous studies have found that "very high avoidance rates by geese" and that collisions being "extremely unusual". There should be reference made to these studies and an indication of where they were undertaken and which species were involved and in what numbers. In order to assess the ability of the conducted radar study to adequately assess the presence and numbers of migrating geese much more information needs to be provided. We recommend that the timing of the deployment of the radar is compared to the known time of passage and numbers of geese recorded at regularly counted sites in the area (e.g. Montrose Basin, Loch of Strathbeg). It will then be possible to show whether the radar was deployed at an appropriate time but should also take into account the variation in goose movements between years. We also recommend that the results of radar ground truthing are included in the ES.

5.4.4 Predicted Impacts
Para 335 – We recommend that the details of the analysis that resulted in the redesign of the turbine layout are included in the ES. Any future analysis of impacts should include indirect effects and disturbance from increased boat traffic for operation and maintenance of the proposed turbines. It should consider all aspects of the turbines such as navigation and aviation warning measures including possible lighting and/or foghorns.

Para 336 – We recommend that for those species where there is insufficient data to apply Distance analysis, plots of the locations and numbers of birds are included, e.g. by varying the size of symbols relative to the number of birds recorded.

Para 338 - The ES should include information on how flight height data was verified.

5.4.6 EOWDC future research and monitoring
Para 343 - We welcome the proposal to continue monitoring during and post-construction and welcome the opportunity to discuss research needs further.

5.6 Marine Mammals

5.6.2.3 Future Boat Based Surveys 2010-2011
Para 392 - From the text it appears that the data presented in the ES will be four months of 'new data' combine with approximately 15 months of 'old data' which didn't cover the same points and used a different method. If it is unclear if this will be sufficient for an assessment and we advise that AOWFL ensure that the mitigation and monitoring of impacts is extremely robust. We also recommend the assessments include as much data as possible, albeit if necessary with some months having less analysis.

5.6.5 Mitigation
There is an opportunity to look at how effective different forms of mitigation are on minimising impacts of installation – noise. This is referred to in 5.7 but not with any detail. As a test centre we recommend that there is a detailed look at underwater noise and robust monitoring of marine mammals (which should include behavioural studies to determine whether behavioural effects are occurring). Ideally we would wish to see a number of readings at various distances from each installation to record noise. This would help gain a better understanding of whether or not various types of mitigation are working or indeed worth doing. We would be happy to meet with AOWFL or their consultants at an early stage to discuss this and try to get the most out of this research.

5.6.6 EOWDC Future Research and Monitoring
C-Pods are now proposed as ''future research' and not for gathering data for the ES. As explained above in the main letter, it is unclear whether there will be enough data for assessing impacts to bottle-nose dolphins both as a feature of the Moray Firth SAC and as EPS, when the ES is submitted. It would be useful to get clarification of what survey protocol will be used for C-Pods, when and where they will be deployed. Please see also our comments in Appendix E.

5.9 Statutory Designations and Conservation
For comments on Natura sites, please refer to our advice in Appendices D and E on the HRA for SPAs and SACs.

Table 5.9 – This should include the River South Esk SAC, to the south of the proposed site. The qualifying interests of the River South Esk SAC are Atlantic salmon and freshwater pearl mussel. The draft Marine Scotland Science report referred to in our comments above indicates that the dominant direction of travel of Atlantic salmon on the south east coast is a northerly one, but there is also some southerly movement. See comments in Appendix E.

The scoping report does not directly consider Ramsar sites and we recommend these are addressed in the ES.

6.5 Seascape, Landscape and visual effects
In general, it appears that the proposed SLVIA outlined takes due cognisance of our previous scoping comments and discussions at meetings. In particular the report recognises the proximity of major and smaller population centres as sensitive receptors, and gives particular consideration to any effects arising as a result of differing wind turbines devices.

6.5.2 Baseline Information
Para 556 – Given the large height of the turbines, it is important to retain a flexible approach to the study area, increasing it if the ZTVs indicate that visual effects are likely to occur in a wider area.

6.5.2.1 Landscape and Seascape Character
Paras 557 - 558 - As we discussed at a meeting with the developer's consultants on 14th April 2010, it is important to consider how the assessments of seascape, landscape and local landscape character types will fit together to prevent duplication and avoid confusion. We would be happy to provide further advice once AOWFL have developed a methodology for this.

6.5.2.2 Visual Amenity
Para 560 – Recreation users at Donmouth LNR should also be considered.

Para. 561 and Table 6.1 - Representative viewpoint locations. Ideally to inform our input into further discussion on viewpoint locations (over and above that previously agreed), it would be useful to have a comparative ZTV, illustrating the extent of changed visibility occurring between the 2009 layout and the current 2010 layout. This would ensure optimum locations are chosen.

Para. 567 - The photomontages should illustrate a range of conditions - eg. sunrise; turbine lighting (dawn/dusk); the international aviation (2.5.2.2) requirement for the turbines to be painted white and aviation warning lighting; the size of the ocean lab (we appreciate this would be a separate application, but some initial indicators of scale, form etc. would be useful).

We had previously suggested allowing for some fixed photomontage 'boards' on site to engage the public. There is no mention of this in the scoping report (within either of the SLVIA or Recreation and Tourism sections) and we recommend that this is undertaken.

6.5.5 Cumulative Impact
Para. 574 - Further engagement on methods for cumulative impact assessment should include both Aberdeen City and Aberdeenshire councils.

Para 576 – This refers to the choice of colour of turbines being used to mitigate landscape and visual impacts, however, section 2.5.2.2 indicates that much of the turbines should be white.

6.8 Recreation and Tourism

6.8.2 Baseline Information

Paras 626-633 – Surfing is another recreational activity that takes place in Aberdeen and kite surfing at Balmedie. All forms of recreation should be considered in the ES and there should be consultation with relevant user groups.

7. Consultations

Para 678 – we recommend that the Whale and Dolphin Conservation Society (WDCS) are added to the list of other consultees. The WDCS have commented on marine mammal survey methods for this proposal and interim reports.

APPENDIX B

HABITATS & BIRDS DIRECTIVES, & HABITATS REGULATIONS

Paragraphs 434-436 of the scoping report outline the Habitats and Birds Directives. The Habitats Directive is transposed into domestic law in Scotland by the 'Conservation (Natural Habitats, &c.) Regulations 1994' which came into force on 30 October 1994 – usually called simply the **Habitats Regulations**. Several amendments have been made to the Habitats Regulations since they came into force.

The Habitats Regulations apply to the inshore zone, and the rules for the protection of marine Natura sites and marine European protected species (EPS) apply here exactly as they do on land.

Habitats Regulations Appraisal

Where a plan or project could affect a Natura site, the Habitats Regulations require the competent authority – the authority with the power to undertake or grant consent, permission or other authorisation for the plan or project in question – to consider the provisions of regulation 48. This means that the competent authority has a duty to:

- determine whether the proposal is directly connected with or necessary to site management for conservation; and, if not,
- determine whether the proposal is likely to have a significant effect on the site either individually or in combination with other plans or projects; and, if so, then
- make an appropriate assessment of the implications (of the proposal) for the site in view of that site's conservation objectives.

This process is now commonly referred to as **Habitats Regulations Appraisal** (HRA). HRA applies to any plan or project which has the potential to affect the qualifying interests of a Natura site, even when those interests may be at some distance from that site.

The competent authority, with advice from SNH, decides whether an appropriate assessment is necessary and carries it out if so. It is the applicant who is usually required to provide the information to inform the assessment. Appropriate assessment focuses exclusively on the qualifying interests of the Natura site affected and their conservation objectives. A plan or project can only be consented if it can be ascertained that it will not adversely affect the integrity of a Natura site (subject to regulation 49 considerations).

Further Information and Advice on HRA

In this scoping response we provide tailored advice for HRA in respect of birds that are qualifying interests of SPAs, and marine mammals, habitats and fish that are qualifying interests of SACs:

- Appendix D – SNH Advice on Habitats Regulations Appraisal for SPAs
- Appendix E – SNH Advice on Habitats Regulations Appraisal for SACs

In respect of this, further information on the qualifying interests and the conservation objectives for each relevant Natura site is available from SNH's Sitelink database[2].

For further advice on the HRA process please see SNH's website[3], including the leaflet on "Natura sites and the Habitats Regulations"[4] which provides a helpful summary. Some of the

---

2 http://www.snh.org.uk/snhi/

key concepts are explained in the European Commission's guidance on Article 6 of the Habitats Directive.[5] Revised guidance updating the Scottish Office Circular 6/1995[6] on the implementation of the Habitats and Birds Directive in Scotland was produced in June 2000. This sets out current Government policy relating to Natura sites.

APPENDIX C

EUROPEAN PROTECTED SPECIES

Certain species are listed on Annex IV of the Habitats Directive as species of European Community interest and in need of strict protection. The protective measures required are outlined in Articles 12 to 16 of the Directive. The species listed on Annex IV whose natural range includes any area in the UK are called 'European protected species'.

SNH is the statutory nature conservation body who provides advice on EPS in respect of the Habitats Regulations in Scotland, including Scottish Territorial Waters.[7] A summary of the legal requirements for EPS is as follows:

> The Conservation (Natural Habitats, &c.) Regulations 1994 as amended. (The Habitats Regulations.)
>
> Protection of certain wild animals
>
> 39. (1) It is an offence –
>
> (a) deliberately or recklessly to capture, injure or kill a wild animal of a European protected species;
>
> (b) deliberately or recklessly –
>
> i. to harass a wild animal or group of wild animals of a European protected species;
>
> ii. to disturb such an animal while it is occupying a structure or place which it uses for shelter or protection;
>
> iii. to disturb such an animal while it is rearing or otherwise caring for its young;
>
> iv. to obstruct access to a breeding site or resting place of such an animal, or otherwise to deny the animal use of the breeding site or resting place;
>
> v. to disturb such an animal in a manner that is, or in circumstances which are, likely to significantly affect the local distribution or abundance of the species to which it belongs;
>
> vi. disturb such an animal in a manner that is, or in circumstances which are, likely to impair its ability to survive, breed or reproduce, or rear or otherwise care for its young; or
>
> vii. to disturb such an animal while it is migrating or hibernating;
>
> (c) deliberately or recklessly to take or destroy the eggs of such an animal; or
>
> (d) to damage or destroy a breeding site or resting place of such an animal.
>
> (2) Subject to the provisions of this Part, it is an offence to deliberately or recklessly disturb any dolphin, porpoise or whale (cetacean).

Scottish Government has also provided guidance on the 2007 amendments addressing EPS – *Explanatory guidance for species related activities.*[8]

[8] Scottish Government Guidance available at: http://www.scotland.gov.uk/Resource/Doc/1221/0050637.pdf

EPS Licences

Licences may be given authorising activities that could affect EPS which would otherwise be illegal under the Habitats Regulations. For Scottish Territorial Waters these licences will be issued either by Scottish Government[9] or by SNH[10] depending on the reasons for the licence request. Licences are only issued under very strict conditions as set out in regulations 44 and 45 of the Habitats Regulations.

As highlighted in Scottish Government Interim Guidance[11], three tests must be satisfied before the licensing authority can issue a licence under Regulation 44(2) of the Conservation (Natural Habitats &c.) Regulations 1994 (as amended) to permit otherwise prohibited acts. An application for a licence will fail unless all of the three tests are satisfied. The three tests involve the following considerations:

- **Test 1** - The licence application must demonstrably relate to one of the purposes specified in Regulation 44(2) (as amended). For development proposals, the relevant purpose is likely to be Regulation 44(2)(e) for which Scottish Government is currently the licensing authority. This regulation states that licences may be granted by Scottish Government only for the purpose of "preserving public health or public safety or other imperative reasons of overriding public interest including those of a social or economic nature and beneficial consequences of primary importance for the environment."

- **Test 2** - Regulation 44(3)(a) states that a licence may not be granted unless Scottish Government is satisfied "that there is no satisfactory alternative".

- **Test 3** - Regulation 44(3)(b) states that a licence cannot be issued unless Scottish Government is satisfied that the action proposed "will not be detrimental to the maintenance of the population of the species concerned at a favourable conservation status in their natural range" (Scottish Government will, however, seek the expert advice of Scottish Natural Heritage on this matter).

Consideration of European Protected Species must be included as part of the application process, not as an issue to be dealt with at a later stage. Any consent given without due consideration to these species is likely to breach European Directives with the possibility of consequential delays or the project being halted by the EC.

APPENDIX D

EOWDC: HABITATS REGULATIONS APPRAISAL (HRA) – SPECIAL PROTECTION AREAS

Introduction

In the following advice for HRA we set out the three steps that need to be considered in order to determine whether or not the European offshore Wind Deployment Centre proposal is likely to have a significant effect on the qualifying interests of SPAs, and any possible adverse impact on site integrity – Appendix B provides more detail on the legislative framework. It is the competent authority (most likely Marine Scotland) who will carry out the HRA, based on our advice and using information and data collated by the developer.

Under HRA, the potential impacts of the EOWDC proposal will need to be considered alone (all aspects of the proposal ie including onshore deployment facilities, substation, cable and offshore research station) and in combination with other plans and projects. It needs to be considered in combination with the Scottish Round 3 zones as well as the following proposed Scottish territorial water sites (Neart na Gaoithe, Inch Cape, Forth Array and Beatrice) and with other types of industry and activity in and around Aberdeen bay and harbour.

Special Protection Areas for inclusion in HRA

We would welcome the opportunity to discuss the scope of HRA with AOWFL (as noted in this response) and we recommend that the following SPAs are considered for individual and also for cumulative assessments:

Troup, Pennan and Lion's Heads SPA
Forth Islands SPA
Fowlsheugh SPA
Buchan Ness to Collieston Coast SPA
Ythan Estuary, Sands of Forvie and Meikle Loch SPA
Loch of Strathbeg SPA
Loch of Skene SPA
Montrose Basin SPA

Please see also our comments in Appendix A, para 299 recommending that gannet colonies further north than Troup Head are also scoped in at this stage (eg Fair Isle).

Advice for HRA in respect of SPA qualifying interests

The steps of the process are as follows; our advice is tailored to consideration of this offshore windfarm:

Step 1: Is the proposal directly connected with or necessary for the conservation management of the SPAs?

The EOWDC proposal is not directly connected with or necessary for the conservation management of any of the SPAs listed above.

Step 2: Is the proposal likely to have a significant effect on the qualifying interests of the SPAs either alone or in combination with other plans or projects?

This step acts as a screening stage: it removes from the HRA those proposals (plans or projects) which clearly have no connectivity to SPA qualifying interests or where it is very obvious that the proposal will not undermine the conservation objectives for these interests, despite a connection. When this screening step is undertaken at an early stage in the development process, it usually means that it takes the form of a desk-based appraisal. We advise that this is kept broad so that potentially significant impacts are not missed out, or discounted too early, in any HRA (or EIA).

The SPA bird interests being considered in respect of offshore windfarms are wide-ranging – many seabirds make long foraging trips, especially during the breeding season, and there are also migratory species to consider such as geese and swans. This means that offshore windfarm proposals may be 'connected to' SPAs at much greater distances than what has so far been experienced in respect of onshore development. Although connectivity is thus established the fact that the proposal is located further away from the designated sites means that direct impacts are less likely on qualifying species while they are within the SPA.

Expert agreement over species sensitivity should help to identify those SPA qualifying interests for which the conservation objectives are unlikely to be undermined by offshore windfarm development, despite any possible connection (e.g. SPA qualifiers which are recorded within a proposed windfarm site but where their flight behaviour and / or foraging ecology means that the windfarm will not have a likely significant effect).

Determination of 'likely significant effect' is not just a record of presence or absence of bird species at an offshore windfarm site, but also involves a judgement as to whether any of the SPA conservation objectives might be undermined. Such judgement is based on a simple consideration of the importance of the area in question for the relevant species. Complex data analysis should not be required at this stage. For example; How many birds have been recorded? What are they using the area for? Is this the only area that they can use for this particular activity? Understanding the behavioural ecology of the species, and the characteristics and context of the proposed windfarm site, will help in determining whether there are likely significant effects. There are three possible conclusions for this step of HRA:

a) The likely impacts are such that there is clear potential for the conservation objectives to be undermined – conclude likely significant effect.

b) The likely impacts are so minimal (either because the affected area is not of sufficient value for the birds concerned or because the risk to them is so small) that the conservation objectives will not be undermined – conclude no likely significant effect.

c) There is doubt about the scale of the likely impacts in terms of the conservation objectives – conclude likely significant effect.

<u>Step 3:</u> Can it be ascertained that the proposal will not adversely affect the integrity of the SPA, either alone or in combination with other plans or projects?

This stage of HRA is termed appropriate assessment, and it is undertaken by the competent authority based on information supplied by the developer, with advice provided by SNH. Appropriate assessment considers the implications of the proposed development for the conservation objectives of the qualifying interests for which a likely significant effect has been determined. These conservation objectives follow a standard format requiring protection of the qualifying bird interests and protection of the habitat in the SPA which supports them.

Conservation objectives for SPA bird species

To ensure that site integrity is maintained by:

(i) Avoiding deterioration of the habitats of the qualifying species.

(ii) Avoiding significant disturbance to the qualifying species.

To ensure for the qualifying species that the following are maintained in the long term:

(iii) Population of the bird species as a viable component of the SPA.

(iv) Distribution of the bird species within the SPA.

(v)	Distribution and extent of habitats supporting the species.
(vi)	Structure, function and supporting processes of habitats supporting the species.
repeat of (ii)	No significant disturbance of the species.

It is important to recognise that the conservation objectives primarily offer site-based protection and that some of them will not directly apply to species when they are outwith the boundaries of the SPA. This is particularly true of objectives **(i)**, **(v)** and **(vi)** which relate to the supporting habitats within the SPA.

Objective **(iii)** however – maintenance of the population of the bird species as a viable component of the SPA – will be relevant in most cases because:

It encompasses direct impacts to the species, such as significant disturbance to qualifying bird interests when they're outwith the SPA.

It addresses indirect impacts such as the degradation or loss of supporting habitats which are outwith the SPA but which help to maintain the population of the bird species of the SPA in the long-term.

Finally, in rare circumstances, it is possible that factors / events outside site boundaries may have the capacity to affect the long term distribution of bird species within the SPA – see objective **(iv)**.

Issues to consider under appropriate assessment

The **key question** in any appropriate assessment for the EOWDC proposal is whether it can be ascertained that this proposal, alone or in combination, will not adversely affect the population of any qualifying bird species as a viable component of the SPAs under consideration.

In considering this matter, we refer to the helpful summary of the main risks of offshore windfarm development to birds provided in Langston 2010.[12] In addition, there may be further issues to consider if the proposal is likely to affect the conservation objectives that relate to bird species while they're in an SPA or to the habitats in the SPA that support them.

- Will the offshore wind proposal(s) cause a deterioration in the habitats of any of the SPAs? *NB. This question relates specifically to the habitats in the SPAs that support the bird interests.*
- Will the offshore wind proposal(s) cause any significant disturbance to bird interests while they're in any of the SPAs? N.B. *See the previous discussion in respect of disturbance outside an SPA.*
- Will the offshore wind proposal(s) alter the distribution of the birds within any of the SPAs?
- Will the offshore wind proposal(s) affect the distribution and extent of the habitats (that support the bird species) in any of the SPAs?
- Will the offshore wind proposal(s) in any way affect the structure, function and supporting processes of habitats in any of the SPAs? NB. *Those habitats which support the bird species.*

[12] Langston (2010). Offshore wind farms and birds: Round 3 zones, extensions to Round 1 & Round 2 sites & Scottish Territorial Waters. RSPB Research Report No. 39.

We highlight that these questions may be applicable to the habitats which support bird interests in any new SPAs designated for inshore and / or offshore aggregations of seabirds – please see JNCC's website for potential areas of search, including Aberdeen Bay.[13]

As noted above, we hope to further discuss these various aspects with AOWFL once a scope for the HRA has been provided.

13 Information on potential new marine SPAs is available at: http://www.jncc.gov.uk/page-4184

APPENDIX E

EOWDC: HABITATS REGULATIONS APPRAISAL – SPECIAL AREAS OF CONSERVATION

Introduction

In the following advice for Habitats Regulations Appraisal (HRA) we set out the three steps that need to be considered in order to determine whether or not the EOWDC proposal is likely to have a significant effect on the qualifying interests of Special Areas of Conservation, and any possible adverse impact on the site integrity of SACs – Appendix B provides more detail on the legislative framework. It is the competent authority (Marine Scotland) who will carry out the final stage of the HRA (appropriate assessment), based on our advice and using information and data collated by the developer.

Under HRA, the potential impacts of the EOWDC proposal will need to be considered alone (all aspects of the proposal ie including onshore deployment facilities, substation, cable and offshore research station) and in combination with other plans and projects. It needs to be considered in combination with the Round 3 development and with other types of industry and activity in the Moray Firth. We therefore recommend that the Beatrice and Round 3 developers collaborate on the assessment of cumulative impacts and we would welcome discussion of this matter and, preferably, a joint meeting between the developers, Marine Scotland and ourselves (SNH and JNCC).

For those SAC qualifying interests that are also European protected species (such as bottlenose dolphin) please see Appendix C for our advice in respect of their EPS status and for EPS licensing arrangements. The advice that we give below solely relates to their consideration as an SAC qualifying interest and how the HRA process therefore applies.

Special Areas of Conservation for Inclusion in HRA

We advise that the applicant will need to consider the following SACs. Further information, including their conservation objectives, is available from http://www.snh.org.uk/snhi/.

SACs designated for marine mammals:

- **Moray Firth SAC** - designated for bottlenose dolphin (*Tursiops truncatus*) and for subtidal sandbank habitat.

SACs designated for fish of conservation concern:

- **River Dee SAC** - designated for Atlantic salmon, freshwater pearl mussel and otter.
- **River South Esk SAC** - designated for Atlantic Salmon and freshwater pearl mussel (Please see our comments in Appendix A, para 271).

SNH advice for HRA in respect of Special Areas of Conservation

The steps of the process are as follows; our advice is tailored to consideration of this offshore windfarm:

Step 1: Is the proposal directly connected with or necessary for the conservation management of the SACs?

The EOWDC proposal is not directly connected with or necessary for the conservation management of any of the SACs listed above.

<u>Step 2</u>: Is the proposal likely to have a significant effect on the qualifying interests of the SACs either alone or in combination with other plans or projects?

This step acts as a screening stage: it removes from the HRA those proposals which clearly have no connectivity to SAC qualifying interests or where it is very obvious that the proposal will not undermine the conservation objectives for these interests, despite a connection. When this screening step is undertaken at an early stage in the development process, it usually means that it takes the form of a desk-based appraisal.

In respect of the above SACs, we identify that the EOWDC may have connectivity to the following qualifying interests, which will therefore require further consideration under HRA. While a desk-based review is helpful for this screening step, this part of the HRA will only be fully completed when the windfarm proposal has been further progressed – when survey work and analyses have been completed, and when the location of / construction methods for windfarm infrastructure, including onshore elements, has been finalised.

There are three possible conclusions to this step of HRA:

a) The likely impacts are such that there is clear potential for the conservation objectives to be undermined – conclude likely significant effect.

b) The likely impacts are so minimal that the conservation objectives will not be undermined – conclude no likely significant effect.

c) There is doubt about the scale of the likely impacts in terms of the conservation objectives – conclude likely significant effect.

However, we are not yet in a position to present definite conclusions for this step, so instead we provide a **summary of our current advice** for each qualifying interest.

- **Marine and coastal habitats** of the Moray Firth .

  We do not consider any aspect of the offshore wind deployment centre will have an impact on the habitat qualifying interest of the Moray Firth SAC

  Summary of our current advice: no likely significant effect.

- **Bottlenose dolphins** of the Moray Firth SAC.

  While the EOWDC proposal is located approximately 140 km from the Moray Firth SAC, the dolphins are not confined to this SAC and will range more widely within the Firth and beyond. Observations around the area of Aberdeen Harbour have confirmed sighting of individual dolphins from the Moray Firth SAC. Construction (and other) noise arising from the proposal is likely to extend beyond the windfarm footprint and may overlap with dolphin use of the surrounding environment. Boat movements, cable-laying and other construction activity may give rise to disturbance. There may also be impacts to the prey species of dolphin – either from the placement of infrastructure or due to noise. We therefore advise that there is potential for the proposal to have likely significant effects on bottlenose dolphins and we discuss below (under step 3) the issues that we think need to be considered.

  It would be beneficial for applicants to collaborate on this issue with other offshore wind developers as appropriate assessment of the cumulative impacts on bottlenose dolphins is likely to be required in combination. Joint discussion and co-ordination of survey and monitoring proposals, mitigation proposals and construction time-tabling would be helpful.

  Summary of our current advice: likely significant effect, so impacts (including cumulative) will need to be considered in appropriate assessment (see step 3).

- **Atlantic salmon** as a qualifying interest of the Rivers Dee and South Esk SACs.

  We recognise that there is a significant data / research gap on this issue, and that very little is known about salmon movements – adults and post-smolts – around the Scottish coastline. Marine Scotland have analysed historic tagging data and should be issuing a report soon, however, it is likely that this report will highlight further research requirements[14].

  We recommend that the applicant assumes all individuals are SAC salmon, and considers the effects on these fish from construction and operational noise / vibration, as well as any other types of disturbance. Mitigation could include timing restrictions on construction work / noisy activities in order to avoid any significant disturbance to migrating salmon, or disruption of their (as yet unknown) migratory routes.

  Onshore infrastructure and / or any required upgrades to roads or bridges may need to be considered under HRA if the work is likely to affect any of these freshwater SACs.

  Summary of our current advice: likely significant effect in relation to offshore infrastructure; impacts (incl. cumulative) will need to be considered in appropriate assessment (see step 3). Consideration of onshore infrastructure may also be required.

- **Freshwater pearl mussels – qualifying interests** of the Rivers Dee and South Esk SACs

  Atlantic salmon (and other salmonids) are integral to the life cycle of freshwater pearl mussel (FWPM), therefore any impacts to Atlantic salmon that prevent them from returning to their natal rivers may have a resulting effect on FWPM populations. While we consider this matter needs discussion in any appropriate assessment we do not identify any survey or research requirements. The impacts are indirect, dependent on the impacts the proposal may have on Atlantic salmon.

  Onshore infrastructure and / or any required upgrades to roads or bridges may need consideration in respect of HRA if the work is likely to affect any of these freshwater SACs.

  Summary of our current advice: likely significant effect, so indirect impacts will need to be considered in appropriate assessment as part of the assessment of any direct impacts on Atlantic salmon (see step 3).

- **Otters** of the River Dee SAC.

  The River Dee SAC is located too far away from the EOWDC proposal for there not to be any likelihood of significant effects on otters there, presuming that no onshore infrastructure is proposed in proximity to this SAC.

  Summary of our current advice: no likely significant effect, although this may need review depending on the proposed location of onshore infrastructure.

Step 3: Can it be ascertained that the proposal will not adversely affect the integrity of the SAC, either alone or in combination with other plans or projects?

This stage of HRA is termed **appropriate assessment**, and it is undertaken by the competent authority based on information supplied by the developer, with advice provided by SNH.

---

[14] We will raise this matter with Marine Scotland and the Crown Estate: we understand that research into the migratory routes of Atlantic salmon is a strategic requirement and a matter of relevance to marine renewables as a whole.

Appropriate assessment considers the implications of the proposed development for the **conservation objectives** of the qualifying interests for which a likely significant effect has been determined. We discuss this below for each of the qualifying interests listed above.

Our advice on the scope of appropriate assessment will become clearer when the development process is further advanced: when baseline data has been collected, and when construction methods, location of infrastructure, choice of port, and other aspects of the proposal have been finalised.

Advice for appropriate assessment in respect of bottlenose dolphin of the Moray Firth SAC

The **conservation objectives** for bottlenose dolphin are: **(i)** to avoid deterioration of the habitats of bottlenose dolphin or **(ii)** significant disturbance to bottlenose dolphin, thus ensuring that the integrity of the Moray Firth SAC is maintained and that the site makes an appropriate contribution to achieving favourable conservation status for each of the qualifying features.

And to ensure for bottlenose dolphin that the following are established then maintained in the long term:

(iii) Population of bottlenose dolphin as a viable component of the site.

(iv) Distribution of bottlenose dolphin within site.

(v) Distribution and extent of habitats supporting bottlenose dolphin.

(vi) Structure, function and supporting processes of habitats supporting bottlenose dolphin.

repeat of (ii) No significant disturbance of bottlenose dolphin.

Based on these conservation objectives the following questions may need to be addressed:

- Will the proposal cause significant disturbance to bottlenose dolphin while they are outwith the SAC such that the viability of this SAC population is affected?
- Will the proposal in any way affect the population viability of the bottlenose dolphins of the Moray Firth SAC?

The last question encompasses the indirect impacts that a windfarm development could have – such as the degradation or loss of supporting habitats or feeding grounds which are outwith the SAC but which help to maintain the population of bottlenose dolphin in the SAC in the long-term. The risk of impacts, and how many of these questions may need answered, will become clearer when the development process is further advanced and construction methods, location of cable routes, choice of port, and other aspects are finalised. It is possible that onshore elements of infrastructure will need to be considered as well as those offshore.

We advise that noise impact assessment is likely to be an important part of assessing any direct disturbance to bottlenose dolphin, including their potential displacement from feeding grounds and other supporting habitats. While we consider that the construction phase may give rise greatest risk of disturbance, we do highlight that impacts during the operational phase also need to be considered, as well as any repowering and decommissioning work. It will also be important for the applicant to consider impacts on prey species.

We **highlight** that cumulative impacts are a key concern and we consider that collaboration between other offshore wind applicants on noise impact assessment is likely to be helpful, along with discussion / co-ordination of mitigation proposals and construction time-tabling.

Advice for appropriate assessment in respect of Atlantic salmon & freshwater pearl mussel

> The SAC conservation objectives for Atlantic salmon and freshwater pearl mussel (where appropriate) are: **(i)** to avoid deterioration of the habitats of the qualifying species or **(ii)** significant disturbance to them, thus ensuring that the integrity of the SACs are maintained and that they make an appropriate contribution to achieving favourable conservation status for each species.
>
> And to ensure for each species that the following are maintained in the long term:
>
> **(iii)** Population of the species, including range of genetic types for salmon, as a viable component of the SACs.
>
> **(iv)** Distribution of the species within sites.
>
> **(v)** Distribution and extent of habitats supporting each species.
>
> **(vi)** Structure, function and supporting processes of habitats supporting each species.
>
> **repeat of (ii)** No significant disturbance of the species.
>
> And for freshwater pearl mussel in particular, to ensure that the following are maintained in the long term:
>
> **(vii)** Distribution and viability of freshwater pearl mussel host species
>
> **(viii)** Structure, function and supporting processes of habitats supporting freshwater pearl mussel host species

In respect of the offshore elements of infrastructure, appropriate assessment will focus on conservation objective **(iii)** – the population viability of Atlantic salmon – considered for the Rivers Dee and South Esk SACs.

There would not be any impacts to supporting habitats in any freshwater SACs arising from offshore infrastructure, however, the placement of onshore infrastructure – including any road / bridge upgrades – may need further consideration. We will be able to give further advice when the applicant presents more information on this aspect.

So the main impacts to Atlantic salmon would arise when the fish are outwith the freshwater SACs, on migration. An adverse impact on site integrity could arise if individuals are significantly disturbed / their behaviour altered / displaced from their migratory routes such that it affects the population viability of the species. The applicant may also need to consider whether the proposal could in any way act as a barrier to salmon movements, whether it might prevent any salmon from accessing the freshwater SACs, in particular the River Dee SAC.

Noise impact assessment is likely to be a key part of any overall appropriate assessment, and all phases of the development should be considered – construction, operation, repowering and decommissioning.

As discussed above, the applicant also needs to consider the potential (indirect) impacts to freshwater pearl mussel (FWPM) arising from offshore infrastructure. This will be a desk-based appraisal following on from the assessment of impacts to Atlantic salmon. We note that direct impacts to FWPM could arise from the placement of onshore infrastructure if this work takes place close to, or is likely to affect, the River Dee SAC.

Ongoing Liaison

We will continue to review our advice on HRA as this proposal progresses, and as survey work, modelling and other analyses are undertaken. We will discuss any strategic research needs with Marine Scotland and the Crown Estate, particularly those in respect of Atlantic salmon.

Executive Summary

Purpose

Items of Unexploded Ordnance (UXO) are regularly encountered within the North Sea and rarely become inert or lose their high explosives effectiveness with age. There is therefore, a potential risk that UXO could be encountered at the Aberdeen Offshore Wind Farm (AOWF). Vattenfall has commissioned 6 Alpha Associates Limited to conduct a detailed UXO desk based study for this wind farm development.

Aim and Objectives

The aim of this document is to address the initial stages of the UXO risk management process by providing a holistic overview of the UXO threats and risks for the marine component of the entire operation. In commissioning 6 Alpha as the project's UXO consultant, Vattenfall intends to:

- Discharge its duty of care to those involved in the development of the project site;
- Ensure that it takes appropriate "best practice" measures to manage all of the risks posed by the UXO threat;
- Protect the development itself from the risks of UXO blight and in doing so protect its investors, investment and reputation;
- Procure the most time efficient and cost effective means of managing and mitigating the UXO risk.

The report will cross reference and account for relevant statutory instruments vis-à-vis UXO risk (with which clients will have to comply), including Heath and Safety at Work legislation as well as the Corporate Manslaughter and Corporate Homicide Act of 2007 and common law liabilities. Additionally, and in particular, the report will explain how and why the Construction Design and Management (CDM) Regulations 2007 apply as does CIRIA's *UXO – A Guide for the Construction Industry*, (the latter providing the first UK "good practice guide", helping developers and the construction industry to deal with UXO).

The report will describe the potential for UXO encounter, the risks that may be posed as a result, as well as how those risks can be reduced to As Low As Reasonably Practicable (ALARP), at best value. In this way we anticipate that Vattenfall will be able to both satisfy and discharge their client's liabilities concerning corporate governance and UXO risk management through the provision of appropriate levels of project safety.

UXO Threat and Risk

The UXO threat is primarily the result of munitions and weaponry used on the Black Dog Range; although there is the background residual risk presented by UXBs and AAA projectiles from WWII. Other threat sources are recorded within the general region however given the nature of these operations and their location, 6 Alpha does not consider that this source will pose a significant threat to the project. The report will summarise this threat and will present a Semi Quantitative Risk Assessment (SQRA) concerning UXO and the effects that they may have upon personnel and the construction work that they are expected to undertake.

Conclusions and Recommendations

The report concludes that outside the Black Dog range template there is generally a low UXO risk to this project, which could be considered as the "background residual risk". 6 Alpha have therefore recommended that the following actions are required to address the UXO risk. This table should be read in conjunction with the "probability of UXO encounter map" at *Appendix 12*.

UXO Probability Rating	Grading	Action Required ahead of Intrusive Works	Associated Additional Costs Low → High
1-2	Remote - Possible	Areas defined as "background residual risk". Use, wherever possible, existing geophysical datasets for UXO risk reduction. Define smallest UXO threat items, interpret the datasets for contacts similar to UXO and avoid during future works. Brief all personnel involved in intrusive works and ensure reactive procedures/guidelines are in place. **6 Alpha Deliverable** - Client's must accept that this is not a 100% survey coverage for UXO, although if conducted by 6 Alpha the risk will be reduced to ALARP.	
3-4	Likely - Very Likely	There are three options for dealing with the risk in these areas: • **Option 1** - Relocate works to areas with a grading of 1 or 2; • **Option 2** – Conduct a UXO Specific Geophysical Survey and avoid targets. This survey should be designed to match the defined UXO threat and provide 100% coverage of specific threat area; • **Option 3** – If target avoidance not possible conduct either diver investigation or ROV inspection, which may discount the item or lead to UXO disposal. **6 Alpha Deliverable** - Once the UXO risk reduction actions have been successfully implemented and subject to our own QA/QC measures, 6 Alpha will sign-off the UXO risk as ALARP.	
5	Almost Certain	6 Alpha would strongly suggest avoiding these areas, and relocation work. As the costs associated reducing the risk to ALARP are likely to be considerable.	

1 Introduction

1.1 Overview

Vattenfall Wind Power Limited (Vattenfall) has commissioned 6 Alpha Associates Limited (6 Alpha) to conduct a detailed Unexploded Ordnance (UXO) desk based study for the Aberdeen Offshore Wind Farm (AOWF); the project's location is depicted at *Appendix 01*. The AOWF development zone is situated off the east coast of Scotland within the North Sea.

Whilst 6 Alpha considers that only marine threat items within 500m of the study will impact on the operation, a much wider search area has been considered for this report to ensure all threats are considered.

Items of UXO are regularly encountered within the North Sea, as confirmed by the media and Royal Navy, and rarely become inert or lose effectiveness with age. Over time, trigger mechanisms (such as fuzes and gaines) can become more sensitive and therefore more prone to detonation. This applies equally to items that have been submersed in water and/or lodged within the seabed. It is possible that significant kinetic energy created by the intense impacts generated by marine engineering, such as cable trenching or site investigation boreholes, could cause an inadvertent detonation.

The aim of this document is to address the gaps in the previous BACTEC study, as identified in the Situation Report (ref. P2219 dated 16th August 2010) by providing a holistic overview of the UXO threats and risks for the entire marine operation. This includes employing background research and factual data, which has been provided by (client engaged) third parties, and upon which we have relied. To ensure a comprehensive and complete report there may be a certain element of duplication from the BACTEC desk study.

1.2 Background

In commissioning 6 Alpha as the project's UXO consultant, Vattenfall intends to:

- Discharge its duty of care to those involved in the development of the project site;
- Ensure that it takes appropriate "best practice" measures to manage all of the risks posed by the UXO threat;
- Protect the development itself from the risks of UXO blight and in doing so protect its investors, investment and reputation;
- Procure the most time efficient and cost effective means of managing and mitigating the UXO risk.

2 Report Methodology

2.1 Structure

This study consists of a desk-based collation and review of readily available documentation and records relating to the possibility of encountering UXO and/or dangerous Explosive Ordnance (EO) related paraphernalia, within the study area. Certain information obtained by 6 Alpha may be either classified or restricted material or, considered to be confidential to 6 Alpha. Therefore summaries of such information have been provided. Please note that our appraisal partly relies on the accuracy of the information contained in these and other third party documents consulted and that 6 Alpha will, in no circumstances, be held responsible for the accuracy of such third party information or data supplied.

In agreement with Vattenfall the following facets will be covered within this report:

- The entire scope of the proposed wind farm project work has been considered;
- The history of the region has been considered, incorporating data from the previous reports;
- Relevant modern military records have been researched and presented;
- Wartime activities have been researched and presented;
- The holistic UXO threat has been considered, including the types that could be encountered, the probabilities of encountering them as well as exposing their potential mechanisms and risks of detonation;
- An outline assessment of how UXO interacts with the natural environment and conditions is made;
- The risks regarding UXO have been assessed;
- A semi-quantitative risk assessment (SQRA) has been undertaken employing 6 Alpha's "Azimuth ©" proprietary risk model;
- The consequences of an inadvertent High Explosive (HE) detonation has been considered;
- Conclusions have been drawn;
- Recommendations, and an overview risk mitigation strategy has been presented.

2.2 Sources of Information

The sources of information consulted for this report include:

- Royal Navy (Northern Diving Unit), Scotland;
- The National Archives, Kew;
- Naval Historical Centre, Portsmouth;
- UK Hydrographic Office, Taunton;
- 6 Alpha's "Agility Database ©" which contains historic maps, aerial photographs and records;
- Development boundary supplied by Vattenfall.

2.3 Standards, Guidance and Best Practice

In producing this document 6 Alpha has consulted the most relevant published guidance and best practice. It should be noted that some of these sources may *prima facie*, not appear to be distinctively relevant to this project/study but, in the absence of specific guidance concerning the management of UXO for the offshore renewable industry, the following sources of guidance are considered most applicable:

- Construction Industry Research & Information Association (CIRIA) – UXO A Guide for the Construction Industry (reference number C681);
- Maritime and Coastguard Agency (MCA);
- British Marine Aggregate Producers Association (BMAPA);
- Health & Safety Executive (HSE).

2.4 Joint Service Explosive Ordnance Disposal Operations Centre, UK

According to Joint Service Explosive Ordnance Disposal Operations Centre (JSEODOC – collocated with one of the British Army's Bomb Disposal Regiments at Didcot, Oxfordshire), UXO discovered during wind farm related operations have presented a problem in the recent past. However, and as yet, there is no clear guidance as to what actions should be taken to mitigate the risk nor in what circumstances the Ministry of Defence (MoD) might respond. JSEODOC directed 6 Alpha to the BMAPA guidance employed for mitigating UXO risk during dredging operations, although this only partly address the UXO risk in a wind farm situation.

In summary the pertinent points gathered from the JSEODOC are:

- There is no legal obligation on the Royal Navy (RN) to respond to UXO incidents outside the UK's 12 nautical mile (Nm) limit;
- Each reported UXO find would be risk assessed on a case by case basis;
- The RN response will depend upon the perceived risk and their commitments to other operations;
- If commercial operations are active in an area where there is a "reasonably foreseeable" risk from UXO, then commercial Explosive Ordnance Disposal (EOD) consultancy and/or contracting support should be arranged. However, in terms of offshore cable laying and foundation installation especially, there is no clear indication as to which areas have "reasonably foreseeable" UXO risk. For dredging operations, by comparison, the level of UXO distribution over the seabed and thus the associated risk is much better clarified and delivered as part of the operating license.

3 Proposed Intrusive Works

3.1 Marine Site Investigation

As part of the project, as is good practice in all offshore renewable projects, geophysical and/or geotechnical work is undertaken. This type of work involves remote and direct sensing techniques that may carry increased risk with regard to UXO. Many systems use the reflection or refraction of energy sources to derive data that can be interpreted to provide a picture of the seabed. The typical energy sources employed are acoustic, pressure or "physical energy" sources that compress or penetrate the seabed. Whilst it is theoretically possible that some of these energy sources could be employed to initiate very sensitive marine explosive ordnance it is considered practically impossible to initiate WWII ordnance in this way; there is no evidence of historic UXO in the marine environment being initiated by conventional methods of marine geophysical survey.

3.2 Marine Cable Installation

The Client will install an export cable to the Scottish mainland; in addition there will be a number if interconnector cables between the turbines. Given empirical evidence it is conceivable that potential interaction with UXO may occur during the following operations:

- **Pre-Lay Grapnel Run (PLGR)** – This is used to prove that the route is clear of disused cables or scrap. It will involve towing a heavy grapnel iron(s) along the route;
- **Cable trenching** – This will follow the PLGR and is expected to be conducted by a variety of methodologies, which will be influenced primarily by water depths and seabed conditions.
- **Deployment of barge anchors** – In areas where the water depth is less than 10m a cable plough may be deployed from a moored cable-laying vessel, to install the cable. The anchor spread will be positioned using a tugboat.

3.3 Turbine Installation

3.3.1 Foundations

Although it has not been confirmed, the foundations for the wind turbine structures are likely to be monopiles. Other techniques and structures are sometimes utilised but for this report we will assume that monopiles will be used. Monopiles are made from welded tubular steel sections, which are driven vertically into the seabed. They are a friction pile system (employing the friction between pile wall and surrounding geology), which supports the weight of the tower and turbine. Indicative monopile dimensions are shown in Table 3.3.1:

Monopile Technical Specification	
Diameter	Up to 6m
Total Length	Up to 90m
Sea bed Penetration	Up to 45m
Steel Plate Thickness	Up to 100mm
Total Weight	200 to 900te

Table 3.3.1 - Typical Monopile Dimensions

Monopiles may be installed using the Drive-Drill-Drive method. The pile is allowed to sink under its own weight and it is then driven into the seabed using a hydraulic hammer. Upon first refusal a drill rig is lowered into the pile and a socket is drilled beneath the toe. Afterwards the pile is again driven into the socket until the required penetration is achieved.

If other foundation techniques are employed the key factor is the force used and the resultant kinetic energy that may initiate UXO. Most foundation techniques usual create this situation.

3.3.2 Scour Protection Systems

It is anticipated that wind turbines will employ anti scour protection system in the form of rock emplacement. This is generally emplaced after turbine installation works are complete. The type and extent of anti scour protection depends upon the soil and sea conditions and mast foundations employed; other types may be employed that will involve interaction and intrusion into the seabed.

4 Sources of UXO Contamination

4.1 General

6 Alpha have conduct detailed research for this project, and after analysing the datasets it is envisaged that there are five principle potential sources of UXO contamination in the region, namely:

- WWII Enemy Bombing;
- Allied Defensive Sea Minefield;
- Military Firing Ranges;
- Munitions related Shipwrecks;
- Munitions Disposal Areas.

However not all of these threats do not directly impact upon the project development zone. From the five sources only one military firing range encroaches within the AOWF boundary.

4.2 British Military Activities and Firing Ranges

4.2.1 Civilian and Military Firing Ranges

There are numerous firing range located along the east coast in the vicinity of AOWF, these are depicted at *Appendix 2A and 2B*. Table 4.2.1 lists the geographically relevant areas and specifies their usage. Of these four sites only Black Dog range has direct impact on the proposed works.

Range Number	Name	Facility
N/A	Black Dog	WWII Military Land Service Ammunition and Current Small Arms Range
N243	Aberdeen	Heavy and light guns used by vessels.
244	Girdleness	Anti-Aircraft Guns Heavy and Light
N/A	Drums Link	Civilian Small Arms Range

Table 4.2.1 – Firing Ranges in proximity of the project.

4.2.2 Black Dog Firing Range

This range has been operational from 1940 to present day. During this time a number of military weapons and munitions have been used on the site. The range by-laws state the range can be utilised for the following:

- Anti Aircraft Small Arms;
- Anti Tank Guns;
- Anti Tank Rifles;
- Machine Guns;
- Mortars;
- Grenades;
- Revolvers and Rifles.

The by-laws document also stipulates that no public interference within the range boundary area is permitted and that any item discovered within the sea danger area should be returned to the sea immediately.

The range at present is assigned to the Army Training Estate (ATE) Scotland. The ranges usage currently is limited to three live firing areas, and a dry training area that may be used day or night. These ranges have been historically used for "Non-Mechanised" weapons systems.

4.2.3 Munition / Explosives Offshore Disposal

Post WWI and WWII, both chemical and conventional munitions were extensively dumped at sea, including in areas off the UK coast. The locations of some of these areas are well known as are the type and numbers of munitions deposited, but in other areas there are problems concerning accuracy of types and numbers dumped. This inaccuracy is incurred because of a combination of factors including; inadequate record keeping, the dumping of items outside designated official dumping areas; and, to an extent, the movement of munitions post dumping as the result of tidal flow.

There is an explosives/munitions disposal area to the south of the project development zone. This area is recorded as a "conventional munitions" disposal site, but is too far away to directly impact upon the project (the location is presented at *Appendix 03*).

4.3 Allied Sea Minefields

A naval mine is a self-contained explosive device placed in the water to destroy ships and/or submarines. They are weapons which are triggered by the approach of a ship. Naval mines can be used offensively, to hamper enemy shipping and lock it into it's harbour, or defensively, to protect Allied shipping and create "safe" zones. Some sources state that up to 70% of sea mines were not recovered after WWII. As a result of enemy sea mining activity, proposals were made in November 1939 to mine the North Sea. These proposals considered the likely effect on fishing as well as the requirement to provide mine-clear sea-channels for British, Dutch and Belgian shipping.

6.4.3 Mine Clearance

At the end of WWII there was a significant sea-mine clearance operation undertaken by both Allied and German Navies, who attempted to clear their respective minefields. This operation was undertaken by one of two methods:

- Using two minesweepers, a sweep-wire (with a serrated edge and an "otter" or "kite" to keep the sweep wire at the required depth), was laid into the water and both ends were attached to a winch at the stern of each ship. The sweep-wire was towed by both vessels over a mined area and, when connected to the "mooring stay" of a moored mine, the ships momentum would then force the stay to the serrated edge of the sweep wire, which cut it. The mine would then (usually), float to the surface for disposal.
- An alternative method was to use one ship only with the sweep wire attached to an oropesa float (to keep the sweep wire away from the ships), and the wire would then cut the mooring stay of the mine (as described above). The untethered mine would then (usually) float to the surface where it was then destroyed, often by rifle fire (however, on occasions the bullet only penetrated the outer casing of the mine, which allowed water to ingress and it would then sink and come to rest on the sea bed; an explosive hazard thus remained).

Historical Admiralty mapping confirmed that minefields that had been situated off the eastern coast were cleared post-War. Whether all those mines that were recorded as being laid, were *de facto* recovered during clearance, could not be confirmed (it should be noted that 100% clearance of minefields, even with today's technology, is not always achievable). The locations of the local mine lays can be seen at *Appendix 04*, they are over 18km away from the development zone and are not considered to present a direct threat to this project.

4.4 Aerial Bombing Campaign

4.4.1 Overview

Limited bombing occurred during WWI, as the main German threat in the marine environment were U-Boats. With the development of aircraft and air delivered weaponry, aerial bombardment became an important phase prior to any possible invasion during WWII. During the early stages of the war, Britain was continuously bombed between 1940 and 1943. Strategic targets along the coastlines of Britain included ports, docks, shipping lanes and power stations. Aberdeen was one such port that was regularly bombed as part of the German campaign.

4.4.2 Shipping Lanes, Sea Convoy Routes and Ports

The east coast ports of Scotland were important commercially and, as WWII progressed, they achieved strategic importance for the transport of coal, as well as for fishing (which was considered key to helping feed the UK's wartime population). A military lesson from WWI was implemented, which saw merchant ships gathered into convoys for protection. Notwithstanding the Royal Navy's attempts to afford such convoys protection, they were regularly attacked from the air. The Luftwaffe also dropped thousands of HE bombs on these convoys and regularly targeted other vessels as the opportunity arose.

Given that there is firm evidence that the vessel, SS Arcangel, was sunk by bombing close to the development boundary (*Appendix 05*), there is the risk that UXBs may remain on the seabed in this region.

4.4.3 Tip and Run

A significant number of air-to-air battles also occurred over this area, some of which resulted in numerous allied and enemy aircraft jettisoning all or part of their payloads i.e. *inter alia* medium and large capacity, UXBs (a tactic known as "Tip and Run"), either in an attempt to escape their pursuers, or to quickly offload weapons from damaged aircraft, before returning to base. Although records of these events are poor, the threat of encountering jettisoned munitions in the sea must be considered an unquantifiable risk, when assessing the background UXO threat for all areas in the North Sea.

4.4.4 Defensive Anti Aircraft Artillery (AAA)

There were two types of AAA battery deployed during WWII; heavy and light. These weapons were deployed on the ranges along the Scottish east coast, notably at Black Dog.

Heavy batteries were static and usually sited in the same position for the duration of the war. They deployed either 4.5 or 3.7 inch guns in groups of 2, 4, 6 or 8 guns per battery. Typically heavy battery was divided between two sites each with four guns and up to several miles apart. The 4.5 inch gun could fire a HE shell (weighing approximately 25kg and fitted with either a barometric or time fuze) 8 miles in 50 seconds. The 3.7 inch gun had a similar ceiling height but smaller calibre shell, again with barometric or time fuzes.

The light batteries were deployed with the 40mm Bofors gun. This weapon could fire up to 120 x 40mm HE shells per minute to approximately 6,000ft; the shells were designed to explode on impact with enemy aircraft. These batteries were not static and could be moved easily to new positions by truck when required.

If AAA shells failed to explode or strike an aircraft they would eventually fall back to land or sea, settling on the seabed in the latter case.

Naval and merchant vessels are commonly equipped with various types of deck guns to protect themselves against enemy air attack. If projectiles or AAA fire missed the target, then it could fall into the sea or over land and may still present a UXO hazard. Again records for this activity are poor and should be considered as a background residual risk.

4.5 Shipwrecks / Downed Aircraft

Shipwrecks in the region confirm that enemy aerial bombing occurred in the region. Although there are no military/munitions related wrecks are recorded within the actual development.

Both merchant and naval vessels that were sunk in WWII may have contained munitions. Empirical evidence has shown that munitions did spill from the ships as they sank and subsequently broke-up. Similarly, aircraft that were shot down or otherwise had to ditch into the sea, may have also contained munitions. In general, the risk of munitions contamination is somewhat less in the vicinity of wrecks as compared with munitions dump-sites because the munitions, in all probability, are most likely to remain enclosed and immobile within the body of the wrecks. However, it may be possible that some items may have been thrown clear of the vessel as it sank or they could become exposed as the wrecks gradually broke up.

5 Explosive Threat Items

5.1 General

Having established potential contamination sources, the following generic ordnance groups are considered likely to present a threat to the proposed development. Clearly, some varieties of UXO are likely to be more common within the project area than others. The table at *Appendix 06*, provides a schedule of dimensions and explosive quantities for the main threat items.

5.2 Weapon Fill Materials

5.2.1 High Explosives (HE)

A HE compound detonates at rates ranging from 1,000m to 9,000m per second, and may be subdivided into two explosives classes, differentiated by their respective sensitivity:

- **Primary Explosives** – are extremely sensitive to mechanical shock, friction and heat to which they will respond by burning rapidly or detonating. Examples include mercury fulminate and lead azide. This characteristic makes them unsuitable to use as base (i.e. main-fill) explosives in military ordnance. Sensitivity is an important consideration in selecting an explosive for a particular purpose, e.g. the explosive in an armour-piercing projectile must be relatively insensitive, or the shock of impact would cause it to detonate before it penetrated the target.
- **Secondary Explosives** – are relatively insensitive to shock, friction and heat. They may burn when exposed to heat in small-unconfined quantities, although the risk of detonation is always present (especially when they are confined and/or are burnt in bulk). Dynamite, TNT, RDX and HMX are classed as secondary high explosives, which are commonly used as, base explosives in military ordnance. PETN is the benchmark compound; those explosives that are more sensitive than PETN are classed as primary explosives.

5.2.2 Low Explosives

A low explosive is usually a mixture of a combustible substance and an oxidant that decomposes rapidly (in a process akin to very rapid burning and known as deflagration).

Under normal conditions, low explosives undergo deflagration at rates that vary from a few centimetres per second to approximately 400m per second. Low explosives are normally employed as propellants, included in this group are e.g. gun-powders, pyrotechnics and illumination devices such as marine markers or flares.

5.2.3 Propellants

In ballistics and pyrotechnics, a propellant is a generic name for those chemicals used for propelling projectiles (e.g. artillery shells or mortars) from a weapon system.

Propellants are always chemically different from high explosives (as compared with those used in munitions for “target effect” for example), as they are not designed to release their energy as quickly and as a result do not produce a blasting/shattering effect (such an effect would damage or destroy the weapon platform e.g. gun/howitzer or mortar).

However, some explosive substances can be used both as propellants and as “burster charges”, (e.g. gunpowder), and some of the ingredients of a propellant may be similar to those employed to make explosives. If bulk propellants are confined and burn very rapidly the result can be similar to that witnessed by a (small) high explosive charge. Propellants therefore, remain highly dangerous and can come in various forms e.g. powder or thin sticks and can be contained in pre-formed containers or bags.

A very typical propellant burns very rapidly but controllably and non-explosively, to produce thrust (generated by rapidly expensing gas, generating pressure), and thus accelerating a projectile/rocket from a weapons platform. In this sense, common or well-known propellants include:

- Gun propellants, such as:
  - Gunpowder (black powder);
  - Nitrocellulose-based powders;
  - Cordite;
  - Ballistite;
  - Smokeless powders.
- Compounds may be mixed with a solid oxidiser (such as ammonium perchlorate or ammonium nitrate), or a rubber (such as HTPB or PBAN), or a powdered metal (commonly aluminium).

5.3 Artillery Projectiles

Artillery projectiles may be classified and grouped as follows:

- **HE** – designed to cause damage by combination of high explosive blast and fragmentation;
- **Fragmentation** – designed to be used primarily against personnel;
- **AP and SAP** Armour Piercing (AP) and Semi-Amour Piercing (SAP) shells are always base fuzed and are generally designed for the attack of lightly armoured vehicles, concrete emplacements dug outs etc. they are not intended for heavily armoured targets.
- **Smoke** – Used for the production of smoke screens; various fillings are used, the most common being white phosphorous;
- **Illuminating** – designed to illuminate an area or specific target at night; a burning flare is suspended from a small parachute to provide an intense white light;
- **Practice** – commonly a solid shot fitted with a so-called “spotting charge” which gives an indication of where it lands.

5.4 Torpedoes

Torpedoes were utilised by a range of vessels including submarines and the surface fleet. Unlike sea mines (which are a “mass-weapon” system deployed in order to strike an opportunity target), torpedoes were usually specifically targeted (i.e. fired and/or guided to a known target) rather than deployed in mass.

The guidance systems used in torpedoes are often sophisticated and include homing systems reliant upon *inter alia* acoustic signature. Any power supply in WWII torpedoes is generally considered expended, and it is therefore highly unlikely that any residual current in fact exists, or that a tiny amount which may still exist, could not still be sufficient to enable the torpedo to function as originally intended.

Whilst it is possible that unexploded torpedoes might be encountered, it is anticipated that their potential discovery is likely to be less frequent than other naval weapons e.g. sea mines.

5.5 Sea Mines

5.5.1 General

Sea mines (which were employed by both sides engaged in WWI and WWII), were designed either to be buoyant or to sink; the former variety tended to be moored but if they were not initiated (or cleared at the end of the War), then they often sank and drifted on the seabed with tides/weather.

Some British mines could be programmed to self neutralise, often by sinking themselves and allowing the ingress of salt water to render the firing circuit inoperable. Although self-neutralising sea mines could not function today as originally designed, the detonators and HE charges remain intact; they are dangerous. Official records also state that not all of the mines had the "sterilisation plugs" fitted to enable self-neutralisation.

Additionally, the detonators in mines are, by design, made from a sensitive explosive compound (often picric-acid based), which remains susceptible to shock to this day; however exposure to saltwater does not generally increase this sensitivity. All WWII vintage sea mines are filled with HE (usually ammonium nitrate and TNT compositions e.g. ammonal or minol), which often remains in sufficiently good condition to detonate, to this day; thus they are dangerous.

5.5.2 Fuzing

Sea mines can be armed with more complex fuzing and initiation mechanisms, which fall into 3 main groups:

- **Hydrostatic Fuzing** – A valve that detects the difference in water pressure (i.e. generated by a passing vessel). Some sophisticated German WWII mines had this type of fuzing and were used in the North Sea;
- **Magnetic Fuzing** – A fuze that detects a displacement of the ambient magnetic field, normally by the introduction of a ferrous metal object (such as a passing vessel);
- **Sonar Fuzing** – Based upon a similar principle as radar, whereby any increased return of the underwater return signal to the sea mine, is interpreted as a potential target vessel and therefore the arming sequence is initiated.

The older generation of moored sea mines were, more commonly, designed to function upon contact with a ship or vessel. The externally mounted chemical horns (or spikes), consisted of a lead outer sheath, which contained two, separated, chemical ampoules. Upon contact, the external horn would crumple, thereby crushing the ampoules and allowing the chemicals to mix. The resultant mixture would immediately produce either an electrical charge or combustion, forming the basis for an explosive reaction and detonation of the bulk high explosive.

5.6 Depth Charges

The depth charge was designed to counter the threat posed by submarines. The generic design resembles a drum containing HE with a hydrostatic fuze, which initiated the main charge at a preset depth (as a result of water pressure). They were fired from the stern or sides of ships (or a combination of both). As the war progressed, the Royal Navy introduced the so-called “Hedgehog” and “Squid” systems, which enabled the depth charge to be fired forward from the bow the ship (which were known as forward throwing charges).

Depth charges varied in size (from 55Kg to 300Kg) and consequently the mass of HE of explosive changed to suit the type of target being attacked. Towards the end of WWII the RN were using a “Mark X” depth charge, which contained 1000kg of explosives; they were fired from tubes mounted on the decks of war-ships.

5.7 German Air-Delivered Weapons

5.7.1 Iron Bombs

Generally, most iron (i.e. air –delivered) bombs are of similar generic construction, consisting of a steel container, a fuze or fuses either located in the nose/tail of the bomb or located laterally (though sometimes in combined locations), and a stabilizing device (i.e. the bomb “tail” to aid accurate aerodynamic flight from the aircraft to the target). The steel container (i.e. the bomb body) contains either the HE content (or other contents e.g. sub-munitions).

Iron bombs are designed in broadly similar shapes (with some variations to ogive shape/angle), but in a much wider variety of masses, depending on the intention of the bombing mission and the targets. Iron bombs are generally categorised as follows;

- **General Purpose** – Designed, as the name suggests, to attack a variety of targets and normally contain an explosive content of approximately 50% of the overall mass of the bomb.
- **Armour Piercing** – Designed to create a mechanically driven entry point in the target prior to detonation, in order to maximise the consequent blast and fragmentation effect. Bunker busting systems, anti-shipping, anti-armoured fighting vehicle and counter-tunnel systems are good examples of the tactical deployment of armour piercing bombs. In general, only 30% of the overall mass contains HE with the remaining 70% made up of steel (in order to maximise penetration and any subsequent fragmentation effect). Armour piercing bombs are always fitted with tail-fuzes.
- **Anti-Submarine** – As the name suggests, primarily designed to attack known underwater targets. These types of bombs are always equipped with a tail fitted hydrostatic fuse and 85 – 90% of the overall mass consists of HE.
- **Incendiary** – These are normally constructed of a thin metal casing containing a thermite (manganese/aluminium) compound. Generally, once the compound is

exposed to oxygen, an instantaneous combustion takes place with the heat generated reaching in excess of 800°C. These bombs were often targeted against high concentrations of industry, general urban development and shipping.

- **Fragmentation** – Fragmentation bombs are normally deployed to maximise the secondary effects of an explosion. The bomb is generally constructed from thick (sometimes segmented), steel, designed to for maximum fragmentation effect. Fragmentation bombs are generally deployed against "soft" unprotected targets.

The larger size high-explosive varieties, were used against shipping i.e. 1,000kg mass and greater, (compared with the smaller bombs (e.g. 50 kg and 250 kg variants), which were often used during "carpet-bombing" campaigns on land).

6 UXO Ground Penetration, Burial and Migration

6.1 General

When assessing the potential for ordnance ground penetration it is essential not to rely solely on either an empirical, statistical and arithmetical formula. Experience has shown that a realistic penetration depth is best estimated by considering a blend of the above approaches supplemented by accounts of Explosive Ordnance Disposal Tasks (and thus empirical evidence) in the area.

6.2 Seabed Migration

Munitions can migrate across the seafloor, the main factors concerning the degree of movement concern *inter alia*; the strength and direction of hydrodynamic currents; the overall shape of the weapon (influencing the degree to which UXO are free to move without obstruction); weapon protrusions such as fins and lugs (the latter being employed for suspension from the aircraft in flight); and the UXO position on the seabed (e.g. in either sediment, gradient or a seabed recess), which could significantly impede movement.

After prolonged exposure to saline water and the action of sea, some munitions can break-up or be otherwise rendered ineffective as high explosive devices; others are still discovered (today), in excellent condition. Additionally, munitions tend to gather in seabed depressions (they roll in, but tidal action often has insufficient momentum to roll them out again). In some areas of the North Sea high concentrations of UXO may gather in such natural seabed "sinks".

6.3 Seabed Burial

Empirical evidence has shown that it is possible for UXO that initially lie on the seabed, to become subsequently buried within the "offshore" environment. This occurs especially where substantial tidal and environmental factors impact seabed conditions e.g. when there are high sedimentation rates, and thus UXO movement (into a seabed depression), and subsequent concealment. Storms and/or exceptional tidal flows could significantly alter the topography of the seabed, and although items of UXO are usually very dense, if they are not moved (and they might during strong tidal flows), they may be concealed easily with the sequential passing of tides and associated sediment movement/deposition.

On this project the highest rates of sedimentation is expected to be close to the shore; accordingly it is possible that munitions may have become buried, over time in that region. Clearly, smaller munitions are more likely to buried (such as AAA or projectiles rather than the larger items of UXO (such as sea mines and iron bombs). When establishing the options for UXO risk mitigation it is important to ascertain the level of potential sediment cover in areas of proposed works.

6.4 Seabed Penetration

The presence of a body of water will have a considerable affect on the conventional and expected penetration depth (into the seabed) for air dropped bombs. Bombs behave uniquely as they enter a body of water and their velocity is reduced significantly before the bomb comes into contact and penetrates the seabed. As a guideline and subject to specific UXO and geotechnical factors the maximum penetration of a 500kg bomb is unlikely to exceed 1m below seabed level, when more than 10m of water is present at the time the munition was delivered).

7 UXO Detonations

7.1 Initiation Scenarios

In 'normal' conditions at sea, UXO does not usually spontaneously explode. Ordinarily, high explosive requires the input of a significant amount of energy to create the conditions for detonation to occur. Although the British Geological Society seismological records suggest that there were 47 spontaneous detonations of dumped munitions in the Beauforts Dyke dumping grounds, between 1992 and 2004. However it is possible that these were the result of munitions deteriorating in the salt-water environment (which is in itself unlikely) and/or becoming more sensitive to shock with age (which is more likely).

Notwithstanding this, in the event of UXO discovery within the construction environment, there are a number of potential initiation mechanisms; they are:

- Direct impact onto the main body of the munition e.g. from the PLGR, jack up barge leg or cable trench;
- Friction impact, initiating the (more sensitive) fuze explosive caused by a number of construction related activities (for example impact from an excavator bucket, piling, or trenching equipment);
- Over pressure caused by piling that may initiate a hydrostatic fuzed munition (where applicable).

During the 1980's British Royal Navy clearance divers were informed, by technical experts from North Atlantic Treaty Organisation (NATO), that WWII-era munitions, which relied on a capacitor in the firing system, would not retain enough electrical charge to function as designed. Therefore very old items, which rely on magnetic or acoustic fuzing to initiate, are not considered a threat, although direct impact to these items may generate enough kinetic energy to initiate the item.

7.2 Detonation Variables

The consequences of munitions detonation have been the subject of a number of studies. It is generally noted that these consequences depend upon:

- The size of the item and its Net Explosive Quantity (NEQ).
- The proximity of the item to vulnerable equipment (and/or other structures).
- The type of explosive and/or fill (e.g. high explosive, incendiary, or specialist).
- Location of the item which may be:

- Floating on the body of water (buoyant mines only);
- On the seabed;
- On the surface;
- Partially buried;
- Totally buried.

- The construction and structural strength of any vessel, equipments or structures near the site of an explosion.

7.3 Underwater High Explosive Detonations

7.3.1 Underwater Detonation Hazards

When an item of UXO detonations underwater there are four main hazards:

- Fragmentation;
- Blast;
- A pulsing and rising gas bubble;
- A shockwave.

7.3.2 Direct Effects of Ordnance Detonation

If a significantly large high explosive item of UXO detonates underwater (e.g. after close contact with pile, jack up barge leg or trenching equipment), then the effect is very similar to that experienced at the surface. A high order detonation causing blast and fragmentation would certainly destroy mechanical equipment or significantly damage (shatter or buckle) part of a cable plough, for example.

7.3.3 Effect of Explosive Shockwave and Gas Bubble on Supporting Vessels

If a mine or a bomb detonated underwater at some distance from the underside of a floating vessel, fragmentation is not a primary consequence. On detonation of a high explosive charge the explosive gasses rapidly form a rising spherical bubble. The momentum imparted to the water in the early stages enables the water to expand until the pressure in the bubble is far less than the hydrostatic pressure of the surrounding water. A violent contraction therefore takes place, followed by a second expansion (almost as rapid as the first), which may be followed by further expansions and contractions.

Each expansion causes a pressure wave that is propagated outwards throughout the water in all directions. As water is highly incompressible the maximum pressure in the initial shockwave is very much higher than would occur in either the ground or in air (but the peak pressure is of much shorter duration). Although these shockwaves become gradually weaker as the bubble rises, the origin of those shockwaves (i.e. centre point of the rising bubble) is often closing with the intended target (i.e. the underside of a floating ship), and therefore it still has sufficient energy to cause considerable shock wave damage at significant distance from the point of initiation. It is possible that the energy could be sufficient to damage and sink a vessel.

8 UXO Risk Assessment Factors

8.1 Source – Pathway – Receptor

The threat in this instance must be considered in light of the proposed operations, the intrusive related activities, as well as the impact on key receptors such as personnel, key installations, high-value equipment and the environment.

8.1.1 Source

6 Alpha has considered that the threat is primarily the result of munitions and weaponry used on the Black Dog firing range, although there is always the potential background residual risk from both UXBs and AAA shells from WWII.

8.1.2 Pathway

The pathway is described as the route by which the hazard reaches the sensitive receptor. Given the nature of the site, the pathways would be during:

- Geotechnical investigation;
- PLGR;
- Marine cable trenching;
- Laying barge anchors;
- Monopile Installation.

8.1.3 Receptors

Sensitive receptors on this site would include:

- Site Investigation Crews.
- Construction Workers/Engineers.
- High-value Equipment.
- Ships/vessels
- Third party shipping/vessels in the immediate vicinity – Note extended safety distances for detonations underwater apply (for reasons we have articulated above).
- Infrastructure and people located along the coastline (close enough to be harmed UXO if was inadvertently detonated).

9 Semi-Quantitative Risk Assessment

9.1 Overview

In undertaking a series of Semi-Quantitative Risk Assessments (SQRA) across the project, we have employed the technical data associated with the items presented within this report and the proposed operation. The following sections transparently outlines the methodology and calculations used in conduction the SQRA for the project. Risk assessment tables are presented at *Appendix 07*.

9.2 Risk Rating

For the purposes of this report, Risk (R) is a function of **Probability** of occurrence (P) and **Consequence** of occurrence (C), where R = P x C. In each case, the Probability and Consequence of the identified threats has been assessed on a scale of 1 to 5. (Where 1 = Very Low, & 5 = Very High) based on expert judgement. These ratings are multiplied together to create Risk scores with a maximum of twenty-five. This allows relative weighting and comparison of risk across the project. Colour coding is provided for ease of use, grouping figures in Green as Low Risk, in Yellow as Medium Risk and Red as High Risk.

Probability			Consequence				
			1 (Very Low)	2	3 (Medium)	4	5 (Very High)
Probability	Very High	**5**	5	10	15	20	25
		4	4	8	12	16	20
	Medium	**3**	3	6	9	12	15
		2	2	4	6	8	10
	Very Low	**1**	1	2	3	4	5

Table 9.2 – Risk Matrix

9.3 Risk Rating Criteria

It is important that the numerical values assigned to the potential probability and impact of a risk match the risk tolerance of the Client. Table 9.3 outlines the risk rating rationale that has been applied in this analysis:

Risk Rating (P x C)	Grading	Risk Appetite (Tolerance)	Action Required
1-5	**Low**	Tolerable or Partly Tolerable	Little/No specific Risk Mitigation Required. Situation should be monitored. Reactive UXO risk mitigation required during operations, but overall, residual risks are carried.
6 - 12	**Medium**	Intolerable	Advance Mitigation Measures should be considered. Situation should be monitored. Risks to be mitigated subject to the mitigation being reasonable, practical and affordable. Note: High Consequence or High Probability that score as Medium Risk events should be afforded the same status as Highly Intolerable but assessed on a case-by-case basis.
15 - 25	**High**	Highly Intolerable	Risk Mitigation Measures should / will be implemented. All risks to be mitigated.

Table 9.3 – Risk Tolerability Table

The risk levels are used to determine the level of mitigation required to reduce the risk to conform to the ALARP principle. In producing the strategy the risk levels are benchmarked against the various degrees of tolerability (shown in Table 9.3 above), to determine what degree of risk is considered acceptable.

9.4 Definition of Consequence and Probability

As is accepted practice in formalised Risk Management, the Risk Rating scales are dimensionless, allowing the user to apply these methods to any desired terminology in order to fit their discrete needs.

9.4.1 Consequence

If the key consequence is financial, then 5 on this scale should equate to the amount of money that will either, stop the contract, close the operation, exceed agreed budget or any other defined critical financial figure. The scale then sub-divides that amount into 5 equal portions down to zero financial impact.

If the key impact figure is the loss of a vessel, then 5 on the scale is equal to total loss of the vessel as an operational asset, and the sliding scale represents vessel operational efficiency loss i.e. 1 = loss of 0% to 20% operational efficiency, while 5 = loss of 81% to 100% operational efficiency.

If the critical impact figure is loss of 50% of operational efficiency, then the scale represents loss of between 0% and 50% in 5 equal steps. This can be applied to any number of scenarios.

The critical consequence associated with UXO however is that associated injury or death. Both are considered unacceptable and therefore such circumstances should be avoided or the risk appropriately managed or otherwise mitigated to ameliorate such a consequence.

9.4.2 Consequences Specific to AOWF

The detonation consequence assessment assigns a site-specific consequence level to any potential UXO that may be encountered at the site. This is achieved by combining the UXO impact distance from sensitive receptors, the Net Explosive Quantity (NEQ) of the item and, where applicable, the average water depth range (assumed here to be in the region of 10-15m). A rating system for assigning impact levels has been derived based on the expected effects of a detonation event on each of the receptors identified in the project consequence matrix is presented at Table 9.4.2. The expected impacts are ranked from 1 (no significant effect) to 5 (major widespread effects / catastrophic).

Impact Level	NEQ	Expected Consequences			
		Human Health	Plant and Equipment	Vessels	Environment
1	*Low Explosive <10kg & High Explosives <5kg*	Injury requiring medical treatment	No noticeable effect	No noticeable effect	Minor disturbance
2	*High Explosive 5-15kg*	Lost time injury < 3 days	Slight superficial damage	Slight superficial damage	Significant disturbance
3	*High Explosive 15-50kg*	Serious debilitating injury	Minor component replacement repair	Repairs - non-structural	Moderate damage to habitats.
4	*High Explosive 50-250kg*	Localised fatalities	Significant component replacement repair	Repairs – structural	Moderate damage to habitats. Some long term effects.
5	*High Explosive >250kg*	Multiple fatalities over extended area	Unit destruction	Localised structural failure and collapse	Localised destruction of habitats. Moderate long-term effects.

Table 9.4.2 – Consequence Matrix

9.4.3 Probability

The Probability scale is simply the assessed likelihood of an event-taking place. If units are required, then the scale frequently used on Project Risk Registers may be utilised.

9.4.4 Probability Specific to the development of AOWF

Based on past experience, the probability levels presented at *Table 9.4.4*, have been used in building the overall risk ratings for this specific project:

Probability Level	Probability of Encountering UXO
1	Remote
2	Possible
3	Likely
4	High Likely
5	Almost Certain

Table 9.4.4 – Probability Matrix

6 Alpha have collated, reviewed and analysed the historical data and conducted an assessment based on the criteria in Table 9.4.4 to produce a chart that demonstrates “probability of UXO encounter” on the project (*Appendix 08*).

This map is not a risk map *per se* because it does not incorporate the activities that might be associated with such an “encounter” nor the likely consequences. However this map is an important tool in the risk management process as it displays areas that require UXO risk mitigation and others which should be avoided.

10 Recommended Risk Mitigation

10.1 Overview

In view of the UXO risk in this region and the proposed engineering works, 6 Alpha has designed the following mitigation strategy to reduce the risk to a level that conforms with the Health & Safety Executive's ALARP principle. This strategy has been developed in order to fully address the UXO risk across the entire development site, whilst working within critical operational and time limitations.

6 Alpha believes that avoidance of potential risk items is the key to successful UXO risk management in this environment. By adhering to robust procedures and operational guidelines the impact to the ongoing development can be significantly reduced. 6 Alpha recommend that the time window between any proactive mitigation works and the proposed works is minimised (within reasonable operational constraints).

It should be noted that the risk from UXO could never be considered 'zero' in the offshore environment, as there is always the potential for UXO migration through natural sedimentation transportation or the recorded deposition of munitions through war, training or disposal.

10.2 Marine Operations

10.2.1 Overview

Prior to undertaking any intrusive work, the "higher UXO threat areas" as displayed at *Appendix 08* should be avoided. In particular 6 Alpha would draw Vattenfall's attention to the Black Dog firing range. If the client does not want to avoid this area, as it is a viable development area, then 6 Alpha would recommend that any intrusive works are mitigated accordingly.

10.2.2 UXO Probability Grading and Mitigation Options

6 Alpha have recommended that the following actions are required to address the UXO risk. This table should be read in conjunction with the "probability of UXO encounter map" at *Appendix 08*.

UXO Probability Rating	Grading	Action Required ahead of Intrusive Works	Associated Additional Costs Low High
1-2	**Remote - Possible**	Areas defined as "background residual risk". Use, wherever possible, existing geophysical datasets for UXO risk reduction. Define smallest UXO threat items, interpret the datasets for contacts similar to UXO and avoid during future works. Brief all personnel involved in intrusive works and ensure reactive procedures/guidelines are in place. **6 Alpha Deliverable** - Client's must accept that this is not a 100% survey coverage for UXO, although if conducted by 6 Alpha the risk will be reduced to ALARP.	
3-4	**Likely - Very Likely**	There are three options for dealing with the risk in these areas: • **Option 1** - Relocate works to areas with a grading of 1 or 2; • **Option 2** – Conduct a UXO Specific Geophysical Survey and avoid targets. This survey should be designed to match the defined UXO threat and provide 100% coverage of specific threat area; • **Option 3** – If target avoidance not possible conduct either diver investigation or ROV inspection, which may discount the item or lead to UXO disposal. **6 Alpha Deliverable** - Once the UXO risk reduction actions have been successfully implemented and subject to our own QA/QC measures, 6 Alpha will sign-off the UXO risk as ALARP.	
5	**Almost Certain**	6 Alpha would strongly suggest avoiding these areas, and relocation work. As the costs associated reducing the risk to ALARP are likely to be considerable.	

Table 10.3.2 – Risk Mitigation Options

11 Conclusions

11.1 Key Findings

In terms of UXO threat, this report has demonstrate that the UXO threat is primarily the result of munitions and weaponry used on the Black Dog Range; although there is the background residual risk presented by UXBs and AAA projectiles from WWII. Other threat sources are recorded within the general region however given the nature of these operations and their location 6 Alpha does not consider that this source will pose a significant threat to the project. This has been reflected in the SQRA tables presented at *Appendix 11*.

It is conceivable that live HE items would have been fired out to sea (from land based weapons platforms) at the Black Dog range and a proportion of UXO could still be present in the area today. Therefore it would be prudent to avoid this area for all future intrusive works.

Due to the relatively slow tidal movement within the North Sea, tides are likely to have a minimal short-term effect on seabed munitions movement. The maximum penetration of a 500kg bomb along this route, is not likely to exceed 1.0m below seabed level. It is conceivable that, if present, any bombs, mines, torpedoes and parachute mines would be on or just below the seabed.

Where detonation occurs underwater, potential damage may result from direct fragmentation as well as the pulsing gas bubble and its resultant shock wave. The main consequence depending upon water depth is likely to include injury to personnel and damage to installation vessels, and associated support vessels and equipment. Given typical water depths seen in the area, assumed to be between 10-15m (TBC), a reasonable and practical working assumption is that any UXO which has a charge weight of 40kg or greater, is capable of causing significant damage.

As many of the sea mines and bombs that may be encountered have a NEQ of around 100kg or greater, the effect of them detonating (even on the seabed), is likely to be catastrophic, and remain extremely serious in the deeper waters.

Project Risk Assessment Tables

Risk Assessment Table notes (applicable to all segments):

1. Risk level is prior to risk mitigation actions for that specific operation but in operational order i.e. previous action may have reduced cumulative risk level;
2. Values for both probability and consequence to be found in main report;
3. Risk mitigation measures are cumulative and assumes that previous stage has been undertaken;

TABLE OF CONTENTS

MARINE ECOLOGY, INTERTIDAL ECOLOGY AND SEDIMENT AND WATER QUALITY

1 The Institute of Estuarine and Coastal Studies (IECS) at the University of Hull was commissioned by Aberdeen Offshore Wind Farm Limited (AOWFL) to undertake the Baseline Technical report for the proposed European Offshore Wind Deployment Centre (EOWDC).

2 The present report focuses on marine ecology baseline information and presents an update of the literature review carried out by Titan Ltd (TES, 2008a) which was based on a previous turbine layout. The Titan Ltd report included analysis of sediment and water quality, benthic ecology, natural fish and shellfish species. This information has been incorporated with the results of the benthic sampling and analysis programme undertaken by the Centre for Marine and Coastal Studies Limited (CMACS Ltd) in September 2010 and additional data from Marine Scotland Science.

1. Information for the Non-Technical Summary

3 The proposed EOWDC area (i.e. the area inside the development lease boundary) shows physical, chemical and biological characteristics resembling those of the surroundings. There is general agreement between scientific literature and survey results.

4 Well-washed fine sandy sediments are present in the site in the vicinity of the proposed EOWDC. A gradient in sediment characteristics has been observed with a decrease in mud and organic content in sediments at inshore, shallower stations. This is as expected given the higher degree of sediment re-suspension caused by tidal movements, wave action and coastal currents in these areas.

5 Contaminant levels measured in sediments during the benthic survey did not raise any concerns, predominantly being below detection limits (organic compounds such as polycyclic aromatic hydrocarbons, polychlorinated biphenyls, organotin compounds), or below international benchmarks indicating potential adverse biological effects in aquatic systems (as for heavy metals). The sediment contamination in the site is in line with the background contamination levels reported for the North Eastern Atlantic zone.

6 The water quality in the Aberdeen area is generally good given the presence of a large sewage outfall for trade and domestic effluent. This is confirmed by the information on the quality of nearby bathing waters for the past few years.

7 The intertidal areas in Aberdeen Bay are mostly represented by sandy shores with moderate exposure to wave action, wind and tidal streams. The intertidal benthic fauna is dominated by mobile crustaceans (such as haustorid amphipods). These habitats may provide feeding grounds to fish species using the adjacent sublittoral areas.

8 The sublittoral benthic community is dominated by polychaetes (mainly *Notomastus latericeus)* and bivalves (mainly *Nucula nitidosa* and *Tellina fabula*). Ophiuridae are also characteristic of the surveyed benthic assemblages, particularly at offshore stations. Depth and distance offshore highly affects benthic assemblages. Assemblages (and biotopes) present within the proposed EOWDC area are consistent with those found further offshore where the benthic community strongly resembles the JNCC biotope SS.SSA.CMuSa.AalbNuc (*Abra alba* and *N. nitidosa* in

circalittoral muddy sand or slightly mixed sediment). At inshore sites sparser benthic assemblages occur, matching well with the biotope SS.SSA.IFiSa.NcirBat (*Nephtys* cirrosa and *Bathyporeia* spp. in infralittoral sand). This latter biotope, however, is not present within the proposed EOWDC area, where only the biotope SS.SSA.CMuSa.AalbNuc occurs. The biotopes SS.SSA.CMuSa and SS.SSA.IFiSa are considered as a priority habitat under the UK BAP designation (sublittoral sands and gravels). The UK Habitat Action Plan aims to ensure that the best examples of sublittoral sand and gravel habitats are protected from the adverse effects human activities, such as wind farm development. However this is also the most common habitat found below the level of the lowest low tide around the coast of the United Kingdom, and is not uncommon in the wider Aberdeen Bay area, hence is not considered to have an especially high ecological importance at the local scale.

9 The invertebrate epibenthic fauna in the site is sparse and is composed of brittle stars, brown shrimp and swimming crabs. The most common fish species are flatfish such as dab and plaice, particularly in inshore stations. Hooknose and whiting are also abundant. Fishing grounds are located farther offshore or northwards with respect to the proposed development area. No specific spawning or nursery grounds are reported in the proposed EOWDC area, although areas with these roles have been identified at a larger spatial scale. The epibenthic survey carried out in the proposed EOWDC site seems to confirm the absence of spawning grounds. A high abundance of juvenile flatfish (plaice and dab) has been recorded in inshore stations, suggesting their use as a nursery. However, it is likely that similar nursery grounds extend over a wider area along the Scottish coast.

10 A number of sites designated for conservation interest (SAC, SPA, Ramsar sites, SSSI and NNR) occur along the coast in the Aberdeen area. However, the proposed EOWDC area and the surroundings do not fall within a designated statutory conservation area and no designated species are present within them, as confirmed by the survey results. There is the possibility that migration routes of Atlantic salmon and sea trout cross the proposed EOWDC site, having the species important spawning areas in the nearby rivers (e.g. River Dee). These species are discussed in detail within the salmon and sea trout assessment for the proposed EOWDC, although there is a notable lack of knowledge on how these salmonids migrate and behave along the east coast of Scotland.

2. Introduction

11 The proposed EOWDC site is a wind farm and deployment centre located approximately between 2 and 4.5 km east of Blackdog, off the Aberdeenshire coast. The project is expected to comprise 11 wind turbines between 4 and 10 MW. An Ocean Laboratory for meteorological and other environmental monitoring is proposed and would be subjected to a separate consent application. The lease boundary for development will cover up to 20 km^2 between northern Aberdeen and Balmedie and this area will be referred to in this document as the “proposed EOWDC area” (green area in Figure 1). Where in text there is discussion regarding the wider area where the proposed development will fall (e.g. lease boundary and its surroundings) this will be referenced as the “proposed EOWDC site”.

12 Offshore wind farm developments are listed under Annex II of the Environmental Impact Assessment Directive (97/11/EC) as “installations for the harnessing of wind power for energy production (wind farms)” and, as such, an Environmental Impact Assessment (EIA) must be carried out in support of any application for development consent. Whilst the proposed EOWDC area is outside any designated statutory conservation areas, there are a number of European Directive designated sites nearby and these should be taken into account in any assessment of potential impacts.

13 Assessing the impact of offshore wind farm developments on marine habitats and species must account for the natural variability within marine ecosystems (e.g. resulting from extreme weather conditions, storms, smothering following natural sediment movement, changes in predator/prey populations) so that distinction between natural and anthropogenically induced change can be made (Hiscock *et al.*, 2002).

14 This section provides baseline data for the physical and chemical properties of the sediment (particle size and persistent contaminants), the macrofaunal communities living within the sediment (infauna) and those species living at the sediment/water column interface (epifauna). Information available from the literature has been integrated with data obtained during benthic and epibenthic surveys carried out in the proposed EOWDC site. These data were collected in order to characterise the benthic ecology in the proposed EOWDC area and its surroundings. The data will also provide a baseline for the assessment of both direct and indirect (e.g. sedimentation) impacts of the scheme in the wider area during future monitoring. A review of existing information on the water quality and nature conservation status in the area is also provided in this section.

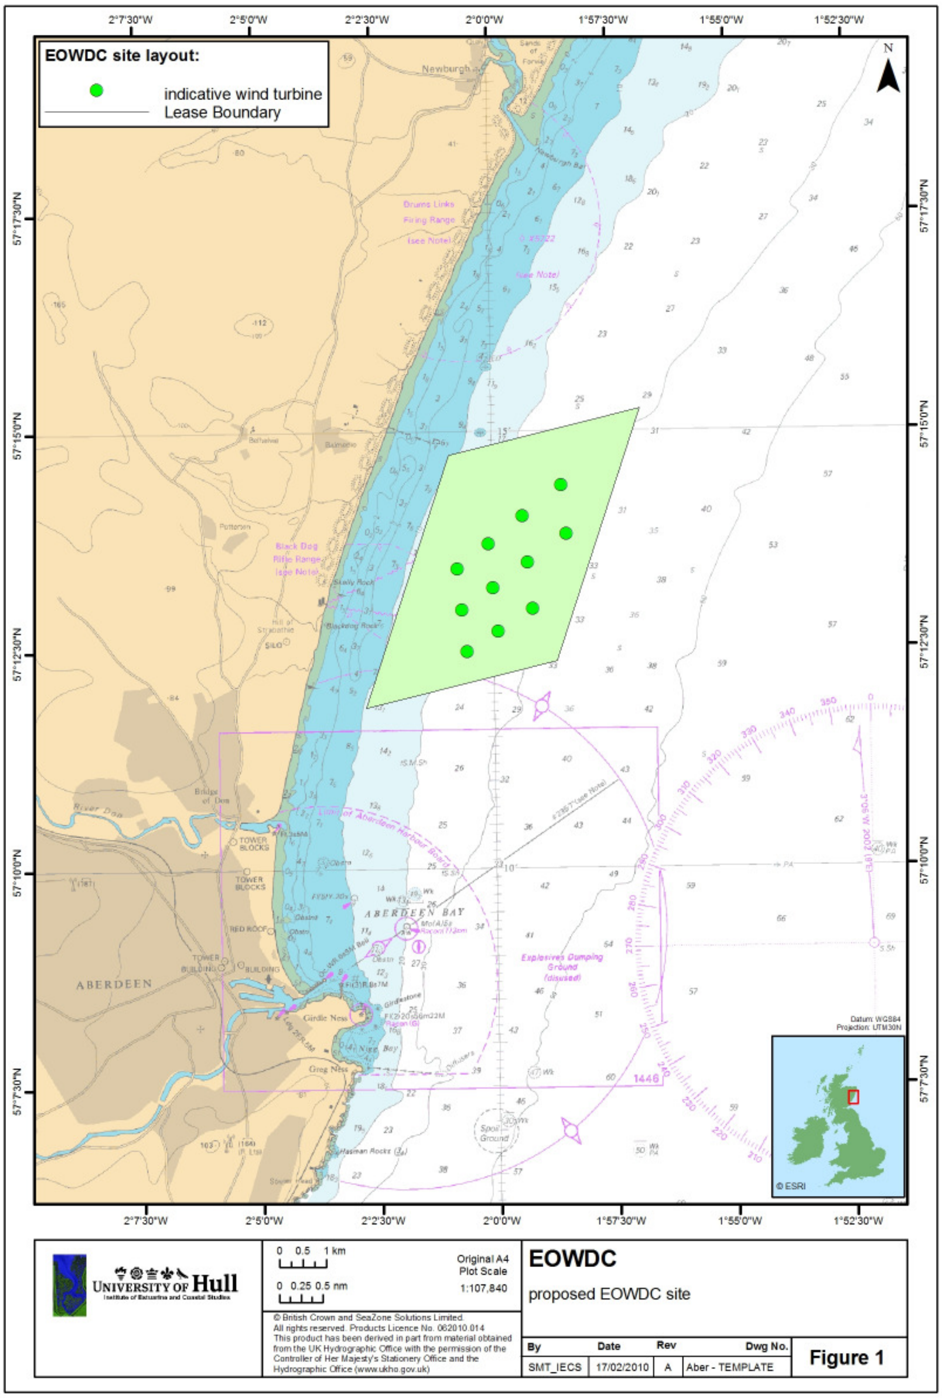

Figure 1. Proposed EOWDC site location in Aberdeen Bay. The wider area where the proposed development will fall is referred to as the proposed EOWDC site, whereas the lease boundary for development is referred to as the proposed EOWDC area (green area in figure).

2.1. METHODOLOGY CONSULTATION

15 Responses to the Request for Scoping Opinion 2010 which were relevant to marine ecology aspects were received from following organisations:

- Sue Lawrence, Area Officer – City of Aberdeen and Aberdeenshire Central, Scottish Natural Heritage (10/09/29);
- Robert Forbes, Senior Planning Enforcement Officer, Aberdeen City Council (10/09/23);
- Nicola Abrams, Senior Planning Officer, Scottish Environmental Protection Agency (10/09/24);
- Fiona Thompson, Marine Scotland (10/12/15)
- Fiona Thompson, Marine Scotland (Scoping Opinion, and Consultee comments therein, in particular comments from Scottish Natural Heritage, Scottish Environmental Protection Agency, Marine Scotland, Association of Salmon Fishery Boards) (11/02/24)

16 A previous Request for Scoping Opinion was submitted in 2005 when the project was a commercial wind farm and responses relevant to marine ecology were received from:

- James C McKie, Fisheries Research Services (FRS) (05/07/06)
- Ron MacDonald, Area manager, Scottish Natural Heritage (05/08/02)

17 The above responses raised main concerns regarding UK BAP priority species, migratory fishes, and elasmobranchs. These aspects were then taken into account when compiling the baseline technical report and main concerns regarding the impact assessment were also addressed in the EIA report and in the Environmental Statement (ES) chapter.

18 Prior to the benthic sampling and analysis programme (CMACS Ltd, 2010), a Method Statement was provided by Vattenfall and agreed with statutory consultees. These documents are listed below:

- Titan Environmental Survey (TES) Ltd (2008b). Marine Benthic Sampling Proposal. Report CS0208/D1/V2. April 2008
- GoBe (2010). Review of proposed Benthic Ecology Sampling

3. Baseline Description

20 A literature review was carried out in 2008 by Titan Environmental Survey (TES) Ltd. describing the North Sea environment and the area around Aberdeen Bay, including references to previous studies (TES, 2008a). The majority of information used to compile the literature review in the present document has come from the TES report (2008a). This information has then been integrated with the results of benthic and epibenthic surveys carried out in the proposed EOWDC site, in order to provide an updated picture of the benthic ecology in the area. In order to characterise the area for the purposes of the EIA only a single faunal sample has been analysed. If the site is consented it is AOWFL's intention to analyse the remaining two samples for the purposes of statistically robust BACI (Before-after Control Impact) type analysis ie pre and post construction comparison.

3.1. General Remarks on the Ecology of the Region

21 This section reports on the general characteristics of the marine ecology in the wider area. The spatial scale that will be chosen to discuss the ecology is the area covered in the Strategic Eenvironmental Assessment 5[1] (Figure 2), where the proposed EOWDC is located.

22 The North Sea is a complex and productive ecosystem, which supports important populations of benthic animals, fish, seabirds and marine mammals. Pelagic and benthic communities are interlinked in more or less tightly coupled food webs which, together with the abiotic environment, make up marine ecosystems.These ecosystems are dynamic and influenced by a range of biological, physical and chemical factors operating over different spatial and temporal scales.

23 Climatic and hydrographic variability, in particular the extent of Atlantic inflow, are important ecological determinants in the North Sea area, particularly affecting the character and extent of plankton communities. In recent years, spring and autumn phytoplankton blooms in the Area SEA 5 have become more evident, with primary production increasing throughout the year. Oceanographic conditions also influence the transport of zooplankton, fish larvae and cephalopods with direct consequences for associated predator populations.

24 Fish spawning areas are found throughout the Area SEA 5, with the juvenile stages of many commercial fish species remaining within coastal nursery areas for a year or two before moving offshore. Offshore areas are characterised by fish communities dominated by haddock (*Melanogrammus aeglefinus*), whiting (*Merlangius merlangus*) and cod (*Gadus morhua*). Migratory species such as herring (*Clupea harengus*) and mackerel (*Scomber scombrus*) are also found although their distribution is seasonal. Diadromous species such as Atlantic salmon (*Salmo salar*), sea trout (*Salmo trutta*), sea lamprey (*Petromyzon marinus*) and European eel (*Anguilla anguilla*) are present, with coastal rivers supporting important populations. Sandeels (*Ammodytes* spp.), a key prey item for a number of seabird and marine mammal species, are distributed throughout the area and are closely associated with well-oxygenated, medium to coarse sand. Important *Nephrops* stocks are found on a range of muddy-sand

[1] In 1999, the Department of Trade and Industry's (DTI) commenced a Strategic Environmental Assessment (SEA) process for offshore energy with a sequence of sectoral SEAs of the implications of further licensing of the UKCS for oil and gas exploration and production. The main focus of SEA 5 was the potential further licensing for oil and gas exploration of offshore areas of the UK Continental Shelf (UKCS) to the east of the Scottish mainland, Orkney and Shetland.

sediments. Benthic communities are intrinsically linked to the physical nature and characteristics of the substratum. As such, the offshore communities are spatially distributed over the area, with distinct species assemblages being associated with particular substratum types. In particular sedentary species with high abundance and biomass dominate in the sheltered coastal areas, whereas exposed beaches have lower diversity, abundance and biomass. Dense populations of intertidal benthos found in many of the sheltered inner firths and estuaries also support important fish and waterbird populations.

25 Key predators include seabirds with colonies along the east coast of Scotland that have been given protected status under the EU "Birds" Directive as Special Protected Areas (SPAs) for the species breeding there, and the number they support. Marine mammals including harbour porpoise (*Phocoena phocoena*), harbour seal (*Phoca vitulina*) and grey seal (*Halichoerus grypus*) are frequently sighted along the north east coast of Scotland, and white-beaked dolphin (*Lagenorhynchus albirostris*) and minke whale (*Balaenoptera acutorostrata*) are present further offshore (particularly during summer). Bottlenose dolphins (*Tursiops truncatus*) are regularly sighted within Aberdeen day with a peak occurrence during the winter and spring months (November-May), when they can be observed almost daily feeding at Aberdeen Harbour.

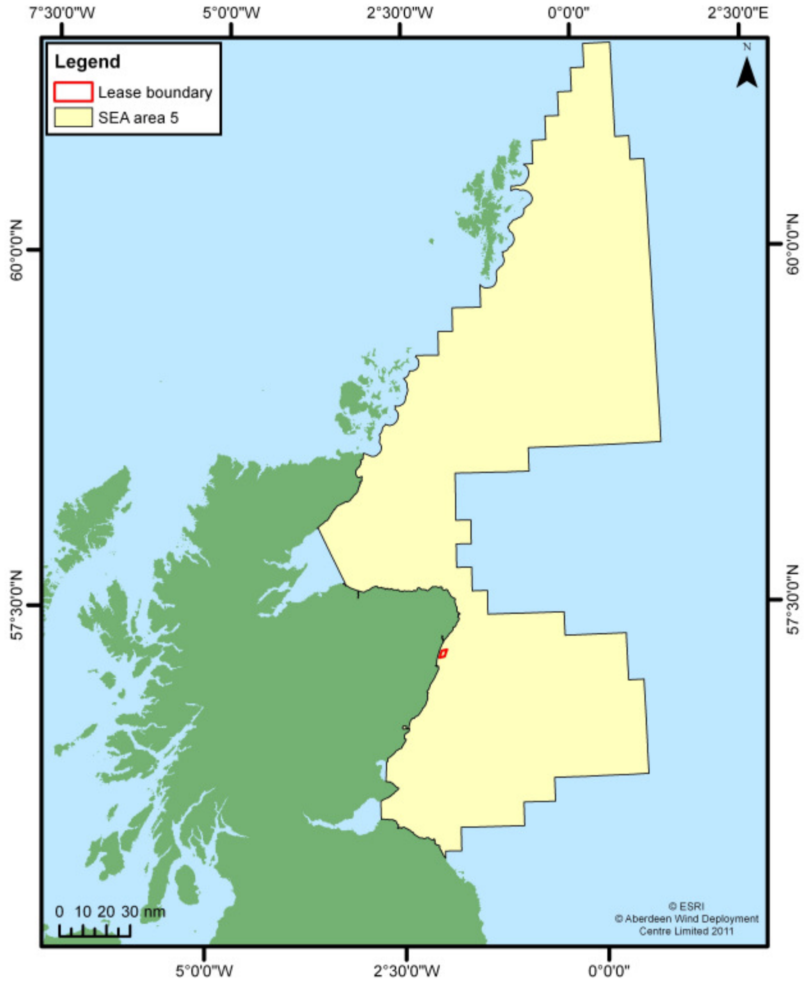

Figure 2. Location of the Strategic Environmental Assessment (SEA) 5 Areaand the proposed EOWDC lease boundary.

3.2. SEDIMENT AND WATER QUALITY

3.2.1. Sediment characteristics and contamination

26 This section reports on the information available on sediment characteristics and contamination for the proposed EOWDC site and the wider Area SEA 5 where it will fall, as gathered from background data and the benthic surveys undertaken by CMACS Ltd in 2010.

3.2.1.1. BACKGROUND INFORMATION

27 The sediments of the Area SEA 5 consist predominantly of sands, sandy gravels and gravel (Figure 3). Gravel and sandy gravel generally occur in nearshore areas where there are very strong tidal and wave driven currents, particularly around Shetland and Orkney. Large mobile sandwaves and sandbanks are also present. Muddy sediments are restricted to deeper waters and very sheltered coastal areas in the Area SEA 5.

28 According tho the broad scale map of seabed sediment distribution in the Area SEA 5 (Figure 3), the sediments off Aberdeen Bay consist predominantly of sand and slightly gravelly sand. Recent surveys carried out in the Aberdeen Bay area confirmed these data:

- A geophysical survey carried out in 2007 by EMU Ltd for AOWFL including swath bathymetry, side scan sonar imaging, shallow seismic profiling, Acoustic Ground Discrimination System (AGDS) and the collection of sediment samples for processing, confirmed the proposed EOWDC site to be dominated by muddy sand with small patches of glacial material towards the shore, and finer sediment features in places with occasional patches of shell fragments in others (EMU Ltd, 2007).
- A geophysical survey carried out in 2010 by OSIRIS Projects for AOWFL, including detailed bathymetric information, seismic profiling and information on magnetic anomalies in/on the seabed, confirmed that in the proposed EOWDC site sediments are mostly fine silty sand, frequently shelly, with localised patches of coarser grained sediments towards the shore (outside the proposed EOWDC lease area) (OSIRIS Projects Ltd, 2010).

29 The main factors affecting water quality and marine organisms are contaminant levels (organic pollutants and metals) and levels of suspended sediments. If present in sufficient concentrations, contaminants may have the potential to disturb biological processes through a variety of mechanisms. These include increased toxicity, mutagenicity, interference with reproductive physiology and availability of food and nutrients.

30 In general, riverine and atmospheric transport accounts for the largest inputs of contaminants to the north-east Atlantic and North Sea. However, transport, shipping, military activities and offshore industries, including oil and gas production, all have the potential to make significant contributions (OSPAR, 2000).

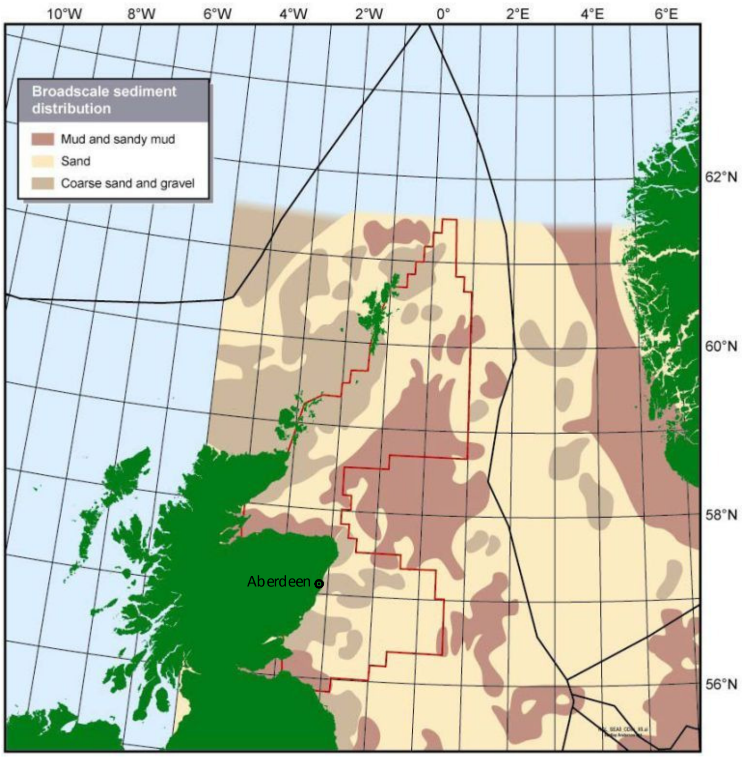

Figure 3. Broadscale seabed sediment distribution in the Area SEA 5. Source: OSPAR 2000.

31 FRS carried out a survey in April 2006 to assess the level of contaminants in the sediments in Aberdeen Bay, with sampling locations falling within the proposed EOWDC site (Appendix 5.1). The data collected during this survey were provided by FRS, and were taken into account to integrate the background information on the sediment contamination in the proposed EOWDC site.

32 Maximum Polycyclic Aromatic Hydrocarbons concentrations (total PAH) of 1732.2 µg/kg dry weight were found at station 11ABZ06 inside the proposed EOWDC area (Appendix 5.1). This concentration can be compared to the background reference concentrations (BCRs), background concentrations[2] (BCs) and provisional background assessment criteria[3] (BAC) provided by OSPAR (OSPAR, 2006). Except for Phenanthrene, Anthracene and Pyrene concentrations at station 11ABZ2006 (which are 5, 8 and 6 times higher than OSPAR's BACs, respectively), the level of PAHs in the sediments in Aberdeen Bay in 2006 can be considered to be near or below background concentrations.

33 In terms of metal concentrations in the sediments of Aberdeen Bay, the average values measured across all sampling sites during the FRS 2006 survey are given in

[2] "Background concentrations" (BCs) are assessment tools intended to represent the concentrations of certain hazardous substances that would be expected in the North-East Atlantic if certain industrial developments had not happened. (OSPAR Agreement 2005-6)

[3] "Background assessment criteria" (BACs) are statistical tools defined in relation to the background concentrations (BCs), which enable testing of whether mean observed concentrations can be considered to be near background concentrations. (OSPAR Agreement 2005-6)

Table 1. Cd concentration was always below detection limits (BDL), as well as Hg concentration (except for station 13ABZ2006) (Table 1, Appendix 5.1). All average concentrations were below OSPAR Background Concentrations (BCs), i.e. those expected in the North-east Atlantic if certain industrial developments had not happened. The results of the FRS 2006 survey also showed that the distribution of metals was rather uniform in the samples analysed (Appendix 5.1).

Table 1. Average metal concentrations (mg/kg dry weight) for all sites from FRS survey (Source: FRS, 2006) and relative Background Concentration BC (OSPAR, 2006).

Metal	As	Cd	Cr	Cu	Hg	Ni	Pb	Zn
FRS 2006 survey	4.717	BDL*	15.693	3.081	0.079	7.385	7.146	21.716
BC	15	0.2	60	20	0.05	30	25	90

*BDL=Below Detection limits

34 Sediment contamination by PAHs, PCBs and heavy metals was also measured during the benthic survey carried out in the proposed EOWDC site by CMACS Ltd in 2010. The main results are provided in the section below.

3.2.1.2. Information taken from CMACS Ltd survey 2010

35 In October 2010, CMACS Ltd undertook benthic environmental surveys in the proposed EOWDC area and in the surrounding marine environment. Sediment samples were collected from 14 stations (6 in and 8 outside the proposed EOWDC area) by means of grab sampling (see Figure 1 in Appendix 5.3 for sampling stations location). Sediment subsamples were analysed for particle size (PSA), total organic carbon, and contamination levels. Further details on the sampling and laboratory methodologies, the data analysis and the raw data are provided in the CMACS Ltd Technical Report (Appendix 5.3).

36 The sediments were homogeneous across the proposed EOWDC area and around it, being generally well sorted (i.e. composed of similar particle sizes in each sample). Fine sand was the dominant sediment type in the area, with medium sand also being present at stations 1, 2, 6, 7, 13 and 14. A silt/clay fraction was also detected at some stations (Figure 4).

37 Spatial distribution of sediment types was related to the variation in depth and distance offshore (with depth and distance from the shore being closely related). The inshore stations (2, 13 and 14, all located outside the proposed EOWDC area) were characterised by well-washed sand with low mud content, as a result of tidal movements, wave action and coastal currents re-suspending sediments in shallower, inshore areas, thus preventing the settlement of finer particles. A lower organic content was also recorded at these inshore stations compared to the others.

38 When comparing the other stations, no major differences were detected in particle size composition between those outside and inside the proposed EOWDC area. Fine-medium sandy bottoms, with a silt/clay fraction and a higher organic content characterised these stations.

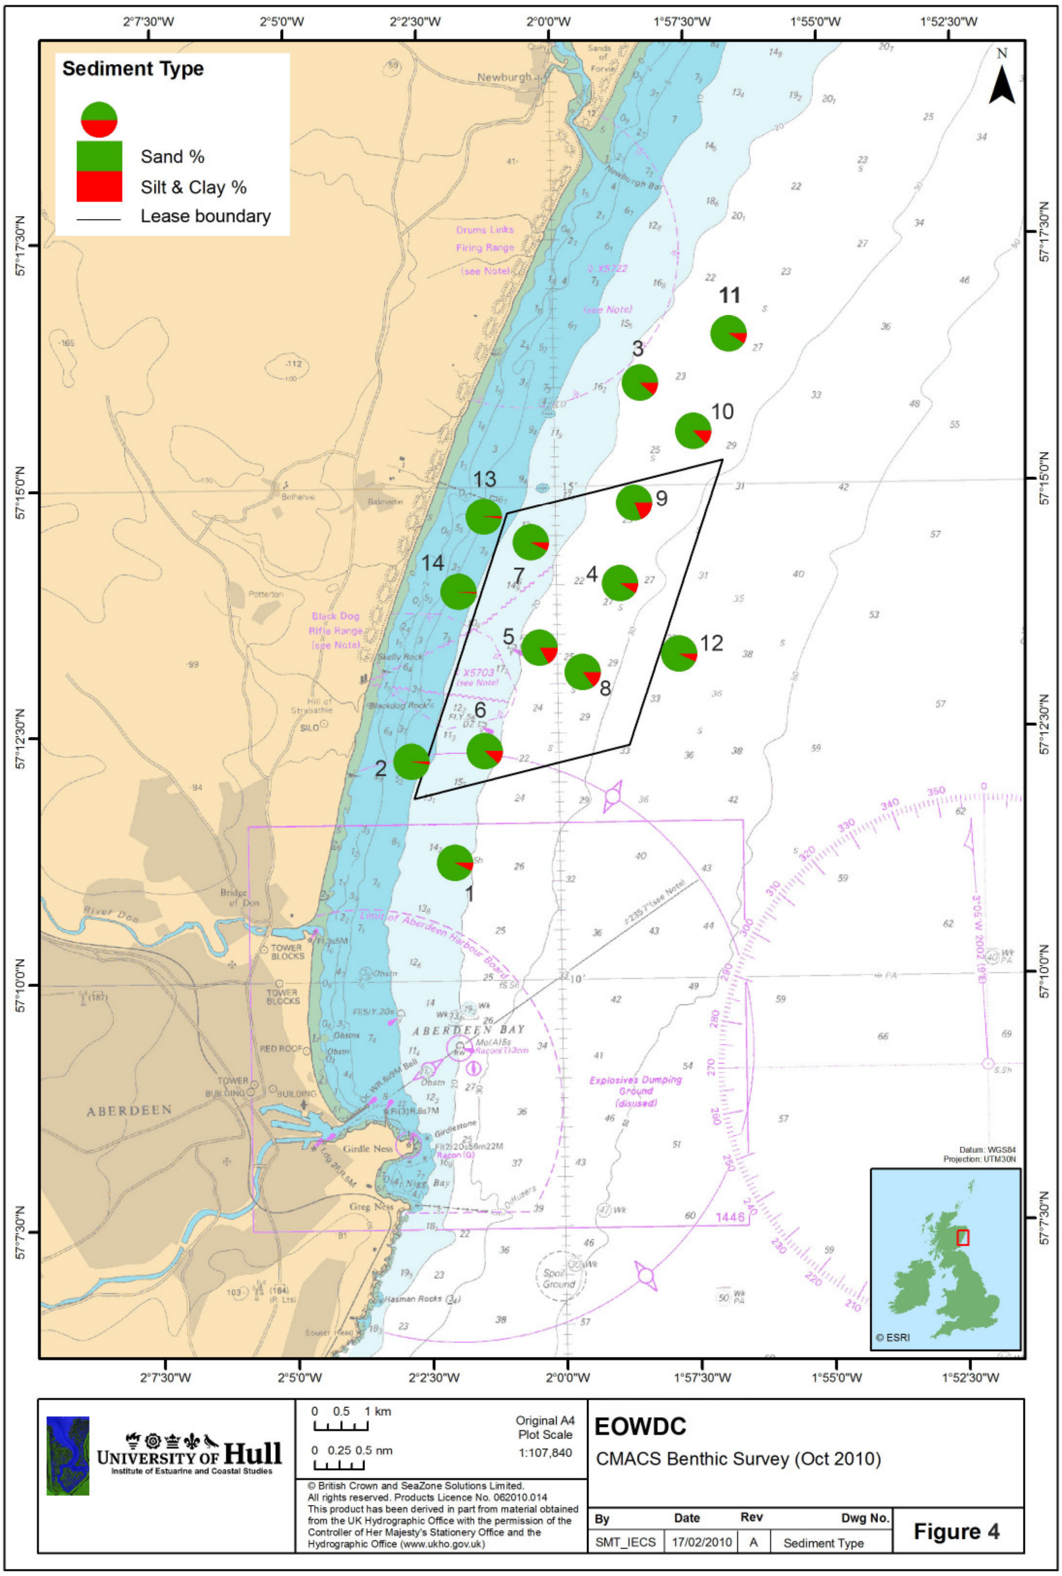

Figure 4. Geographical distribution of sand and silt/clay content across the proposed EOWDC site (stations are numbered as from CMACS Ltd Technical Report, Appendix 5.3). Map drawn by IECS based on CMACS Ltd 2010 data.

39 Mean concentrations of all PAH[4] and PCB[5] compounds were below the detection limits of 0.1 mg kg^{-1} and 0.01 µg kg^{-1}, respectively. Also concentrations of tributyl tin and other organotin compounds were all below detection levels (< 0.02 mg kg^{-1}) in all samples. For certain PAM compounds their detection limit exceeded the Interim Sediment Quality Guidelines levels (ISQG) and the Probable Effects Levels (PEL) given by CCME (2001) (see CMACS Ltd Technical Report for details, Appendix 5.3).

40 Mean concentrations of heavy metals, including cadmium, chromium, copper, lead, mercury, nickel and zinc were below the ISQG and PEL values. Arsenic concentrations exceed the ISQG of 7.24 mg kg^{-1}, but only at station 11 (7.6 mg kg^{-1}) (Appendix 5.3). However, this value is well below the PEL value for this contaminant, and, following dilution and dispersion, upon disturbance should not cause any pollution problems. Heavy metal concentrations were similarly distributed throughout the area although levels of zinc were slightly lower at station 13 than in the other stations (Appendix 5.3).

3.2.2. Water quality

41 This section reports on the background information available on water quality in the area of the proposed EOWDC site.

42 Sewage discharges are associated with coastal communities along the Area SEA 5 coastal margin, ranging in size from <100 to >100,000 population equivalent. The population equivalent and the sensitivity of waters receiving the discharges determine the level of treatment required. With regard to sewage sludge, which is left over from the treatment process, UK legislation now prohibits the disposal of sewage sludge to sea (DTI, 2004a).

43 The Ythan Estuary and lower River Don are designated as Sensitive Areas on account of eutrophication (possibly due to run-off from agricultural land), none of the east Scottish, Orkney and Shetland coasts are classified as such. Estuarine and coastal waters formerly identified as *Less Sensitive Areas* (*High Natural Dispersion Areas* under the transposing regulations) have now all been revoked (after Defra website[6]).

44 Various Bathing Waters and Shellfish Production Waters have been designated on the east coast of Scotland, north of Aberdeen. The Bathing Waters Directive (76/160/EEC) requires the monitoring of microbial indicators of faecal contamination (faecal coliform, total coliform and faecal streptococci) during the bathing season. Forty of Scotland's 60 identified Bathing Waters are located in the Area of SEA 5 and in 2003 monitoring by SEPA classified all 40 as "excellent" (i.e. meeting the Directive's guideline quality standards) or "good" (i.e. meeting the Directive's mandatory quality standards) (DTI, 2004a).

45 Overall, the water quality in the vicinity of Aberdeen is generally good, despite the presence of a large sewage outfall for trade and domestic effluent. Two main bathing waters have been identified near the proposed EOWDC site: Aberdeen –

[4] Polycyclic aromatic hydrocarbon, one of a class of chemical compounds, organic pollutants

[5] Polychlorinated biphenyls are a class of organic compounds

[6] http://www.defra.gov.uk/environment/quality/water/waterquality/sewage/sensarea/sensareas-summary.htm

Ballroom/Footdee and Balmedie Country Park Beach. The water quality of these bathing waters has been generally good for the past few years (source: Marine Conservation Society - http://www.goodbeachguide.co.uk).

3.2.3. Conclusions

46 The results of the sediment grab surveys carried out by CMACS Ltd in 2010 (Appendix 5.3) confirmed the presence of well-washed fine sandy bottoms in the proposed EOWDC area and its surroundings. A spatial pattern of increasing mud and organic content in bottom surface sediments was observed with increasing depth and distance offshore. This would be expected given the higher degree of sediment re-suspension in shallower, inshore areas, due to tidal movements, wave action and coastal currents preventing the settlement of finer particles.

47 As indicated by previous studies (e.g. the FRS benthic survey in 2006 (Appendix 5.1)), the sediment contamination in the proposed EOWDC site is in line with the background contamination levels provided for the North-eastern Atlantic area (OSPAR, 2000). Contaminant levels measured in sediments during the 2010 CMACS Ltd benthic survey (Appendix 5.3) confirm that there are no elements of concern in the area. Concentrations of the contaminants present are either below detection limits (as for PAH, PCB and organotin compounds) or below international benchmarks (ISQG and PEL) indicating potential adverse biological effects in aquatic systems (as for heavy metals).

48 The water quality in the Aberdeen area is generally good, despite the presence of a large sewage outfall for trade and domestic effluent. This is confirmed by the information on the quality of nearby bathing waters for the past few years which is generally good (Marine Conservation Society - http://www.goodbeachguide.co.uk).

Summary of sediment characteristics, contamination and water quality

Overall, the composition of the sediments is homogeneous across the survey area. The sediments at the inshore stations within the study area are characterised by fine well-sorted sands, whereas sediments further offshore and in deeper water are composed of very fine muddy sands.

The concentration of contaminants is below the Probable Effects Level (PEL) throughout the area for all contaminants measured. Arsenic is marginally above the Interim Sediment Quality Guidelines level (ISQG) but still below the PEL. All hydrocarbons, organotin and PCB concentrations are below the limit of detection.

The water quality in the Aberdeen area is generally good, as confirmed also by the information on the quality of nearby bathing waters for the past few years.

3.3. INTERTIDAL BENTHIC ECOLOGY

49 This section addresses the background information available on the intertidal benthic assemblages present along the north east coast of Scotland in general and in Aberdeen Bay in particular.

3.3.1. Background information

50 Most of the shores of the east Scottish mainland are moderately exposed to wave action, having a northerly or north-easterly orientation and the complex shore geology has created a high diversity of intertidal habitats. Sandy beaches are more prominent on the north-east coast of Scotland (Rattray Head and north of Aberdeen), south of Montrose (Lunan Bay) and south of the Firth of Tay (Tentsmuir, West Sands). The intertidal substratum in the Aberdeen Bay is also mostly sandy, with rocky platforms and boulders/loose rock southwards of Aberdeen (River Dee) and northwards of the Ythan Estuary. Also the sandy foreshore from Aberdeen to the Ythan Estuary is interrupted by a few rock platforms around Blackdog Rock, whereas the shores from Duncansby Head to Coldingham Bay are predominantly rocky.

3.3.1.1. SEDIMENTARY SHORES

51 The intertidal fauna on the east Scottish sandy beaches can be generally described as follows (Stephen, 1930; Eleftheriou and McIntyre, 1976; Eleftheriou and Robertson, 1988):

- the upper foreshore is inhabited mainly by the crustaceans *Talitrus saltator* and *Bathyporeia pilosa*;
- the middle and lower reaches have a fauna of crustaceans such as *Eurydice pulchra*, *Haustorius arenarius*, *Bathyporeia pelagica* and *B. sarsi*, along with the polychaetes *Paraonis fulgens*, *Eteone longa*, *Ophelia rathkei* and *Scolelepis(Scolepepis) squamata*;
- the lower foreshore is inhabited by polychaetes (*Spio filicornis*, *Nephtys cirrosa*, *Spiophanes bombyx* and *Lanice conchilega*), crustaceans (*Bathyporeia elegans*, *B. guilliamsoniana*, *Pontocrates altamarinus*, *Pontocrates arenarius, Atylus swammerdami* and *Monopseudocuma gilsoni*) and bivalves (*Angulus tenuis* and *Donax vittatus*).

52 Besides these general characteristics, some differences occur in the faunal composition of sandy beaches according to the degree of exposure to wind and wave action (Eleftheriou and Nicholson, 1975; Eleftheriou and McIntyre, 1976; Eleftheriou and Robertson, 1988). Extreme exposure, in fact, limits species richness by eliminating or restricting the sedentary forms of many bivalves and polychaetes, favouring in turn the presence of a fragile fauna of crustaceans. In turn, intertidal assemblages in sheltered beaches are generally dominated by sedentary species with high abundance and biomass.

53 A moderate degree of exposure to wave action, wind and tidal streams characterises most of the open coast beaches of Eastern Scotland, due to their easterly and north-easterly orientation. This type of beaches is generally short, steep and consists of medium sand and their intertidal fauna is restricted to 9-26 species and includes very few sedentary forms (Eleftheriou and Robertson, 1988). It is generally dominated by

fast swimming crustaceans such as the haustorid (*H. arenarius* and *B. pelagica*) and oedicerotid amphipods (*Pontocrates* spp.) and also cirolanid isopods (*E. pulchra*), whose overall abundance and biomass are low (Eleftheriou and Robertson, 1988). A local study carried out in Nigg Bay, to the south of the River Dee, confirmed the dominance of haustorid amphipods (*H. arenarius*) (Hart, 1971). This study highlighted also a dominance of the spionid polychaete *Scolepis cirratulus*in this beach, another species typical of exposed intertidal sandflats.

54 More sheltered beaches along the Scottish east coast are found at the inner part of firths, and are protected by headlands or by sandbanks. Tentsmuir and St. Andrews in Fife are some examples. They are generally flat or gently undulating, with fine sandy sediments, and their fauna consists of 24-48 species of which a high percentage are sedentary forms present in high abundance and biomass (Eleftheriou and Robertson, 1988). The intertidal fauna, in fact, is dominated by bivalves such as *Angulus tenuis* and *D. vittatus*, the polychaetes *N. cirrosa, S. filicornis, S. (Scolelepis) squamata* and the cumaceans *Bodotria pulchella* and *Cumopsis goodsir*. In those beaches with a flattish profile and a high retention of seawater there may be some evidence of an incursion of subtidal species well into the intertidal, such as *Tellina fabula*, as well as the amphipod *B. guilliamsoniana*, mysids, the polychaete *Nephtys hombergii* and several cumaceans (Eleftheriou and Robertson, 1988).

3.3.1.2. Rocky Shores

55 The littoral rocky shoreline extends sublittorally as outcrops of bedrock of variable extent and size. On vertical surfaces barnacles and limpets replace fucoid algae as the dominant organisms. The communities of plants and animals occurring on hard substrata between the tidal extremes are dependent on a combination of factors: wave exposure, shore topography, geology and geographical location. However, it should be noted that important stretches of hard substrata on the east coast are either only partially surveyed, or, in some cases, there is no information available.

56 The macroalgae of the rocky outcrops of north-eastern Scotland were studied by Wilkinson (1979) who found 80 species not previously recorded from the area. The first British record of the brown algae *Sorapion kjellmanii* was also recorded from this area, as reported by Bennett and McLeod (1998). Early records by Jack (1890) provided information on the marine algae of the rocky shores in the vicinity of Arbroath.

57 In the early 20th century, the distribution of fucoid algae was described for the Ugie (Peterhead), the Ythan (Newburgh), the Don (Aberdeen) and the Dee (Aberdeen) estuaries (Chater, 1927). The Ugie and the Don were similar in that they were both small estuaries supporting an abundance of the fucoid alga *Fucus ceranoides*. Much of the Ythan consisted of muddy shores but where rock occurred it supported a variety of fucoids. A range of fucoid algae also characterised the lower part of the Dee estuary but only *F. ceranoides*, which can tolerate reduced salinity, penetrated the estuary beyond Victoria Bridge, Aberdeen. The Don was then heavily polluted by effluent from a paper mill, but since the installation of a biological treatment plant, water quality has much improved and the estuary was declared a Local Nature Reserve in 1993 (Bennett and McLeod, 1998). The paper mill has now closed.

58 A large number of common and widespread intertidal faunal species are found on the rocky shores along the east coast of Scotland. Chitons (*Lepidochitona* and *Acanthochitona*), gastropods such as *Nucella lapillus, Patella aspera, P. vulgata, Margarites helicinus*, and several species of *Littorina* and nudibranchs (*Onchidoris spp., Archidoris, Facelina, Aeolidia*) are present on these habitats. A large gastropod

fauna including *Ansates pellucida*, several species of *Lacuna* and some pyramidellids have been also recorded, in association with *Fucus* fronds and laminarian stipes (Eleftheriou *et al.,* 2004).

3.3.2. Conclusions

59 The intertidal substratum in Aberdeen Bay is mostly sandy and moderately exposed to wave action, wind and tidal streams. Hence, an intertidal assemblage typical of moderately exposed beaches, as described above, is likely to be found along the shores possibly affected by the proposed EOWDC development. The dominant species in it (errant amphipods and spionid polychaetes) are adapted to living in a highly perturbed environment, and general unspoilt conditions are reported for most of the coast in the area (Bennett and McLeod, 1998). Hence, although the available data are dated, it is considered unlikely that the intertidal fauna has significantly changed since the data were collected.

60 Sandy intertidal habitats may also function as feeding grounds for the juveniles of many fish species (e.g. plaice *Pleuronectes platessa*; Gibson, 1973; Kuipers, 1977), hence supporting the populations of the adjacent sublittoral areas.

Summary of Intertidal Benthic Community

The open coast beaches of east Scotland are generally moderately exposed to wave action, wind and tidal streams, and the complex shore geology has created a high diversity of intertidal habitats. Sandy beaches are more prominent, although rocky shores are also present along the coast.

In the Aberdeen area, sandy shores are present, with an intertidal fauna being generally dominated by mobile crustaceans (such as haustorid amphipods) and showing a lower diversity, abundance and biomass than more sheltered sandy beaches (such as those at St. Andrews), where sedentary species dominate on richer assemblages.

3.4. SUBLITTORAL BENTHIC ECOLOGY

61 This section reports on the information available on sublittoral benthic fauna for the proposed EOWDC site and the wider area (North Sea and Area SEA 5), as gathered from background data and the CMACS Ltd 2010 benthic survey (Appendix 5.3).

3.4.1. Background information

62 In spite of the fact that the North Sea has been one of the most studied marine environments in the world, historically most investigations have concerned fish populations. As a result there was relatively little information available about the benthic fauna up until 30 years ago, particularly with regard to the northern North Sea (TES, 2008a). The need for further investigations covering the northern and central areas of the North Sea was widely acknowledged (Kingston and Rachor, 1982). Recently this gap has been partly filled by intensive small-scale surveys required for oil and gas exploration in the area. A Working Group on North Sea Benthos was established in 1981 by the International Council for the Exploration of the Sea (ICES). The Working Group organised a survey of the North Sea benthos, which was completed in early 1986. Wide-ranging benthic surveys (Basford and Eleftheriou, 1988; Eleftheriou and Basford, 1989; Basford *et al*., 1989, 1990, 1993; Künitzer *et al*., 1992), as well as epifaunal surveys (Dyer *et al*., 1982, 1983; Jennings *et al*., 1999; Zulhke, 2001) have also been undertaken, providing a database for the description of the benthic fauna of the entire North Sea. A thorough literature review for the Aberdeen Bay area was carried out in 2008 by TES Ltd, describing the North Sea environment and the area around Aberdeen Bay, including references to previous studies, and little new information has become available since its release (TES, 2008a).

63 At the North Sea scale, Künitzer *et al*. (1992) describe a division of the infauna between northern and southern assemblages occurring along the 70 m depth contour. Assemblages were further separated by the 30, 50 m and 100 m depth contour as well as by the sediment type. Cold water species did not occur further south than the northern edge of the Dogger Bank, which corresponds to the 50 m depth contour, whereas warm water species were not found north of the 100 m depth contour. The factors structuring species distributions and assemblages seemed to be temperature, the influence of different water masses (e.g. nutrient rich Atlantic water), the type of sediment and the food supply to the benthos. Much of the primary productivity in the northern North Sea is associated with the input of nutrient rich water from the North Atlantic and this has an effect on the benthic community structure in the northern part of the North Sea. At a North Sea scale, assemblages of other benthic groups such as the meiofauna (Huys *et al.,* 1992) and the epifauna (Dyer *et al.,* 1983; Frauenheim *et al.,* 1989) are structured and grouped within similar spatial patterns as the macrobenthic infauna assemblages.

64 The major division in macro-zoobenthic assemblages between the deeper northern and the shallower southern North Sea was confirmed by the findings of recent macrobenthic infaunal and environmental data from various sources, published by ICES in 2007 (Rees *et al.,* 2007). Separation of assemblages occurred along the Frisian Front at around 30 m depth and at the northern lower slope margin of the Dogger Bank (at a depth between 50 and 70 m). The influence of Atlantic inflow was again highlighted to be an important factor in structuring northern communities. General trends of increasing diversity and density are correlated with increasing latitude and depth.

65 Changes in community structure along the British coast between 1986 and 2000 were also described by Rees *et al*. (2007). A general trend of decreasing species richness was observed with a parallel increase in species abundance. Rees *et al.* (2007) suggest that increased abundances of cold-temperate species, such as the small polychaete *Paramphinome jeffreysii* and the interface-feeding *Myriochele* spp., north of the 50 m contour line could be an indication of the influence of colder northern water masses.

66 Within Aberdeen Bay, Stephen (1933, 1934) reported on a group of samples from around Aberdeen (20 – 40 m depth) and a transect of eight stations extending offshore in a south-easterly direction to the 100 m contour. The above stations, along with another fifteen dispersed widely throughout this sub-division of Area SEA 5, were considered to be from a community characterised by the presence of *Ophiura affinis* and *Echinocyamus pusillus*. Stephen (1933, 1934) concluded that there was large-scale geographic similarity in the offshore fauna and that it was less abundant than the inshore fauna. Stephen (1933, 1934) also noted a sub-community off the north-east coast of Aberdeenshire. Here large numbers of broken *Sabellaria* tubes (species of high nature conservation importance), probably originating from the masses growing near Rattray Head, formed the substratum for a community characterised by the molluscs *Astarte compressa, Cardium fasciatum, Venus ovata* and *Leda (*now *Nuculana) minuta*, and the polychaetes *Glycera lapidum* and *Ophelia limacina*.

67 At a later date, McIntyre (1958) described the benthos of the east coast fishing grounds with reference to surveys of St. Andrews and Aberdeen Bays. He found the fauna to be dominated by lamellibranchs and polychaetes together with the bivalves *A. alba, T. fabula, Nucula turgida* and *Ensis* sp. In addition the polychaetes *L. conchilega, Sigalion mathildae, Notomastus latericeus* and *Nephtys* spp. were dominant in both bays. Aberdeen Bay had a quantitatively richer fauna than St. Andrews Bay. The poorer offshore fauna was dominated by *A. alba* at St. Andrews and by *N. turgida* in Aberdeen Bay.

68 According to the results of a drop down video survey undertaken in 2007 by EMU Ltd for AOWFL, two main biotopes were described in the proposed EOWDC area, namely SS.SSa.CMuSa and SS.SSa.CCS. Tide-swept circalittoral coarse sand, gravel and shingle (SS.SCS.CCS) is a habitat occurring generally at depths of over 15-20 m and is typical of tidal channels of marine inlets, along exposed coasts and offshore. As with shallower coarse sediments, this biotope is characterised by robust infaunal polychaetes, mobile crustacea and bivalves. Circalittoral non-cohesive muddy sands (SS.SSa.CMuSa) is a biotope characterised by a silt content of the substratum typically ranging from 5% to 20%. This biotope is generally found in water depths of over 15-20 m and supports animal-dominated communities characterised by a wide variety of polychaetes, bivalves and echinoderms.

69 The proposed EOWDC site is located between two main estuarine areas: the Ythan Estuary, northwards, and the River Dee estuary, southwards. The invertebrate fauna of the Dee estuary was studied by Eleftheriou (1964). As might be expected, the maximum densities of marine, estuarine and freshwater species were found at the mouth, middle and head of the estuary respectively. The Ythan Estuary is a small meso-tidal bar-built estuary (Davidson *et al*., 1991) lying approximately half way between Peterhead and Aberdeen on the east coast of Scotland. It is a well-understood small-scale ecosystem (Raffaelli, 1992) and has been the subject of many studies based at the Culterty Field Station of the University of Aberdeen. At the mouth of the Ythan the sediments are sandy with stones and mussel beds and with occasional patches of muddy sand. In the middle reaches of the estuary the

sediments are muddy sand becoming finer further into the inner estuary (Baird and Milne, 1981). The faunal community is well studied with the amphipod *Corophium volutator*, the gastropod mollusc *Hydrobia ulvae*, the polychaete *Hediste diversicolor* and the bivalve *Macoma balthica* being widely distributed. Species such as the cockle *Cerastoderma edule*, the gastropod *Littorina littorea,* the shore crab *Carcinus maenas* and the mussel *Mytilus edulis* exhibit more localised distributions (Bennett and McLeod, 1998). Increasing weed cover (*Enteromorpha intestinalis*) led to increases in the the abundance of the opportunistic polychaete species *Capitella capitata* in the 1980s. Also local populations of less common species occur in the Ythan, such as the annelid *Lumbriculus variegatus*, the very local mollusc *Hydrobia ventrosa* and the very rare marine midge *Halocladius braunsi* (Scottish Natural Heritage, http://www.snh.org.uk/pdfs/publications/nnr/ForvieNNRTheReserveStory.pdf).

70 Also, rocky platforms and boulders/loose rock occur to the south of Aberdeen (River Dee) and to the north of the Ythan Estuary, with the littoral rocky shoreline extending sublittorally as outcrops of bedrock of variable extent and size. The invertebrate fauna associated with these habitats is described in Section 3.3. Intertidal Benthic Ecology of the present document.

3.4.2. Information taken from CMACS Ltd Survey 2010

71 The CMACS Ltd benthic grab survey was conducted in October 2010, using a standard weighted Day grab with a 0.1 m^2 sample area for all sediment sampling. Fourteen stations were visited in total, 6 in (and 8 outside) the proposed EOWDC area (see Figure 1 in Appendix 5.3 for sampling stations location). Macrofaunal analysis was carried out at the CMACS Ltd laboratory in the Isle of Man which participates in the National Marine Biology Analytical Quality Control Scheme. Further details on the sampling and laboratory methodologies, the data analysis and the raw data are provided in the CMACS Ltd Technical Report (Appendix 5.3). Additional analyses carried out by IECS on CMACS Ltd benthic data are provided in Appendix 5.4.

72 A total of 70 species was recorded from the survey area as a whole. The key dominant species (making up 85% of total abundance in the area) are reported in Table 2.

73 The mean number of species recorded across the sites was 18.3 (ranging from 10 to 32), whereas abundance values ranged from 17 to 145 individuals/0.1 m^{-2} (with an average value of 60.43 individuals/0.1 m^{-2}) (Appendices 5.3 and 5.4).

74 In general, the greatest number of species and abundances were recorded from the deeper stations in the proposed EOWDC site. This is likely to be due to the increasing depth and distance from the shore and the fact that there was a relatively high proportion of silt/clay present at these stations. This is supported by the data collected from stations 4, 8 and 9 which are located in the proposed EOWDC area (Figure 4). These stations have the highest number of taxa and are all in waters deeper than 27 m. When considering stations outside the proposed EOWDC area, this pattern was less evident, as, for example, stations at depths between 28 and 31 m showed either high (station 10) or low (station 3 and 11) number of taxa.

75 The species diversity (measured by the Shannon-Wiener diversity index H'(log_2) and the Pielou's evenness index (J') varied throughout the area with some of the shallower stations (such as station 1) having a more varied species composition and

some of the deeper stations (e.g. station 8) being more dominated by large numbers of a single species (as indicated by the lower values of the evenness index) (Appendix 5.4). The values of these indices across the stations, together with the relatively low abundance ratio, indicate a general even spread of the individuals between the species, suggesting that the communities are not dominated by one or very few species.

76 The dominant faunal groups found were polychaetes (Annelida), crustaceans and the molluscs (Appendix 5.3). The dominant species of polychaetes were *N. latericeus*, *S. bombyx*, *Galathowenia oculata*, *Pholoe baltica*, *N. cirrosa* and *Nephtys assimilis*. The most abundant molluscs were the bivalves *N. nitidosa*, *T. fabula*, *Kurtiella bidentata* and *A. alba*. The most abundant crustaceans were the amphipods, such as *Bathyporeia guilliamsoniana* and *Ampelisca brevicornis*. Other groups accounted for less than 7% of the total faunal abundance.

77 The most abundant species across the survey area as a whole was the annelid worm *N. latericeus* (243 individuals being found across 12 out of the 14 stations). *N. latericeus* is a polychaete (bristle worm) with a wide distribution across the North Sea and is generally thought to be found in low numbers. It is thought to inhabit sediment with a mud content of 0-50%, preferring sediments with a mud content of 10-30% (Warwick and Davies, 1977). This species is found across the survey area (Appendix 5.3), particularly in relatively deep locations. The stations where *N. latericeus* was particularly prevalent are all deeper than 25 m.

78 The second most common taxa at the proposed EOWDC site were juvenile brittle stars from the Ophiuridae family (Appendix 5.4). It is likely that these are *Ophiura ophiura*, but small juveniles are often difficult to identify to species level. The distribution of this taxon shows that these are more abundant towards the south of the lease boundary, stations 5, 6 and 9 having the highest numbers of juvenile Ophiuridae. These sites were all classed as muddy sand, suggesting the juvenile brittle stars have an affinity for muddier sediment types.

79 The third most abundant species was *N. nitidosa* (Appendix 5.4), which is a bivalve mollusc found throughout the North East Atlantic and European coastal waters. *N. nitidosa* shows a similar distribution to *N. latericeus*, being present at higher abundances in deeper waters. However, when compared with *N. latericeus* individual numbers per station were considerably lower.

80 The forth most abundant species was *T. fabula* (Appendix 5.4), which is a small burrowing bivalve commonly found in most coastal areas and occurring in a wide range of sediments. The distribution of *T. fabula* shows that it was absent from the closest inshore stations but appears to be present throughout the rest of the survey area, showing overall higher abundances outside the proposed EOWDC area. Although *T. fabula* was the third most abundant species, individual numbers are low and do not exceed 12 at any stations.

Table 2. Key infaunal species (top 85% abundance) for the survey area as a whole (CMACS Ltd Benthic Survey 2010).

Species	Taxonomic group	Ranked abundance
Notomastus latericeus	Polychaeta	1
Ophiuridae juv.**	Echinodermata	2
Nucula nitidosa	Bivalvia	3
Tellina fabula	Bivalvia	4
Spiophanes bombyx	Polychaeta	5
Galathowenia oculata	Polychaeta	6
Acrocnida brachiata	Echinodermata	7
Pholoe baltica	Polychaeta	8
Kurtiella bidentata	Bivalvia	9
Abra alba	Bivalvia	10
Nephtys cirrosa	Polychaeta	11
Nephtys assimilis	Polychaeta	12
Amphiura filiformis	Echinodermata	13
Nephtys sp. juv.	Polychaeta	14
Chamelea striatula	Bivalvia	15
Amphiuradae sp. juv.	Echinodermata	16
Bathyporeia guilliamsoniana	Amphipoda	17
Thyasira flexuosa	Bivalvia	18
Diastylis bradyi	Cumacea	19

**Ophiuridae juv. include Ophiuridae juv and *Ophiura* sp. Juv

81 The multivariate analysis carried out on the species abundance data highlighted the presence of two distinct groups of stations showing different benthic assemblages (Appendices 5.3 and 5.4). All the stations in the proposed EOWDC area (stations 4-9) and 5 of the stations outside it (stations 1, 3, 10-12) (Group A) showed benthic assemblages characterised by higher species richness and abundance than the rest of stations (stations 2, 13 and 14; Group B), located inshore, outside the proposed EOWDC area. Dominant species in stations from the Group A are the polychaete *N. latericeus*, followed by the bivalves *N. nitidosa* and *T. fabula* and brittle star of the family Ophiuridae. In turn, the polychaete *N. cirrosa* and amphipods dominated the benthic assemblage in stations from Group B, though with very low abundances if compared to the values recorded in the other group. The patterns in the species distribution and communities observed were found to be highly related to sedimentary and depth parameters (mainly median grain size, % sand, % silt/clay and depth, as indicated by the BIOENV analysis). Such a correlation between sediment types and depth is likely to reflect the difference between shore positions.

82 The infaunal communities are clearly strongly influenced by the depth and distance offshore (these two being indistinguishable on this open coast). The above results (combining faunal and sediment data) allowed the identification of two major biotopes in the survey area (Appendices 5.3 and 5.4). The biotope SS.SSA.CMuSa.AalbNuc (*A. alba* and *N. nitidosa* in circalittoral muddy sand or slightly mixed sediment) occurred at the majority of stations (these are the stations included in Group A defined by the multivariate analysis presented above). The biotope SS.SSA.IFiSa.NcirBat (*N. cirrosa* and *Bathyporeia* spp. in infralittoral sand) occurred at the inshore stations (these are the stations included in Group B defined by the

multivariate analysis presented above) where a much lower silt/clay content was detected (being predominantly fine-medium sands).

3.4.3. Conclusions

116 The proposed EOWDC area supports a benthic infaunal community similar to that occurring in the surrounding environment. There are no major differences in the community characteristics (species richness, abundance and diversity) or the taxonomic structure between the stations inside and outside the proposed EOWDC area (when considering similar depth conditions).

117 Overall, the benthic faunal characteristics in the area reflect those reported in the literature for Aberdeen Bay, with particular regard to the study by McIntyre (1958). Benthic infauna is quantitatively dominated by polychaetes (Annelida), such as *N. latericeus*, and the bivalves *N. nitidosa* and *T. fabula*. Ophiuridae are also characteristic of the surveyed benthic assemblages, particularly at offshore stations. This is consistent with previous findings of Stephen (1933, 1934) regarding the Aberdeen Bay area.

118 Most of the surveyed area is characterised by circalittoral non-cohesive muddy sands supporting animal-dominated communities characterised by a wide variety of polychaetes, bivalves and echinoderms, partly confirming the biotope analysis carried out in 2007 by EMU Ltd. In particular, the dominant benthic community strongly resembles the JNCC biotope SS.SSA.CMuSa.AalbNuc (*A. alba* and *N. nitidosa* in circalittoral muddy sand or slightly mixed sediment).

119 Although the previous biotope analysis (EMU Ltd., 2007) also described the presence of tide-swept circalittoral coarse sand, gravel and shingle (SS.SCS.CCS) in a small patch within the proposed EOWDC area, this biotope was not identified during the CMACS Ltd benthic survey in 2010. However, it should be noted that biotope analysis by EMU Ltd 2007 was based on geophysical data only. An additional biotope was described by CMACS Ltd study at inshore sites (outside of the proposed EOWDC area) not explored in 2007. These sites are characterised by finer sands, with sparser benthic assemblages matching well with the biotope SS.SSA.IFiSa.NcirBat (*N. cirrosa* and *Bathyporeia* spp. in infralittoral sand).

120 The differentiation between the benthic assemblages in the area is clearly strongly influenced by the depth and distance offshore, with the assemblage/biotope in the proposed EOWDC area being consistent with those found at stations located outside the lease boundary at a greater distance offshore.

Summary of Infaunal Community and Biotope Mapping

Species richness, abundance and diversity are variable across the site. These biological parameters are somewhat higher at deeper offshore stations than inshore ones. Numbers of species and abundance are somewhat lower outside the proposed EOWDC area; however, Shannon-Weiner diversity remains similar.

Two types of communities occur across the proposed EOWDC site, mainly reflecting sedimentary and depth characteristics. A community with a low number of species and abundance is present at inshore shallow stations with fine-medium, well-washed, sandy sediments. This community is characterised by the polychaete *N. cirrosa* and amphipods. A community with a relatively high number of species and abundance occurs at the offshore stations (including those present in the proposed EOWDC area), where the sediments are generally classified as muddy sand. The most abundant species in this community are the polychaete *N. latericeus*, the bivalves *N. nitidosa* and *T. fabula* and brittle stars of the family Ophiuridae.

These two communities can be characterised by two major biotopes: SS.SSA.CMuSa.AalbNuc (*A. alba* and *N. nitidosa* in circalittoral muddy sand or slightly mixed sediment) and SS.SSA.IFiSa.NcirBat (*N. cirrosa* and *Bathyporeia* spp. in infralittoral sand).

3.5. EPIBENTHIC FAUNA AND FISHERY ECOLOGY

121 This section reports on the information available on epibenthic invertebrate and fish fauna for the proposed EOWDC site and the wider area (North Sea and Area SEA 5), as gathered from background data and the epibenthic surveys carried out in the area in 2010 by CMACS Ltd (specifically for this project) and Marine Scotland Science (MSS, not for this project).

3.5.1. Background information

3.5.1.1. EPIBENTHIC INVERTEBRATES

122 Dyer *et al.* (1982) mapped the abundances of the most common or locally abundant epifauna species in the North Sea. Seven of these occurred in Area SEA 5: the echinoderms *Echinus acutus* and *Asterias rubens*, the polychaete *Hyalinoecia tubicola*, the red sea pen *Pennatula phosporea*, Dead Men's Fingers *Alcyonium digitatum*, the Norway Lobster *Nephrops norvegicus* and the bryozoan *Flustra foliacea*.

123 In Aberdeen Bay, Stephen (1933, 1934) reported on a group of samples from around Aberdeen (20 – 40 m depth) and a transect of eight stations extending offshore in a south-easterly direction to the 100 m contour. The above stations, along with another fifteen dispersed widely throughout this sub-division of Area SEA 5, were considered to be from a community characterised by the presence of *Ophiura affinis* and *Echinocyamus pusillus*. Stephen (1933, 1934) concluded that there was large-scale geographic similarity in the offshore fauna and that it was less abundant than the inshore fauna. Stephen (1933, 1934) also noted a sub-community off the north-east coast of Aberdeenshire. Here large numbers of broken *Sabellaria* tubes (species of high nature conservation importance), probably originating from the masses growing near Rattray Head, formed a substratum for a community characterised by the molluscs *A. compressa, C. fasciatum, V. ovata* and *N. minuta*, and the polychaetes *G. lapidum* and *O. limacina*.

3.5.1.2. SPAWNING AND NURSERY GROUNDS

124 The offshore area around Aberdeen is reported as a spawning ground for many commercially important species. The juvenile stages of many of these species remain within coastal nursery areas for a year or two before moving offshore. The offshore areas are characterised by fish communities dominated by haddock, whiting and cod, with saithe (*Pollachius virens*) and Norway pout (*Trisopterus esmarki*) being associated with deeper waters. Lemon sole (*Microstomus kitt*) are distributed throughout the central and northern North Sea and are pelagic spawners (February to June, with peak spawning period between April and May; Coull *et al.*, 1998). Little is known about this species' spawning habitats, and it is thought the lemon sole spawns throughout its range (CEFAS, 2001).

125 According to broad scale maps of fishery sensitivity areas in British waters, spawning grounds of herring, lemon sole and sandeel *Ammodytes marinus*, and nursery areas for lemon sole, sprat *Sprattus sprattus*, saithe, plaice and sandeel are present in the area where the proposed EOWDC site is located (Coull *et al.*, 1998 – see Appendix 5.2).

126 These maps have been updated for some species with more recent larval and juvenile data obtained from ichthyoplankton and groundfish surveys (CEFAS, 2010). The updated maps seem to confirm the spawning of sandeel in the area, while highlighting also the presence of nursery areas of herring, whereas a minor importance as spawning or nursery grounds was highlighted for plaice in the area (no updated data were available for lemon sole, sprat and saithe). Sandeel and herring play a key role in the North Sea food web. Sitting in a mid-trophic position, they are major predators of zooplankton and the principal prey of many top predators such as Atlantic salmon and sea trout. Sandeel eggs are demersal, and are laid in sticky clumps on sandy subratrata from November to February (Coull *et al.*, 1998). On hatching, the larvae become planktonic, resulting in a potentially wide distribution (CEFAS, 2001). Herring is a migratory species and is found throughout the area, although its distribution is seasonal.

127 The above mentioned maps represent very broad scale distributions and do not take into account the different suitability of habitats for the species within the highlighted areas. Sandeel, for example, is closely associated with well-oxygenated, medium to coarse sand, hence its distribution will be limited to this suitable habitat (not detected in the proposed EOWDC area, where fine to very fine sandy sediments occur). In addition, spawning grounds are dynamic features of fish life history and are rarely fixed in one location from year to year. Although some fish species exhibit the same broad patterns of distribution from one year or season to the next, others show a large degree of variability. For sediment spawners, not all suitable sediment areas might be used in every year and areas used will depend on the size of the spawning stock. Also the locations of nursery areas can change from year to year depending on factors such as water temperature or the availability of food. It is therefore difficult to define the limits of nurseries precisely. The maps provided in Appendix 5.2 as well as those provided by CEFAS (2010) must therefore be considered an indication of the likely positions of juvenile and egg concentrations, representing the widest known distribution rather than a definitive description of the limits of all spawning and nursery grounds.

128 No specific information has been found in the literature on the use of the proposed EOWDC site as a fish nursery or spawning ground. However, an indication that no specific spawning or nursery grounds are present within the site came from the Marine Scotland Licensing Operations Team in its scoping response (2010).

3.5.1.3. Migratory Species

129 There are several species that migrate between fresh and salt waters (diadromous species) in the North Sea, such as Atlantic salmon, sea trout, sea lamprey, river lamprey (*Lampetra fluviatilis*), European eel, twaite shad (*Alosa fallax*), allis shad (*Alosa alosa*) and sparling (*Osmerus eperlanus*) (Barne *et al.*, 1996; DTI, 2004b).

130 Atlantic salmon, anadromous sea trout and European eel, in particular, may use the coastal areas of Scotland for feeding and migration and are of high economic and / or conservation value (see Section 3.6. Nature Conservation Status). However the knowledge on the migration routes of these species along the east coast of Scotland is rather scarce and uncertain (Malcom *et al.*, 2010). Further details on this issue are provided in the salmon and sea trout assessment for the proposed EOWDC.

3.6.1.4. Non-commercial fish species

131 The numbers of exploited and non-exploited fish species from coastal areas of Area SEA 5 were estimated by Swaby and Potts in 1993 (in Swaby and Potts, 1996,

1997a, b, c). Information on the distribution and abundance of non-commercial species comes from records made during routine groundfish surveys, landings data, historical records as well as scientific studies. The most abundant species found in near-surface surveys in areas from Aberdeen to off Shetland were rocklings (Gadidae), members of the herring family (Clupeidae) and three-spined sticklebacks (*Gasterosteus aculeatus)* (Swaby and Potts, 1996).

3.5.1.5. CEPHALOPODS

132 Cephalopods are important elements in food webs and interact with commercial fisheries of finfish. Evidence exists that fishing pressure has changed ecological conditions and shifts in community structure have occurred with cephalopod stocks slowly replacing predatory fish stocks (Caddy and Rodhouse, 1998). Their commercial significance to world fisheries is relatively recent but is increasing (Boyle and Pierce, 1994). According to Stephen (1944) frequently occurring cephalopod species in the North Sea include *Eledone cirrhosa*, *Sepiola atlantica*, *Sepiola pfefferi*, *Sepietta oweniana*, *Rossia macrosoma*, *Rossia glaucopis*, *Sepia officinalis*, *Loligo vulgaris*, *Loligo forbesi*, *Alloteuthis subulata*, *Illex coindetii*, *Todaropsis eblanae* and *Todarodes sagittatus.* Infrequently occurring species are *Bathypolypus arcticus*, *Benthoctopus piscatorum*, *Sepietta neglecta*, *Sepia elegans*, *Onychoteuthis banksi*, *Architeuthis monachus*, *Architeuthis harveyi*, *Sthenoteuthis caroli* and *Brachioteuthis riisei.* The main commercial species in Scottish waters is the long-finned squid *L. forbesi* (Boyle and Pierce, 1994; Pierce *et al.*, 1994a, b, 1998). Since 1995, annual UK landings of loliginid squid have ranged between 1600 and 3200 tonnes, making the UK the second most important fishery nation for loligonid squid within the ICES region after France. Figure 5 shows the total squid landings for Area SEA 5 in 1998. Although squid are caught off the Aberdeen coast, this area is not the most important in terms of Area SEA 5 as a whole.

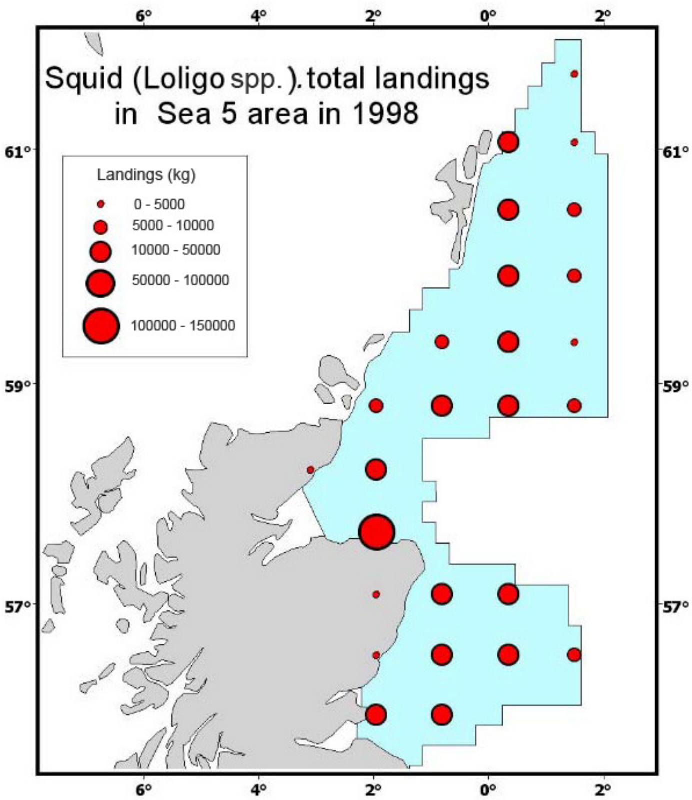

Figure 5. Squid total landings in Area SEA 5 in 1998. Source: Stowasser *et al.* (2004).

3.5.1.6. ELASMOBRANCHS

133 Elasmobranchs are cartilaginous fish that share life history characteristics which make them vulnerable to over fishing (e.g. slow growing, late maturity, low fecundity), meaning that once depleted, populations take a long time to recover.

134 Several elasmobranchs species (sharks, skates and rays) occur in the Scottish waters. According to the results of the Centre for Environment, Fisheries and Aquaculture Science (CEFAS) groundfish surveys, spiny dogfish *Squalus acanthias* and starry ray *Amblyraja radiata* are frequently found in the North Sea, as well as lesser-spotted dogfish *Scyliorhinus canicula* and cuckoo ray *Leucoraja naevus* (Ellis *et al.*, 2005). Other less frequent species are tope *Galeorhinus galeus*, smoothound *Mustelus asterias,* spotted ray *Raja montagui*, common skate *Dipturus batis*, sandy ray *Leucoraja circularis*, shagreen ray *Leucoraja fullonica*, thornback ray *Raja clavata* (Ellis *et al.*, 2005). Many of these species have depleted populations, with the common skate being nearly extirpated from the UK waters (Fowler *et al*., 2004). As a result many species of sharks and rays are on the OSPAR list of Threatened and Declining Species due to their removal as both target and non-target species of fishery (Scottish Government, 2011). These species are found mainly off the north-west coast of Scotland (e.g. spiny dogfish, shagreen ray, thornback ray, spotted ray) (Scottish Government, 2011), where their main nursery areas are located (CEFAS, 2010). Hence a significant occurrence of these species in the shallow area where the proposed EOWDC site is located is unlikely.

135 Porbeagle sharks (*Lamna nasus*) are also found throughout the North Atlantic, with the largest population in UK waters found to the north of Scotland. Recorded sightings of porbeagle sharks within the North Sea have generally occurred offshore in the central North Sea, between May and September (Weir, 2001).

136 The Basking shark, *Cetorhinus maximus,* is the world's second largest fish species, with a circum-global distribution in warm-temperate to boreal seas. Sightings data indicate that this species is common along the west coast of the UK as far north as the Shetland Islands, and is infrequently recorded off the east coast of the UK mainland (Figure, 6). According to TES (2008a) a basking shark was reported during a boat survey close to the proposed EOWDC area on the 16th November 2007. A survey carried out by Travers *et al.*, 2008, also in 2007, did not record any basking sharks in Aberdeen Bay and it may be that the TES sighting was an unusual and isolated event.

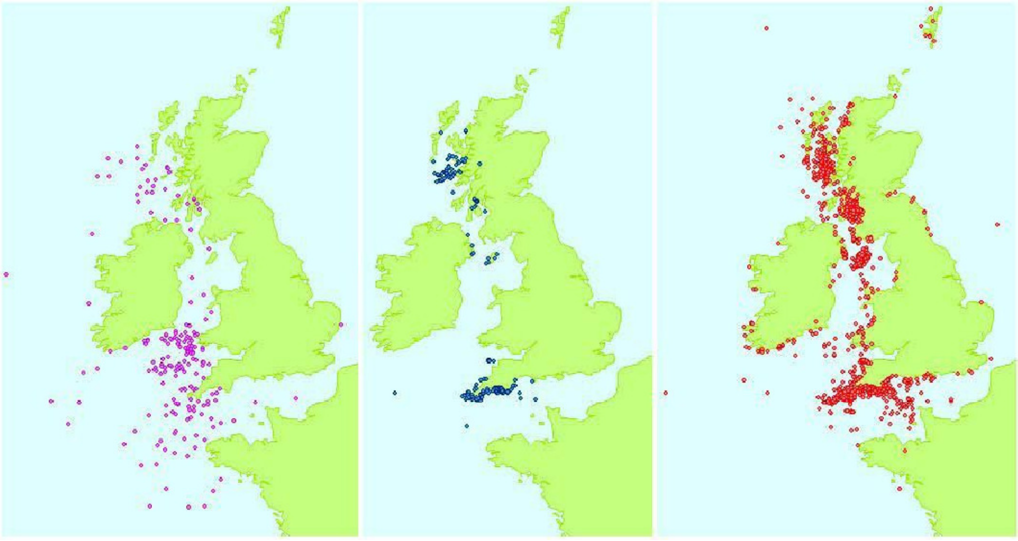

Figure 6. Distributions of basking sharks on the European continental shelf, determined using three independent methods: pink, tag geolocations; blue, scientific surveys; red, public sightings. Survey and sightings data from CEBS partners. Source: Basking shark population assessment research project – Report produced by CEFAS on behalf of the Global Wildlife Division, Defra.

3.5.2. Information taken from CMACS Ltd and MSS Epibenthic Surveys 2010

137 Epifaunal benthic surveys were undertaken in October 2010 in the proposed EOWDC area and in the surrounding marine environment by the CMACS Ltd (Appendix 5.3). Additional benthic survey data, collected in the same year (in September), were presented by MSS and these have been analysed by IECS (Appendix 5.5) and the results integrated with the CMACS Ltd survey results. In both cases, data were obtained by the combination of video camera surveys and epibenthic trawls in the area.

138 The CMACS Ltd epibenthic survey programme comprised 15 underwater camera stations (6 in the proposed EOWDC area, and 9 outside it, as a reference) and 10 stations which were sampled using a 2 m scientific beam trawl (4 stations inside and 6 outside the proposed EOWDC area). Further details on the CMACS Ltd epibenthic survey methods and data analysis are provided in Appendix 5.3.

139 The MSS survey was carried out in Aberdeen Bay at 14 video camera stations and at 7 stations sampled by means of Agassiz trawl net. Most of the stations were located in the area where CMACS Ltd survey took place, except for stations TV 42, TV 43, TV44, ABAG4 and ABAG5, located 1 to 5 km further offshore (see Appendix 5.5 for station locations). Further details on the MSS epibenthic survey and on the data analysis (carried out by IECS on MSS data) are provided in Appendix 5.5.

140 The main results obtained from the CMACS Ltd and MSS 2010 surveys (detailed in Appendices 5.3, 5.4, and 5.5) are presented here and compared to the data obtained during a previous epibenthic survey carried out in 2006 (April 7th) in Aberdeen Bay by FRS[7] (Table 3).

[7]The 2006 FRS survey consisted of 3 epifaunal trawls (between 12 and 25 m of depth) with video footage being obtained during the same survey. The raw data were provided by FRS in 2006, during the first consultation round.

Table 3. Species from Aberdeen Bay caught in epifaunal trawls during 2006 survey. Source: FRS, 2006.

141 A fairly uniform seabed was observed in the proposed EOWDC area during CMACS Ltd and MSS 2010 surveys and no sensitive habitats were observed during the camera surveys. The sediments were mainly composed of fine sand, silt/clay and shell fragments, and sand ripples on the sea bed were noticeable. The observed sediment characteristics were consistent with the results of sediment analysis (Section 3.2. Sediment and Water Quality). No seaweed was recorded at these stations. The epifauna was sparse, with only brittle stars being seen regularly in high numbers. Also some fish species, mostly plaice and common dab (*Limanda limanda*), were detected.

142 During the MSS survey, deeper areas farther offshore (1 to 5 km far from the proposed EOWDC area) were also explored in addition to the shallow areas surveyed by both MSS and CMACS. These deeper sites comprised areas of mixed sediments including coarse sediments, stones, pebbles and boulders with silt/clay particles. Relatively slow current speeds and lower water turbidity were also recorded at these stations. A more diverse and abundant epifauna was recorded with the common starfish *Asterias rubens*, the bryozoan *Flustra foliacea* and dead man's fingers *Alcyonium digitatum* occurring in large numbers at these stations. Attached epifaunal species (anemones, bryozoans, sponges) were also notable on the video footage.

143 The trawl surveys carried out in the area in 2010 by CMACS Ltd and MSS gave similar results on the overall structure of epifauna assemblages. It is of note that similar sampling methods were employed in all surveys. Specific differences may be ascribed to the different timing of sampling (September for the MSS survey, late October for the CMACS Ltd survey) and to the different areas explored during the two surveys (with the MSS survey also covering offshore areas).

144 Brittle stars were always present as a quantitatively important taxon in the invertebrate epifaunal community of the studied site (Appendices 5.3 and 5.5). These organisms are typical of sandy and muddy sandy sea beds from the shallow sublittoral through to 200 m depth. The common starfish was also found in the area. It is common and widespread throughout British coastal waters and occurs in most

sublittoral zones, particularly on soft sediments. These results confirmed the observations carried out previously by FRS in the Aberdeen area in 2006 (Table 3).

145 The brown shrimp *Crangon crangon* dominated the epifaunal invertebrate assemblage in the CMACS Ltd catches (late October 2010), whereas it was not detected in the MSS catches (September 2010), where brittle stars dominated the epifaunal assemblage (Figure 7). Although *C. crangon* is common in shallow coastal waters, its abundance is highly seasonal in these areas (Campos and van der Veer, 2008). Larger catches are usually obtained in autumn, when *C. crangon* is generally present in large numbers in the shallower fishing grounds near the coast. Peak autumn landings in recent years have proven to extend later in the autumn season (Campos and van der Veer, 2008) hence higher abundances of the species are expected in late October than in September.

146 In late October 2010 (CMACS Ltd survey), high abundances of the swimming crab *Liocarcinus holsatus* were also recorded in the area (Figure 7). This is a common species which is found throughout in the North Sea. Its high abundance in the CMACS Ltd samples can be related to the presence and abundance of the brown shrimp in the area in late October since this species is the principle food source for swimming crabs.

147 The distribution of invertebrate epifauna across the site was clearly related to depth and distance from shore. Some correlations between species distribution and sediment type were also suggested by the results. Higher numbers of brittle stars, for example, were associated with muddy areas although there were some muddy areas where brittle stars abundance was low. *C. crangon* also showed an apparent correlation with softer sediment types and in general, a higher number of taxa was also detected at deeper stations than in the shallower, inshore stations (CMACS Ltd survey 2010, Appendix 5.3).

148 In terms of fish fauna, the dominant species in the area were always two flatfish species, the common dab and plaice, with these two species being found throughout the entire survey site in 2006 (FRS survey, Table 3) and in 2010 (CMACS Ltd and MSS surveys, Appendices 5.3, 5.4, and 5.5, Figure 8). These are common species around the UK coastline, usually found within a few meters to about 100 m water depth. The majority of individuals from these commercial species were caught as juveniles below the legal landing size.

149 Hooknose *Agonus cataphractus* was also abundant in the survey area in both 2010 surveys (Figure 8). This is a small, non commercial species that is common around UK coastal areas, particularly on sandy seabeds.

150 Other abundant species included Norway pout, which was particularly abundant in the September 2010 catches (MSS survey), and whiting, which was more abundant in late October (CMACS Ltd survey). Both species showed a high degree of temporal variability.

151 As well as dab, plaice and whiting, other species of commercial fish included sprat, haddock, witch (*Glyptocephalus cynoglossus*), bib (*Trisopterus luscus*) and grey gurnard (*Eutrigla gurnardus*).

152 Sandeels were also present in the catches, in particular in late October, although low abundances were detected during the 2010 CMACS Ltd survey in the area (43 individuals overall, mainly at shallower inshore stations).

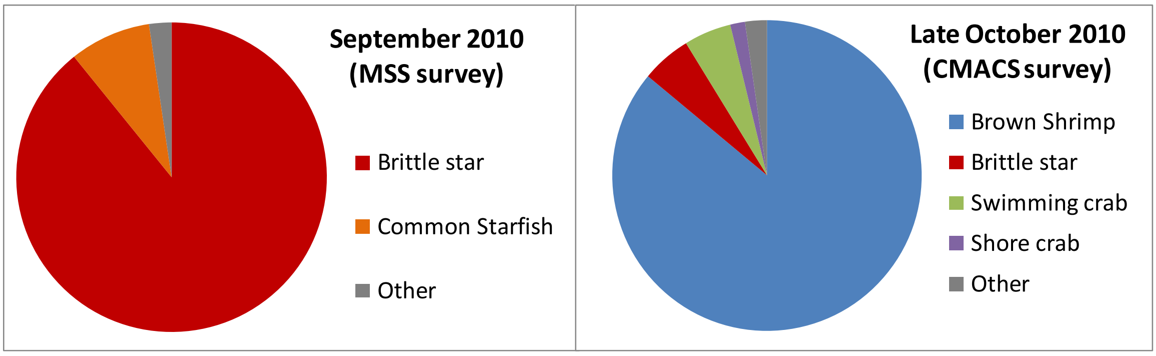

Figure 7. Composition (% abundance) of the invertebrate epifauna assemblages in the study area based on the two surveys carried out in 2010.

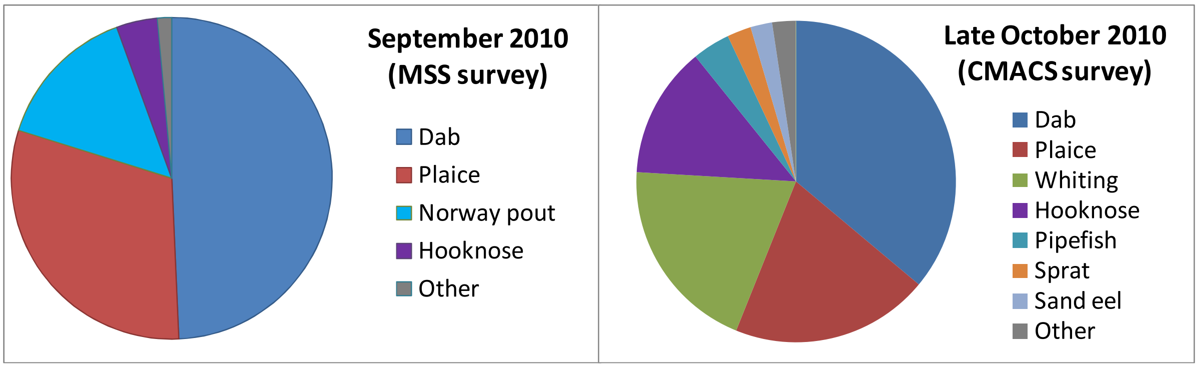

Figure 8. Composition (% abundance) of the fish assemblages in the study area based on the two surveys carried out in 2010.

153 The distribution of fish fauna across the site (the 2010 CMACS Ltd and MSS surveys) seemed related to depth and/or distance from shore. In general, higher numbers of fish taxa occurred at the more inshore locations, this pattern being contrary to that detected for epifaunal and infaunal assemblages. Dab and plaice, in particular, were recorded with higher numbers at the shallower, inshore stations, whereas hooknose and whiting were more abundant in deeper waters. Differences among fish assemblages were particularly evident when comparing offshore stations (station 8 of the 2010 CMACS Ltd survey and station ABAG4 of the 2010 MSS survey) with the inshore stations. Lower abundances of flatfish and brittle stars characterised the offshore areas, and this can be related mainly to the greater depth and distance from the shore.

3.5.3. Conclusions

154 Overall, the epibenthic invertebrate fauna in the area is sparse and composed of brittle stars, brown shrimp and swimming crabs (the latter two species being mainly represented later in the autumn period). The most common fish species are flatfish, such as dab and plaice, particularly at inshore areas. Hooknose and whiting are also abundant. These survey findings confirm what is reported in the literature.

155 According to large scale mapping, the proposed EOWDC area appears to fall within nursery and spawning grounds of several fish species which are either of commercial interest (such as flatfish) or may constitute important feeding resources for other fish predators (e.g. sandeel and herring). However, no specific spawning and nursery grounds are known to exist in the proposed area (MS-LOT reference in Scoping response 2010).

156 The low abundance of sandeels recorded during the surveys in the proposed EOWDC area and its surroundings seems to support the absence of a spawning ground for the species in the area. During autumn and winter, sandeels usually lie dormant, buried in the sediment, hence bottom trawl surveys carried out in these periods should have provided good estimates of the abundance of local populations (Greenstreet *et al*., 2010). The observed low abundances of sandeels could possibly be ascribed to a preference of the species towards coarser sandy bottoms (Dickey-Collas *et al*., 2010), not present in the proposed EOWDC area. Sandeel is also a key prey species for Atlantic salmon and sea trout, which have important spawning areas in nearby rivers (e.g. River Dee). The low abundance of sandeels in the proposed EOWDC area suggests the area is not an important feeding ground for these predator species.

157 The epibenthic survey in the area recorded high abundances of juveniles of flatfish species. The inshore, shallower coastal areas are likely to serve as nursery grounds for flatfish (mainly plaice and dab) extending over a wider area along the Scottish coast (Appendix 5.2).

158 The coastal waters in the Aberdeen Bay, where the proposed EOWDC area is situated, are likely also to be used as migratory routes by the Atlantic salmon and the sea trout, which have important spawning areas in nearby rivers (e.g. Rivers Dee and Esk). This is discussed within the salmon and sea trout assessment for the proposed EOWDC.

159 Other relevant commercial fish species (e.g. whiting, cod, Norway pout), although present in the proposed EOWDC area, are associated mainly with deeper waters. It therefore seems unlikely that the proposed EOWDC development will raise concerns regarding their distribution. The same is considered valid for other species of interest, for example basking sharks or squids.

160 The only elasmobranch recorded during the 2010 epibenthic surveys in the proposed EOWDC site was the cuckoo ray, but its presence was occasional in the catches.

Summary of Epifaunal and Fish Community

The invertebrate epifaunal community includes brittle stars, brown shrimp and swimming crabs (the latter two species being mainly represented later in the autumn period).

The most common fish species are dab and plaice which were recorded at all stations in relatively high numbers. The distribution of these flatfish species, found mainly at juvenile stages, suggests the presence of nursery grounds in the shallow inshore areas.

Hooknose is also abundant, as well as whiting (particularly in October). Sandeel is present in the area, although in low numbers.

The distribution pattern for whiting and hooknose shows an increase in individuals with increasing depth and distance from the shore. This is not the case for dab and plaice which are recorded in high numbers near the shore.

3.6. Nature Conservation Status

161 Several sites designated for conservation interest are present in the general area of Aberdeen. These are:

- Special Areas of Conservation (SACs), i.e. strictly protected sites designated under the EC Habitats Directive (92/43/EEC).
- Special Protection Areas (SPAs), i.e. strictly protected sites classified for rare and vulnerable birds, and for regularly occurring migratory species, in accordance with Article 4 of the EC Birds Directive (79/409/EEC).
- Ramsar sites, i.e. wetlands of international importance designated under the Ramsar Convention.
- Sites of Special Scientific Interest (SSSIs), i.e. sites that, within the UK, are nationally important for plants, animals or geological or physiographical features, and are protected by law.
- National Nature Reserves (NNR), declared by Scottish Natural Heritage as a selection of the very best parts of UK SSSIs.

162 A list of these sites and the species and habitats they have been designated for is provided in Table 4. None of the above mentioned sites falls within the proposed EOWDC area, the closest designated sites being at a distance of 5 to 7 km from it (Table 4).

163 A range of national and international designation acts, plans and directives (e.g. the Wildlife and Countryside Act 1981, the UK Biodiversity Action Plan (UK BAP), the OSPAR Initial List of Threatened and/or Declining Species and Habitats, the European Habitats Directive, the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES)) identify conservation priority habitats and species which are under threat because of their rarity and/or rate of decline, and, as such, need protection.

164 According to these designations and to the information gathered from the recently published Scotland's Marine Atlas (Scottish Government, 2011) several benthic organisms of conservation significance occur in the inshore and shelf subtidal areas along Scottish coasts (e.g. the bivalve molluscs *Arctica islandica* and *Atrina fragilis,* the reef forming species *Sabellaria spinulosa* and *Modiolus modiolus*). None of these species are present in or close to the proposed EOWDC area, as confirmed also by the benthic surveys carried out in the site (CMACS Ltd and MSS surveys 2010).

165 As regards fish, Table 5 provides the list of designated species possibly occurring along the coast of east Scotland and reports their likelihood of occurrence in the proposed EOWDC site, according to the information gathered from literature and from the results of the epibenthic surveys carried out by CMACS Ltd and MSS in 2010.

166 Many of the inshore habitats in the Aberdeen area are reported as important nursery and spawning grounds of species like herring and sandeels, which constitute important feeding resources for other fish and bird species of conservation interest (e.g. Atlantic salmon and trout). However, according to the epibenthic surveys

carried out in the area and to the information gathered in Section 3.5 epibenthic Fauna and Fishery Ecology, sandeel occurs in the proposed EOWDC site but in low numbers and it is unlikely to be an important food source for salmonids in this area. In turn, herring has not been recorded in the proposed EOWDC site during the epibenthic surveys in 2010, and its spawning grounds are likely to be located further offshore.

167 Cod and whiting have been recorded in the proposed EOWDC site during the epibenthic surveys in 2010. However, cod was present in very low numbers, occurring only in the MSS survey 2010, and both species, although present in the proposed EOWDC area, are associated mainly with deeper waters. Plaice was also present in the 2010 epibenthic catches from the proposed EOWDC site, with higher numbers at the shallower, inshore stations.

168 Migration routes of Atlantic salmon and sea trout might cross the proposed EOWDC site, having the species important spawning areas in the nearby rivers (particularly in the River Dee) (see salmon and sea trout assessment for proposed EOWDCfor details.) Indirect impacts on these migratory species might also lead to an indirect impact on the River Dee SAC populations of freshwater pearl mussel (*Margaritifera margaritifera*). This is a rare and threatened species, being one of primary reasons for the selection of the River Dee SAC, and highly dependent on the presence of Atlantic salmon and sea trout as hosts for their larvae.

169 Other migratory fish, which move from seas to freshwater habitats to spawn and which could occur in the area include the sparling (Osmerus eperlanus) (or European smelt) and the common sturgeon (Acipenser sturio). The sparling is of conservation importance and is included in the UK Biodiversity Action Plan Species List, whilst the common sturgeon is critically endangered, included on the IUCN Red List and on Schedule 5 of the Wildlife & Countryside Act, Annexes II & V of the EU Habitats Directive and Appendix II of the Bern Convention, as well as on the UKBAP Priority Species List.

170 However, although once relatively widespread in rivers around Scotland, the breeding status of the sparling is now extremely restricted in Scottish rivers (Cree, Forth and Tay), and the common sturgeon is not known to have bred in Britain.

171 As such, whilst the occasional occurrence of these species in waters in Aberdeen Bay cannot be ruled out (although available data would not suggest a presence), it is considered unlikely that the proposed EOWDC would have any significant impact on these two species and therefore they have been scoped out of further assessment.

172 As already mentioned (Section 3.5. Epibenthic Fauna and Fishery Ecology), elasmobranch species occur mainly off the north-west coast of Scotland or farther offshore than the proposed EOWDC site. No significant records in the proposed EOWDC site are reported. The only elasmobranch occasionally recorded during the epibenthic surveys 2010 in the proposed EOWDC site is the cuckoo ray. In contrast to the elasmobranchs reported in Table 5, this is a smaller, rapidly growing and more fecund species for which a stable or increasing population abundance is reported (Fowler *et al.,* 2004).

173 Priority habitats have also been recognised under the UK BAP, being considered of particular importance for biodiversity conservation. Together with the habitats created by the reef forming species *S. spinulosa* and *M. modiolus*, other habitats such as native oyster (*Ostrea edulis*), blue mussel (*M. edulis*) and eelgrass (*Zostera marina* and *Nanozostera noltii*) beds occur frequently in the intertidal and subtidal

areas along the coasts of Scotland. However, these habitats occur mostly on the west coast of Scotland, and none of them is present in in Aberdeen Bay (Scottish Governement, 2011). This was also confirmed by the benthic surveys carried out in the proposed EOWDC site (CMACS Ltd and MSS surveys 2010).

174 The dominant substratum found in the proposed EOWDC site matches well with the UK BAP habitat "sublittoral sands and gravels". This habitat is described as well sorted medium and fine sands on exposed coasts subjected to frequent wave action and variable tidal currents are typified by errant polychaetes such as *N. cirrosa* and isopods such as *Bathyporeia* spp (common in full salinity areas of many estuaries) (JNCC, 2008). Illustrative Level 4 biotopes for this habitat are SS.SSa.CMuSa (Circalittoral muddy sand) and SS.SSa.IFiSa (Infralittoral fine sand), as those found in the proposed EOWDC site. The UK Habitat Action Plan aims to ensure that the best examples of sublittoral sand and gravel habitats are protected from the adverse effects of fishing, dredging, aggregate extraction and other activities such as wind farm development. Therefore, where wind farms are proposed, their development should respect, and where possible further, the objectives and targets for priority habitats and species listed in the UK Biodiversity Action Plan. However, it must be noted that sublittoral sand and gravel sediments are the most common habitats found below the level of the lowest low tide around the coast of the United Kingdom. The biotope SS.SSA.CMuSa.AalbNuc is not uncommon in the wider Aberdeen Bay area, and although *A. alba* is a common food source for *Asterias rubens* and different species of demersal fish (MarLIN), it is not considered to have an especially high ecological importance at the local scale.

Table 4. Designated sites in a range up to 150 km from the proposed EOWDC development.

Designation	Site (approx. distance from the proposed EOWDC)	Designated for
SAC	River Dee (7.5 km)	Atlantic salmon, freshwater pearl mussel and otter
	Sands of Forvie (7.2 km)	Embryonic shifting dunes, shifting dunes along the shorelines with *Ammophilia arenaria*, decalcified fixed dunes with *Empetrum nigrum*, humid dune slacks
	Buchan Ness to Collieston (12.2 km)	Vegetated sea cliffs
	Garron Point (30 km	Narrow-mouthed whorl snail *Vertigo angustior*
	Moray Firth (150 km)	Bottlenose dolphin, sandbanks which all the times are covered by seawater
SPA	Ythan Estuary, Sands of Forvie and Meikle Loch (7.2 km)	Breeding population of common tern; breeding population of little tern; breeding population of sandwich tern; Wintering population of pink-footed goose; regularly supporting at least 20,000 waterfowl of which the notable components are redshank, lapwing, eider and pink-footed goose
	Buchan Ness to Collieston (9.5 km)	Regularly supporting at least 20,000 seabirds of which the notable components are guillemot, kittiwake, herring gull, shag and fulmar
	Loch of Skene (21 km)	Over wintering area for greylag goose and whooper swan, breeding population of tufted duck, supporting waterfowl assemblages of which the notable components are wintering goldeneye, goosander, common gull
	Fowlsheugh (31.1 km)	Breeding population of guillemot; breeding population of kittiwake; regularly supporting at least 20,000 waterfowl of which the notable components are razorbill, herring gull, fulmar, guillemot and kittiwake
	Loch of Strathbeg (47.6 km)	Sandwich tern, supporting waterfowl assemblages of which the notable components are pink-footed goose, greylag goose, teal and goldeneye
	Troup, Pennan and Lion's Heads (74.3 km)	Supporting seabird assemblages of which the notable components are fulmar, kittiwake, guillemot, herring gull and razorbill

Designation	Site (approx. distance from the proposed EOWDC)	Designated for
	Forth Islands (124.4 km)	Gannet, shag, lesser black-backed gull, roseate tern, Arctic tern, common tern, Sandwich tern, puffin; supporting seabird assemblages of which the notable components are cormoranyt, herring gull , kittiwake, razorbill and guillemot
Ramsar sites	Ythan Estuary, Sands of Forvie and Meikle Loch (7.2 km)	Aggregation of breeding sandwich tern, aggregation of non-breeding pink-footed goose and waterfowl assemblage
National Nature Reserve	Forvie (7.2 km)	Sand dune, foreshore, estuarine, spit, dune heath, slacks, rough pasture and cliffs habitat
SSSI	Foveran Links (4.8 km)	Sand dune, coastal geomorphology, vegetation assemblages, migrating birds, large moulting and passage flocks of seaduck and divers occurring off-shore, nesting site for the little tern
	Corby, Lily and Bishops lochs (6.7 km)	Non-breeding graylag goose; mesotrophic loch, aquatic vegetation, wetland sites
	Sands of Forvie and Ythan Estuary (7.2 km)	Non-breeding population of pink-footed goose, breeding populations of Sandwich tern, common tern, eider, breeding bird assemblage; sand dune; coastal geomorphology
	Nigg Bay (10 km)	Quaternary geomorphology
	Collieston to Whinnyford (15 km)	Seabird colony; breeding: kittiwake, guillemot, razorbill, fulmar, shag; maritime cliff; dalradian geology
	Meikle Loch and Kippet Hills (17 km)	Non-breeding: Greylag goose, pink-footed goose, teal; quaternary geomorphology
	Bullers of Buchan (25 km)	Seabird colony; breeding: kittiwake, guillemot; maritime cliff; coastal geomorphology

Table 5. Fish species designations possibly occurring along the east coast of Scotland.

3.6.1. Conclusions

175 Several sites designated for conservation interest (SAC, SPA, Ramsar sites, SSSI and NNR) occur along the coast in the Aberdeen area, but none of the designated areas coincide with the proposed EOWDC site.

176 The species designated under national and international legislation have been considered and are not thought to occur within the proposed EOWDC area (at least not in significant numbers). This is mainly due to the habitat preferences of the different species which locate them far from the proposed EOWDC area (e.g. further offshore or within estuarine areas). However, the possibility of migration routes of Atlantic salmon and sea trout crossing the proposed EOWDC site needs to be taken into account, the species having important spawning areas in the nearby rivers.

177 Many of the inshore habitats in the Aberdeen Bay area are reported as important nursery and spawning grounds of species like herring and sandeel, which constitute important feeding resources for other fish and bird species of conservation interest (e.g. Atlantic salmon and sea trout). According to the epibenthic surveys carried out in the proposed EOWDC site and to the information gathered in Section 3.5. Epibenthic Fauna and Fishery Ecology, sandeel is not present at high densities and is unlikely to be an important food source for salmonids in this area.

178 The dominant substratum found in the proposed EOWDC site corresponds to the UK BAP habitat “sublittoral sands and gravels”, well illustrated by the biotopes SS.SSa.CMuSa (Circalittoral muddy sand) and SS.SSa.IFiSa (Infralittoral fine sand).

Summary of Nature Conservation Status

Several sites designated for conservation interest (SAC, SPA, Ramsar sites, SSSI and NNR) occur along the coast in the Aberdeen area.

According to the knowledge on the distribution of nationally and internationally designated species, and following the results of the surveys carried out in the area, none of the designated species occur in the proposed EOWDC area or in its surroundings. The presence of migration routes of salmonids in the area is discussed in the salmon and sea trout assessment for the proposed EOWDC.

The dominat substratum found in the proposed EOWDC site corresponds to the UK BAP habitat “sublittoral sands and gravels”, well illustrated by the biotopes SS.SSa.CMuSa (Circalittoral muddy sand) and SS.SSa.IFiSa (Infralittoral fine sand).

4. Summary

179 This document provides the baseline information on the marine ecology of the proposed EOWDC area in Aberdeen Bay. Information from the available literature was integrated with the results from benthic and epibenthic surveys carried out within the proposed EOWDC area and in the surroundings. A combination of camera (15 stations), grab (14stations) and trawl (10 stations) sampling was undertaken by CMACS Ltd for OSIRIS Projects Ltd on behalf of AOWFL in October 2010. Additional benthic survey data were provided by FRS (survey carried out in April 2006) and MSS (survey carried out in September 2010), and information on sediments was available from EMU Ltd (2007) and OSIRIS Projects Ltd (2010) work.

180 According to a geophysical survey carried out by EMU Ltd for AOWFL, the seabed sediments in the proposed EOWDC site are dominated by muddy sand with small patches of glacial material towards the shore, and finer sediment features in places with occasional patches of shell fragments in others. The sediment analysis carried out by CMACS Ltd in 2010 complemented these results, showing a homogeneous composition of the sediments in the area, with a common pattern of variation following the gradient of depth and distance from the shore. At inshore stations, medium-fine well-sorted sands dominate, whereas sediments farther offshore and at deeper sites are dominated be fine-very fine muddy sands.

181 According to the CMACS Ltd 2010 survey results, there are no contaminants in the sediments showing concentrations above the Probable Effect Level (PEL) and all hydrocarbons, organotin and PCB concentrations were below detectable limits. Among heavy metals, only Arsenic was marginally above the Interim Sediment Quality Guidelines (ISQG) level but still below the PEL. Overall, the sediment contamination in the area is in line with the background contamination levels reported for the North-eastern Atlantic area.

182 The intertidal substratum in the area is mainly composed of sandy shores. The intertidal macrofauna is dominated by haustorid amphipods (*H. arenarius* and *B. pelagica*) and in some cases the spionid polychaete *S. cirratulus*, whereas sedentary species are less abundant, in agreement with the moderate exposure of the shores.

183 The sublittoral benthic survey results showed that the infaunal community changed mainly along the gradient of depth/distance offshore. The infaunal community at inshore shallower stations was characterised by low number of species and abundance, and was dominated by the polychaete *N. cirrosa* and amphipods. A relatively high number of species and abundance was detected at the stations farther offshore, where the most abundant species were the polychaetes *N. latericeus*, the bivalves *N. nitidosa* and *T. fabula* and brittle stars *Ophiura* sp. These two communities characterise two major biotopes: SS.SSA.CMuSa.AalbNuc (offshore) and SS.SSA.IFiSa.NcirBat (inshore). The Level 4 biotopes SS.SSA.CMuSa and SS.SSA.IFiSa are considered as a priority habitat under the UK BAP designation (sublittoral sands and gravels).

184 The invertebrate epifaunal community present in the proposed EOWDC site is sparse and composed mainly of brittle stars, brown shrimp and swimming crabs (the latter two species being mainly represented later in the autumn period). The most common fish species were dab, plaice, whiting and hooknose, recorded at all stations in relatively high numbers. The distribution pattern for whiting and hooknose showed an increase in abundance with increasing depth and distance from the shore, whereas dab and plaice were recorded with higher numbers near the shore. The latter species, in particular, were present in the area mainly as juveniles, suggesting

the presence of nursery grounds for these flatfish along this part of the Scottish coast.

185 Although extensive spawning grounds for several species are known to be present along the east coast of Scotland, no specific spawning grounds are reported in the proposed EOWDC site. This seems to have been confirmed, e.g. for sandeel and herring, by the results of the epibenthic survey, which showed no significant abundances of the species in the trawl catches. This could also be explained by the preference of these species for coarser bottom sediments than those present in the proposed EOWDC site.

186 The wider east coast around Aberdeen displays a wide variety of habitats. Some of them are rare in a national and/or international context, or support important bird colonies, hence being designated as areas for conservational interest (SAC, SPA, Ramsar sites NNR and SSSI). However, no such areas are present within the proposed EOWDC area and in the close vicinity. Furthermore, designated species and habitats (except for the above mentioned UK BAP habitat sublittoral sands and gravels) have not been found in the site. No main conservation concerns have been identified for the area. However, the possibility that migration routes of Atlantic salmon and sea trout cross the proposed EOWDC site must be taken into account. A separate assessment of Atlantic salmon and sea trout has been undertaken.

CMACS LTD BENTHIC SURVEY 2010 – TECHNICAL REPORT V3 (FEB. 2011)

APPENDIX 5.4.

INTEGRATIVE ANALYSES CARRIED OUT BY IECS ON CMACS LTD 2010 BENTHIC DATA

5.4.1. Introduction

1 Additional analyses were carried out by IECS on the benthic data obtained during the CMACS Ltd survey in 2010, in order to update and integrate results of the CMACS Ltd Technical Report (Appendix 5.3).

5.4.2. Additional data analysis

2 Measured values and descriptive statistics for primary and derived biological parameters were calculated by IECS both for the survey area as a whole and for individual stations. The following biological parameters were calculated using PRIMER v. 6 (Plymouth Routines in Marine Ecological Research):

- The total number of species (S) at each station and for the survey area as a whole;

- Total abundance (A) of organisms expressed as individuals / 0.1 m^{-2} at each station;

- Abundance ratio (A/S) which gives an indication of the level of dominance of particular species within a community. Low values indicate a low number of organisms spread between a large number of species whereas high values indicate few species each with a large number of individuals (i.e. the community is dominated by very few species occurring at high abundances);

- Shannon-Wiener diversity (H'(log_2)), incorporating both species richness and evenness (a measure of the distribution of the individuals between the species):

  $$\mathbf{H' = - \sum p_i \log_2 p_i}$$

  Where,
  p_i = proportion of individuals in the ith species = n_i / N
  n_i = number of individuals of the ith species in the sample
  N = total number of individuals

  High values of H' indicate high diversity. Differences in the absolute values of the index obtained here with respect to those reported in the CMACS Ltd Technical Report (Appendix 5.2) likely arise from a different basis for the logarithm used in the H' index calculation (not specified in the CMACS Ltd Technical Report).

- Pielous Evenness index (J') gives a measure of the relative abundance of each species:

  $$\mathbf{J' = H' / \log_2 S.}$$

  Low values (close to zero) indicate that a community is dominated by one or few species and indicate low diversity. Communities where there is an even spread of the individuals between the species (J' values approaching 1) are considered to be diverse.

3 Description of the biological communities for individual stations and for the survey area as a whole was carried out by ranking the species in terms of their abundance, percentage contribution to the community (% dominance) and cumulative percent dominance.

4 Multivariate techniques allowing comparison of communities based on their component species and their relative importance in terms of abundance were also applied to faunal data. In order to complement multivariate analyses carried out by CMACS Ltd (namely cluster and MDS analyses, see Appendix 5.3) BIOENV was used to determine relationships between environmental and biological parameters in order to identify the combination of environmental variables best relating to community structure patterns. This procedure allows the calculation of rank correlations between the Euclidean distances of samples based on environmental variables and benthic community dissimilarity.

5.4.3. Results

5 The biological parameters for benthic fauna were variable, as demonstrated by the coefficient of variation values, ranging from 9.2 to 70.3% across the survey site, reflecting the variable and possibly mobile or frequently disturbed nature of the sediments (Table 1).

6 The number of species ranged from 10 at station 14 to 32 at station 12 with between 20 and 30 species being recorded from stations 4, 5, 8, 9 and 10 (Figure 1). The mean number of species recorded across the site is 18.3. Abundance values ranged from 17 individuals / 0.1 m^{-2} at station 14 to 145 individuals / 0.1 m^{-2} at station 8, with an average value of 60.43 individuals/0.1 m^{-2} (Figure 2).

7 Shannon-Weiner diversity (H'(log_2)) was highest at station 10 (H'=3.7) with diversity being greater than 3 at the majority of stations (Figure 3). Pielou's evenness (J') values ranged from 0.65 at station 8 to 0.95 at station 14 and all values were greater than 0.7 (Figure 4). These values, together with relatively low abundance ratio (A/S, Figure 5) indicate an even spread of the individuals between the species and that the communities are not dominated by one or very few species.

8 A total of 70 species were recorded from the survey area as a whole, most of them recorded in low numbers (Table 2). The top 85% abundance of the community was composed of 19 species and was dominated by the polychaete *N. latericeus* (85% frequency of occurrence) and brittle stars of the family Ophiuridae (93% frequency of occurrence, including juvenile individuals from the family Ophiuridae and from the genus *Ophiura*) which together accounted for 42% of the total benthic abundance (Table 2) and were present in abundances ranging from 1 to 46 individuals / 0.1 m^2. Other species present in notable abundances included the bivalves *N. nitidosa*, *T. fabula*, and the polychaetes *S. bombyx* and *G. oculata* (Table 2).

Table 1. Descriptive statistics for the biological parameters across the area as a whole (IECS analysis of data collected during CMACS Ltd Benthic Survey 2010).

*Total A – sum abundance values for all stations, % Dom – dominance, Cum % - cumulative %, FO % - frequency of occurrence

**Ophiuridae juv. – this contains Ophiuridae juv and *Ophiura* sp. Juv (these two taxa were analysed separately in the CMACS Ltd Technical Report, Appendix 5.3).

9 The two groupings of stations identified by the multivariate analyses carried out by CMACS Ltd (Appendix 5.3) were interpreted in the light of the assemblage species richness and of the main species contributing to the similarity within the two groups. For the purpose of clarity, stations 2, 13 and 14 were named “group B”, whereas the other stations were named “group A” (see Figures 17 and 18 in Appendix 5.3).

10 The richest community in terms of number of species and abundance was in group A, including 11 stations. The most impoverished community, in terms of the number of species and abundance, was in group B.

Table 3. Characteristic taxa within each cluster and frequency of occurrence across the proposed EOWDC site. Top 21 species in terms of abundance presented for group A, for group B all species included (IECS analysis on data from the CMACS Ltd Benthic Survey 2010).

Group A	Total Ab.	% Dom	FO %		Group B	Total Ab.	% Dom	FO %

Scoloplos armiger	6	0.8	45		*Abra prismatica*	1	1.8	33

11 Stations of group A are located farther from the shore and characterised by fine muddy sand. This group contains 64 species, and the top 21 species in

terms of abundance. Predominant species of this group are the polychaete *N. latericeus*, which contributed over 30% into community, followed by the bivalves *N. nitidosa* and *T. fabula* and brittle stars of the family Ophiuridae (Table 3).

12 Stations of group B are located inshore and are characterised by fine-medium well-washed sand. This group is poor in terms of number of species (with a total number of species of 22) and abundance (Table 3). The most abundant taxa in this group is the polychaete *N. cirrosa* and amphipods, although still these taxa were recorded in very low numbers (Table 3).

13 The BIOENV test (based on all sediment physical parameters) indicated that the highest correlation between physical parameters and the species assemblages (r= 0.766) was with median mm grain size, % sand, % silt/clay and depth. Therefore, the patterns in the species distribution and communities appear to best relate to sedimentary and depth parameters.

14 The above results allowed the identification of two major biotopes in the survey area, as detailed in Appendix 5.3. According to the biotope descriptions provided in the CMACS Ltd Technical Report, these two biotopes are: SS.SSA.CMuSa.AalbNuc (*A. alba* and *N. nitidosa* in circalittoral muddy sand or slightly mixed sediment) and SS.SSA.IFiSa.NcirBat (*N. cirrosa* and *Bathyporeia* spp. in infralittoral sand) (an error in the legend of the biotope mapping in Figure 19 of the CMACS Ltd Technical Report was found, hence the amended map is provided in Figure 6 below).

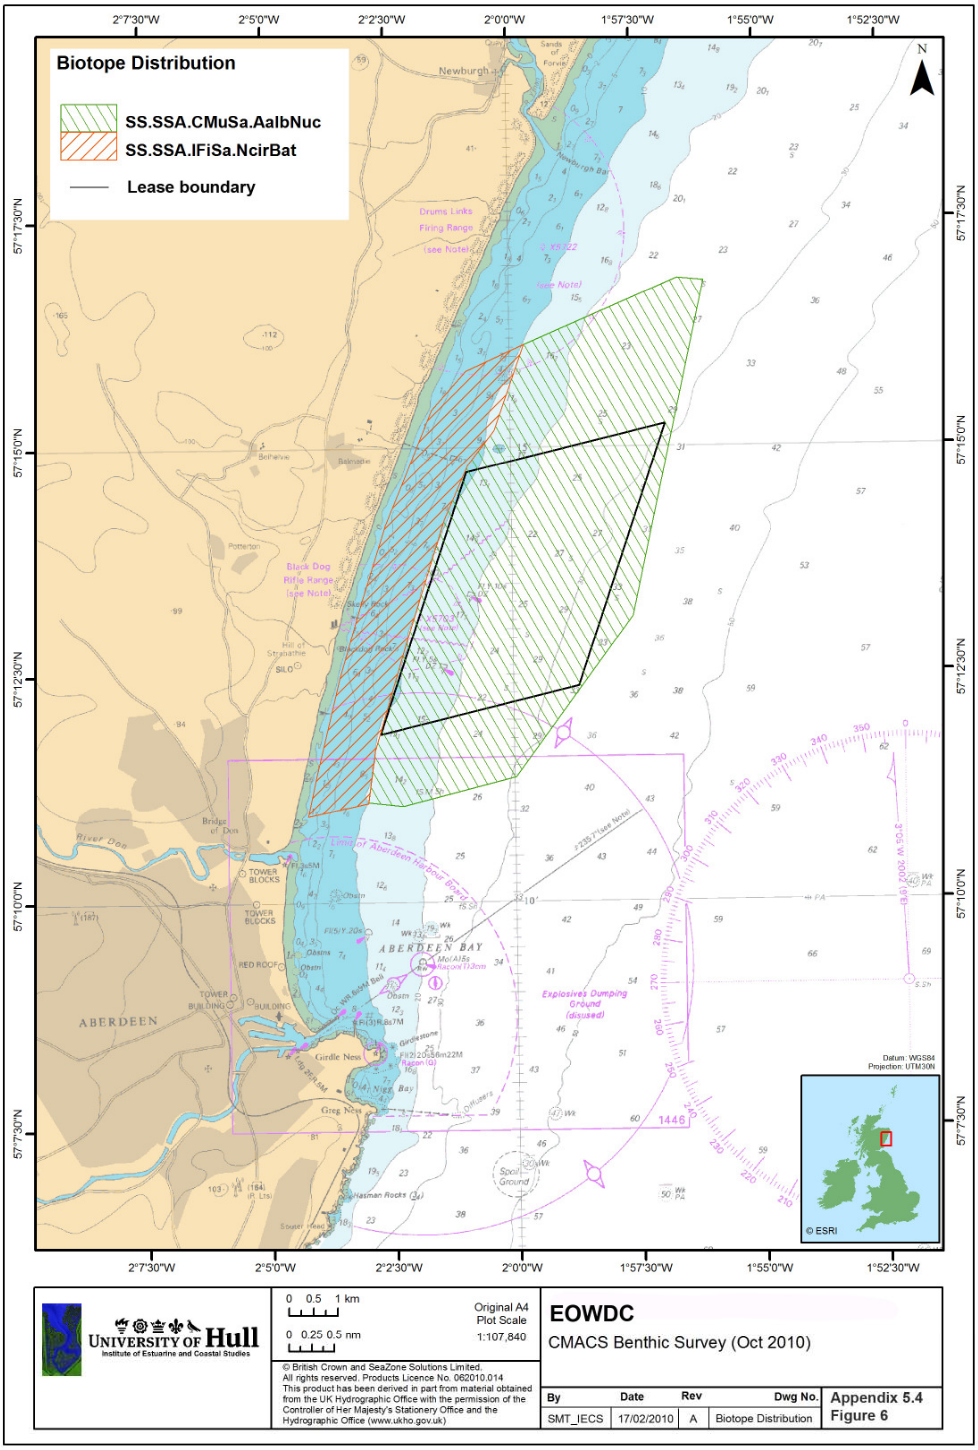

Figure 6. Biotope map showing the estimated extent of the two biotopes present (modified and redrawn from the CMACS Ltd Tecnical Report, Appendix 5.3).

APPENDIX 5.5.

MSS EPIBENTHIC SURVEY

The detailed methods and results of the epibenthic survey carried out by MSS in 2010 in the proposed EOWDC site are presented.

The data were provided by MSS and analysed by IECS.

5.5.1. Field sampling

1 MSS carried out an epibenthic survey in Aberdeen Bay in September 2010 on the FRV Alba Na Mara. Both data from video camera surveys and epibenthic trawls were obtained.

2 The TV tows were taken at 14 stations and trawl samples were taken from 7 locations. Most of the stations were located inshore, except for 6 stations (TV41, TV42, TV43, TV44, ABAG4 and ABAG5), which were located farther offshore (Figure 1).

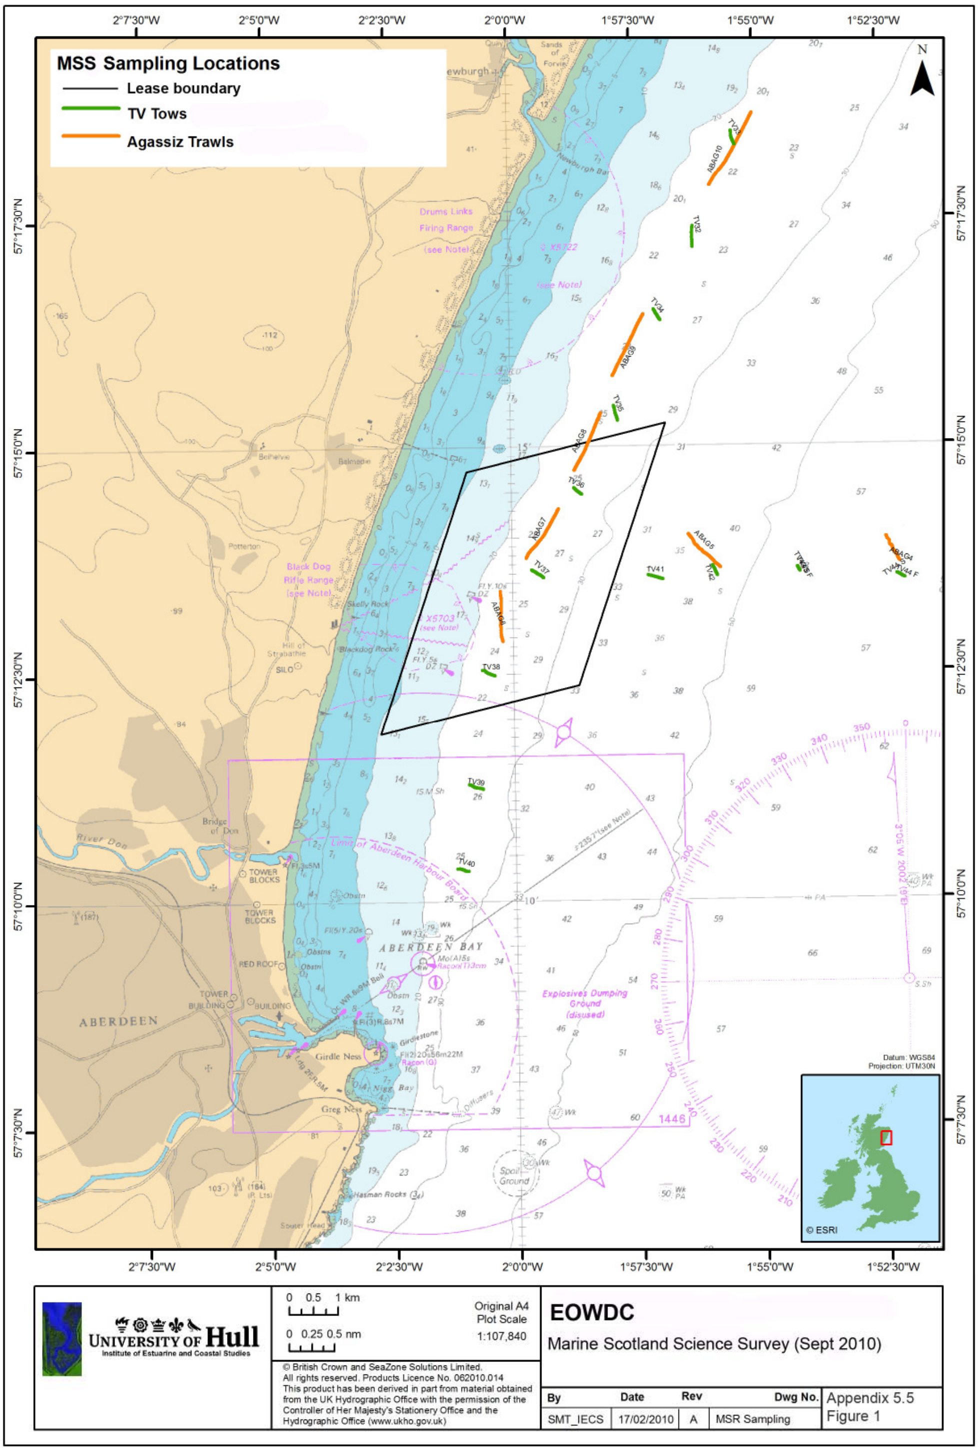

Figure 1. Trawl and video stations (MSS survey 2010).

3 The seabed video-footage was collected using a drop-frame TV system with video and digital still capabilities. The drop-frame was deployed with an armoured cable over the stern of the vessel typically steaming ahead at 1 knot into the tide or wind, whichever was the strongest. Once the drop-frame had reached the sea bed, a tow of typically ten to forty minutes duration was completed and the device then retrieved. The drop-frame was positioned approximately 1 m above the sea bed to ensure the best focal range for the digital camera. Vertical positioning of the drop frame is gauged by the deployment of a steel weight off the base of the drop frame which should only touch the sea bed surface. During deployment, a written record of macrobenthos, litter and sea bed type was recorded on an appropriate datasheet every minute. Digital stills were also recorded at approximately 1 minute intervals. Arc View was used to record the locations of the drop-frame TV and of the digital stills recorded during the tow. The video-footage was recorded directly onto DVD and the digital stills downloaded from the camera after the recovery of the drop-frame onto the vessel.

4 Epibenthic sampling was carried out by means of 2 m Agassiz trawl. It was deployed over the stern of the vessel while steaming ahead at between 1 and 2 knots. The Agassiz trawl was lowered to the seabed at a speed of up to 50 m per second. Once the Agassiz trawl had reached the sea bed, a tow of typically ten minutes duration was completed and then the Agassiz trawl was retrieved. The data on trawl position, vessel speed, towing direction and water depth were recorded using a datasheet and directly into Arc View. Once on deck, all animals were removed from the cod end and belly of the net and then transferred to the vessel's fish house for processing. All animals caught were identified, sorted and counted immediately on board the vessel. Non-biological material was thrown overboard during sorting.

5.5.2. Data analysis

MSS survey data were analysed by IECS.

5 Measured values and descriptive statistics for primary and derived biological parameters were presented both for the survey area as a whole and for individual stations. The following biological parameters were calculated using PRIMER v. 6 (Plymouth Routines in Marine Ecological Research):

- The total number of species (S) at each station and for survey area as a whole;
- Total abundance (A) of organisms expressed as individuals / 0.1 m^{-2} at each station;
- Shannon-Wiener diversity (H'(log_2)), incorporating both species richness and evenness (a measure of the distribution of the individuals between the species).

  $$H' = -\sum p_i \log_2 p_i$$

  Where,
  p_i = proportion of individuals in the ith species = n_i / N
  n_i = number of individuals of the ith species in the sample
  N = total number of individuals

  High values indicate high diversity.

- Pielou's Evenness index (J') gives a measure of the relative abundance of each species:

  $J' = H' / \log_2 S$.

  Low values (close to zero) indicate that a community is dominated by one or few species and indicate low diversity. Communities where there is an even spread of the individuals between the species (J' values approaching 1) are considered to be diverse.

6 Description of the biological communities for individual stations and for the survey area as a whole was carried out by ranking the species in terms of their abundance.

7 Multivariate techniques were also applied, allowing comparison of communities based on their component species and their relative importance in terms of abundance. Such techniques enable the interpretation of large data sets as a whole rather than examination of different components individually. Calculation of the Bray-Curtis similarity coefficient gives the percentage similarity between each pair of samples (i.e. all samples are compared with each other) and can be plotted in the form of a dendrogram, or an ordination plot (using Multi Dimensional Scaling) so that groups of samples with distinct community structures can be identified.

8 Multivariate analysis was carried out on the trawl data using the PRIMER v6.0 program to determine difference in epifaunal community structure between sample stations, particularly between those inside and outside the proposed EOWDC area. Sample data were fourth-root transformed prior to analysis, to reduce the effect of dominant species. A multi-dimensional scaling (MDS) diagram was generated to visualize the similarity among sites.

5.5.3. Results

9 The detailed results from the video analysis are presented in Appendix 5.6. The video footage from the inshore stations (TV32 to TV40) showed very similar characteristics of the sea bed. At all videos from these sites, the high current speed, large amount of organic matters and significant amount of silt/clay content was recorded. Due to the high sediment load, a very poor diversity of epifauna was observed. Brittle stars *Ophiura* sp. were observed in high numbers, but it was difficult to enumerate them using the video footage due to the poor visibility. Some fish species, mostly plaice and common dab were also detected. Sediments were mainly composed of fine sand, silt/clay and shell fragments. Sand ripples on the sea bed were also noticeable. No seaweed was recorded at these stations.

10 The sediments at stations TV41 and TV42 were very similar to those described above, but with greater content of shell fragments. Current speed at these stations was somewhat slower, and sand ripples were very noticeable. Species of brittle stars and common starfish *Asterias rubens* were recorded on the sea bed.

11 Mixed types of sediments were recorded further offshore (stations TV43 and TV44), with coarse sediments, stones, pebbles and boulders with silt/clay particles detected at these stations (Appendix 5.6). A relatively slow current

speed was present and the water was clear. Common starfish, bryozoans *Flustra foliacea* and dead man's fingers *Alcyonium digitatun* were present in large numbers at these stations. Attached epifaunal species (anemones, bryozoans, sponges) were also notable on the video footage (Appendix 5.6).

12 In total 14 species of fish, 7 species of decapods and 8 species of other invertebrates were recorded in trawl samples (raw data are provided in Appendix 5.7).

13 Fish accounted for 30% of the overall abundance in the trawl catches, with the predominant species being common dab *Limanda limanda* and plaice *Pleuronectes platessa* (Figure 2). These species were recorded in particularly high numbers (total of 823 and 510 individuals respectively) at the inshore stations (Appendix 5.7). Norway pout *Trisopterus esmarki* was also abundant, but only at station ABAG10 (240 individuals) (Appendix 5.7). Other species were recorded with lower abundances.

14 Crustacea accounted just for 1% of the overall abundance in the trawls catches, with the predominant species being harbour crab *Liocarcinus depurator* and circular crab *Atelecyclus rotundatus* (Figure 2).

15 Sixty-nine percent of the overall trawl catch abundance was accounted for by other invertebrate species, with brittle stars being the predominant taxon (Figure 2).

16 Low numbers of fish species and abundance were generally recorded at the offshore stations, although decapods occurred with a higher number of species and abundance in these areas (particularly at station ABAG4) (Figures 3 and 4). At inshore stations large numbers of brittle stars and common starfish were present (Figure 4, Appendix 5.7). The largest number of common starfish was recorded at the furthest offshore station ABAG4, and was also observed from the video analysis for this station. Higher species diversity and evenness values were found at offshore stations ABAG5 and ABAG4, as well as at station ABAG10 (Figures 5 and 6).

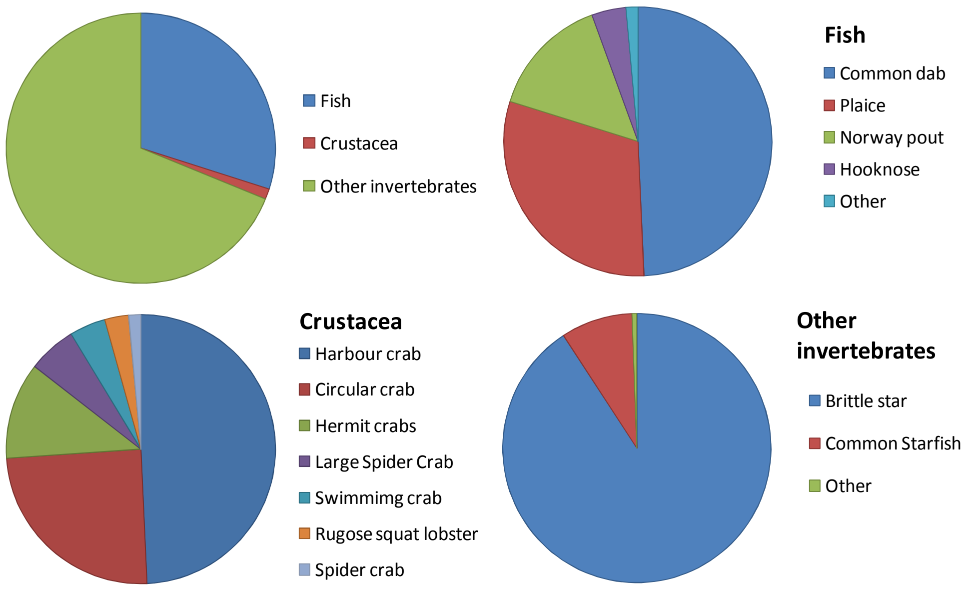

Figure 2. Overall composition (% abundance) of the epibenthic trawl catches carried out by Marine Scotland Science (September 2010).

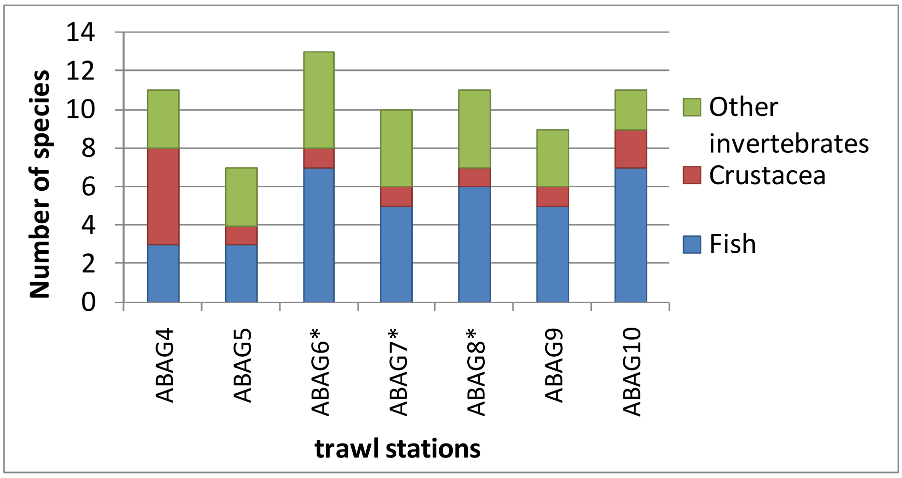

Figure 3. Number of species in the epibenthic trawl catches carried out by MSS (September 2010) at the 7 stations in Aberdeen Bay (asterisks indicate trawls inside the proposed EOWDC area).

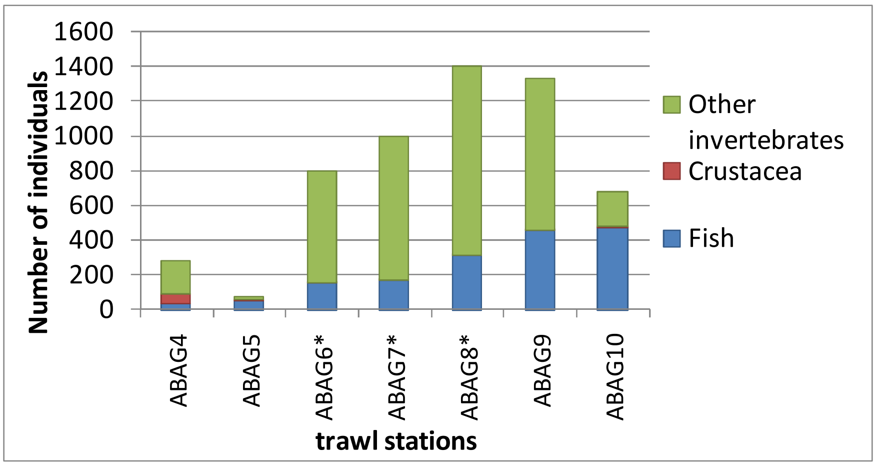

Figure 4. Total abundance in the epibenthic trawl catches carried out by MSS (September 2010) at the 7 stations in Aberdeen Bay (asterisks indicate trawls inside the proposed EOWDC area).

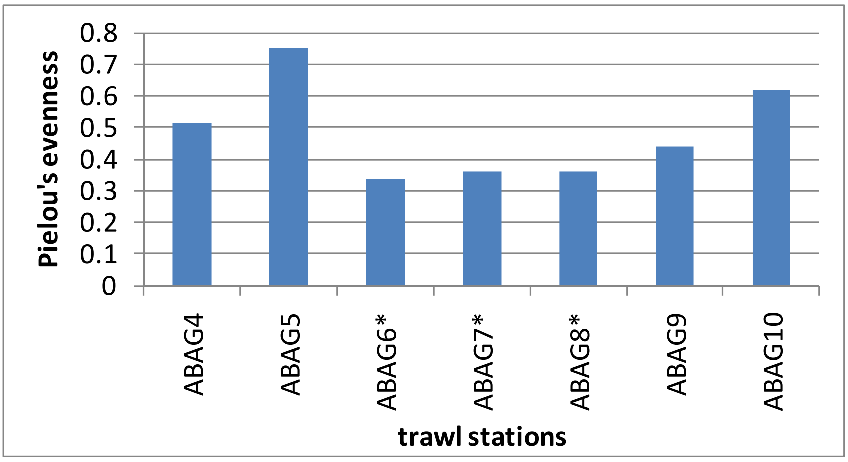

Figure 5. Pielou's evenness index measured on the epibenthic trawl catches carried out by MSS (September 2010) at the 7 stations in Aberdeen Bay (asterisks indicate trawls inside the proposed EOWDC area).

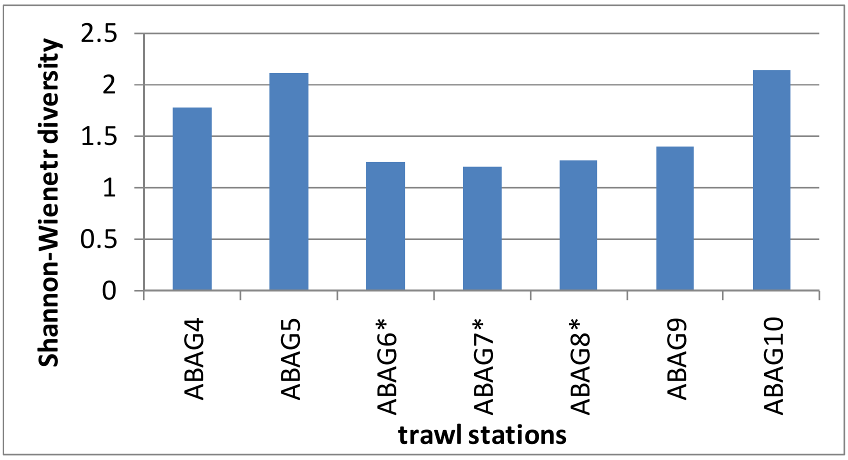

Figure 6. Pielou's evenness index measured on the epibenthic trawl catches carried out by MSS (September 2010) at the 7 stations in Aberdeen Bay (asterisks indicate trawls inside the proposed EOWDC area).

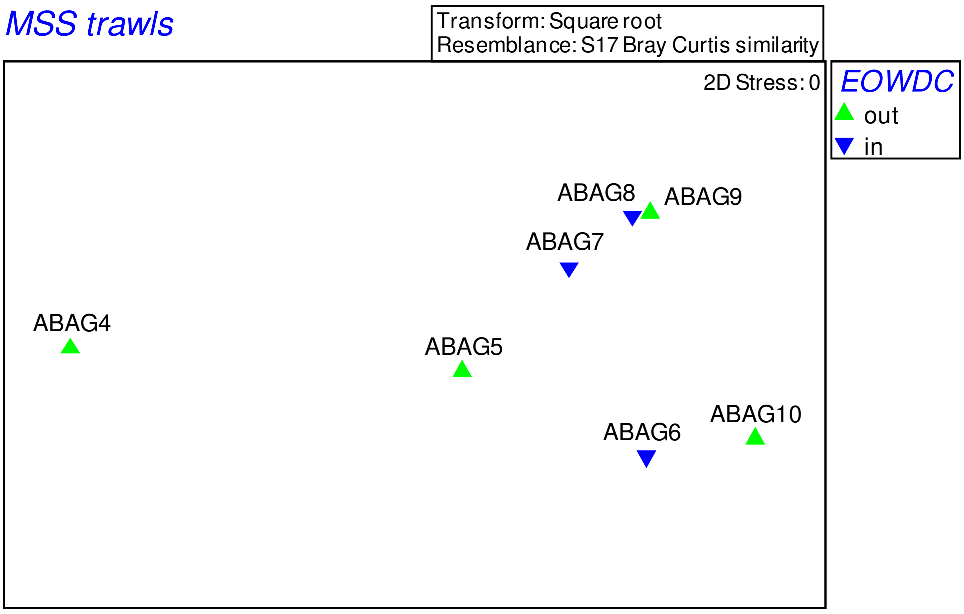

Figure 7. MDS plot (√√ transformed) based on the species abundance composition at each station (distinguished by their location inside or outside the proposed EOWDC area) (MSS epibenthic survey 2010).

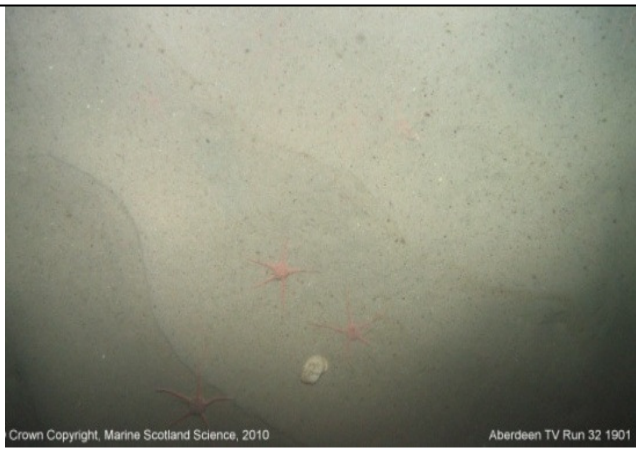
17 The Multi Dimensional Scaling (MDS) diagram, representing similarities among stations according to the structure of epibenthic assemblages (in terms of species abundance) is shown in Figure 7. No major differences were detected between stations located inside the proposed EOWDC area, and those outside. In turn, station ABAG4, located farther offshore (Figure 1), showed an epibenthic assemblage well distinguished from the assemblage in the other stations. This result was mainly ascribed to the higher abundance of hooknose, harbour and circular crabs, and of common starfish present at the station, as well as to a lower abundance of flatfishes (common dab and plaice) and brittle stars compared to the other stations, and this can be related to the differences in depth and distance from the shore.

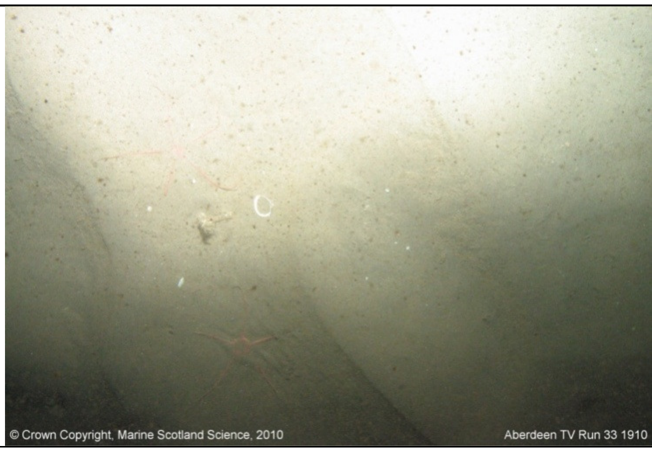
APPENDIX 5.6.

MSS EPIBENTHIC SURVEY 2010 – ANALYSIS OF VIDEO RUNS

VIDEO NO.	**TV32: 15/09/2010**
Duration (mins)	10
Summary	High current speed, large amount of Suspended Organic Solids. *Ophiura* sp. present, but hard to see them on the video footage due to muddy water. Some shell material and dead shells on the sea bed. Sand ripples, fine muddy sand, no weed
Real time	
17.19	*Asterias rubens* x 1
17.19	Plaice
17.21 17.26	*Asterias rubens* x 5
17.26	Plaice or dab x 1
17.27	*Asterias rubens* x 1
17.27	Plaice or dab x 1
17.28	Plaice or dab x 1; *Asterias rubens* x 1



VIDEO NO.	**TV33: 15/09/2010**
Duration (mins)	10
Summary	High current speed, large amount of Suspended Organic Solids. Camera jumps, very bad visibility. Sediments are as described above.
Real time	
17.47	Plaice x 1
17.47	Pisces indet. x 1
17.48	*Asterias rubens* x1
17.50	Plaice or dab x 2
17.53	*Ophiura* sp. x 6
17.54	Plaice or dab x 1
17.55	Plaice or dab x 1



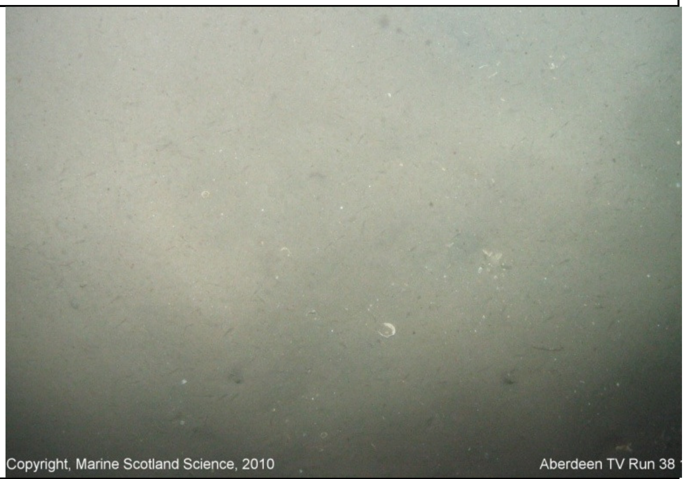
VIDEO NO.	**TV34: 16/09/2010**
Duration (mins)	10
Summary	High current speed. Sediments are as described in video 32.
Real time	
7.24 7.25	*Asterias rubens* x 4
7.26	Plaice or dab x 1
7.28	Crustacea indet.
7.29	*Asterias rubens* x 3
7.30	Plaice x 1
7.31	*Asterias rubens* x 2

VIDEO NO.	**TV35: 16/09/2010**
Duration (mins)	10
Summary	High current speed. Sediments are as described in video 32.
Real time	
7.47	Common dab x 1
7.49	*Asterias rubens* x 1
7.49	Plaice x 1
7.49	*Asterias rubens* x 1
7.50	Plaice x 2
7.50 7.51	Plaice or dab x 2
7.51	*Asterias rubens* x 1
7.51	Plaice x 1
7.51	Common dab x 1
7.53	*Asterias rubens* x 2
7.54	Common dab x 1
7.54	*Asterias rubens* x 3
7.55	Common dab x 2
7.56	See weed?
7.56	*Asterias rubens* x 1

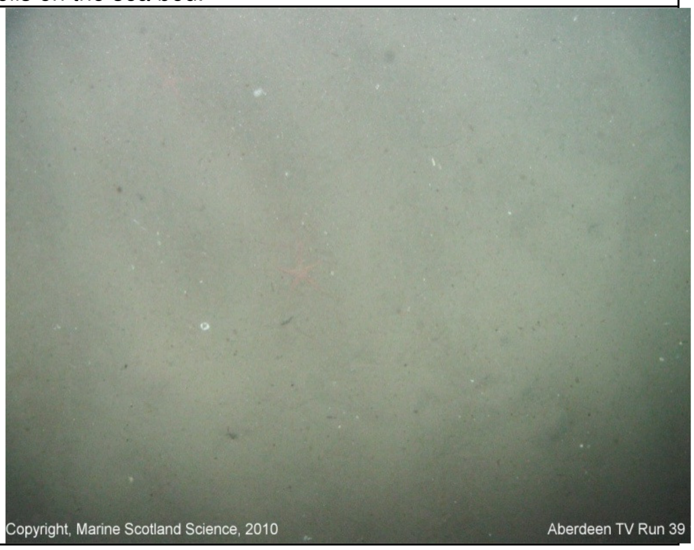
VIDEO NO.	**TV36: 16/09/2010**
Duration (mins)	10
Summary	High current speed. Sediments are as described in video 32.
Real time	
8.12	*Asterias rubens* x 1
8.13	Plaice or dab x 1
8.13	*Asterias rubens* x 1
8.14	Plaice or dab x 1
8.15	*Asterias rubens* x 1
8.16	Empty razor shells
8.18	Plaice or dab x 1
8.20	*Asterias rubens* x 3
8.20	*Solea solea* x 1
8.21	*Asterias rubens* x 1
8.21	Plaice or dab x 1
8.21	*Asterias rubens* x 1
8.21	Plaice or dab x 1

VIDEO NO.	**TV37: 16/09/2010**
Duration (mins)	10
Summary	High current speed, large amount of Suspended Organic Solids. *Ophiura* sp., *Asterias rubens* and *Flustra folicea* spread widely, but not clear on the video footage due to very muddy water. Some shell material and dead shells on the sea bed. Sand ripples, fine muddy sand, no weed.
Real time	
8.39	Crustacea indet.
8.39	*Asterias rubens* x 1
8.39	*Flustra foliacea*
8.40	Common dab x 1
8.40	Plaice or dab x 1
8.40	*Asterias rubens* x 1
8.41	Plaice or dab x 1
8.41	Common dab x 1
8.42	*Asterias rubens* x 4
8.42	Common dab x 1
8.42 8.43	*Asterias rubens* x 3
8.43	Crustacea indet.
8.43	Pipe fish
8.43 8.44	*Asterias rubens* x 2
8.44	Razor shells x 1
8.44 8.46	*Asterias rubens* x 5
8.46	Common dab x 1
8.47	*Asterias rubens* x 1
8.47	Razor shells x 1
8.48	*Asterias rubens* x 1

VIDEO NO.	**TV38: 16/09/2010**
Duration (mins)	10
Summary	Large amount of Suspended Organic Solids. Water is very muddy. Silt/clay type sediment on the surface, some burrows are visible. Some shell material and dead shells on the sea bed.
Real time	
9.04	Common dab x 2
9.06 9.08	*Asterias rubens* x 7
9.08	Common dab x 1
9.09	*Asterias rubens* x 2
9.12	Asterias rubens x 1; Razor shells x 1
9.14	*Asterias rubens* x 2
9.14	Echinodermata indet.



VIDEO NO.	**TV39: 16/09/2010**
Duration (mins)	10
Summary	Large amount of Suspended Organic Solids. Water is very muddy. Silt/clay presented on the sediments surface, fine sand sediments, sand ripples. Some shell material and dead shells on the sea bed.
Real time	
9.31	Common dab x 1
9.32	Plaice or dab x 3
9.34	Pisces indet. x 1
9.34 9.36	*Asterias rubens* x 5
9.36	Plaice or dab x 1
9.38	Razor shells x 1
9.38	Plaice or dab x 1
9.39	Ohiuroidea spp.
9.39	*Asterias rubens* x 1



VIDEO NO. Duration (mins)	**TV40: 16/09/2010** 8	
Summary	Large amount of Suspended Organic Solids. Water is very muddy. Silt/clay type sediment on the surface, fine sand sediments. Some shell material and dead shells on the sea bed.	
Real time		
9.55	*Asterias rubens* x 1; Whelk (Buccinum sp.)	
9.56	*Asterias rubens* x 1	
9.56	Decapoda indet.	
9.57	Common cockle?	10.01	*Asterias rubens* x 1	
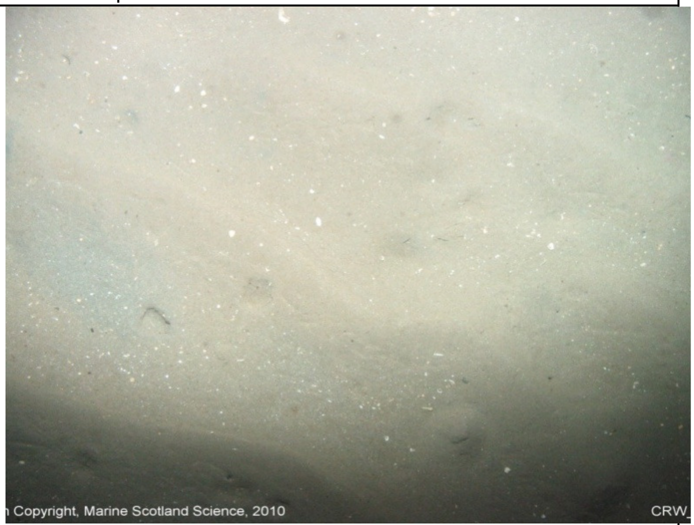
10.02	Crustacea indet.	
VIDEO NO. Duration (mins)	**TV41: 16/09/2010** 10	
Summary	Very similar sediments as above, large amount of Suspended Organic Solids. Silt/clay and fine sand on the sediment surface. Some shell material and dead shells on the sea bed. Species of *Ophiura* sp. and *Asterias rubens* present on the surface.	
Real time		
11.02	Ohiura sp.	
11.03	Gastropod x 1	
11.03 11.05	*Asterias rubens* x 5	
11.08	Razor shells x 1	
11.08	Sea urchin?	
11.09	*Asterias rubens* x 1	
11.10	*Ohiura* sp.	
11.10 11.12	*Asterias rubens* x 5	
11.12	*Ohiura* sp. X 2	

VIDEO NO.	**TV42: 16/09/2010**
Duration (mins)	10
Summary	The sediment is mostly the same type as described above, but slightly darker in colour. Relatively slow current speed.
Real time	
11.23	*Asterias rubens* x1; Decapoda indet. x 1
11.24	*Asterias rubens* x5
11.25	Crustacea? x 1
11.25	Whelk (Buccinum)
11.25	*Asterias rubens* x 2
11.27	*Flustra foliacea* x 1
11.27	*Asterias rubens* x 1
11.27	*Ohiura* sp. x 1
11.27	*Asterias rubens* x 1
11.28	*Flustra foliacea* x 1
11.28	*Asterias rubens* x 6
11.29	*Flustra foliacea* x 1
11.30	*Asterias rubens* x 1
11.30	Sponge?
11.31	*Asterias rubens* x 1
11.31	*Ohiura* sp. x 1
11.31 11.33	*Asterias rubens* x 6



VIDEO NO.	**TV43: 16/09/2010**	
Duration (mins)	10	
Summary	Mostly coarse sediments, stones, pebbles and boulders presented. Silt/clay particles covering coarse sediments. Relatively slow current speed, some attached epifauna present (Anemones, bryozoans, sponges), large amount of corals (*Alcyonium digitatun*) and sea stars.	
Real time		
11.46	*Alcyonium digitatun* x 2	
11.46	*Alcyonium digitatun* x 2; Echinodermata? x 1	
11.46 11.48	*Asterias rubens* x12; *Alcyonium digitatun* x10; *Flustra foliacea* x 2; Actiniaria indet.x 1	
11.48 11.51	*Asterias rubens* x 21; *Alcyonium digitatun* x 19; *Flustra foliacea* x 1; Crustacea indet. x 3; Whelk x 1;	
11.51 11.55	*Asterias rubens* x 23; *Alcyonium digitatun* x 43; *Flustra foliacea* x 14?	

VIDEO NO.	**TV44: 16/09/2010**
Duration (mins)	10
Summary	Coarse sediments, pebbles and stones, mixed types of sediments. Moderate currents speed, some attached epifauna recorded (Anemones, bryozoans), large amount of sea stars *Asterias rubens*.
Real time	
12.12 12.17	*Asterias rubens* x 137; *Alcyonium digitatun* x 10; *Flustra foliacea* x 4; *Ohiura* sp. x 1; Decapoda indet. x 2; *Cancer pagurus* x 1;
12.18 12.19	*Asterias rubens* x 50; *Alcyonium digitatun* x 7; *Flustra foliacea* x 3
12.20	*Asterias rubens* x 41; *Alcyonium digitatun* x 11; *Flustra foliacea* x7
12.21	Pectinidae spp. x 1

APPENDIX 5.7.

MSS EPIBENTHIC TRAWL SURVEY 2010 – RAW DATA

Epifaunal composition from trawl survey (MSS survey 2010).

Common Name	**Species name**	**ABAG4**	**ABAG5**	**ABAG6**	**ABAG7**	**ABAG8**	**ABAG9**	**ABAG10**	**Totals**
Fish									
Common dab	*Limanda limanda*	4	20	80	90	211	331	87	823
Plaice	*Pleuronectes platessa*		31	60	70	92	123	134	510
Norway pout	*Trisopterus esmarki*					2	2	240	244
Hooknose	*Agonus cataphractus*	34	5	11	12	5	2		69
Long rough dab	*Hippoglossoides platessoides*						2	5	7
Flounder	*Platichthys flesus*			1				4	5
Cod	*Gadus morhua*					1		2	3
Greater pipefish	*Syngnathus acus*			1	1				2
Red Gurnard	*Aspitrigla cuculus*					2			2
Whiting	*Merlangius merlangus*			1					1
Cuckoo Ray	*Raja naevus*			1					1
Dragonet	*Callionymus lyra*	1							1
Long spined scorpionfish	*Paracentropogon longispinis*				1				1
Long-spined Bullhead	*Taurulus bubalis*							1	1
Crustacea species									
Harbour crab	*Liocarcinus depurator*	30				1		3	34
Circular crab	*Atelecyclus rotundatus*	17							17
Hermit crabs	*Pagarus* sp.	2		2				4	8
Large Spider Crab	*Inachus* sp.	4							4
Swimming crab	*Necora puber*		2		1				3
Rugose squat lobster	*Munida rugosa*	2							2
Spider crab	*Macropodia deflexa*						1		1
Other species									
Brittle star	*Ophiura albida*		2		780	1040	850		2672
Brittle star	Ophiuroida			619				200	819

Common Name	Species name	ABAG4	ABAG5	ABAG6	ABAG7	ABAG8	ABAG9	ABAG10	Totals
Common Starfish	*Asterias rubens*	183	13	16	42	52	24	3	333
Common heart urchin	*Echinocardium cordatum*		1	5	4	1	2		13
Sea urchin	*Psammechinus miliaris*	4							4
Astrapecten	*Astropecten polyacanthus*			1	1	1			3
Whelk	*Neptunea* sp.	1							1
Sea mouse	*Aphrodite aculeata*			1					1

European Offshore Wind Deployment Centre

Environmental Statement

Appendix 9.2: Marine Ecology, Intertidal Ecology, Sediment and Water Quality EIA Technical Report

A project part-funded by the European Union under the European Economic Plan for Recovery in the field of Energy

1 MARINE ECOLOGY, INTERTIDAL ECOLOGY AND SEDIMENT AND WATER QUALITY

1 The Institute of Estuarine and Coastal Studies (IECS, University of Hull) was commissioned by Aberdeen Offshore Wind Farm Limited (AOWFL) to undertake the Environmental Impact Assessment (EIA) for the proposed European Offshore Wind Deployment Centre ("EOWDC"). The EIA process described in this report provides a description of the potential impacts of construction, operation and decommissioning upon the benthic ecology and fish communities within the proposed development area. A summary of the baseline data is also provided with detailed information presented in Section 1.1.1.

1.1 Information for the Non-Technical Summary

1.1.1 Background

2 This report assesses the possible environmental impacts of the proposed EOWDC off the coast of Aberdeen on the marine ecology of the area. The assessment process involves a review of the potential development options and assesses the option with the potential to have the greatest impact on each receptor, the 'worst case scenario'.

3 The various receptors that may be impacted by the development have been grouped into the following broad categories:

- invertebrates such as worms, shrimps and molluscs that live in the intertidal (beach) and subtidal (seabed) sediment;
- fish and shellfish (such as crabs and lobster) that live on the seabed and in the water column.

4 Potential impacts to these groups are considered in the context of the three main stages of the development – construction, operation and decommissioning.

5 The proposed development site contains physical, chemical and biological characteristics which resemble those of much of the surrounding area of Aberdeen Bay. These include a substratum of predominantly fine sandy sediment with no contaminants present at a level of concern and a generally good water quality. The animals living in the sediment of the beaches in the vicinity of the development are mostly mobile crustaceans which may provide food for fish living in the area. On the seabed, the main animals living in the sand are worms, with the most common species being *Notomastus latericeus*, and bivalves (mainly *Nucula nitidosa* and *Tellina fabula*). The community of animals living on the surface of the seabed is quite sparse but includes brittle stars and swimming crabs. The most common fish species using the area are flatfish such as dab and plaice, with hooknose and whiting also abundant. Fishing grounds are located outside the development area to the north and no specific spawning or nursery grounds have been identified in the development area.

6 A number of sites designated for their conservation importance (e.g. under European and UK law) occur along the coast in the Aberdeen Bay area.

None of these are located within the proposed development area (i.e. within the lease boundary). The closest Special Area of Conservation (SAC) to the site is the River Dee SAC, located 7.5 km south of the proposed EOWDC area, which supports three Annex II species, the freshwater pearl mussel, Atlantic salmon and otter.

1.1.2 Assessment of Impacts

7 Impacts on animals living in the beach sediment near the development are considered to be largely restricted to the construction phase when cable laying may disturb their habitat and lead to some small scale short-term direct habitat loss (from trenching) and indirect loss (from smothering by spoil). However, following cable installation, it would be expected that a rapid recolonisation of the habitat would occur. As such, the overall impact is assessed as being of minor to negligible significance. Decommissioning effects are expected to be similar, or below the level of those for construction. During the operation of the wind farm, it is probable that the cabling will increase the temperature of the surrounding sediment by a small amount. This is a very localised effect and, as the cable is likely to be buried at a minimum depth of 0.6m, well below the zone where most animals live (e.g. the top 15 cm of sediment), impacts would be of negligible significance.

8 Potential impacts to animals living on and in the seabed are expected to include temporary loss of and damage to the seabed soft sediment habitat (and associated animals) from the construction of foundations and associated scour protection and 'habitat loss' during the operational phase. The area of loss will be relatively small in the context of the development area, and partially offset by the creation of new hard substratum habitat associated with the new structures. The habitat which would be lost is not of a particularly high conservation value, and is characteristic of much of the wider Aberdeen Bay area. As such, habitat damage and loss are considered likely to be localised and of low magnitude and the impact has been assessed as minor at a habitat scale. Other minor issues with regard to sediment re-suspension during construction may occur, but given that the communities in the area are likely to be adapted to naturally high levels of such conditions, impacts are considered to be negligible. Similar types of impact have been identified for the decommissioning phase, although a lower significance is anticipated. The operational phase could also create potential impacts from the effects of underwater noise pressure and vibration, electromagnetic fields (EMF) and a temperature rise in the sediments around the cables. The effects on fauna are anticipated to be extremely localised and thus negligible. A potential impact from noise and vibration could also occur, particularly during construction works, but this has been assessed as of negligible to minor significance, due to the low magnitude of the effect and the low to medium sensitivity of the receptor.

9 Fish and shellfish in the development area are potentially going to be affected by noise and vibration generated during wind farm construction work (mainly from piling). However, these effects are likely to be short-term and intermittent, and their magnitude is expected to decrease with distance from the noise source. The most abundant species in the proposed development area tend to be less sensitive to noise and vibration than many species, and no significant sensitive fish habitats (spawning or

nursery grounds) occur in the proposed development area. Furthermore, most fish are able to move out of an area when conditions become unsuitable. However, due to sound propagation towards deeper waters, this impact might affect spawning populations of herring along the coast in Aberdeen Bay, even if no important spawning grounds of the species are present directly on the proposed development site. Due to the paucity of presence/absence data of herring spawning grounds in the wider area of influence of noise disturbance around the proposed EOWDC site, a precautionary approach has been adopted. As such, worst case impacts from construction noise on fish are considered to be of minor to possibly moderate significance, but with a strong likelihood that they are of no more than a minor significance. Other potential impacts on fish and shellfish during construction may arise from sediment re-suspension, contaminant release from construction works and loss of key habitats, but these have been assessed as of negligible to minor significance. Similar types of impact to those described above have been identified for the decommissioning phase, although a further lower significance is assessed due to the absence of a permanent habitat loss. Potential impacts on fish during the operational phase mainly arise from electromagnetic emissions associated with cabling. Research, e.g. through COWRIE, has identified Elasmobranchs as having a medium to high sensitivity to EMF. However, whilst they may occur within the development site, data would indicate their presence to be in low numbers and as such, the magnitude of the effect is considered to be low and the significance of the impact minor.

1.1.3 Cumulative & In-Combination Effects

10 Potential cumulative impacts arising from the possible presence of other activities and installations in the proposed development area have been assessed. The only plan or project identified near the proposed development area is the proposed Ocean Laboratory which, if approved, would be installed in close proximity to turbine location 1. Impacts arising from the construction, operation and decommissioning of this structure are likely to be broadly similar (in type) to those assessed for an individual turbine located within the proposed EOWDC. However, these impacts are likely to be of lower significance compared to those caused by the wind farm development, given the smaller scale of the Ocean Laboratory. As such, most effects would be masked by existing operations and any additive effects are considered to be minimal in the context of existing predicted impacts.

11 As the status of the freshwater pearl mussel is dependent upon the presence/absence of salmonids, the potential direct and indirect impacts of the proposed development on this species have been addressed within the salmon and sea trout assessment for the proposed EOWDC. The Habitats Regulations Assessment has also been addressed in this way. The Assessment should conclude no impact other than that consistent with impacts to the salmonid population.

1.2 Introduction

12 The Environmental Impact Assessment (EIA) process seeks to identify those impacts associated with the development through all phases of its evolution. These are based on knowledge of the existing environment (baseline conditions), the definition of the project proposed and the response of the environment to the potential changes. Where possible, mitigation is built into the project design to reduce impacts "at source", and where this is not possible a range of mitigation measures may be applied to reduce any residual impacts which might arise, often with a monitoring condition attached.

13 The construction, operation and decommissioning of an offshore wind farm will inevitably have some impact upon the physical properties of the seabed and the quality of the overlying water with consequent impacts upon the benthic communities and fish present and, ultimately on their predators (sea mammals and birds). Although these impacts have been widely monitored (see CEFAS, 2010a for a recent review), a certain degree of uncertainty still occurs, particularly in relation to the long-term and cumulative impacts of a proposed development and any other licensed and proposed activities within the area (CEFAS, 2010a). However, with respect to the benthic environment, many of the impacts of construction and estimated recovery times are expected to be similar to those associated with other anthropogenic activities, such as dredging, which are well documented (e.g. Kenny and Rees, 1994, 1996; Newell *et al.*, 2004; Cooper *et al.*, 2006, 2007, 2011).

14 This document provides information on the impacts of the proposed development on different aspects of the marine environment, namely intertidal benthos, subtidal benthos and epibenthos, and fish and shellfish communities. Potential effects on plankton assemblages have not been assessed in detail, as they are not considered to be an important issue in the impact assessment of offshore wind farms (Wilson *et al*., 2010). In addition to the absence of any substantive conservation reasons of targeting plankton within the EIA process, potential impacts on this group are unlikely due to its high natural spatial and temporal variability.

15 Where specific life stage aspects have been identified then these have been considered in the appropriate section (e.g. spawning areas and larval fish stages).

16 The EIA process has been carried out for individual components of the construction, operational and decommissioning stages and the potential impacts and their severity and permanency are characterised and discussed.

1.2.1 Methodology Consultation

17 Information on the EIA methodology and on the issues to be addressed during this process has been derived from relevant consultation responses such as:

- Sue Lawrence, Area Officer – City of Aberdeen and Aberdeenshire Central, Scottish Natural Heritage (10/09/29);

- Robert Forbes, Senior Planning Enforcement Officer, Aberdeen City Council (10/09/23);
- Nicola Abrams, Senior Planning Officer, Scottish Environmental Protection Agency (10/09/24);
- Fiona Thompson, Marine Scotland (10/12/15);
- Fiona Thompson, Marine Scotland (Scoping Opinion, and Consultee comments therein, in particular comments from Scottish Natural Heritage, Scottish Environmental Protection Agency, Marine Scotland, Association of Salmon Fishery Boards) (11/02/24).

18 The main points provided in the above consultation responses were:

- to consider onshore elements as part of the EIA process;
- to address aspects like the duration of impacts and timing of works;
- to take into consideration impacts on elasmobranchs other than basking and porbeagle sharks;
- to make appropriate links to fish and shellfish where there are strong habitat associations for certain species.
- to account for potential indirect impacts on pearl freshwater mussels and to make explicit reference also to River South Esk SAC when considering potential in-combination impacts.

All of these comments have been addressed within the EIA process.

1.2.2 Key Guidance Documents

A number of guidance documents are available to inform and direct the impact assessment process:

- IEEM, 2010. *Guidelines for ecological impact assessment in the United Kingdom*. Final document.
- *Environmental impact assessment: guide to procedures* http://www.communities.gov.uk/documents/planningandbuilding/pdf/157989.pdf
- *Guidelines on information to be contained in Environmental Impact Statements (EIS)* http://www.epa.ie/downloads/advice/ea/guidelines/EPA_advice_on_EIS_2003.pdf
- CEFAS, 2004. *Offshore wind farms: guidance note for Environmental Impact Assessment in respect of FEPA and CPA requirements.* Version 2. Prepared by the Centre for Environment, Fisheries and Aquaculture Science (CEFAS) on behalf of the Marine Consents Unit (MCEU). 45pp.
- EMEC, 2008. *EIA guidance for developers at the European Marine Energy Centre*. GUIDE003-01-03 20081106 21

- European Commission, 1999. *Guidelines for the assessment of indirect and cumulative impacts as well as impact interactions*. Document no. NE80328/D1/3.

- Metoc Plc., 2000. *An assessment of the environmental effects of offshore wind farms.* Report prepared for the Department of Trade and Industry/ETSU by Metoc Plc. [ETSU W/35/00543/REP].

- Scottish Government, 2010. *Renewables Action Plan*. Renewable Energy Division, June 2009.

- Scottish Natural Heritage, 2004. *Marine renewable energy and the natural heritage: an overview and policy statement.* Policy Statement No. 04/01.

- Scottish Natural Heritage, 2010. *Renewable energy and the natural heritage.* Ref No. 2010/02.

1.2.3 Data Information and Sources

Baseline data for the EIA process for this development have been derived from a range of published and grey sources, primarily:

- *European Offshore Wind Deployment Centre (EOWDC) request for an Environmental Impact Assessment (EIA). Scoping Opinion.* August 2010 (referred to as Scoping Report 2010).

- *EOWDC Baseline technical report for the European Offshore Wind Development Centre* (referred to as Baseline Report 2011).

- Seazone Hydrospatial Data, 2011. Provided for use on the European Offshore Wind Deployment Centre (Aberdeen Bay) under Seazone Licence Number 012005.003.

- OSPAR, 2004. *Draft background document on problems and benefits associated with the development of offshore windmill farms (OWF).* Annex 1. Report BDC/03/4/2-E.

- OSPAR, 2006. *Review of the current state of knowledge on the environmental impacts of the location, operation and removal/disposal of offshore wind-farms*. Publication Number: 278/2006.

- OSPAR, 2008. *Assessment of the environmental impact of offshore wind-farms.* Publication Number: 385/2008

- OSPAR, 2009a. *Assessment of the environmental impacts of cables.* Publication Number: 437/2009.

- OSPAR, 2009b. *Overview of the impacts of anthropogenic underwater sound in the marine environment*. Publication Number: 441/2009.

- Bio/consult, 2006. EIA Report – Fish - Horns Rev 2 Offshore Wind Farm. Doc. No. 2676-03-001.

- CEFAS, 2010. *Strategic review of offshore wind farm monitoring sata associated with FEPA licence conditions*. Final Report. Project code ME1117.
- SCIRA, 2006. *Preliminary assessment of WTG foundation types and their influence on the seabed. SCIRA Offshore Energy Limited Sheringham Shoal Windfarm.* Document No. SCIRA-8-1-2-SS-RP-04385 Rev. A4.

1.2.4 Impact Methodology

19 The assessment methodology used in this document follows a broadly common approach based around the IEEM Guidelines (IEEM, 2010), but adapted to address issues in the subtidal environment.

20 Impacts were assessed separately for each component of the marine ecology (receptors) and for the different project phases. The criteria in the assessment were based on the combined evaluation of the magnitude of effects and the sensitivity of each receptor.

21 In order to assess the magnitude of an effect, its spatial extent, duration and scale were taken into account. This information was gathered from available literature and previous assessments of similar effects, taking into account the technical information on the development structures and methodologies (e.g. power and number of turbines, footprints of foundations, etc.).

22 The assessment of the sensitivity of a receptor was based on its importance and recoverability. This information was mainly derived from the baseline technical report and, where possible, from additional assessments of impacts on the same or similar receptor.

23 The evaluations of the magnitude of effect and of the sensitivity of receptor were then combined in a final assessment of the impact significance, following the matrix in Table 1.

Table 1. Matrix for Significance of Impact

	Sensitivity of Receptor (based on importance and recoverability)				
		Very High	**High**	**Medium**	**Low**
Magnitude of Effect (based on spatial, duration and scale of effect)	**Very High**	Major	Major	Major	Moderate
	High	Major	Major	Moderate	Minor
	Medium	Major	Moderate	Moderate	Minor
	Low	Moderate	Minor	Minor	Negligible
	Negligible	Minor	Negligible	Negligible	Negligible

1.2.5 Implications of Significance

24 Where the significance is classified as moderate to major or major this is considered to be a potentially significant effect. It should be noted that significant effects need not be unacceptable or irreversible.

1.2.6 Cumulative and In-Combination Impact Assessment Methodology

1.2.6.1 Cumulative Impact

25 Schedule 3 of the Electricity Works EIA (Scotland) Regulations 2000 requires that the potential for cumulative impacts should be considered and, where appropriate, assessed.

26 Guidance for the assessment of cumulative impacts is given in the guidance note for EIA in respect of FEPA and CPA requirements (CEFAS, 2004), which states that assessment must cover the potential impacts of any development cumulatively with those of all adjacent wind farm consented and proposed sites.

27 Cumulative impact assessment should include impacts that arise from any reasonably foreseeable project/development activities in the area, such as for example other wind farms, aggregate extraction and dredging, navigation and shipping, established fishing activities, existing and planned construction of subsea cables and pipelines, potential port/harbour developments, oil and gas installations.

28 As such the cumulative assessment addressed where predicted impacts of the EOWDC construction and operation could interact with impacts from other industry sectors within the same region and impact sensitive receptors. This may be through direct effects or spatially/temporally separated impacts on the same population of a receptor.

29 Broad scale information was gathered from the recently published Scotland's Marine Atlas (Scottish Government 2011) and from Seazone Hydrospatial Data (2011). No active international and inshore telecommunications cables are present within or close to the proposed development site (one international cable, CNS FIBRE OPTIC, is present, and approximately 20km north of the development area). An out of use BT submarine cable is present, laid from the shore to the proposed EOWDC area, but this is expected to remain *in-situ*, hence no additional impacts are anticipated to occur.

30 Similarly, no additional potential port/harbour development is present in the area.

31 With regard to renewable energy installations and power cables, no other wind farms are sited or planned for development near the proposed development site. The closest wind farm developments to the EOWDC site are the proposed Firth of Forth developments 58 km to the south and the Moray Firth developments 117 km to the north.

32 In addition, no oil and gas installations were identified near the proposed development, nor any aggregate extraction sites. On the north-east coast, the St Fergus gas terminal is the largest single gas importing facility in the UK, receiving gas from a large number of North Sea fields. However it is located far north of the proposed development area (approx. 40 km). Oil production from a number of central and northern North Sea fields feeds into the main pipeline at the Forties Charlie platform from where it is transported 175 km to Cruden Bay. These installations are located well to

the north of the proposed EOWDC area, hence no cumulative impacts are likely to occur.

33 No important fishing grounds are present within the proposed development area as confirmed by the baseline data. This is also supported by the results of a shipping activity survey carried out in 2009-2010, highlighting the presence of very few fishing vessel routes crossing the proposed EOWDC area (Scoping Report, 2010).

34 The proposed installation of an Ocean Laboratory on the wind farm site has also been considered as a source of additional impact. This particular development will be subject to a separate consent application which would be discussed with the relevant consenting authorities. The impacts of the construction, operation and decommissioning of the Ocean Laboratory are likely to be similar (in type) to those derived from the wind farm development, given that similar foundation type and installation methodologies will be used, but of a smaller magnitude given the developemnt size. Cumulative impacts with the Ocean Laboratory are considered for each impact.

1.2.6.2 In-Combination Impacts

35 The assessment of in-combination impacts considers any other industrial activities or plans or projects which could in-combination have an impact upon species and areas protected under the Habitats Directive. The main industries that have been considered for potential in-combination impacts are the aggregate industry, oil and gas and shipping.

36 The only species protected by the Habitats Directive and with the potential to be subject to significant in-combination effects, is the freshwater pearl mussel which is a qualifying feature of the River Dee SAC. The fresh water pearl mussel is a long-lived filter feeding species, which only lives in rivers and streams. Scottish populations of this species are of world-wide importance as half the world's known breeding population of pearl mussels are found in Scotland. Besides requiring clear and fast flowing waters and gravelly-sandy bottoms, the species is highly dependent on the presence of salmon and trout in the river. In summer (July to September), after reproduction, pearl mussel pelagic larvae are released; most of them are swept away downstream, whereas some are inhaled by juvenile Atlantic salmon and sea trout and they encyst onto their gills. This allows larvae to be retained in the freshwater environment and be transported upstream, where they drop off the gills the following spring (May to early June) and, if settling in clean, sandy or gravelly substrates, they settle and start to grow (Skinner *et al.*, 2003).

37 Due to these life cycle requirements and the distance of designated SACs for this species from the proposed EOWDC area (> 7 km), it is considered that the freshwater pearl mussel is unlikely to be subject to direct impacts from the proposed development, however, indirect effects might arise as a result of possible impacts on their host populations (Atlantic salmon and sea trout).

38 Therefore, the characterisation of potential in-combination impacts of the development on migratory salmonids and on the freshwater pearl mussel are addressed separately within the salmon and sea trout assessment for the proposed EOWDC. It is expected that any in-combination impacts on the freshwater pearl mussel will not be significant if the impact on the salmonid population is not significant.

1.2.7 Worst Realistic Case

39 As part of the proposed development project, there is the intention to install a mix of "first run of production" wind turbines on a mix of conventional and novel foundations. The final types of structures (e.g. turbine or foundation) will be unknown at the time of the consent application and will be decided post consent during the detailed engineering design phase.

40 Eleven wind turbines are to be installed in the proposed development area, with the possible deployment of 4 wind turbines in 2013, and of 7 wind turbines in 2014 (although all 11 could potentially be installed in 2013). Each of these wind turbines will be of between 4 and 10 MW generative capacity. Five different foundation types are under consideration (namely concrete/steel monopile, jacket on piles, tripod on piles, gravity base structure, and suction caisson/bucket). The various options may require different levels of scour protection and different installation methods (Scoping Report, 2010; Chapter 3, Description of the Proposed Development).

41 Based on the technical information available to date (see chapter 3, Description of the Proposed Development), and following the 'Rochdale Envelope Approach', the impact assessment has used a 'worst case scenario' in order to assess the worst possible impacts of the proposed development on the marine ecology of the area. This approach provides flexibility to AOWFL in a changing market but also ensures that all possible impacts of the test site have been assessed.

1.3 Impact Assessment

42 Different sources of impact on marine communities (intertidal and subtidal benthos, fish and shellfish) have been identified. The potential impacts, mitigation measures, residual and in-combination impacts, and monitoring related to these different sources are presented separately for the different project phases.

43 The assessment of impacts which are likely to arise during construction of the proposed development took into account the different activities which are likely be carried out during this project phase, such as shipping, transport of components to site, assemblage on site, anchoring, jack-up rigs installation, excavation, foundations and cable installation.

44 With regards to the operational phase, the assessment has accounted for the potential impacts arising from the physical presence of the development structures (wind turbines, foundations, scour, cables) in the area.

45 Decommissioning and removal of the structures, foundations and cables will be necessary within a period of 22 years (i.e. the maximum design life of the proposed EOWDC). Piled foundations will be cut below the seabed and anything above this will be removed. Suction and gravity base type foundations will be fully removed. It is likely that the subsea cables would be left buried and notified as being disused, and therefore no associated impacts are anticipated. Removal of cables is not intended except where surveys before decommissioning identify a risk of them becoming uncovered.

46 It is anticipated that the decommissioning approach would follow industry standards at the relevant time in the future. The expected effects of decommissioning activities are expected to be broadly similar to those associated with the construction phase (OSPAR, 2004).

1.3.1 Water Quality Impairment (Release of Contaminants)

1.3.1.1 Construction & Decommissioning Phase

Potential Impacts

47 Barges, tugs, jack-up rigs and other support vessels will be required to transport components to/from site and assemble/remove them on site (further details in Chapter 3, Description of the Proposed Development).

48 There is potential for contaminants to be accidentally released directly during the construction and decommissioning works, including drilling lubricants, degreasing agents and detergents from vessels, as well as subsequent release of sewage, ballast water, chemicals (oil). If grout and anti-fouling paints are to be used, then grout spills can alter the pH of the local environment temporarily, whereas biocides are, by their nature, toxic to marine species. A consequent impairment of water and sediment chemical quality might arise. Adherence to regulatory operational standards such as MARPOL 73/78, the UK Merchant Shipping (prevention of pollution) Regulations 1983 and the Merchant Shipping (Prevention of Pollution by Garbage) Regulations 1988, UK Offshore Chemical Regulations 2001 will ensure that such a potential release is minimised. Any potential discharges are likely to be very localised and short-term in duration. In addition, the proposed EOWDC development is located in an area of high hydrodynamic energy and a high level of dispersion and dilution of any contaminants is expected. The overall magnitude of this effect is therefore assessed as negligible.

49 The construction and decommissioning works (including cabling) will re-suspend seabed sediment, with the potential for any sediment-bound contaminants to be released into the water column, impairing water quality. Data from sediment analyses (CMACS, 2010) show that no significant sediment contamination has been detected, therefore this issue has been scoped out of the assessment.

50 If an accidental spillage occurs, there may be potential adverse biological effects of contaminant release on subtidal benthos, fish and shellfish receptors.

51 Possible toxic effects on subtidal benthos would be restricted to the immediate area of the construction site (site-specific effect), and the effect would be reversible. The potential impact on benthos has been assessed as of negligible magnitude, the receptor of medium sensitivity (due to the fact that this receptor is sedentary and unable to move away from the effect) and therefore the significance of the impact would be negligible.

52 Contrary to the situation for the most of the benthos, the fish fauna has the ability to escape from the local affected area if conditions become poor, hence its sensitivity to contaminant release is assumed to be lower than for benthos. The potential impact on fish has been assessed of negligible magnitude, the receptor of medium to low sensitivity and therefore the significance of the impact would be negligible.

Mitigation

53 No additional mitigation for this impact is required.

Residual Impacts

54 The residual impacts have been assessed as of negligible significance.

Cumulative Impacts

55 As any impacts would be extremely localised and, given adherence to operational standards, unlikely, cumulative impacts are not expected.

In-Combination Impacts

56 No in-combination impacts are predicted.

Monitoring

57 No specific monitoring is required.

1.3.1.2 Operational Phase

58 This impact is unlikely to occur during the operational phase.

1.3.2 Sediment Resuspension / Redeposition

1.3.2.1 Construction & Decommissioning Phase

Potential Impacts

59 Activities during foundation installation and removal of the above-seabed structures are predicted to generate levels of suspended sediment above those found naturally. In terms of the volume of sediment disturbance, the worst case scenario is based on the installation/removal of the 11 x 10 MW wind turbine array as a single phase, with gravity base foundations used (see Coastal Processes Assessment, Section 8. Further sediment resuspension and deposition will also result from the cable laying activities in the proposed development area.

60 The surface sediments over the majority of the proposed EOWDC site comprise fine sand, and any disturbance to such sediments is likely to result in bed-load transport rather than in suspension. Given the weak tidal currents in the area (responsible for the sediment transport offshore) (ABPmer, 2011), it is likely that, following disturbance by the bed levelling process, sandy material would fall close to the point of disturbance and

then become part of the active baseline sedimentary regime. However, areas with a higher proportion of silt content also occur within the lease boundary of the proposed wind farm site. Disturbance of finer material from this area would result in fine sediments being transported in suspension and dispersing over a wide area. It is likely that the main effects would be restricted to the EOWDC area (and the areas around the cables) given the localised nature of the sediments that might be resuspended and the probability of relatively local dispersion. Consequently, an assessment of the potential effects of the increase in suspended sediments can be limited to those receptors that exist within the proposed EOWDC site.

61 Potential adverse biological effects of sediment resuspension/redeposition in the aquatic system may affect subtidal benthos, fish and shellfish receptors.

62 Raised levels of suspended sediment may impact benthic communities through clogging of respiratory and feeding mechanisms. Sediment displacement may cause smothering of the bed and the benthos in the immediate area of the construction/decommissioning site (Hiscock *et al.*, 2002; Metoc Plc, 2000; OSPAR, 2004). Sediment displacement may also lead to temporary changes in the characteristics of the sediments, such that they no longer provide an optimum habitat for existing communities to function. However, benthic communities in circalittoral sands are generally well adapted to high energy conditions and will tolerate changes such as sediment disturbance, increased turbidity or increased levels of suspended sediments relatively well, with an ability to recover rapidly in the case of strong impacts (Kaiser & Spencer, 1996; Elliot *et al.*, 1998; Connor *et al.*, 2004). This is confirmed by the assessment of the sensitivity of the benthic communities in the proposed development site with respect to the sediment disturbance carried out on the basis of data given in MarLIN (Appendix 1). None of the biotopes present are sensitive to increased suspended sediment loads, are of only low sensitivity to sediment disturbance, and are expected to recover immediately after smothering. Consequently, <u>the potential impact on benthos has been assessed as of low magnitude, the receptor of low sensitivity and therefore the significance of the impact would be negligible</u>.

63 An increase in sediment loads above background levels caused by the construction and decommissioning activities has the potential to locally affect fish and shellfish receptors in the proposed EOWDC site. It is likely that mobile fish in the vicinity of any excavation and piling work would temporarily move from the area as soon as noise levels increase and would, therefore, not be exposed to the greatest increases in suspended sediment levels that would arise locally. Effects on non-mobile organisms (e.g. many shellfish) are expected to be greater as they are less able to escape from the affected area if conditions become poor. However, no significant populations of sedentary shellfish were recorded within the proposed development site. Given the relatively homogeneity of the benthic habitat in this coastal area, escaping fish are likely to find similar habitats in adjacent, unaffected, areas (e.g. suitable nursery habitats for flatfish). Although there are no direct data to describe this, indications on habitat use and population levels in these surrounding areas would suggest that there is some assimilative capacity here for displaced populations. As such, these adjacent areas may be capable of buffering

the local and temporary impairment of the habitat within the proposed development area. Furthermore, the species recorded in the baseline surveys will to some extent be adapted to regular increases in suspended sediments above background levels due to the natural conditions that exist in the Aberdeen Bay. In fact, suspended sediments in this area are relatively high compared to many other UK coastal areas with significant fluctuations resulting from tidal or weather (storm) events.

64 Increased sediment deposition may also lead to potentially adverse impacts upon fish spawning habitat, with particular regard to demersal spawners (e.g. sandeel and herring). Deposition of sediment (and particularly fine sediment) onto such habitats may reduce water flow to the eggs and subsequently reduce their oxygenation. However, only low levels of deposition are likely to occur within the proposed EOWDC site and outside the site boundaries deposition would be negligible. In addition, no specific spawning grounds were detected in the proposed development area.

65 Based on the fact that (a) the effects will be temporary and localised; (b) no important spawning or nursery grounds are present or are strictly localised within the proposed development area; (c) the majority of fish resources recorded within the site are typical of the wider region, already adapted to natural increases in suspended sediment levels, and mobile, the potential impact on fish has been assessed as of low magnitude, the receptor of low to medium sensitivity and therefore the significance of the impact would be negligible to minor.

Mitigation

66 Given the negligible to minor significance of the impact, no specific mitigation is required.

Residual Impacts

67 The residual impacts have been assessed as of negligible to minor significance.

Cumulative Impacts

68 The additional impacts arising from the construction and decommissioning of the Ocean Laboratory on the proposed EOWDC site are likely to be of lower significance than those caused by the wind farm development, given the smaller scale of the Ocean Laboratory. Given the negligible to minor impact identified during wind farm development construction, it is unlikely that there would be the potential for significant cumulative impacts particularly as construction periods for the proposed installations are unlikely to overlap. This would also be the case for the decommissioning phase.

In-Combination Impacts

69 None anticipated.

Monitoring

70 The coastal processes studies for the proposed EOWDC identified that even for the worst case development scenario suspended sediments levels are expected to be within naturally occurring ranges, therefore there is not anticipated to be any advantage in monitoring this aspect.

1.3.2.2 Operational Phase

71 This impact is not expected to occur during the operational phase.

1.3.3 Habitat Loss

1.3.3.1 Construction & Decommissioning Phase

Potential Impacts

72 As highlighted in Section 1.3.1, barges, tugs, jack-up rigs and other support vessels will be required to transport material for the foundations/piling, together with the turbine components themselves to the site. The legs of jack-up barges and the anchorage of construction vessels are likely to result in physical disturbance and abrasion and/or displacement of the seabed with a consequent habitat loss occurring. Although the exact method of wind turbine placement has yet to be finalised, it is likely that jack-up rigs would be required with the worst case scenario involving the installation of the 11 x 10 MW wind turbine array. Footprint area will depend on the final vessel set-up, and the worst case scenario has been assumed to be a maximum of 12 (6 legged jack-up and 6 legged barge) footprints per turbine. Taking into account multiple operations, this could entail an area of impact of up to 4200 m^2/turbine. This would lead to a seabed disturbance area corresponding to 0.2% of the total proposed EOWDC area (20 km^2). Coastal process modelling for the proposed EOWDC demonstrates that the impacts upon the seabed from construction and decommissioning are considered to be of negligible significance.

73 Temporary habitat loss will also arise both in the intertidal and subtidal areas following cable lying. Cables running both between the turbines and to the shore are generally placed in trenches and buried in order to prevent damage to the cable and to prevent disturbance to fishing activities. Options for cable laying include trenching prior to cable laying or by ploughing or jetting directly into the sediment (further details in Chapter 3, Description of the Proposed Development). Each of these methods may be employed in the proposed EOWDC site, although ploughing and jetting are most appropriate to the substrate in the area. Furthermore, the movement of heavy construction vehicles on the intertidal area could cause churning and/or compaction of the surface sediment, resulting in further habitat loss (further details in Chapter 3, Description of the Proposed Development) , the worst case impact, in relation to direct substratum loss in the subtidal and intertidal area, would result from ploughing, with a loss of 10.38 m^2 of habitat per meter of cable laid (including the likely footprint of equipment used). This would lead to a total seabed loss of 0.27 km^2 from the export cable laying (max 26 km total length), and a 0.13 km^2 from the inter-array cable laying (max 13 km total length), this latter area corresponding to 0.7% of the proposed lease boundary. The depth of impact is anticipated to be up to 3 m but final working depth would be based on further studies and suited to the seabed conditions. Any loss will be temporary as, once instated, the sediment would either be backfilled or re-deposit naturally over the cables.

74 Construction activities, in particular foundation installation, will lead to further seabed habitat loss directly within the footprint of these structures. This impact is dealt in detail in Section 1.3.3.2.

75 Potential adverse biological effects of temporary habitat loss will affect benthic communities, both in the subtidal and in the intertidal areas.

76 Impacts on the subtidal benthic ecology would include damage or mortality to invertebrate species (Hiscock *et al.*, 2002). Due to the relatively small area affected at any one time, recolonisation may be rapid after the construction/decommissioning activities have ceased. Within the proposed development area one biotope type, SS.SSA.CMuSa.AalbNuc, has been identified. The higher level biotope SS.SSA.CMuSa of which SS.SSA.CMuSa.AalbNuc is a component is designated as a UK BAP priority habitat. However, the Level 4 biotope SS.SSA.CMuSa.AalbNuc is not uncommon in the wider Aberdeen Bay area, and although *Abra alba* is a common food source for *Asterias rubens* and different species of demersal fish (MarLIN, http://www.marlin.ac.uk/habitatimportance.php), it is not considered to have an especially high ecological importance at the local scale. In addition, the biotope is considered to have a high recoverability, and only a small percentage of the total benthic habitat in the proposed development area is expected to be lost (<1%, considering both foundation and cabling activities). Furthermore the impact will be temporary as it is expected that much of the seabed would be returned to a similar physical condition soon after the disturbance ceases. As such the potential impact on subtidal benthos has been assessed as of low magnitude, the receptor of low to medium sensitivity and therefore the significance of the impact would be negligible to minor.

77 A localised (site-specific) and temporary impact on intertidal benthos would arise from the laying/removal of the export cable route. Although the exact location of the cable route is currently unknown, as this is dependent on the location of the onshore substation, available data show that the coast in this area is characterised by moderately exposed sandy beaches, with the intertidal fauna dominated by haustorid amphipods (*Haustorius arenarius* and *Bathyporeia pelagica*) and in some cases the spionid polychaete *Scolelepis cirratulus* (Hart, 1971). According to the JNCC biotope classification, this habitat matches with the biotope LS.LSa.MoSa.AmSco (Amphipods and *Scolelepis* spp. in littoral medium-fine sand) (Connor *et al.,* 2004), occurring in coarse sandy beaches on exposed and moderately exposed shores, with sediment grain sizes ranging from medium to fine, often with a fraction of coarser sediment. The recoverability of this biotope from substratum damage is considered to be high, as is its recoverability from smothering (MarLIN).

78 Observations of the temporary habitat disturbance and benthic recolonisation following pipe laying operations carried out in the Lavan Sands near Bangor (North Wales) highlighted a continual repopulation of the disturbed area by mobile organisms, such as the gastropod *Hydrobia ulvae*, during the construction works, and a rapid post-disturbance recolonisation (Rees, 1978). Several species, including the polychaetes *Arenicola marina*, *Eteone longa* and *Scoloplos armiger* were recruited preferentially to the disturbed area. Longer lived species (e.g. *Scrobicularia plana*) showed higher depression of their numbers, lower recruitment and took several years to return in significant numbers after

the pipeline operations had been completed (Rees, 1978; Hiscock *et al.*, 2002). However, for the proposed EOWDC, such an effect is likely to be negligible, as larger, longer lived, usually sedentary species are not found with significant abundances in the exposed shores along Aberdeenshire coast. In turn, the recolonisation of the disturbed intertidal areas by opportunistic species along the Aberdeenshire coast, following the completion of the proposed EOWDC development construction and decommissioning activities, is expected to be rapid, hence the effect would also be reversible over the short to medium term. <u>The potential impact on intertidal benthos has then been assessed as of low magnitude, the receptor of low to medium sensitivity and therefore the significance of the impact would be negligible to minor.</u>

Mitigation

79 Given the negligible to minor impact assessed, no specific mitigation measures are required. However, good construction practices will be discussed with contractors and could include backfilling trenches to just below the adjacent beach surface level to allow natural accretion to fill the upper surface.

Residual Impacts

80 Residual impacts of negligible to minor significance are expected which will be reversible.

Cumulative Impacts

81 The additional impacts arising from the construction and decommissioning of the Ocean Laboratory on the proposed EOWDC site are likely to be of lower significance than those caused by the wind farm development. Furthermore, the supply cable from the Ocean Laboratory to shore is likely to be routed via the main wind farm export cable route, potentially installed in the same trench. Given the minor impact identified during wind farm development construction/decommissioning, it is unlikely that there would be the potential for significant cumulative impacts particularly as construction periods for the proposed installations are unlikely to overlap.

In-Combination Impacts

82 None envisaged.

Monitoring

83 No specific monitoring planned.

1.3.3.2 <u>*Operational Phase*</u>

Potential Impacts

84 The installation of wind turbine foundations will lead to permanent habitat loss directly within the footprint of the turbines, supporting structures and any protection. The extent of such impacts will be highly dependent on the final choice of the structures to be installed (wind turbines, foundations and scour protection). Due to the greater extent of the total footprint and the requirement for seabed preparation/levelling, the installation of 11 × 10 MW wind turbines with gravity base foundations has been considered to have the greatest potential impact on the seabed communities, with the 'worst worst-case' scenario assuming that no scour protection is provided (according to the coastal process assessment for the proposed EOWDC). Each gravity base foundation area (including scouring) would be a

maximum of 1865 m^2, leading to a total loss of 0.03 km^2 seabed area within the lease boundary, corresponding to 0.17% of the lease boundary (including foundation + scour footprint) (see Section 8.2). Not taking in to account potential scouring or scour protection the total habitat loss from each gravity based structure would be 1,257 m^2 with a total loss of 0.0138 km^2 seabed area corresponding to 0.07% of the lease boundary. In areas of mobile sands, such as those present within the proposed development site, the substratum exposed by scour is likely to be of a similar type to that naturally present, although the high current speeds in the development area may cause a reduction in sediment fines in any scour pits. However, as scour develops and reaches equilibrium, instability is unlikely to occur for more than 12 hours at any foundation location (see Section 8.2).

85 Potential adverse biological effects of permanent habitat loss within the footprint of the wind farm structures will affect subtidal benthic communities, fish and shellfish.

86 The permanent loss of seabed will affect the infaunal component of the benthic community. In the case of this development, the soft sediment communities present will include the robust polychaetes and bivalves. The less mobile epifaunal organisms will also be affected, such as the abundant brittle stars in the area. More mobile epifaunal organisms (such as shrimps and crabs) are likely to avoid any direct effects by moving away from the affected area.

87 The direct habitat loss that will occur within the proposed lease boundary will be the SS.SSA.CMuSa.AalbNuc biotope. This will include a direct loss of 0.17% of the biotope within the proposed development area (assuming a worst case of 40 m diameter gravity base foundations and associated scour). The higher level biotope SS.SSA.CMuSa includes SS.SSA.CMuSa.AalbNuc which is designated as a UK BAP priority habitat. However, given the extent of the Level 4 biotope in the wider area, it is not considered to be of particular ecological importance at the local scale, and as such, the overall impact of the direct habitat loss on benthic communities in the development area will be small, although permanent. The potential impact on subtidal benthos has been assessed as of low magnitude, the receptor of medium sensitivity and therefore the significance of the impact would be minor.

88 Direct habitat loss within the footprint of the proposed development structures may potentially impact sensitive habitats such as fish and shellfish spawning and nursery grounds. Broad scale studies place the proposed EOWDC site within spawning and nursery habitats for a number of commercial and non-commercial species (Coull *et al.,* 2008; CEFAS, 2010b). However, baseline studies did not identify the proposed development site as being of particular importance to fish and shellfish communities. No ‘hot spots’ of biodiversity or important sensitive habitats, such as spawning and nursery grounds, were detected in the proposed development area. Furthermore, with respect to non-commercial species, such as dragonet and gobies, the potential loss of spawning and nursery habitat from the proposed wind farm development would represent a negligible proportion of similar habitat for these species, as these habitats are ubiquitous throughout the Aberdeen Bay strategic area. The same conclusion has been reached for some commercial species, such as

flatfish, which have potential nursery areas extending in the shallow waters along Aberdeenshire coast, and which may buffer any local nursery habitat impairment from the proposed EOWDC.

89 As such, the loss of potential sensitive habitats due to the installation of the main wind farm structures is likely to be a very small proportion of similar habitats in the wider area. Furthermore, no significant spawning grounds, e.g. for sandeel, herring or Norway lobster, have been identified in the proposed development area and in its surroundings, possibly due to these species' preference for coarser (as for sandeel and herring) or muddier (as for *Nephrops*) sediments than those in the survey area. No significant populations of these species were found in the proposed development site during the epibenthic surveys carried out to assess the baseline conditions. The surveys suggest the minor importance of the site as feeding ground for other important predator species, such as Atlantic salmon and sea trout (sandeel and herring being important prey for such fish species). Given the above considerations, the potential impact on fish has been assessed as of low magnitude, the receptor of medium sensitivity and therefore the significance of the impact would be minor.

Mitigation

90 Given the minor impact assessed, no specific mitigation is required.

Residual Impacts

91 Residual impacts of minor significance are expected.

Cumulative Impacts

92 The additional impacts arising from the construction and decommissioning of the Ocean Laboratory on the proposed EOWDC site are likely to be of lower significance than those caused by the wind farm development. Given the minor impact identified during wind farm development construction/decommissioning, cumulative impacts will also be of minor significance.

In-Combination Impacts

93 None envisaged.

Monitoring

94 No specific monitoring planned.

1.3.4 Effects of the Physical Presence of the Submerged Structures

1.3.4.1 Construction & Decommissioning Phase

Potential Impacts

95 This impact is likely to occur during the operational phase.

1.3.4.2 Operational Phase

Potential Impacts

96 The presence of the wind turbine and their foundations is likely to modify the hydrodynamic regime around the development site (Elsam Engineering A/S and ENERGI E2 A/S, 2005; OSPAR, 2006). The resistance from the

foundations can influence the current and wave conditions in the wind farm area, leading to possible alteration to the character of the topography of the seabed in terms of sand wave redistribution, although this latter impact is expected to be local. However, the coastal process (see Section 8.2) modelling work has shown that impacts upon tidal currents and residual flows as a result of the proposed EOWDC will be of negligible significance.

97 The physical presence of foundations, turbines and any scour protection will provide an artificial reef structure for colonisation by aquatic organisms, known as the "reef effect" (Wilson, 2007).

98 Potential biological effects of the physical presence of the wind farm structures may affect subtidal benthos, and fish and shellfish communities.

99 The submerged wind turbine structures are likely to provide a new habitat for colonisation by epifaunal and encrusting species, as well as by fish, thus leading to changes in the benthic and fish communities in the area (Hiscock *et al*., 2002; Lewis *et al.,* 2002; OSPAR, 2004). Based on the epifaunal communities present in the area, colonisation by bryzoans, sponges, hydroids and the encrusting polychaete *Pomatoceros* spp. is likely, together with several decapod, mollusc and echinoderm species. Infaunal organisms, or those requiring some sediment, may colonise areas of sediment deposition between rocks. Colonisation of the wind turbines by encrusting organisms may provide a new food source for local fish and shellfish and may also create new habitats that could provide refuges for many fish species. Once fully installed and operational, the wind turbine structures would form a hard substratum that did not exist previously in the area and which would be colonised quickly by communities of benthic organisms and other associated species including commercially important species of fish and shellfish. The overall effect of the foundations and scour protection will be to replace small areas of the existing sandy biotopes with typical hard substrate epifaunal communities. This is likely to increase (albeit extremely locally) the overall species diversity and productivity (Wickens & Barker, 1996; Grossman *et al.,* 1997; OSPAR, 2004). Epibenthic colonisation is dependent upon water depth, hydrography and the degree of scour, with the greatest degree of colonisation being associated with areas of more stable substrata. It should be noted that changes to the sediment properties as a result of scour may prevent recovery of the original benthic community, although they may possibly increase local biodiversity and may also provide a food source for fish and crustaceans (Hiscock *et al*., 2002).

100 Bio/Consult (2004b, 2005b) concluded that the epifauna on the turbine foundations at the Horns Rev Offshore Wind Farm off the Danish coast led to an eight-fold increase in biomass compared with the typical soft sediment fauna of the area (even though the colonisation on the turbines appeared not to be particularly high in this area due to strong scouring effects). Monitoring reports from other offshore wind farm sites describe the invertebrate recolonisation succession, with common mussels, barnacles (Cirripediae) and red macroalgae dominating the fouling community in the wind farm submerged structures in the first year after the structure deployment (Birklund, 2005; Leonhard and Pedersen, 2005). The organisms that develop on submerged wind farm structures may provide a new, direct food source for certain fish and shellfish species. Alternatively, encrusting species may attract small organisms, such as

mantis shrimps, to graze upon the wind turbines, and these species would themselves be a potential food source for larger fish species. For example, the new hard substrate communities may provide a valuable food source for fish species such as North Sea cod and pout (Bouma and Lengkeek, 2009). The use of wind turbine foundations as spawning and nursery grounds has also been suggested following the observation of the presence of abundant juvenile crab species and egg masses of invertebrates on the foundations and scour protection (Leonhard and Pedersen, 2005).

101 Wind turbines may also produce some form of aggregation of local fish stocks, acting as Fish Aggregation Devices (FAD) (CEFAS, 2010a). This effect has been observed, for example, at the Burbo Bank offshore wind farm, in Liverpool Bay at the mouth of the River Mersey (CEFAS, 2010a).

102 Based upon the evidence from monitoring programmes at existing offshore wind farm sites, there is a possibility that the submerged structures in the proposed EOWDC site would provide a new habitat leading to a positive impact on the benthic biodiversity and also attracting certain fish and shellfish species. However, although the overall effect of the hard structures is considered to be positive, it is considered as localised and it is judged unlikely that populations as a whole in the area would increase above existing levels. The potential impact on benthos, epibenthos and fish has been assessed as of low magnitude, the receptor of low sensitivity and therefore the significance of the impact would be negligible (although positive).

103 The physical presence of wind turbine structures might also adversely affect the shoaling behaviour of pelagic fish, such as sprat and herring, leading to possible dispersal of shoals. Sprat and herring exhibit shoaling behaviour throughout their life cycle for a number of reasons, including aiding migration to spawning grounds and increasing protection from predators. Consequently, a disruption to shoaling activity or behaviour as a result of the presence of wind turbines may potentially have an adverse effect on the local ecology of these species. However, there is relatively little evidence to prove or disprove the claim that offshore wind turbines may disrupt shoaling behaviour. In reality, if a large shoal of pelagic fish does come across a wind turbine, or multiple wind turbines, it is judged unlikely that the integrity of the shoal would be significantly adversely affected. Such behaviour may occur naturally (e.g. due to the presence of wrecks or other underwater obstructions) and whilst the shoal may become temporarily fragmented it is likely that the strong behavioural instinct to reform the shoal would result in the shoal integrity being restored quickly. Based upon the considerations above in relation to shoaling behaviour and the potential spacing of the wind turbines in the proposed EOWDC site, the potential impact on fish has been assessed as of low magnitude, the receptor of low sensitivity and therefore the significance of the impact would be negligible.

Mitigation

104 No mitigation is required for this impact.

Residual Impacts

105 The residual impact is assessed as of negligible significance.

Cumulative Impacts

106 The additional impact arising from the physical presence of the Ocean Laboratory on the proposed EOWDC site is likely to be of lower significance than that one caused by the wind farm development. Given the negligible impact identified for the wind farm development, it is unlikely that there would be the potential for significant cumulative impacts.

In-Combination Impacts

107 The potential direct and indirect impacts of the proposed development on salmonid, and indirect impacts on freshwater pearl mussel, populations of the River Dee and River South Esk SACs have been addressed within the salmon and sea trout assessment for the proposed EOWDC.

Monitoring

108 Monitoring will be agreed with the relevant statutory authorities and requirements incorporated into the Marine Licence.

1.3.5 Noise and Vibration

1.3.5.1 Construction & Decommissioning Phase

Potential Impacts

109 Noise is associated with many activities during wind farm development, e.g. construction works, vessel movements, piling activities, etc. It is in respect of pile-driving that the greatest levels of noise are likely to arise, being predominantly low frequency underwater noise, that can travel large distances and that can lead to acute short term disruption of the marine fauna (Hiscock *et al.*, 2002; Nedwell *et al.*, 2007, 2011; OSPAR, 2008). Other sources of noise, such as for example rock dumping (for provision of scour protection), cable trenching of inter-array cables, or increased vessel traffic during construction/decommissioning activities are unlikely to contribute significantly to background noise (which might be relatively high, due for example to the large volumes of shipping already occurring in the area) or to provoke significant effects on marine fauna (Nedwell *et al.,* 2003).

110 In the context of the construction/decommissioning of the proposed EOWDC development, the worst case scenario is assumed to be the installation of the largest piles (8.5 m) (Nedwell *et al.*, 2011). This has the likely potential to cause disturbance over the greatest distances, although on a reduced number of occasions (Parvin *et al.,* 2006). According to the underwater noise modelling carried out in support of the EOWDC and accounting for the worst case scenario, the expected peak to peak Source Level of this pile driving operation will be around 250 dB re 1 µPa @ 1 µm, with a propagation with lower losses in deeper waters, out to the east of the proposed development site (Nedwell *et al.*, 2011).

111 Potential biological effects of the underwater noise produced during construction works could affect subtidal benthos, and fish and shellfish communities.

112 The impacts of noise during wind turbine array construction upon the benthic communities are not well understood (Metoc Plc, 2000; OSPAR, 2009b). There have been no specific investigations on the effects of marine construction and industrial activities on marine invertebrates (OSPAR, 2009b). However a certain amount of physical damage to invertebrate organisms living in close proximity to pile driving activities is expected. The effects of the pressure wave will be higher on sessile invertebrates, as the more mobile benthic organisms would be able to move away from the area. Significant impacts such as mortality of larval fish and crustaceans are likely to be constrained to within a few metres of the piling activity (Dr J Allen, pers. comm.). However, recruitment to areas where damage could have occurred is likely to be rapid due to the presence of other benthic organisms in the vicinity. The potential impact on benthos has been assessed as of low magnitude, the receptor of low to medium sensitivity and therefore the significance of the impact would be negligible to minor.

113 The approach to the assessment of the resulting effects on fish in the United Kingdom is to concentrate on times when fish can be considered to be at their most vulnerable to noise disturbance (e.g. spawning seasons, migration, etc.) for those species at risk on a case by case basis (OSPAR, 2008). Fish are receptive to noise with hearing and the detection of vibrations being two of their most developed senses. Typically fish hear at very low frequency (typically 10 Hz to 1000 Hz) (Nedwell and Brooker, 2008). Different species of fish have different hearing abilities, the main reason for this being ascribed to adaptive physiology. According to this, fish have been distinguished as hearing “specialists” (having specialisations that enhance hearing, as for example swim bladder or gas filled bullae) and “generalists” (not having such specialisations). Hearing “specialists” tend to detect sound pressure with greater sensitivity and in a wider bandwidth than “generalists”. In particular, herring and sprat are considered as highly sensitive species to noise; species like dab, plaice, salmon and sandeel are considered to have low sensitivity to noise and vibrations, whereas intermediate sensitivity is reported for gadoids (cod, haddock, hake), mackerel and eel (Nedwell *et al.,* 2003).

114 The noise associated with the construction of offshore wind farms (particularly piling noise) may affect marine fish through immediate or delayed fatal injuries (often caused by ruptures to swim bladders in fish, or gas sacks of some larval stages), other injuries such as deafness may impact upon survival, and through behavioural effects (including avoidance). In the case of high intensity sound, damage effects on the air-filled body spaces may occur, leading to possible mortality.

115 The negative effects on fish arising from piling noise produced during the construction works are likely to be limited to within a predictable distance from the source of noise. According to the underwater noise modelling carried out in support of the EOWDC, lethal effects are expected out to a range of 3 m from the piling works, whereas the expected distance for physical injuries is 60m (Nedwell et al., 2011). However, it must be considered that fish are able to move away from the disturbed area. A minimum safe standoff distance from piling operations has been estimated as of 1750 m for hearing specialists like herring, and of 20 m for hearing generalists like dab (Nedwell et al., 2011). According to this information, and as dab and plaice are the most common fish species in the area

(Baseline Technical Report 2011), it is likely that the great majority of fish would vacate the area before significant damage is done, and that impacts would generally be of low magnitude. A 'soft start' to piling, whereby the power of the piling activity is increased slowly over time, should allow fish to move away from the site prior to noise levels increasing, reducing the risk of lethality and possible physical impairment.

116 The spatial range within which behavioural disturbance to fish is present has also been calculated by Nedwell *et al.* (2011). The maximum estimated range from piling is of 20-24 km for herring, extending mainly out to the east of the site (given the higher attenuation in shallow waters), whereas it is around 6 km for dab. Disturbance to flatfish populations is likely to be low, given the low sensitivity of these demersal species to noise disturbance. In turn, disturbance of herring during their spawning period (autumn) could potentially have effects upon the overall reproduction for the year. No important spawning grounds of the species are present directly on the proposed development site, but no specific data on their presence in the surroundings are available. However, this sensitive habitat might occur offshore within the area of disturbance from piling noise, given the presence of suitable sediment types (gravelly sands) for herring spawning 15-20 km offshore from the proposed EOWDC area (Seazone Hydrospatial Data, 2011). Therefore, although there is every likelihood that the impactis likely to be negligible to minor, the absence of data to categorically demonstrate an absence of spawning sites within the area of effect means that a precautionary approach is required, and as such there is the possibility that the significance of the impact is moderate on spawning populations of herring along the coast in Aberdeen Bay.

117 Underwater noise generated during construction could have a physiological or lethal effect particularly on young fish (eggs and larvae). A conservative estimate of 230-240 dB re 1 µPa @ 1m has been used as a limit for likely significant levels of damage to young stages of fish (Gausland, 2003). According to the estimates obtained by Nedwell *et al.* (2011) for the proposed EOWDC, 240 dB would be reached within approximately 3 m of an 8.5 m monopile. Hence, as a conservative but also very simplistic estimate, the mortality of all eggs and larvae may be assumed within the 3 m radius of piling. However, considering that the mortality levels characterising fish eggs and larvae are naturally high, such an effect over a wider marine ecological context would be negligible.

118 A potential impact of underwater noise production (mainly by piling activities) might also affect salmonid migration routes in the area. This aspect is assessed in the salmon and sea trout assessment for the proposed EOWDC..

119 Given the above considerations, the potential impact on fish has been assessed of low to possibly medium magnitude, receptor of medium sensitivity and therefore the significance of the impact would be minor to possibly moderate. The latter classification mainly derives from the aforementioned precautionary approach adopted in the assessment of the possible effect on herring spawning grounds, given the lack of specific data on their local distribution within the area of influence of the impact.

Mitigation

120 No additional mitigation is required.

Residual Impacts

121 Residual impacts on benthos will be of negligible to minor significance and are expected to be of a short-duration. Given that the construction effects are likely to be short-term, intermittent and of low to medium magnitude, residual impacts on fish are anticipated to be of minor significance, although a possibly moderate significance is acknowledged, following the aforementioned precautionary approach.

Cumulative Impacts

122 Given that the additional impacts arising from the construction and decommissioning of the Ocean Laboratory on the proposed EOWDC site are likely to be of lower significance than those caused by the wind farm development, and that construction periods for the proposed installations are unlikely to overlap, it is unlikely that there would be the potential for significant cumulative impacts.

In-Combination Impacts

123 The potential direct and indirect impacts of the proposed development on salmonid, and indirect impacts on freshwater pearl mussel, populations of the River Dee and River South Esk SACs have been addressed within the salmon and sea trout assessment for the proposed EOWDC.

Monitoring

124 Monitoring will be agreed with the relevant statutory authorities and requirements incorporated into the Marine Licence. In the case salmon and sea trout, AOWFL will consult with Marine Scotland, Scottish Natural Heritage and the Dee, Don and Ythan Salmon District Fishery Boards in order to identify feasible and relevant monitoring options.

1.3.5.2 <u>Operational Phase</u>

Potential Impacts

125 Current evidence from noise monitoring at operational offshore wind farms suggests that the noise generated is generally at a low frequency, which may be within the best hearing frequency for many fish species, but of a level that is typically lower than sound generated by most vessel activity, even when considering the worst case of 11 x 10 MW operating wind turbines. The noise and vibration produced would increase with increasing wind speeds, with a corresponding increase in background noise levels also expected in these conditions, such that there would be a broadly constant level above background noise (Nedwell and Howell, 2004).

126 Potential biological effects of the underwater noise and vibration produced during the operational phase could affect subtidal benthos, and fish communities.

127 The impacts of noise and vibration during turbine operation, upon the benthic communities are not well understood. A relatively low level of operational noise is expected across all options and it is unlikely that benthic invertebrates would be significantly affected. Certain invertebrate species, including edible crab, have been frequently seen in very high numbers living on the piles of large operating wind turbines. Leonhard and Pedersen (2005) reported a total of 70 invertebrate taxa recorded during

post-construction surveys (in March and September) within the Horns Rev offshore wind farm, including 14 epifaunal species newly recorded within the seabed area. This study also indicated an increase in edible crab and suggested that the wind turbine foundations can function as hatchery and nursery grounds for some species. Several of the species found at Horns Rev are also found across the Aberdeen Bay including the brown shrimp, edible, harbour and hermit crab. The potential impact on benthos has been assessed as of low magnitude, the receptor of low sensitivity and therefore the significance of the impact would be negligible.

128 Operating wind turbines would produce near field noise and vibration which may be detected by fish using their lateral line systems. As fish are thought to use particle displacement (i.e. vibrations caused by the back and forth movement of water molecules) for prey (and predator) detection, it is possible that the operating wind turbines would disguise such signals. However, Hoffman *et al*. (2000) state that the regular, low-frequency hydrodynamic fields generated by operating wind turbines are likely to be perceived very differently by fish in comparison to the fields generated by animals.

129 Herring has a fairly broad response to the low frequency components of underwater sound, with a hearing threshold at levels below 80 dB re 1 µPa (Enger 1967), and as such may potentially detect such noise. Other fish species tend to have much poorer hearing and the noise levels generated by the operating wind farm may be below that required in order to stimulate an avoidance response. Gadoid species such as cod have been shown to aggregate around noisy underwater structures such as operational oil and gas rigs (Valdemarsen 1979; Soldal *et al*., 2000). This is because the cod either habituate to the operational wind turbine noise, or tolerate it because of the benefits provided (e.g. shelter from currents or an increase in food source). Post-construction surveys for fish and benthic invertebrates within the Horns Rev wind farm recorded a number of species which included hearing-sensitive species such as the sprat and mackerel, and schools of cod (Elsam Engineering A/S and ENERGI E2 A/S, 2005).

130 The potential impact on fish has been assessed as of low magnitude, the receptor of low to medium sensitivity and therefore the significance of the impact would be negligible to minor.

131 There is also the possibility that operational underwater noise and vibration might affect salmonid migration routes in the area, but this has been assessed within the salmon and sea trout assessment for the proposed EOWDC.

Mitigation

132 No specific mitigation measure is recommended.

Residual Impacts

133 Residual impacts are assessed as of negligible to minor significance.

Cumulative Impacts

134 No cumulative impacts are anticipated.

In-Combination Impacts

135 None envisaged.

Monitoring

136 No specific monitoring required.

1.3.6 Electromagnetic Fields

1.3.6.1 Construction & Decommissioning Phase

Potential Impacts

137 This impact is likely to occur during the operational phase.

1.3.6.2 Operational Phase

Potential Impacts

138 It was shown by CMACS (2003) that industry standard AC offshore cables (three-core XLPE) do not generate an electric field outside the cable directly. However, a magnetic field is generated in the local environment by the alternating current in the cable, and this generates an induced electric field close to the cable. The potential impacts of electromagnetic fields (EMF) in the marine environment are the subject of ongoing research under the auspices of the Collaborative Offshore Wind Research Into the Environment (COWRIE; Huddleston, 2010).

139 Potential biological effects of the EMF produced during the wind farm operation may affect subtidal benthos and fish communities.

140 The fields produced by the sub-sea power cables used in offshore wind farm developments are within the ranges that could affect the behaviour of electro-sensitive fish species and species sensitive to magnetic fields, although very little information on the importance of any such changes in behaviour is available (OSPAR, 2006, 2008). The main area of concern relates to impacts on electro-sensitive fish species such as elasmobranchs, which may be attracted to the EMF emissions of buried cables or forced to avoid an affected area entirely.

141 The potential for EMF to have similar effects on benthic invertebrates is extremely limited. Although little information is available, it can be assumed that electro- and magnetic-sensitivity is of negligible influence on the behaviour, distribution and orientation of the range of benthic species found within the proposed EOWDC area. This assumption appears to be supported by the results of monitoring studies carried out at Horns Rev (Bio/Consult, 2004a, 2005a) and North Hoyle (NPower Renewables, 2008), which showed no evidence of a change in the benthic community, during operation that could be attributed to the presence of the wind farm. The potential impact on benthos has been assessed as of low magnitude, the receptor of possibly low sensitivity and therefore the significance of the impact would be negligible.

142 Field studies on fish provided the first evidence that operating cables change migration and behaviour of marine animals (Klaustrup, 2006). The potential environmental receptors of EMF impacts include a range of species that are considered to be of up to high level importance (most

elasmobranchs, all migratory and commercial fish species). Gill *et al.* (2009) undertook research on EMF and benthic elasmobranchs and concluded that they can respond to EMF, but that the response is unpredictable and in some instances does not occur, with a degree of species and individual specifics.

143 Magnetic field and field anomalies may be used by fish for orientation especially when migrating (Fricke, 2000). This is the case, for example, for European eel, Atlantic salmon and sea trout juveniles, as reviewed by Gill and Bartlett (2010). Possible effects on salmonids migration are detailed within the salmon and sea trout assessment for the proposed EOWDC and are not considered for the impact assessment in this section.

144 Elasmobranch fish (sharks and rays) are of particular interest to the offshore wind farm industry given their ability to detect very low levels of electromagnetic field. Elasmobranch fish can detect magnetic fields which are weak compared to the earth's magnetic field, these fishes being more than ten-thousand fold as electrosensitive as the most sensitive teleosts (OSPAR, 2009a). In addition it is currently thought that elasmobranch stocks are in decline (Ellis *et al.,* 2005) and whilst the reasons for this are poorly understood (although overfishing is widely perceived to be important) it is possible that the impacts of EMF may contribute to this decline. Hence, these receptors' electro-sensitivity can be considered as high. However, the presence of sharks and rays in the Aberdeen Bay is scarce, as gathered from the Baseline Report 2011, hence the effect is likely to be of low magnitude.

145 Indirect impacts on fish behaviour might arise also from attractive or repulsive electrical fields. An attractive artificial field may induce a food search investigation of seabed by individual animals, hence leading to a waste of energy. A repulsive field, in turn, could have a direct impact by actively repelling animals, thereby interrupting normal behaviour and potentially excluding habitat from use.

146 The orientation of the export cable route in the proposed EOWDC development is considered to be optimal for minimising potential impacts on fish species moving into and out of the Aberdeen Bay from the North Sea, as the corridor runs roughly up the centre and parallel to the coast of the Aberdeen Bay. This would allow access into and out of the Aberdeen Bay from both north and south. The potential impact on fish has been assessed as of low magnitude, the receptor of medium to high sensitivity and therefore the significance of the impact would be minor.

Mitigation

147 No specific mitigation is required. Industry standards and best practice arising out of ongoing research work would be adopted for the EOWDC development where practicable.

Residual Impacts

148 Residual impacts are assessed as of minor significance.

Cumulative Impacts

149 The additional impact arising from the physical presence of the Ocean Laboratory on the proposed EOWDC site is likely to be of lower significance than that one caused by the wind farm development. During the operational phase, the additional impact is likely to be generally minor,

leading to a cumulative impact of minor to moderate significance. In addition, no important fishing grounds are present in the proposed development site, and as such, the possible additional impact on fish and shellfish receptors arising from fishing activities is considered to be low.

In-Combination Impacts

150 The potential direct and indirect impacts of the proposed development on salmonid, and indirect impacts on freshwater pearl mussel, populations of the River Dee and River South Esk SACs have been addressed within the salmon and sea trout assessment for the proposed EOWDC.

Monitoring

151 Monitoring will be agreed with the relevant statutory authorities and requirements incorporated into the Marine Licence.

1.3.7 Heating

1.3.7.1 Construction & Decommissioning Phase

Potential Impacts

152 This impact is likely to occur during the operational phase.

1.3.7.2 Operational Phase

Potential Impacts

153 There is potential for heating effects of cables on the surrounding habitats in the intertidal area (from the export cable) and in the subtidal area (from export and inter array cables). Depending upon the properties of the cables, the electrical current running through them and the thermal resistance of the surrounding sediments, there is potential for temperature increase in the sediments around the cables. Studies in Long island and Connecticut showed that a pair of 4.1 inch diameter sublittoral cables (40 km long; 330 MW; 140 kV direct current) buried to 1.8 m caused an estimated increase in seabed surface temperature of 0.1 ^{o}C and an estimated increase in overlying water temperature of 0.000003 ^{o}C (London Array Ltd, 2005). These cables and conditions are comparable to those at the proposed EOWDC development.

154 Potential biological effects of sediment heating around the cables might impact on the intertidal and subtidal benthos, by affecting the physiology and survival of certain species, or altering the benthic community by leading to emigration or immigration in the impacted area.

155 However, given that the cables will be buried to at least 0.6 m, the overall effect of sediment heating on the intertidal fauna is expected to be low (if detectable) in magnitude and very localised, as the majority of animals in intertidal areas inhabit the top 15 cm (Eleftheriou and McIntyre, 2005). The potential impact on intertidal benthos has been assessed as of low magnitude, the receptor of low sensitivity and therefore the significance of the impact would be negligible. Such an impact would be expected to be largely reversible once operation ceases.

156 It is also likely that the heating effects on the sublittoral conditions associated with both the array and shore transmission cables will be both extremely small, and extremely localised. Such effects may well be below limits of detection, particularly when considered in the context of natural fluctuations in temperatures (London Array Ltd, 2005). The potential impact on subtidal benthos has been assessed as of low magnitude, the receptor of low sensitivity and therefore the significance of the impact would be negligible.

Mitigation

157 No mitigation measures are required.

Residual Impacts

158 The residual impact on intertidal and subtidal benthic communities arising from sediment heating is expected to be negligible and reversible.

Cumulative Impacts

159 The additional impacts arising from the construction and decommissioning of the Ocean Laboratory on the proposed EOWDC site are likely to be of lower significance than those caused by the wind farm development. Furthermore, the supply cable from the Ocean Laboratory to shore is likely to be routed via the main wind farm export cable route, potentially installed in the same trench. Given the minor impact identified during wind farm development operation, it is unlikely that there would be the potential for significant cumulative impacts.

In-Combination Impacts

160 No in-combination impacts are anticipated.

Monitoring

161 Monitoring will be agreed with the relevant statutory authorities and requirements incorporated into the Marine Licence.

1.3.8 EOWDC Future Research and Monitoring Opportunities

162 The presence of a Ocean Laboratory in association with the proposed wind farm development would provide a good opportunity to allow research organisations to undertake long-term environmental studies on several aspects of the marine ecology in the area, as well as monitoring of the actual impacts and of the efficacy of possible mitigation measures applied.

163 Research information on the impacts of noise and vibration on fish, could be initiated in the area for the different project phases.

164 Research into the relative benefits of reef and FAD effects from the newly introduced artificial structures could also be carried out, taking into account their impact on commercial fisheries.

165 On a local scale, these effects can enhance fishing success, or increase fish populations by also supporting fish breeding and recruitment. Hence, research on the role of these newly created habitats and the monitoring of the structure and functioning of associated communities (species richness, biodiversity, functional guilds, population status) over time is suggested.

166 Additional research could also be carried out to determine (and audit) actual operational increases in temperature in the sediments around the cables and its effect on intertidal benthic communities (structure and functioning of the community, behavioural responses).

1.3.9 Summary of Impact Assessment

167 The potential impacts arising from the proposed wind farm development and related to the worst case scenario, as explained before, are summarised in table 2.

Table 2. Impact Assessment Summary

Impact source	Project phase	Receptor	Magnitude of Effect	Sensitivity of Receptor	Significance	Possible Mitigation	Significance after Mitigation	Monitoring	Cumulative / In-combination impacts
Water quality impairment (release of contaminants)	Constr. / Decomm.	Subtidal benthos and epibenthos	Negligible (built-in mitigation measures will be undertaken)	Medium	Negligible	--	Negligible	--	Negligible
		Fish and shellfish	Negligible (built-in mitigation measures will be undertaken)	Low to Medium	Negligible	--	Negligible	--	Negligible
Sediment Resuspension / Redeposition	Constr. / Decomm.	Subtidal benthos and epibenthos	Low	Low	Negligible	--	Negligible	--	Negligible
		Fish and shellfish	Low	Low to Medium	Negligible to Minor	--	Negligible to Minor	--	Negligible to Minor
Habitat Loss	Constr. / Decomm.	Intertidal benthos	Low	Low to Medium	Minor	--	Minor	--	Minor
		Subtidal benthos and epibenthos	Low	Medium	Minor	--	Minor	--	Minor
Habitat Loss	Operation	Subtidal benthos and epibenthos	Low	Medium	Minor	--	Minor	--	Minor

Impact source	Project phase	Receptor	Magnitude of Effect	Sensitivity of Receptor	Significance	Possible Mitigation	Significance after Mitigation	Monitoring	Cumulative / In-combination impacts
		Fish and shellfish	Low	Medium	Minor	--	Minor	--	Minor
Physical Presence of the Submerged Structures	Operation	Subtidal benthos and epibenthos	Low	Low	Negligible	--	Negligible	--	Negligible
		Fish and shellfish	Low	Low	Negligible	--	Negligible	--	Negligible
Underwater noise and vibration	Constr. / Decomm.	Subtidal benthos and epibenthos	Low	Low to Medium	Negligible to Minor	--	Negligible to Minor	--	Negligible to Minor
		Fish and shellfish	Low to Medium	Medium	Minor to possibly Moderate	Noise mitigation at source (e.g. soft-start procedure)	Minor to possibly Moderate	Monitoring will be agreed with the relevant statutory authorities	Minor to possibly Moderate
	Operation	Subtidal benthos and epibenthos	Low	Low	Negligible	--	Negligible	--	Negligible
		Fish and shellfish	Low	Low to Medium	Negligible to Minor	--	Negligible to Minor	--	Negligible to Minor
Electromagnetic fields	Operation	Subtidal benthos and epibenthos	Low	Low	Negligible	--	Negligible	--	Negligible

Impact source	Project phase	Receptor	Magnitude of Effect	Sensitivity of Receptor	Significance	Possible Mitigation	Significance after Mitigation	Monitoring	Cumulative / In-combination impacts
		Fish and shellfish	Low	Medium to high	Minor	--	Minor	--	Minor
Heating	Operation	Intertidal benthos	Low	Low	Negligible	--	Negligible	--	Negligible
		Subtidal benthos and epibenthos	Low	Low	Negligible	--	Negligible	--	Negligible

1.4 Summary

168 This report assesses the possible impacts of the proposed European Offshore Wind Deployment Centre ("EOWDC") off the coast of Aberdeen on the marine ecology present within the development site and within the wider Aberdeen Bay area. The status of different receptors (namely intertidal benthos, subtidal benthos, epibenthos, shellfish and fish) has been assessed against the possible effects arising from the construction, operation and decommissioning activities in the proposed development site.

169 As the details of the main physical structures of the development (e.g. turbine foundations, scour protection, cable array) and installation methods have not yet been decided, the impact assessment has been based on an identified worst case scenario. This has generally been assumed as the installation of 11 turbines and foundations rated at a generative capacity of 10 MW, and with the installation of these occurring over a single phase. Further installation details where applicable have also selected a worst case in terms of the likely highest impact option to individual receptors.

Intertidal Benthos

170 Impacts on intertidal benthos are considered to be restricted to laying/removal (during construction and decommissioning phases) and to the presence (during operational phase) of the export cable connecting the offshore wind farm development to the onshore substation. Cable laying or removal would cause a localised and temporary disruption to the status of the soft sediment intertidal communities along the cable route through direct habitat loss (trenching) and indirect loss (smothering by spoil). However, following instatement, it would be expected that a rapid recolonisation would occur, initially by opportunistic species and then by a more characteristic infauna. Greater impacts are expected on longer-lived sedentary species, due to their lower recoverability rate, but these species are of minor importance in the intertidal benthic assemblage of the moderately exposed shores typical of the Aberdeenshire area. As such, the overall impact is assessed as of minor to negligible significance.

171 Data indicate that an increase in temperature can be also detected in sediments around export cables, and that this might possibly affect the physiology and mortality of benthic species, with subsequent alteration of intertidal benthic communities. Although little information on the effect of small temperature changes on benthic communities is available, any effect is likely to be highly localised and of very low magnitude. As cables will be buried to a depth of around 60 cm or more, i.e. below the depth that most animals occur, impacts are predicted to be negligible.

Subtidal Benthos & Epibenthos

172 Potential impacts on subtidal benthic and epibenthic fauna are expected to arise during the construction phase, due to habitat disturbance and permanent habitat loss, accidental release of contaminants from construction works and underwater noise.

173 Based on a worst case design and installation option for the proposed development and knowledge of the prevailing baseline sediment conditions

in the area (e.g. low sediment contamination levels), impacts from habitat damage and loss are considered likely to be localised and of low magnitude. The benthic biotope present in the potentially affected area has a generally low sensitivity to temporary habitat disturbance, has no particularly high conservation value and is not uncommon in the wider area. Overall subtidal habitat loss impacts during the construction phase have therefore been assessed as of minor significance.

174 Minor issues have been raised with regard to the effects of increased turbidity and sediment re-suspension on benthic and epibenthic subtidal communities during construction. However, given that the infaunal communities in the area are likely to be adapted to naturally high levels of such conditions, impacts are predicted to be of negligible significance. Similar types of impact can be identified for the decommissioning phase, although a lower significance is assessed in this case, due to the absence of a permanent habitat loss (linked to the footprints of installed structure which are expected to be readily recolonised after removal).

175 The operational phase will involve an ongoing ‘habitat loss’, the effects of which are considered of low magnitude. Given the medium sensitivity of the receptor the impact has been assessed as of minor significance. Possible additional issues identified for the operational phase include the effects of underwater noise, electromagnetic fields (EMF) and heat. The potential sensitivity of the receptors has been identified as low and effects during the operational phase have been assessed as of low magnitude. Impact significance is therefore negligible.

Shellfish & Fish

176 Noise and vibration generated during wind farm construction work (mainly from piling) are likely to have the greatest impacts on the fish fauna of an area, potentially leading to injuries, mortalities and behavioural effects. For the EOWDC development, these effects are likely to be short-term and intermittent, and their magnitude is expected to decrease with distance from the noise source. Most fish are able to exhibit avoidance behaviour that can naturally reduce impact levels when conditions become unsuitable. Soft start procedures will allow fish to move away from the noise source before maximum noise levels are reached. Furthermore, the most abundant species in the proposed development area (e.g. flatfish) are believed to have low sensitivity to noise and vibrations, and no significant sensitive fish habitats (spawning or nursery grounds) occur in the proposed development site. Such sound pressure has the potential to propagate outside the proposed development site, and could potentially affect hearing sensitive habitats further offshore (e.g. herrings spawning grounds), although there are no data available on the local distribution of these habitats in the possible range of disturbance of piling noise. Due to this lack of information, it has been necessary to adopt a precautionary approach and an overall assessment of construction noise impacts on fish (using the worst case development scenario) is considered to be of minor to possibly moderate significance.

177 Other potential impacts on fish and shellfish during construction may arise from sediment re-suspension and contaminants release, but these have been assessed as of negligible to minor significance due to their effect being highly localised and temporary. Similar types of impact to those

described above can be identified for the decommissioning phase, although a further lower significance is assessed in this case.

178 Potential impacts on fish during the operational phase mainly arise from electromagnetic emissions associated with cabling, these considered to be being of minor significance. EMFs from subsea cables might interfere with electro-sensitive fish, such as medium sensitive salmonids (medium sensitivity) and elasmobranchs (high sensitivity). However, the presence of sharks and rays in Aberdeen Bay is infrequent hence the effect has been assessed of low magnitude and the impact of minor significance. Impact on migrating salmonids is assessed in detail within the salmon and sea trout assessment for the proposed EOWDC.. Cable burial can provide a possible mitigation to such an impact, and, given the current general paucity of information, it is considered that industry standard mitigation measures should be implemented at the time of construction/operation. Residual impacts are therefore considered to be of minor significance.

179 Other potential impacts to fish and shellfish may arise from underwater noise generated during operational activities, whilst the presence of seabed/water column structures could affect shoaling behaviour of pelagic fishes. However these impacts are considered to be of low magnitude, due to the generally low disturbance intensity (for noise) and temporary effect (for shoaling disruption). A further impact could arise from the “reef effect” and “FAD effect” associated with the presence of the artificial hard substratum structures. However this impact is assessed as being positive (providing new habitat which would be of value for many fish and shellfish), although given the extent of such features within the wider development site, any positive effects would be negligible.

Cumulative impacts

180 Potential cumulative impacts arising from the possible presence of other activities and installations in the proposed development area have been assessed. However, no other such plans or projects were identified near the proposed development site, except for the proposed Ocean Laboratory, which should be installed on the wind farm site itself. Additional impacts arising from the construction, operation and decommissioning of this structure are likely to be broadly similar (in type) to those assessed for the wind farm development. However, these impacts are likely to be of lower significance compared to those caused by the wind farm development, given also the smaller scale of the Ocean Laboratory. Hence cumulative impacts have been assessed as of the same significance levels of those arisen from the proposed development.

181 The potential direct and indirect impacts of the proposed development on salmonid, and indirect impacts on freshwater pearl mussel, populations of the River Dee and River South Esk SACs have been addressed within the salmon and sea trout assessment for the proposed EOWDC.

Water Framework Directive and Good Ecological Status

182 The EU Water Framework Directive (WFD) requires Member States to produce a series of River Basin Management Plans (RBMPs) which are designed to ensure that water bodies achieve Good Ecological (and chemical) Status (GES).

183 The proposed development site is located within the area of the River Basin Management Plan for water body Cruden Bay to the Don Estuary (Identifier Code 200117). This water body has been classified as having an overall High with High Confidence Status with an overall Ecological Status of High and Chemical Status of Pass. As such, within the context of the WFD, the water body currently meets the objective of Good Ecological Status. Within the requirements of the WFD, water bodies have to be maintained in GES.

184 In order for the Cruden Bay to the Don Estuary water body to be maintained in GES, there are a series of measured parameters included in the classification, which contribute to the status values outlined above. These parameters synthesise attributes for chemical and biological determinands, including water quality metrics such as Dissolved Oxygen and pollutant levels; biological metrics such as benthic invertebrates (infaunal quality index), alien species and phytoplankton; and hydro-morphologic attributes.

185 As part of the baseline ecology review and subsequent impact assessment phase, details of such metrics have been characterised and assessed.

186 Based on the findings of this assessment process, it is considered that the construction, operation and decommissioning of the proposed development will have a generally negligible impact on the immediate ecology of the surrounding waters and seabed, and no significant medium or far field impacts. It is considered that the development would have no measurable effect on the attributes used to classify the water body as being in Good Ecological Status, and will not lead to the deterioration of Good Ecological Status at the site.

187 The conclusion of the assessment process is therefore that the development will not affect the Good Ecological Status of the Cruden Bay to the Don Estuary water body.

1.5 Appendices

1.5.1 Appendix 1. Sensitivity of benthic biotopes present in the proposed EOWDC area (based on data given in MarLIN)

Biotope	**SS.SSA.IFiSa.NcirBat**	**SS.SSA.CMuSa.AalbNuc**
Dominant species	*Nephtys cirrosa, Pontocrates altamarinus*, *Bathyporeia* sp.	*Notomastus latericeus, Nucula nitidosa, Tellina fabula,* Ophiuridae*, Pholoe baltica, Abra alba*
Stations (CMACS survey 2010)	2, 13, 14	1, 3, 4*, 5*, 6*, 7*, 8*, 9*, 10, 11, 12
Sensitivity to increased suspended sediments	Not sensitive	Very low
Sensitivity to abrasion and physical disturbance	Very low	Low
Smothering recoverability	Immediate	Immediate
Substratum loss recoverability	Very high	High

* stations within the proposed development lease boundary (see Appendix 2)

1 NON TECHNICAL SUMMARY

This report presents the results from baseline ornithological surveys undertaken in order to inform the Environmental Impact Assessment (EIA) prepared for the proposed European Offshore Wind Deployment Centre (EOWDC) and the findings of the impact assessment undertaken.

The proposed EOWDC development lies to the north of Aberdeen, in Aberdeen Bay, approximately 2 km at its closest point, off the coast. The proposed development comprises of the potential installation of 11 wind turbines and a potential future option of an ocean laboratory, which would be subject to a separate application. The EOWDC is a test centre for wind turbine technology and therefore the potential structures of the wind turbines that could be installed are currently unknown. In order to take these uncertainties into account a worst case scenario has been applied when assessing the potential impacts.

Prior to undertaking any assessment a variety of bird surveys have been commissioned since 2005 aimed at identifying the potential bird sensitivities that may occur within Aberdeen Bay throughout the year. The surveys comprised of monthly boat-based bird surveys undertaken between February 2007 and April 2008 and again from August 2010 to present. Further boat-based bird surveys are planned until at least August 2011. Due to the proximity of the proposed development to land, Vantage Point surveys have been undertaken on a monthly basis for a period of three years between March 2005 and October 2005 and March 2006 to March 2008. The surveys complimented those undertaken by boat and provide data on birds present in nearshore waters of Aberdeen Bay. In addition to the boat-based and Vantage Point surveys, three studies using radar have been commissioned: in October 2005, April 2007 and April 2010. These radar studies provided information on the use of Aberdeen Bay over a wider area and during periods of darkness and or poor visibility.

The data from all the surveys have been used to help inform the impact assessment.

The impact assessment has considered all species of bird recorded from all surveys undertaken in Aberdeen Bay. It has also considered other sources of published data, e.g. North-east Scotland Bird Reports, JNCC aerial surveys (Söhle *et al.* 2006; Lewis *et al*. 2008) and the Birds of North-east Scotland (Buckland, Bell & Picozzi 1990).

The potential impacts on all bird species that were identified as qualifying species for a Special Protected Area (SPA) have been assessed in detail within the impact assessment. Other species which were recorded in significant numbers and had the potential to be impacted by the proposed EOWDC have also been addressed within the main impact assessment, Section 4. All other species that occurred in low numbers for which it was determined that there is unlikely to be a significant effect based on the data collected and relevant published documents have been summarised at the end of the report.

For the purposes of this impact assessment an evidence based approach has been used to determine potential impacts as well as expert judgement based on the baseline information and results from other offshore wind farms. An impact matrix has been used to provide a structure and consistency of approach and has been used as tool to help inform the impact assessment. However, the results from the impact matrices have not been considered to be definitive, nor in isolation. The assessment is ultimately based on the latest published data available on potential impacts, i.e. wherever possible an evidence based approach has been adopted.

The impact assessment recognises that under the EIA Regulations, significance is used to determine the relative importance of an effect on a feature. Whereas under the Habitats Regulations it is a coarse filter to determine whether a further Appropriate Assessment is required (IEEM 2010). In determining the level of significance for the EIA the recommendations made in Maclean *et al.* (2009) have been used.

Two types of sensitivity have been identified: Non-impact and Species specific sensitivities.

Non-impact sensitivities are based largely on legislative requirements and population sizes. Species with relatively small populations and/or are qualifying species for a designated site have been considered to be of high sensitivity. Species with larger populations or are a non-qualifying species are assessed as having a lower sensitivity.

Species specific sensitivities have been undertaken in line with recommendations made in Maclean *et al* (2009). Sensitivities of species groups to particular impacts have been ranked and combined with the non-impact sensitivities to give an overall sensitivity. The main types of impact identified are:

- Collision Mortality,
- Barrier effect,
- Displacement (including disturbance and indirect impacts, i.e. depletion of prey).

Collision Risk

Collision risk modelling has been undertaken based upon the Band *et al.* (2000) model. For the purposes of this assessment a range of avoidance rates have been considered to give a range of potential mortality rates. The avoidance rates used are 98%, 99% and 99.5% based on SNH guidance (SNH 2010). However, in order to determine potential effects a precautionary 98% has been used for nearly all species within this EIA. Not all species recorded within Aberdeen Bay are at significant risk of collision. The level of risk depends on a large extent as to whether the species frequently flies at rotor height. Birds can fly at any height and may change depending upon weather conditions or behaviour. However, by using data from both site specific boat-based survey data and other extensive data sets from other offshore wind farm locations a large sample size of flight heights are available for collision risk assessment. The species selected for collision risk modelling have been selected on their frequency of flying at rotor height and the frequency at which they are recorded in Aberdeen Bay. Collision risk modelling was undertaken on the following species:

- Red-throated diver
- Fulmar
- Gannet
- Cormorant
- Pink-footed goose
- Barnacle goose
- Common scoter
- Guillemot
- Common gull
- Herring gull
- Kittiwake
- Sandwich tern
- Common tern

Barrier effect

Barrier effects may arise should the species avoid flying through the proposed development and by doing so incur additional energetic costs required to fly the extra distance around the turbines (Speakman, Gray & Furness 2009; Masden *et al.* 2010).

The risk of an impact is largely dependent on the number of times a bird may have to cross the obstruction and also the individuals' fitness. Should a bird be required to avoid an area only once or twice a year when undertaking a migration then it is likely that the potential impact will be lower than if a bird regularly flies around a barrier, e.g. between a feeding or roosting site (Speakman, Gray & Furness 2009).

In order to assess the potential impacts from displacement it is assumed that, unless data from other wind farms indicated otherwise, all individuals avoid flying through the site and detour around it and by doing so fly further than would have otherwise been the case. To calculate the potential length of a detour it is assumed that the detour started 1 km in front of the proposed development and that the bird detoured back on to the original course 1 km beyond the proposed development. Where appropriate, results from energetics modelling have been considered to assess the potential incremental increase in daily energy expenditure (Speakman, Gray & Furness 2009).

Displacement

Disturbance caused by the proposed EOWDC may lead to displacement of birds from potential feeding areas, resulting in effective habitat loss. Displacement may be caused by disturbance from vessels associated with the proposed development or from secondary impacts, i.e. the depletion of prey in the development area. The significance of the displacement is difficult to quantify but for species that rely on localised or patchy food supplies the affect may be more significant than it is for species that have a wide area of food supply. Based on the Maclean *et al.* (2009) report, the impact assessment has considered sensitivity of a species depending on its habitat flexibility, i.e. how restricted is the species to a particular habitat preference.

Significance of impact

The potential significance of the impact is based on the possible magnitude of an effect occurring and the overall sensitivity of each species to the impact. The results from which indicate the likely significance any impact may have on the receptor. However, this is only an indicative sensitivity and evidence from existing wind farms and expert judgement is used to determine whether the potential impact was likely to be either significant or adverse.

Where the potential significance is identified as being negligible or minor it is considered to be of limited or no concern. Moderate significance is of concern but may be tolerable depending on the causes that give rise to the potential impact. Major concerns are considered to be a potentially significant effect.

Determining potential adverse effects.

The Habitats and Birds Directives require an assessment to be undertaken to determine whether there are any potential adverse effects on a species. In order to do this the impact assessment has identified all the relevant SPAs for which there may be an interaction with the qualifying species and the proposed development. The assessment to ascertain whether there is an adverse effect on site integrity is a judgement based one based on the best available evidence.

Assessment of cumulative impacts

The cumulative impact assessment considers all other industries which have the potential to impact on the birds that may be present at the proposed development location, these include:

- Offshore renewables,

- Shipping,
- Aggregates,
- Dredging,
- Oil & gas.

Offshore renewable projects that have been identified as having the potential for a cumulative effect include two developments in the Moray Firth and three in the Firth of Forth. The sites in the Moray Firth are approximately 150 km to the north and those in the Firth of Forth approximately 120 km to the south of the proposed development.

The construction of the proposed EOWDC may overlap with construction activities being undertaken at other planned developments. However, given the stage of development of the renewable projects yet to be constructed and the uncertainty as to the types of foundations and turbines that will be used, there is sparse information available to incorporate into any impact assessment, which limits the effectiveness of cumulative assessments considering conceptual projects yet to be subject to a formal planning application and for which no environmental or design data are currently available.

Therefore, the cumulative impact assessment can only be undertaken with data available from the currently operating Beatrice demonstrator project in the Moray Firth. Although, the assessment does wherever possible consider potential cumulative impacts from other yet unconsented renewable projects.

Shipping associated with the harbour which has been undertaken in Aberdeen Bay over many centuries with currently approximately 16,000 vessel movements per year. There are no known plans that are likely to cause a significant increase in the level of shipping currently being undertaken in Aberdeen Bay and any impacts shipping may currently be having on the birds within Aberdeen Bay will be part of the baseline.

There are no aggregates activities within Aberdeen Bay. There are no licensed dredging sites within Aberdeen Bay but occasional dredging of the harbour may occur, with the next dredging scheduled for 2012.

Aside from associated shipping there are no oil and gas related activities within Aberdeen Bay.

Assessment of in-combination impacts

The Conservation (Natural Habitats, & c.) Regulations 1994 (as amended) require that a Habitats Regulations Appraisal (HRA) must be conducted by a competent authority. The HRA considers the implications for European sites in view of the European sites conservation objectives, in respect of any plan or project which is not directly connected with or necessary to the management of the European site for conservation purposes and which is likely to have a significant effect on the European site either alone or *in-combination* with other plans or projects.

Therefore the term ‘in-combination’ will be used when considering the impacts of the proposals with other plans or projects on European sites.

The main industries considered for potential in-combination impacts are proposed offshore wind farms, aggregate industry, dredging, oil and gas and shipping. Of these, proposed offshore wind farms and shipping are the only activities identified for which there is a potential for an in-combination impact.

Impact assessment summary

The results of the initial impact assessment identified 36 species of bird that due to either their conservation status, i.e. are a qualifying species for an SPA or due to the numbers recorded within the proposed development area could be impacted by the proposed development.

Following the use of matrices to indicate the significance of a potential impact arising from the construction, operation and decommissioning of the proposed development an evidence based assessment has been undertaken to determine the overall significance of the potential impacts.

The results indicate that for most species the proposed development is likely only to have a negligible or a minor effect on the species present.

However, the impact assessment has identified the potential for impacts of moderate significance on four species of bird: red-throated diver, little tern, Sandwich tern and common tern.

Red-throated diver may be displaced from the area of the proposed development during construction, operation and decommissioning phases. Site specific data indicate that although the higher numbers of red-throated diver occur to the north of the proposed development area a proportion of the local regional population may be displaced. The effects of the possible displacement on red-throated divers are unknown but could be significant were all those displaced not to survive. However, this scenario is considered improbable as the red-throated diver is not resident in Aberdeen Bay and the proposed development is in an area not favoured by red-throated diver. Any Divers that may be displaced will be able to move to other suitable foraging areas. Therefore, although the impact may be moderate in terms of displacement the actual impact on the Diver population within Aberdeen Bay will be negligible or minor.

Three species of Tern were identified as being at potential risk of a moderately significant impact due to possible indirect impact on their prey should pile driving occur during the construction period. However, it is also considered that any displacement of prey would be temporary as fish would return to the area following cessation of piling. Consequently, the possible impacts were considered to be of a temporary nature and would not have a long-term effect.

Mitigation and Monitoring

Detailed mitigation and monitoring measures aimed to avoid, remove or reduce any potentially significant impacts will be developed more fully during consultation with the Regulator and their statutory advisors and other stakeholders.

The main potential impacts arising from the proposed development relate primarily to direct or indirect displacement effects on Divers and Terns. Mitigation measures that may be considered as measures to help avoid, remove or reduce them include:

- Minimising the proposed development area as far as practicable in the early design stage.
- Vessel management plans to ensure vessels minimise disturbance as far as practicable,
- Installing Foundation types that reduce noise levels during construction,
- Timing and duration of installation,
- Minimising aviation and navigation lighting.

It is important that monitoring is undertaken that is designed to address specific concerns or potential impacts identified during the EIA process. Poorly designed *ad hoc* monitoring is likely to be inefficient and not provide useful or meaningful results. It is therefore important that a detailed monitoring programme is developed in collaboration with the Regulator and statutory advisors and taking note of key stakeholders comments during the consultation period. A detailed monitoring programme aimed at specific issues or concerns would be developed with the Regulator and advisors should consent be granted.

2 BIRD SURVEY METHODS

2.1 Introduction

Three different types of bird surveys have been undertaken since 2005 in order to obtain suitable ornithological survey data to inform the Environmental Impact Assessment and, if required, Habitat Regulations Appraisals.

Monthly boat-based surveys were undertaken between February 2007 to April 2008 and an additional 12 months of surveys commenced in August 2010. In addition to the Boat-based surveys, three years of Vantage Point surveys were undertaken from March 2005 to October 2005 and between March 2006 and March 2008 and three radar surveys were carried out in October 2005, April 2006 and April 2010 (Figure 2-1).

The results from these surveys along with additional information have been used to help inform the Environmental Impact Assessment.

2.2 Boat-based Survey Methodology & Data Analysis

Survey Area and Transects Route

There have been two periods of boat-based bird surveys undertaken in support of the proposed development.

Between February 2007 and April 2008 boat-based surveys were undertaken on a monthly basis. Each survey covered an area of 101.6 km^2, which included the then proposed development site plus a buffer zone and a 'control' survey area located immediately to the north (Figure 2-2). The 'control' survey area of 50.8 km^2 was the same size as the then proposed EOWDC site (including the buffer zone). The site proposed at the time the surveys were being undertaken represented 12% of the total area surveyed, and 24% of the proposed EOWDC survey area. The distance of the shoreline to the proposed EOWDC survey area varied between 0.6 km to 7 km and to the 'control' survey area between 0.5 km to 6 km. The 'control' survey area was positioned in an area exhibiting similar physical attributes (bathymetry and seabed type) to that of the development site survey area (IECS 2008).

Various transect designs were considered when establishing the survey methodology (e.g. parallel to the coast, perpendicular and zigzag). At the time it was considered that a perpendicular alignment provided the best option in terms of data collection and analysis, as it best captured environmental factors such as depth and wave exposure. As such, the sampling design comprised a grid of systematically spaced line transects approximately perpendicular to the coast. The transects, spaced 1 km apart, were conducted perpendicular to the coast on an approximately east-west orientation (Figure 2-2).

The 'control' and development areas each consisted of 10 main transects 6.5 km long, together with nine short legs 1 km long, and therefore constituted two separate samples. The 20 transects were travelled over two days, preferably on two consecutive days (with 10 transects per day). The transects were steamed at a constant speed of approximately 8 knots. The survey route was designed to give a total boat transect length of 74 km per site, considered to be approximately the maximum length of transect which can be covered in daylight hours during the winter at this location.

The 'short legs', which preserved the spacing of 1 km between the main transects, were surveyed to gather additional data. The shoreward side was always covered in both the inshore and offshore short legs. To ensure coverage of the shallow areas, it was necessary to operate the 300 m band transect on the port side when commencing from the south end of the site, and on the starboard side when starting from the north end of the site. The four start points for the 'control' and proposed EOWDC survey areas were randomised between the surveys. The transect band on the main transects were operated alternatively on the port and starboard sides to avoid the sun glare.

In order to reduce disturbance to birds (and marine mammals) prior to and after surveying, the survey vessel did not travel through the survey area when positioning or returning from the northernmost extent of the site. Instead, the boat followed an offshore route outside the survey area.

Following the completion of the Year 1 bird surveys the location and size of the proposed development was amended. This meant that although the previous surveys did cover the revised location for the proposed development (Figure 2-3), to ensure better potential for future monitoring an alternative survey area was designed for the boat-based bird surveys undertaken since August 2010 (Figure 2-4).

In addition to the differing survey area due to the revised location of the proposed development, the survey design was also amended to take into account advances in understanding of the limitations in using Before After Control Impact (BACI) designs. The use of the gradient approach allows distance from the development footprint to be included as a covariate within the analysis. Consequently, it improves the future potential to detect change in seabird distributions and abundances. Three areas were surveyed each month to the north, south and eastwards outwards to 25 km allowing a gradient approach to be used (SMRU 2011b). The total surveyed area each month was 339 km^2, comprising of three strata: 150.8 km^2 (north), 82.8 km^2 (south) and 105.2 km^2 (offshore) (Figure 2-4).

The surveys undertaken since August 2010 have also been undertaken in equally spaced zigzag line transect as opposed to linear parallel surveys as previously undertaken. By doing so this allows continuous surveying and less time wasted in transit between parallel transects. It also provides coverage of the full depth, distance to shore and wave exposure gradients present. The survey design was carried out using the Distance software to ensure even coverage probability within each stratum.

The start point of transects routes was randomised to account for any confounding effects of time of day and port activity e.g. bird activity may decline from a morning peak and port activity increase.

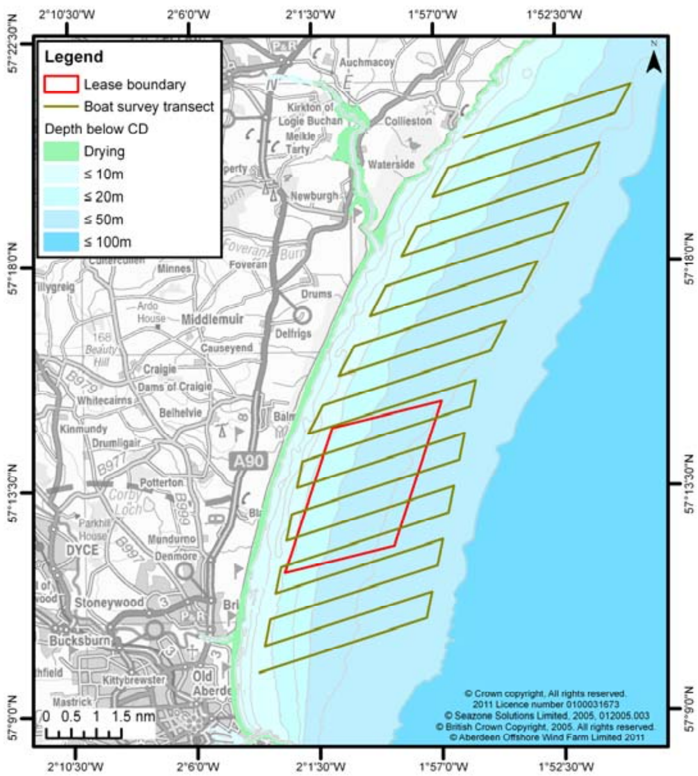

Figure 2-3: Areas surveyed from boats for birds and marine mammals between February 2007 and March 2008 and the revised EOWDC location.

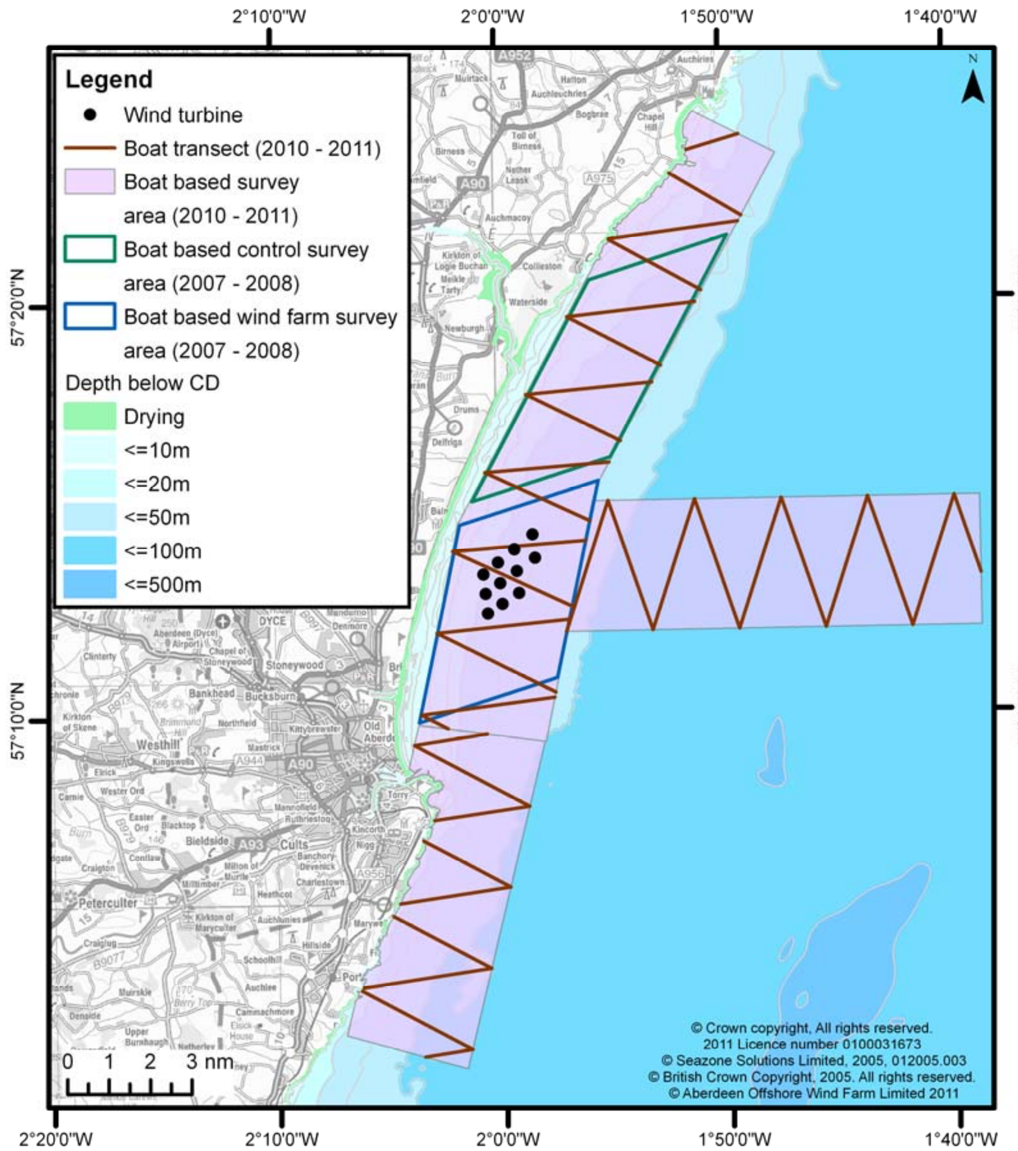

Figure 2-4: Survey strata and transects in the context of previous areas surveyed and the approximate area of the development site.

Survey Programme

Between February 2007 and March 2008 and August 2010 to January 2011, surveys were conducted once every month during daylight hours and efforts were made to undertake the survey over two consecutive days. Due to issues arising outwith the control of the project no surveys were undertaken during October 2011 and December 2011. However, double the number of surveys will be undertaken in periods of potentially higher sensitivity in June and July 2011. Surveys were primarily conducted in conditions of less than sea state 3 with consideration given to residual swell levels prior to the surveys being undertaken. The times of the surveys were dependent on the weather conditions, availability of the survey boat and of the observers. However, the survey programme was scheduled to cover different tidal states, and times of the day (where possible during the longer hours of daylight in the summer), in order to get an adequate coverage of the factors that may affect the distribution, abundance and activities of birds and marine mammals in the Aberdeen Bay area.

Boat-based surveys were conducted in February 2008 to coincide with the Vantage Point (VP) watches (See Section 2.3) with shore-based observations undertaken by an experienced bird/marine mammal observer, to monitor any potential disturbance of birds and marine mammals by the survey vessel.

Sampling Methods

Both boat-based survey programmes employed the standard seabird census techniques for use on a boat platform as described by Camphuysen *et al.* (2003). The methods involved a band transect, operated on one side and ahead of the ship, and with short time-intervals in a continuous series, to sample short stretches of water with a known surface area and location.

All surveys were undertaken by a team of three experienced observers who had been Joint Nature Conservation Committee (JNCC) European Seabirds at Sea (ESAS) trained and included observers who had completed the JNCC's Seabirds at Sea Team (SAST) training course for seabird surveyors (Edinburgh 2005 & 2006), and had experience of surveying seabird populations including numerous ship-based seabird surveys.

Observers undertook a 90º scan with a 300 m band transect using a snapshot technique. The 300 m strip on one side of the ship with the best visibility (least glare etc.) was divided into a series of distance bands running perpendicular to the ship (using the Camphuysen *et al.* 2003 divisions).

Birds observed within the band (A-D) were noted as being '*in transect*'. Flying birds were recorded '*in transect*' using the *snapshot technique* to overcome biases caused by the flux of flying birds. Bird data were summarised on field data forms every minute using a snapshot at a speed of 8 kts (frequency of snapshot could be adjusted according to the speed of the boat). A recording interval of 1 minute was considered to be most applicable for such a relatively small area and coastal location, subsequently allowing a more detailed analysis of species distribution.

Two observers were present on the observation deck counting birds simultaneously. The role of the primary observer was to detect by naked eye, birds on the sea (within transect) and in the air through an arc of 90º. The secondary observer recorded observations and assisted the primary observer in the detection of birds by naked eye. The third observer was dedicated to the forward detection of divers and seaducks, which are known to flush from the sea surface at considerable distance from the vessel. In contrast to the first two observers, detection of birds by the third observer was made by continuous forward scanning using high quality binoculars in order to improve the detection of escaping and diving birds. Each bird was only recorded once, and 'ship associates' were ignored. The third observer assisted the main team of two observers during the spring migration (March, April & May) and autumn migration (September & October) when it was thought that potentially large movements of divers, seaducks and auks might occur during these periods. All three surveyors alternated roles during surveys to reduce observer fatigue and standardise findings.

Distance and band estimates of Observers were checked during surveys to ensure consistency across transects and observers.

In addition to the parameters required by the ESAS methodology, extra information was recorded by the observers in order to assess the potential problems of double counting and bird disturbance (particularly to Divers and seaducks) created by the survey vessel. The extra information included the behavioural response from the approaching vessel (e.g. escaped/dived or flushed) and the distance at which the birds responded.

For each observation the details shown in Table 2-1 were recorded.

Table 2-1: Biological variables collected by bird surveyors and order of recording priority.

1	Species:	Identification to species level. However, this is not always possible and in this case the most precise identification possible should be given e.g. common guillemot/razorbill, large gull sp. (great black-backed gull/lesser black-backed gull and herring gull).
2	Numbers:	Number of individuals present within the sighting.
3	Transect:	A tick placed in a column of the recording sheet if the bird is '*in transect*'. A blank is left if the bird is not '*in transect*'.
4	Behaviour:	On the water or flying.
5	Distance from the ship:	Distances of the bird from ship are estimated using a range finder, and coded as follows. For birds on the water the SAST sub-divide the 300 m band transect into four zones. A: 0-50 m, B: 50-100 m, C: 100-200 m, D: 200-300 m and E> 300 m. For flying birds; 1: 0-100 m, 2: 100-1,000 m and 3: > 1,000 m.
6	Flight height:	The distribution of flying height is estimated and assessed from the ship, by categorising any birds seen in flight to its altitude. Categories are expressed as 0-2 m, 2-10 m, 10-15 m, 15-25 m, 25-50 m, 50-100 m, 100-200 m, >200 m to avoid confusion. Flight height categories follow the COWRIE guidelines.
7	Direction:	Flight direction of each sighting is recorded.
8	Behavioural response to survey vessel:	Flushed to flight (F) or diving in response to survey vessel (E/D).
9	Distance of response:	Distances of the bird flushed to flight or diving from the ship estimated in metres.
10	Plumage, moult, age and sex of the bird:	Where age is unknown, a blank is left otherwise coded as follows: A: Adult and IMM: Immature. For plumage, S: summer and W: winter are used.
11	Cetaceans:	Cetacean and sea mammal sightings recorded where appropriate.

Additional environmental data in the form of a survey log was maintained during the surveys, with data collated including weather conditions and sea state, as well as additional observations such as positions of fishing boats and other vessels, with observational data on species logged on modified SAST recording sheets. Prior to the survey programme commencing, all transect start and finish points were inputted into the ship's GPS system, and subsequent transects were then steamed using these co-ordinates. Survey logging of transects was determined using a handheld GPS. Output from the GPS provided the position (in latitude and longitude), speed, and bearing of the boat for every time interval recorded.

Boat-based Surveys Data Treatment and Analysis

Estimating population size in the ship-based survey areas

Total population size within an area surveyed was estimated using a variety of methods, including:

- Extrapolation of density
- Distance sampling; and
- Summed interpolated (kriged) abundances derived from geostatistical analyses

The effectiveness of the methods for producing accurate total population size estimates is discussed in McSorley *et al.* (2005). Distance sampling is a widely applied method of estimating total numbers and is currently the only method that allows estimation of 95 confidence limits. This method, using the *Distance* computer programme, is used as a primary method of estimating population size for the most frequently recorded species in this report. However, *Distance* may not produce accurate results where the numbers of observations are very small; where this is the case, use of an alternative method is necessary to estimate population size. Where distance sampling was not possible (<50 different observations), simple extrapolation of the overall sample density was used to estimate the total numbers of birds in the ship-based seabird survey areas. Further details are provided below.

Distance sampling using Distance computer programme

Distance sampling is a widely used and accepted statistical method that accounts for a major source of potential underestimation during surveys. The method has been demonstrated to produce accurate population estimates for seabirds (Buckland *et al.,* 2001), and is widely available and accessible through the use of Distance 5.0 software (Thomas *et al.,* 2002).

There are four basic assumptions of distance sampling that should be adhered to if an unbiased density estimate is to be obtained:

1. Birds directly on or close to the transect line are always detected.
2. Birds are detected at their initial location prior to natural movement or movement in response to the observer's presence. It is assumed that birds do not move in response to the survey platform.
3. Distances are accurately measured.
4. Objects are distributed randomly with respect to the survey transects.

All birds recorded on the sea surface '*in transe*ct' (on the main transects) were included for analysis. The data input to the *Distance* computer programme was restricted to those collected on the main transects, as the inclusion of data from 'short legs' risked double sampling of birds from the areas at the corners where the boat turned to begin the next main transect (Buckland *et al.*, 2001).

Data collected during the 'snapshot' (i.e. flying birds in 'transect') were not suitable for distance sampling (Camphuysen *et al*. 2003). Since only data collected on the sea surface may be included in the distance sampling analyses, the population estimates may be artificially reduced, as they exclude birds in flight. In order to rectify overall population estimates, estimation of birds in flight using extrapolation of birds recorded at the time of the snapshot (i.e. 'in transect'), were added to population estimates on the sea surface.

The population size in flight was estimated by multiplying the overall density in flight by the total study area.

Extrapolation of overall estimate

Where distance sampling using the *Distance* computer programme was not possible (<50 observations), simple extrapolations of the overall density were used to estimate the total number of birds in the ship-based seabird survey areas. The extrapolation of overall density is a relatively quick and simple method of estimating total abundance within the sampled area. However, this method makes assumptions about the data used; overall density assumes that birds are uniformly distributed across the study site (i.e. there is no clumping due to social aggregation or habitat selection), and use of mean density is only accurate if sample densities are normally distributed.

Correction factors were applied to birds on the water to account for variations in detection at different distances from the ship's trackline. These were applied by multiplying the number of birds recorded for a species by its correction factor to give a value with which to calculate the density of each seabird species on the water. Due to the small sample size, it was not possible to calculate correction factors for the study area, instead published corrections factors based upon large data sets were applied to the data (Table 2-2).

The population size on the water was estimated by multiplying the corrected overall density per sampled area by the total study area. As correction factors cannot be applied to flying birds recorded 'in transect', simple extrapolation was used to estimate population size in flight as discussed in previous section. Estimated populations in flight and on water were added together to produce a total population size for the 'control' and proposed EOWDC survey areas.

Table 2-2: Correction factors from Skov *et al.* (1995).

Species	Correction Factors
Red-throated diver	1.4
Great cormorant	1.2
Northern fulmar	1.2
Northern gannet	1.4
Mew (common) gull	2.2
Common scoter	1.7
Herring gull	1.2
Great black-backed gull	1.7
Black-legged kittiwake	1.8
Sandwich tern	1.5
Common tern	1.5
Common guillemot/razorbill	1.6
Common guillemot	1.6
Razorbill	1.6
Atlantic puffin	2.0

Population estimate tables

Where distance sampling using the *Distance* computer programme was not possible (<50 observations), simple extrapolations of the overall density were used to estimate the total number of birds in the ship-based seabird survey areas. Table 2-3 shows the species and months eligible for *Distance* during the Year 1 survey programme.

Table 2-3: Summary table of month/species where *Distance* was applicable in the 'control' and proposed EOWDC survey areas.

Species	EOWDC survey area	'control' survey area
Red-throated diver	N/A	N/A
Common scoter	N/A	N/A
Common eider	N/A	N/A
Northern fulmar	N/A	N/A
Northern gannet	N/A	N/A
Great cormorant	N/A	N/A
Common gull	N/A	N/A
Herring gull	N/A	N/A
Great black-backed gull	N/A	N/A
Black-legged kittiwake	N/A	July 07
Sandwich tern	N/A	N/A
Common tern	N/A	N/A
Common guillemot	Feb 07, May 07 to Oct 07	May 07 to Oct 07
Razorbill	N/A	Aug 2007
Common guillemot / razorbill	N/A	N/A
Atlantic puffin	N/A	Sept 07

2.3 Vantage Point surveys

Vantage Point (VP) Surveys were undertaken from a total of six locations between March 2005 and March 2008: Two locations were used throughout: Drums and Balmedie and two were in very similar locations: Blackdog and Murcar, and Donmouth and Promenade (Table 2-4) (EnviroCentre 2007a,b; Alba Ecology 2008a,b).

Table 2-4: Vantage Point Survey Locations in Aberdeen Bay.

Years	Site	Elevation (metres)
March 2005 – October 2005	Promenade	10
March 2006 – March 2008	Donmouth	11
March 2005 – October 2005	Murcar	15
March 2006 – March 2008	Blackdog	16
March 2005 – October 2005 March 2006 – March 2008	Balmedie	21
March 2005 – October 2005 March 2006 – March 2008	Drums	16

Watches were conducted during daylight hours in conditions of good visibility, by a single observer with binoculars and telescope for two hours from each VP site. Two surveys were undertaken at each location most months, with up to four surveys per month in the then proposed EOWDC area (Donmouth and Blackdog) (Figure 2-5). Surveys were conducted at dawn and dusk (alternating between dawn and dusk surveys between each site visit). Dawn surveys started approximately 30 minutes before sunrise and dusk surveys extended to sunset or within about 15 minutes after.

At the start of each survey (along with any changes during the survey), the observer recorded the weather conditions, visibility, cloud cover, sea state, time of high tide and height (from tide tables), wind speed and direction, times of sunrise and sunset. In conditions of poor visibility (<1 km) surveys were not conducted or aborted if necessary.

The one to two hour long surveys were broken into 10 minute intervals, during which the observer counted all the individual birds moving through their telescope field of view (straight out from the VP, covering 0-3km and approximately 60°), noting their direction of flight, estimated distance from shore and flight height. If the birds exhibited notable behaviour, such as feeding, roosting, diving and fighting, this was also recorded.

Distance from shore was categorised into 0-1 km, 1-2 km, 2-3km and 3+ km distance bands, where possible based on marker buoys (Balmedie: 1 km (NJ990175) and Blackdog: 2.3 km (NJ986132)). Flight height was categorised in to 0-30 m, 30-150 m and 150+ m height bands, based on the size of the proposed wind turbines.

At the start of each survey period, the visible area was scanned with binoculars and the species, approximate number and behaviour of any birds on the sea surface and shore was recorded. During the two hour long survey general notes on birds on the sea surface and on the shore within the immediate field of view were recorded. Any significant changes to large feeding flocks out at sea or large movements of birds along the foreshore were also recorded.

A total of 294 VP surveys and 582 hours of surveys have been undertaken over a period of three years from six sites and across four different areas of Aberdeen Bay (Table 2-5).

Table 2-5: Vantage Point survey summary.

	No. of VP Surveys	No. of Hours
Drums	55	114
Balmedie	52	102
Blackdog	84	167
Murcar *	10	16
Donmouth	83	163
Promenade *	10	20
Total	294	582

* - Data collected between March 2005 and October 2005.

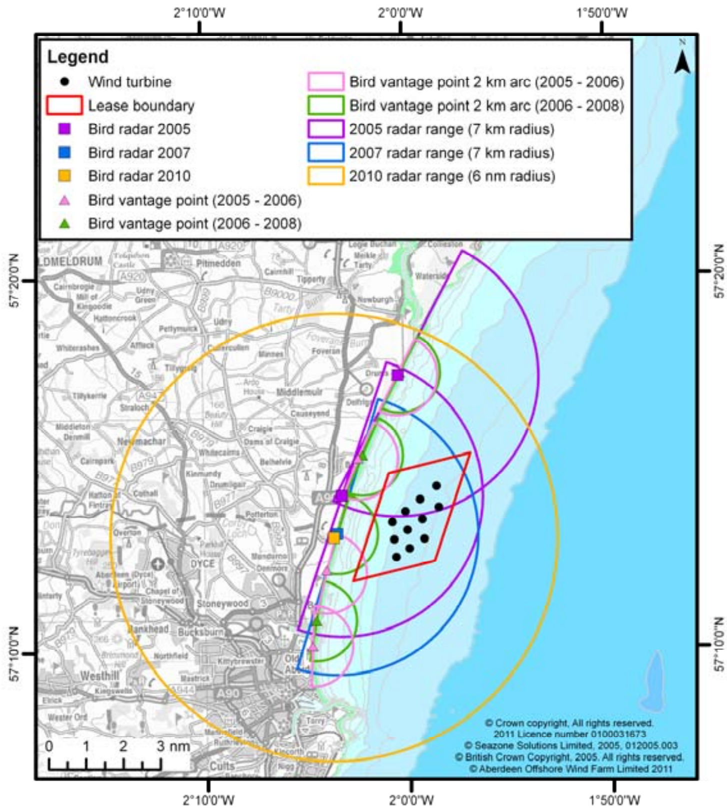

Figure 2-5: Location of the Vantage Point and radar survey sites and the location of the proposed EOWDC.

Data obtained from Vantage Point surveys has been used to compliment the data collected further offshore from boat-based surveys. The benefits of Vantage Point surveys are that data on seabird distributions passing close to shore are obtained which may otherwise be missed from purely boat-based surveys. Comparing the data with that obtained from boat-based surveys a better understanding of bird distributions are obtained. However, it is recognised that there is an increasing probability of birds being missed with increasing distance from the observer and unlike with boat-based data it is not possible to produce detectability functions to data collected by Vantage Points. In order to calculate detectability functions it is assumed that there is an even density of birds across the area or that there is a constant age or sex ratio. This is not the case from shore-based counts and therefore detectability functions cannot be produced from data collected from Vantage Point surveys.

2.4 Bird Detection Radar Surveys

Bird Detection radar has been used on three occasions during periods predicted to be of high migration in Aberdeen Bay: October 2005, April 2006 and April 2010 (Table 2-6).

The use of Bird Detection radar has allowed the tracking of bird movements continuously up to a range of 11 km including during periods of darkness or poor weather conditions. The radar could detect bird movements, their flight trajectory, flight speed and altitude to a height of 1.4 km. In favourable conditions the radar could track birds for up to 22 km and could detect animals as small as insects. The radar was used in all weather conditions including periods of poor visibility, rain and during hours of darkness.

The original surveys were undertaken at Easter Hatton and Drums but were later moved to Blackdog, closer to the proposed development area (Figure 2-6, Figure 2-7). The survey undertaken in April 2010 was aimed to coincide with period of peak pink-footed goose migration. However, delays in starting meant that it was not deployed until 24 April.

In addition to manning and monitoring the live radar screens, detailed vantage point field monitoring synchronised with the radar deployment was undertaken during the surveys. The observers confirmed the species and composition of the tracks initially detected by radar as well as providing additional information such as flock size and formation, height and flight behaviour. The radar ornithologists swapped between the roles of radar monitoring and visual tracking approximately every 2 hours in order to minimise observer fatigue during periods of observation (Walls *et al.* 2010).

Table 2-6: Location and duration of radar studies undertaken in Aberdeen Bay.

Location	Range (km)	Start Date	End date	Running time (hr)	
Drums	7	24 October 2005	29 October 2005	115	Walls *et al.* 2006
Easter Hatton	7	29 October 2005	3 November 2005	104	Walls *et al.* 2006
Blackdog	7	11 April 2007	26 April 2007	N/A	Simms *et al.* 2007
Blackdog	11	14 April 2010	29 April 2010	124	Walls *et al*. 2010

3 IMPACT ASSESSMENT METHODOLOGY

3.1 Introduction

This section identifies the potential impacts arising from the proposed development on birds. It is based on site specific data from Aberdeen Bay obtained in order to inform the project and for the purposes of this assessment. It also draws upon other published information on the birds likely to be present in the area, i.e. North-east Scotland Bird Reports and JNCC reports. The results are summarised for each species in Section 4.

Whenever possible additional information from existing offshore wind farms has been used in order to inform the impact assessment.

A request for a formal scoping opinion was made in 2010 and a number of comments were received with respect to potential ornithological impacts arising from the proposed project. These have been considered when undertaking this impact assessment.

The assessment is based on the project parameters as outlined in the project description (Section 3).

3.2 Potential Impacts

There are a large number of publications that provide detailed analysis of the potential impacts the development of an offshore wind farm may have on birds (e.g. Percival 2001; Langston & Pullan 2003; Drewitt & Langston 2006; Zucco *et al*. 2006).

The conclusions from all the publications identify three (or four if disturbance is considered separate from displacement) main potential impacts:

Collision risk: Birds are at risk of colliding with wind turbines. The level of collision depends on the location and size of the development and the species present. Different species are at varying risks of collision depending on a number of factors including the heights at which they fly and the proportion of time that they are flying at within the range of the rotor blades. Species such Auks, Divers and Scoter fly predominantly below rotor height where as other species such as Gulls may more frequently fly at rotor height. Avoidance rates are very important in determining the level of risk. Far field avoidance, where birds make detours to avoid flying through the wind farms at distances of one or more kilometres has been reported for many species, e.g. Gannets, Geese and Swans and sea-duck and near-field avoidance where a bird makes a quick detour at relatively close proximity to the wind turbines, e.g. Gulls and Terns. Other factors influencing collision risk include the frequency of passage, i.e. breeding birds flying through a site to and from a breeding colony and potentially weather conditions and visibility with birds at potentially greater risk during periods of poorer weather or at night. Overall, the majority of studies pertaining to offshore wind farms have indicated very low collision risks with most species having near-field avoidance rates of 99% or more and some far-field avoidance rates ranging from 50% for Divers and eider to over 90% for gannets and common scoter. The potential significance of any collision mortality depends on the population size, its conservation status the longevity of the species and its fecundity rate. Long-lived species with low fecundity rates and with small or declining populations are at greatest risk of being significantly affected by collision mortality.

Displacement: Birds that would otherwise use an area may avoid entering the wind farm and therefore be displaced. The displacement may be caused by a number of reasons. Birds may not enter the site due to the physical presence of the wind turbines as may be the case for red-throated diver or they may be disturbed (a disturbance impact) from the site by the vessels associated with the development, e.g. Divers and Scoter. There may also be an indirect impact on the food supply that could be reduced and therefore birds search elsewhere for their prey, e.g. Terns.

The level of displacement reported has varied across species and sites with some displacement identified for Divers, cormorants and possibly Auks. The significance of any displacement, should it occur, is dependent on the scale and duration of impact and whether other suitable sites are available to which the birds may go.

Barrier effects: Birds may avoid flying through the wind farms and select to fly over or around them. Should they choose to fly around them then this may entail flying further than they would otherwise have done so. Many species have been recorded avoiding offshore wind farms by flying around them, often by altering course at a distance of 1 km or more, e.g. wildfowl and gannets. This increase in flight distance causes a corresponding increase in energy expenditure that may, depending on the frequency that the effect occurs and the fitness of the individual bird, have a negative impact on the bird. The greatest concerns arise when birds undertake frequent flights around the wind farm, e.g. to and from feeding grounds or roost sites.

The impact assessment has been based on the above recognised potential effects.

3.3 Temporal Scales

There are four main phases in the development proposed programme that are considered:

- Pre-construction,
- Construction,
- Operation,
- Decommissioning,

Pre-construction phase

During the pre-construction phase baseline data have been obtained using boat-based, land-based and radar surveys. The collection of the data over a number of years provides baseline information on usage of the proposed development area and further afield by birds that have the potential to be impacted. It provides the basis upon which the potential impacts can be assessed and against which any changes in populations can be measured

Construction phase

The construction phase is of relatively short duration and consequently potential impacts arising from it are predicted to also be of short duration. As this is a demonstrator project the exact type of turbines that may be installed is still to be determined.

Construction activities involve the use of a number of vessels to install the turbines and cables that may cause disturbance and consequently displacement to species that avoid vessels, e.g. Divers and Scoter. The installation of turbines may cause the temporary displacement of prey species depending on the installation technique, e.g. pile-driving.

Operational phase

Potential impacts arising from the operational phase are collision mortality, displacement and barrier effects. There may be some disturbance from maintenance vessels that could cause displacement and a very small loss of habitat due to the direct physical impact on the seabed of the eleven wind turbines.

Decommissioning

How the turbines will eventually be decommissioned is still to be determined but it will involve the use of a number of vessels and the use of cutting equipment. The potential effects arising from decommissioning are predicted to be similar to those from installation, i.e. displacement.

3.4 Designated Sites

Although the proposed site does not lie within a designated area, there are a number of SPAs along the east coast of Scotland that have the potential to be impacted by the proposed development. For the purposes of the EIA, qualifying species from SPAs between Troup, Pennan and Lion's Head 74 km to the north and Forth Islands SPA approximately 134 km to the south have been considered (Table 3-1) and assessed against the relevant Conservation Objectives. The selection of sites is based largely on the potential foraging areas or known passage routes of the species recorded during surveys undertaken within the proposed development area.

For the purposes of the impact assessment all SPA species have been considered to be Very Highly sensitive if individually cited or Highly sensitive if cited as part of an assemblage. The potential effects on SPA species are assessed within the main impact section (Section 4).

Conservation Objectives

To avoid deterioration of the habitats of the qualifying species (listed [*for each site*]) or significant disturbance to the qualifying species, thus ensuring that the integrity of the site is maintained; and

To ensure for the qualifying species that the following are maintained in the long term:

- Population of the species as a viable component of the site,
- Distribution of the species within site,
- Distribution and extent of habitats supporting the species,
- Structure, function and supporting processes of habitats supporting the species,
- No significant disturbance of the species.

Table 3-1: SPAs identified as being at potential risk of adverse effect from proposed project.

SPA	Approximate distance EOWDC (km)	Qualifying species
Troup, Pennan and Lion's Head SPA	74.3	Article 4.1 - *Breeding* - Guillemot Article 4.2 - at least 20,000 seabirds breeding season, 150,000 individual seabirds including: razorbill, kittiwake, herring gull, fulmar guillemot.
Loch of Strathbeg SPA	47.6	Article 4.1 - *Breeding* - Sandwich tern. *Winter* - barnacle goose, whooper swan. Article 4.2 - *Winter* - greylag goose , pink-footed Goose Article 4.2 - supporting at least 20,000 waterfowl. Over winter supports 49,452 individual waterfowl including: teal, greylag goose, pink-footed goose, barnacle goose, whooper swan.
Buchan Ness to Collieston Coast SPA	9.5	Article 4.2 - supporting at least 20,000 seabirds. Breeding the area regularly supports 95,000 individual seabirds including: guillemot, kittiwake, herring gull, shag, and fulmar.
Ythan Estuary, Sands of Forvie and Meikle Loch SPA	7.2	Article 4.1 - *breeding* Sandwich tern, common tern, little tern. Article 4.2 - *wintering* pink-footed geese, common eider, *breeding*, diverse assemblage of breeding seabirds (13 species). regularly supporting over 20,000 waterfowl including redshank and lapwing.
Loch of Skene	21	Article 4.2 - *winter* greylag goose.
Fowlsheugh SPA	31.1	Article 4.2 by regularly supporting in excess of 20,000 individual seabirds. The colony regularly supports 145,000 seabirds. The colony further qualifies under Article 4.2 by regularly supporting populations of European importance of the migratory species: common guillemot, black-legged kittiwake, razorbill, fulmar, herring gull.
Montrose SPA	61	Article 4.2 - *winter* - greylag goose, knot, pink-footed goose, redshank. Article 4.2 - supporting at least 20,000 waterfowl. Winter, the area regularly supports 54,917 individual waterfowl, including: dunlin, oystercatcher, common eider, wigeon, shelduck, redshank, knot, greylag goose, pink-footed goose.
Firth of Tay and Eden Estuary	96	Article 4.1 - *Breeding* - little tern, Marsh harrier *Winter*; bar-tailed godwit Article 4.2 - *Winter*; greylag goose, pink-footed Goose, redshank. Supporting at least 20,000 waterfowl. In winter, the area regularly supports 34,074 individual waterfowl including: velvet scoter, pink-footed goose, greylag goose, redshank, cormorant, shelduck, common eider, bar-tailed godwit, common scoter, black-tailed godwit, goldeneye, red-breasted Merganser, goosander, oystercatcher, grey plover, sanderling, dunlin, long-tailed duck.

Firth of Forth SPA	124	Article 4.1 - *Passage*; Sandwich tern, Winter; bar-tailed godwit, golden plover, red-throated diver, Slavonian grebe. Article 4.2 - *Winter* - knot, pink-footed goose, redshank, shelduck, turnstone. Article 4.2 - supporting at least 20,000 waterfowl. Winter, regularly supports 86,067 individual waterfowl including: scaup, Slavonian grebe, golden plover, bar-tailed godwit, pink-footed goose, shelduck, knot, redshank, turnstone, great crested grebe, cormorant, red-throated diver, mallard, curlew, common eider, long-tailed duck, common scoter, velvet scoter, goldeneye, red-breasted Merganser, oystercatcher, ringed plover, grey plover, lapwing, dunlin, wigeon
Imperial Dock, Leith SPA	130	Article 4.1 - breeding season common tern.
Forth Islands SPA	134	Article 4.1 - breeding season – Arctic tern, common tern, roseate tern, Sandwich tern. Article 4.2 - Breeding season – gannet, lesser black-backed gull, puffin, shag. Article 4.2 - Supporting at least 20,000 seabirds Breeding season the area regularly supports 90,000 individual seabirds including razorbill, guillemot, kittiwake, herring gull, cormorant, fulmar, puffin, lesser black-backed gull, shag, gannet, Arctic tern, common tern, roseate tern, Sandwich tern.

3.5 EIA Methodology

Species regularly recorded offshore and that are qualifying species for an SPA presented in Table 3-1 have been assessed in the main section of this document (Section 4). Records of all other species are summarised in section 5. However, it is recognised that species may also occur in the area that were not recorded and others may have been under recorded due to their nocturnal flights or intermittent migration. However, there is no recorded evidence of any migration corridor across Aberdeen Bay and therefore for those species only infrequently recorded or were not recorded offshore, i.e. many waders, wildfowl and passerines no further assessment has been made as there is not likely to be any significant or adverse effect to these species from the proposed development.

It is recognised that the strict use of a matrix approach when undertaking an EIA can be inflexible and risks drawing erroneous conclusions. However, the use of an impact matrix can and does provide structure to an otherwise judgemental process and as long as the matrix is used appropriately it can be a useful tool in identifying the overall potential significance of an impact. The development of impact specific matrices by Maclean *et al.* (2009) has provided more focussed and robust matrices specific to potential impacts.

For the purposes of this EIA an evidence based approach has been used to determine potential impacts as well as expert judgement based on the baseline information and results from other offshore wind farms. An impact matrix has been used to provide a structure and consistency of approach and has been used as tool to help inform the impact assessment. The structure and content of the tables are based on those originally developed by Percival *et al.* (1999) and developed further by Maclean *et al.* (2009). They have been widely used in various similar forms for nearly all offshore wind farms. However, the results from the impact matrices have not been considered to be definitive, nor in isolation. The assessment is ultimately based on the latest published data available on potential impacts, i.e. wherever possible an evidence based approach has been adopted.

Determining Significance.

What may be considered to be significant differs across legislative requirements.

Under the EIA Regulations, significance is used to determine the relative importance of an effect on a feature. Whereas under the Habitats Regulations it is a coarse filter to determine whether a further Appropriate Assessment is required (IEEM 2010).

In determining the level of significance for the EIA the recommendations made in Maclean *et al.* (2009) have been used.

Two types of sensitivity have been identified:

- Non-impact specific sensitivity
- Species specific sensitivity

For non-impact sensitivities a series of definitions have been used to describe the potential sensitivity of the species to the impact (Table 3-2) (Percival 1999).

Very High: - For the purposes of the EIA a very high sensitivity was identified for all species, which are listed as cited interests for an SPA and within range of potential interaction, i.e. was within the known foraging range of the species. Foraging ranges were taken from Roos (2010) and Thaxter *et al.* (2010). The SPAs that were identified as having a potential for interaction are presented in (Table 3-1).

High: - A definition of high sensitivity was given for species identified as being part of an SPA assemblage or within the potential area of impact greater than 1% of the national population could be affected. Species for which less than 300 pairs nest in the UK were also considered as being of high sensitivity.

Medium: - Species were considered to be of medium sensitivity if a regionally important population was potentially affected. For the purposes of the EIA the regional population was defined as being between the Firth of Forth and Troup Head. Regional populations were based on latest SPA populations and mean 5 year peak WeBS counts (Table 3-15). If greater than 1% of the regional population was considered as being potentially effected then the species was considered to be Medium sensitivity.

Low: All species that were not covered by any of the above categories were given a low sensitivity.

Table 3-2: Definition of terms relating to the non-impact sensitivity of the species.

Sensitivity	Definition
Very High	Cited interest of SPAs. Cited means mentioned in the citation test for the site as a qualifying species for which the site is designated.
High	Other species that contribute to the integrity of the SPA. An impact on a local population of more than 1 per cent of the national population of a species. An impact on ecologically sensitive species (e.g. large birds of prey or rare birds - <300 pairs in Britain.
Medium	Regionally important population of a species, either because of population size or distributional context, EU Birds Directive Annex 1, EU Habitats Directive priority habitat/species or Species of European Conservation Concern (SPEC) and or Wildlife and Countryside Act Schedule 1 species (if not covered above). UK BAP priority species (if not covered above).
Low	Any other species of conservation interest (e.g. species listed on the Birds of Conservation Concern not covered above).

Further refined species specific sensitivity assessment has been undertaken in line with recommendations made in Maclean *et al* (2009). Sensitivities of species groups to particular impacts are ranked and combined with the non-impact sensitivities to give an overall sensitivity. The main types of impact identified are:

- Collision Mortality,
- Barrier effect,
- Displacement (including disturbance and indirect impacts, i.e. depletion of prey).

Collision Mortality

Collision risk modelling has been undertaken based upon the Band *et al.* (2000) model.

The Risk is assessed based on the probability of a bird flying through the rotor swept area and the probability of it colliding. This is then multiplied by number of flights predicted to occur through rotor swept area based on site specific data and no avoidance.

However, data from existing offshore wind farms indicate that there is a significant avoidance of wind turbines, typically greater than 99% (e.g. Pettersson 2005, Petersen *et al*. 2006) and the probability of a bird colliding takes this into account by including an avoidance rate. For the purposes of this assessment a range of avoidance rates have been used to give a range of potential mortality rates. The avoidance rates used are 98%, 99% and 99.5% based on SNH guidance (SNH 2010) but it is also noted that Maclean *et al*. (2009) recommended avoidance rates of 99% or greater. However, in order to determine potential effects a precautionary 98% has been used for nearly all species within this EIA.

Not all species recorded within Aberdeen Bay are at significant risk of collision. The level of risk depends on a large extent as to whether the species frequently flies at rotor height. Birds can fly at any height and may change depending upon weather conditions or behaviour. However, by using data from both site specific boat-based survey data (Table 3-3) and other extensive data sets from other offshore wind farm locations a large sample size of flight heights are available for collision risk assessment.

The species selected for collision risk modelling were selected on their frequency of flying at rotor height and the frequency at which they were recorded in Aberdeen Bay. Collision risk modelling was undertaken on the following species:

- Red-throated diver
- Fulmar
- Gannet
- Cormorant
- Pink-footed goose
- Barnacle goose
- Common scoter
- Guillemot
- Common gull
- Herring gull
- Kittiwake
- Sandwich tern
- Common tern

Body sizes were obtained from BTO BirdFacts website (BTO 2011).

Annual Mortality Rates were obtained from BTO BirdFacts website (BTO 2011).

Avoidance Rates from SNH (2010).

Flight speeds were obtained from Pennychuick (1997), Alerstam *et al*. (2007).

Table 3-3: Flight heights of birds recorded in Aberdeen Bay.

Species	Boat-based surveys 2007-2008		
	Sample size	%>15 m	%>25 m
Red-throated diver	55	7	0
Black-throated diver	3	0	0
Common scoter	377	30	1
Velvet scoter	7	0	0
Common eider	93	3	0
Long-tailed duck	17	0	0
Wigeon	1	100	100
Teal	1	100	100
Tufted duck	2	0	0
Goldeneye	2	0	0
Fulmar	213	1	0
Manx shearwater	9	0	0
Gannet	404	29	17
Cormorant	44	7	0
Shag	17	0	0
Great skua	8	63	25
Arctic skua	16	38	19
Long-tailed skua	1	1	0
Black-headed gull	4	0	0
Common gull	494	71	33
Kittiwake	907	43	22
Herring gull	362	55	40
Lesser black-backed gull	1	100	1
Great black-backed gull	128	79	60
Common tern	22	23	14
Arctic tern/Com. tern	24	17	0
Sandwich tern	79	53	4
Guillemot	271	1	1
Razorbill	354	0	0
Guillemot/Razorbill	398	0	0
Puffin	32	0	0
Little auk	7	0	0
Golden plover	2	0	0
Oystercatcher	1	100	100
Dunlin	2	0	0
Curlew	2	0	0
Shelduck	7	14	0
Barnacle goose	817	62	35
Goose sp.	85	100	100
Meadow pipit	7	0	0
Swift	1	0	0
Skylark	1	0	0

Flight heights were collected as being at greater than 15 m and greater than 25 m. Those at 25 m or above have been considered to be at risk of collision. It is not possible to produce frequency plots of flight heights from these data but existing published data from other offshore developments have been used to put into a wider context using a much larger data set the data collected from Aberdeen Bay.

Species sensitivities are based on the results from the collision risk modelling and the adult survival rates (Table 3-4) combined with the non-impact sensitivities (Table 3-2) to give an overall sensitivity presented in Table 3-5.

Table 3-4: Sensitivity of population based on adult survival rate.

Sensitivity Due to Population recovery Time	Definition
Very High	Annual Survival > 0.90 – Fulmar, Gannet, Manx shearwater, Barnacle goose, Eider, Auks, Kittiwake, Lesser black-backed gull, Great black-backed gull, Black-headed gull, Common tern, Arctic tern
High	Annual Survival 0.85 – 0.90 – Cormorant, Shag, Pink-footed goose, greylag goose, Shelduck, Skuas, Herring gull, Common gull, sandwich tern, Little tern
Medium	Annual Survival 0.80 – 0.85 – Divers, Swans,
Low	Annual Survival <0.80 Ducks, Grebes [(1)] Waders

Source: BTO Birdfacts (2011) 1 = Abt & Konter (2009)

Table 3-5: Overall sensitivity of species to collision.

Non-impact Sensitivity (Table 3-2)	Sensitivity of Receptor (based on adult survival rate) (Table 3-4)			
	Very High	High	Medium	Low
Very High	Very High	Very High	High	Medium
High	Very High	High	High	Medium
Medium	Very High	High	Medium	Low
Low	High	Medium	Low	Low

Barrier effect

Barrier effects may arise should the species avoid flying through the proposed development and by doing so incur additional energetic costs required to fly the extra distance around the turbines (Speakman, Gray & Furness 2009; Masden *et al.* 2010). The risk of an impact is largely dependent on the number of times a bird may have to cross the obstruction and also the individuals' fitness. Should a bird be required to avoid an area only once or twice a year when undertaking a migration then it is likely that the potential impact will be lower than if a bird regularly flies around a barrier, e.g. between a feeding or roosting site (Speakman, Gray & Furness 2009).

In order to assess the potential impacts from displacement it was assumed that, unless data from other wind farms indicates otherwise, all individuals avoided flying through the site and detoured around it and by doing so had to fly further than would have otherwise been the case. To calculate the potential length of detour it was assumed that the detour started 1 km in front of the proposed development and the bird detoured back on to the original course 1 km beyond the proposed development. The original distance the bird would have flown if had not detoured is subtracted from the additional distance the bird has flown to get a figure for the potential increase in distance travelled. However, it is also recognised that some birds may start to detour at greater distance than 1 km and others may not and some may not detour at all.

It was assumed that all flights were potentially along the longest axis, i.e. north-south.

The total length of the proposed development is approximately 4 km and the width 2 km. The distance flown in order to avoid the proposed development from 1 km all round is 7.2 km. Therefore, the incremental increase in flight distance caused by flying around the proposed development is 3.2 km.

Where appropriate, results from energetics modelling have been considered to assess the potential incremental increase in daily energy expenditure (Speakman, Gray & Furness 2009).

To assess the potential sensitivity of a species to a barrier effect a species specific sensitivity, based on wing loads (Table 3-6), combined with non-impact sensitivities (Table 3-2), have been used to provide an overall sensitivity (Table 3-7) after Maclean *et al.* (2009).

Table 3-6: Species sensitivity due to barrier effects.

Sensitivity due to barrier effects	**Species**
Very High	Black-throated diver
High	Red-throated diver
Medium	Ducks,
Low	Fulmars, Skuas and Gulls Gannets, Terns, Waders & Passerines

Table 3-7: Overall sensitivities due to barrier effect

Non-impact Sensitivity (Table 3-2)	**Species Sensitivity due to barrier effects** (Table 3-6)			
	Very High	High	Medium	Low
Very High	Very High	Very High	High	Medium
High	Very High	Very High	High	Medium
Medium	Very High	High	Medium	Low
Low	High	Medium	Low	Low

Displacement

Disturbance caused by the proposed EOWDC may lead to displacement of birds from potential feeding areas, resulting in effective habitat loss. This may be caused by a number of reasons but for some species for which displacement have been identified it is not known why displacement occurs. Displacement may be caused by disturbance from vessels associated with the proposed development or from secondary impacts, i.e. the depletion of prey in the development area. However, whatever the cause, the effects are the same; birds are displaced from an area and relocate to somewhere else. The significance of the displacement is difficult to quantify but for species that rely on localised or patchy food supplies the affect may be more significant than it is for species that have a wide area of food supply. Based on the Maclean *et al.* (2009) report the impact assessment has considered sensitivity of a species depending on its habitat flexibility, i.e. how restricted is the species to a particular habitat preference (Table 3-8). Potential impacts relating to disturbance by vessels are addressed in the species accounts.

The overall sensitivity is based on the species specific and non-impact sensitivities (Table 3-9).

Table 3-8: Species sensitivity due to displacement.

Sensitivity due to habitat flexibility	Species
Very High	Red-necked grebe
High	Divers, Scoter, Cormorant , Great-crested Grebe
Medium	Eider, Common Tern, Arctic Tern, Little Gull
Low	Sandwich Tern, Great Black-backed Gull, Auks, Great Skua, Black-headed Gull, Kittiwake, Gannet, Lesser Black-backed Gull, Herring Gull, Fulmar.

Table 3-9: Overall sensitivity due to displacement.

Non-impact Sensitivity (Table 3-2)	Species Sensitivity due to barrier effects (Table 3-8)			
	Very High	High	Medium	Low
Very High	Very High	Very High	High	Medium
High	Very High	Very High	High	Medium
Medium	Very High	High	Medium	Low
Low	High	Medium	Low	Low

For the purposes of the assessment two assumptions have been made as to the level of displacement that may occur. For Divers and Auks it is assumed that there is total displacement within the proposed EOWDC area and out to 1 km beyond the furthest turbine. There is then a further 50% displacement of birds out a further 1 km. For other species of seabird for which displacement effects may occur, e.g. seaduck, it is assumed that there is total displacement within the proposed development area and 80% displacement out to 1 km and 20% displacement out an additional 1 km. This takes into account the current understanding of the differing potential displacement effects on species but is still precautionary, as for many species displacement effects of this magnitude have not been recorded.

In order to determine potential number of birds at risk of being displaced the maximum recorded density obtained from any location from any of the boat-based surveys has been used. This provides a very precautionary number for the potential numbers of birds displaced, as for the majority of species peak densities were recorded outwith the proposed development area.

A worked example is presented in Table 3-10.

Table 3-10: An example of calculations used for potential displacement.

Calculations used for displacement	
Area	*Peak density of common scoter – 23.1 birds/km^2*
Area of EOWDC – 4.3 km^2	4.3 * 23.1 = 99
Area of 1 km buffer at 80% displacement = 12.3 km^2	(12.3 * 23.1)*0.8 = 227
Area of 2 km buffer at 20% displacement = 20.3 km^2	(20.3 * 23.1)/0.2 = 94
Total displaced	99+227+94 = 420

Magnitude of effect

The magnitude of effect for potential displacement and collision mortality is based on the definitions developed by Percival (1999) (Table 3-11). However, this is not suitable for determining the potential magnitude arising from barrier effect and consequently the assessment of the potential magnitude of barrier effects is based on Maclean *et al.* (2009)
Table 3-12).

Table 3-11: Definition of potential magnitude of an effect from collision mortality and displacement.

Magnitude	**Definition**
Very High	Potential total loss or very major alteration to key elements/features of the baseline conditions such that post development character/composition/ attributes will be fundamentally changed and may be lost from the site altogether. Guide: >80% of population/habitat lost
High	Potential for major alteration to key elements/ features of the baseline (pre-development) conditions such that post development character/composition/attributes will be fundamentally changed. Guide: 20-80% of population/habitat lost
Medium	Potential for loss or alteration to one or more key elements/features of the baseline conditions such that post development character/ composition/ attributes of baseline will be partially changed. Guide: 5-20% of population/habitat lost
Low	Potential for a minor shift away from baseline conditions. Change arising from the loss/ alteration will be discernible but underlying character/ composition/ attributes of baseline condition will be similar to pre-development circumstances/patterns. Guide: 1-5% of population/habitat lost
Negligible	Potential for a very slight change from baseline condition. Change barely distinguishable, approximating to the “no change” situation. Guide: <1% of population/habitat lost

Table 3-12: Criteria used to determine one of the components of the magnitude of impact due to barrier effect.

Magnitude of impact	Definition
Very High	(i) Wind farm is located between breeding site and key foraging area of a species flying through the site in nationally or internationally important numbers and/or (ii) is located close to key stopover, breeding or wintering site of species flying through the site in internationally important numbers and/or (iii) is located along the migration route of a species flying through the site in internationally important numbers.
High	(i) Wind farm is located close to key stopover, breeding or wintering site of species flying through the site in nationally important numbers and/or (ii) is located along the migration route of a species flying through the site in nationally important numbers.
Medium	(i) Wind farm is located between breeding site and key foraging area of a species flying through the site in regionally important numbers (ii) is located close to key stopover, breeding or wintering site of a species flying through the site in nationally important numbers (ii) Is located along the migration route of a species flying through the site in regionally important numbers.
Low	(i) Wind farm is located between breeding site and key foraging area of any other breeding species and/or (ii) is located close to a key stopover, breeding or wintering site of any other species and/or (iii) likely to be located on a migration route of any other species.
Negligible	None of the above

By combining the overall sensitivity of a receptor with the potential magnitude an indicative overall significance of the impact to the receptor is obtained (Table 3-13). However, it is recognised that this is only indicative and evidence from existing wind farms and expert judgement is used to determine whether the potential impact is likely to be either significant or adverse.

Table 3-13: Potential significance of impact.

Magnitude	Overall Sensitivity of Receptor			
	Very High	High	Medium	Low
Very High	Major	Major	Major	Moderate
High	Major	Major	Moderate	Minor
Medium	Major	Moderate	Moderate	Minor
Low	Moderate	Minor	Minor	Negligible
Negligible	Minor	Negligible	Negligible	Negligible

Implications of significance

Where the potential significance is identified as being negligible or minor it is considered to be of limited or no concern. Moderate significance is of concern but may be tolerable depending on the causes that give rise to the potential impact. Major concerns are considered to be a potentially significant effect.

It should be noted that the significance derived at by the use of matrices is only a guide and the final conclusions of the impact assessment for each species is drawn upon the currently available evidence for each species.

Determining potential adverse effects.

To determine potential adverse effects the assessment is based on the Conservation Objectives and qualifying species of the site.

To identify whether an impact is potentially adverse with respect to potential impacts on population levels a measure based upon the 1% of baseline mortality rate has been used as a guide. This guidance is based on an EC Report on the application of the Birds Directive and although does not relate specifically to impacts from wind farms does provide suitable guidance against which an assessment can be made (EC 2000). If there is an increase in the baseline mortality rate of more than 1% then there is the potential for an adverse effect.

In order to determine whether there is the potential for an adverse effect the SPA population of the species has to be determined. Population levels can increase or decrease often by natural change. Consequently, the population within the SPA citation may not be comparable with the more recent counts and by making an assessment against historical population levels as published in the sites citation an inaccurate conclusion may be drawn. For the purposes of this assessment the latest SPA population figures have been used, although it is recognised that the population at the time of citation may still be relevant. The figures have been obtained from SNH and JNCC sources (SNH 2011, JNCC 2011a) (Table 3-15).

For many species of bird present in Aberdeen Bay it is likely that birds of the same species may be from different SPA sites, e.g. guillemots may be from Fowlsheugh SPA, Troup, Pennan and Lion’s Head SPA and Buchan Ness to Collieston SPA. It is not possible to identify from which specific SPA the birds present within Aberdeen Bay are from. Without this information the assessment assumes that any birds potentially at risk of an impact are all from a single SPA. However, it also recognises that this will not be the case and a proportion of birds will be from other designated sites.

Ultimately the approach to ascertaining whether there is a potential adverse effect on site integrity is a judgement based on the totality of the evidence available.

3.6 Assessment of cumulative impacts

The assessment of cumulative impact considers all other activities that have the potential to significantly impact on the birds that may be present at the proposed development location, these possible activities include:

- Offshore renewables,
- Shipping,
- Aggregates,
- Dredging,
- Oil & gas.

Offshore renewable projects that have been identified as having the potential for a cumulative effect include two developments in the Moray Firth and three in the Firth of Forth. The sites in the Moray Firth are approximately 150 km to the north and those in the Firth of Forth approximately 120 km to the south of the proposed development (Table 3-14).

The construction of the EOWDC is planned for 2013 and 2014 and so there is the potential for an overlap in construction activities in 2014 with Neart Na Gaoithe and Beatrice offshore wind farms. However, given the stage of development of the renewable projects yet to be constructed and the uncertainty as to the types of foundations and turbines that will be used, there is sparse information available to incorporate into any impact assessment, which limits the effectiveness of cumulative assessments considering conceptual projects yet to be subject to a formal planning application and for which no environmental or design data are currently available.

Therefore, the cumulative impact assessment can only be undertaken with data available from the currently operating Beatrice demonstrator project in the Moray Firth. Although, the assessment does wherever possible the potential cumulative impacts from other yet unconsented renewable projects.

Shipping associated with Aberdeen harbour, has been undertaken in Aberdeen Bay over many centuries with currently approximately 16,000 vessel movements per year. There are no known plans that are likely to cause a significant increase in the level of shipping currently being undertaken in Aberdeen Bay and any impacts shipping may currently be having on the birds within Aberdeen Bay will be part of the baseline.

There are no aggregates activities within Aberdeen Bay. There are no licensed dredging sites within Aberdeen Bay but occasional dredging of the harbour may occur, with the next dredging scheduled for 2012.

Aside from associated shipping there are no oil and gas related activities within Aberdeen Bay.

Table 3-14: Potential renewable energy developments.

Name of development	Developer	MW	Possible number of Turbines	Project timeframe construction
The Beatrice Demonstrator	Joint Venture Talisman and Scottish and Southern Energy	10	2	Installed operational
The Moray Firth Eastern Development	Moray Offshore Renewables Ltd	1,300	67	Construction starts 2015
The Moray Firth Western Development	Moray Offshore Renewables Ltd	1,300	Not yet known	Unknown >2015 (EIA commences 2013)
Beatrice	Sea Energy Renewables Ltd & Scottish and Southern Energy	920	184	2014
Firth of Forth: Phase 1	SeaGreen	1,075	215	2015
Firth of Forth: Phase 2	SeaGreen	1,435	287	Unknown >2015
Firth of Forth: Phase 3	SeaGreen	955	191	Unknown >2015
Neart na Gaoithe	Mainstream Renewable Power	420	130	2014
Inch Cape	SeaEnergy	905	181	2015

3.7 Assessment of in-combination impacts

The Conservation (Natural Habitats, & c.) Regulations 1994 (as amended) require that a Habitats Regulations Appraisal (HRA) must be conducted by a competent authority. The HRA considers the implications for European sites in view of the European sites conservation objectives, in respect of any plan or project which is not directly connected with or necessary to the management of the European site for conservation purposes and which is likely to have a significant effect on the European site either alone or *in-combination* with other plans or projects.

Therefore the term ‘in-combination’ will be used when considering the impacts of the proposals with other plans or projects on European sites and their associated qualify features or species.

The main industries considered for potential in-combination impacts are proposed offshore wind farms, aggregate industry, dredging, oil and gas and shipping. Of these, proposed offshore wind farms and shipping are the only activities identified for which there is a potential for an in-combination impact.

Table 3-15: National, Scottish and Regional SPA species populations.

Species	Season	National Pop^{n}	Scottish Pop^{n}	Regional SPA Pop^{n}	1% regional SPA Pop^{n}

3.8 Impact assessment summary

The results from undertaking the impact assessment based on the matrices are summarised below in three separate tables:

- Collision risk
- Barrier effect
- Displacement

Each of the results are considered further within the individual species assessments presented in Section 4 where the use of site specific information, evidence from existing offshore developments and expert judgement are used to determine the risk and potential significance from each impact for each the main species recorded during the studies undertaken.

Table 3-16: Potential sensitivities and significance of impact from collision risk.

4 SPECIES ACCOUNTS

4.1 Whooper swan (*Cygnus cygnus*)

4.1.1 Protection & Conservation Status

The whooper swan is listed in Annex I of the Birds Directive, Appendix II of the Bern Convention, Appendix II of the Bonn Convention, Schedule 1 under the Wildlife and Countryside Act, 1981 and is on the Amber List of Species of Conservation Concern.

4.1.2 Background

Whooper swan		
GB Population	Breeding: <15 prs. Winter: 10,678 ind.	Holling 2010 Calbrade *et al*. 2010
Scotland	Breeding: 3 – 7prs Winter: 4,142	Forrester *et al.* 2007
International threshold	210 ind.	Calbrade *et al*. 2010

Designated east coast sites where species is a noted feature	Loch of Strathbeg – 333 ind	SNH 2011 JNCC 2011a
European population estimate	Breeding 16,000 – 21,000 Wintering >65,000	Birdlife 2004
European population trend	Status: 'Large increase' Trend: 'secure'	Birdlife 2004
World population	180,000 'adults'	Birdlife 2011

Whooper swans are a rare breeding bird in the UK and Scotland with less than 15 pairs nesting each year, approximately half of which nest in Scotland. Wintering birds arrive from their main breeding grounds in Iceland during October and November and spend the winter on lowland farmland, lochs and marshland (Forrester *et al*. 2007). In North-east Scotland small numbers of whooper swans can occur in many of the freshwater lochs but the main wintering area is the Loch of Strathbeg where over 300 whooper swans have occurred in recent years, although up to 600 were present there in the early 1980's (Buckland, Bell & Picozzi 1990).

Satellite tagging studies have indicated that the majority of whooper swans migrating along the east coast are associated with the wintering sites in East Anglia but no birds were recorded flying along the North-east coast of Scotland with birds crossing the Firth of Forth moving predominantly north-west/south-east direction (Griffin, Rees & Hughes 2010).

Boat-based surveys

No whooper swans were recorded during boat-based surveys undertaken in Aberdeen Bay.

Vantage Point surveys

The only record of whooper swan during any of the surveys was of a flock of five birds, which were recorded inland heading north-west at Drums during October 2005. The birds were flying at approximately 20 m altitude.

Bird Detection Radar

No whooper swans were recorded during any of the radar studies undertaken.

4.1.3 Summary of Results

Only one flock of whooper swans was recorded during surveys undertaken in Aberdeen Bay. The flock was flying inland and below 20 m.

4.1.4 Initial Assessment of Significance

Whooper swan	Overall sensitivity	Magnitude	Significance
Collision	High	Negligible	Negligible
Barrier	High	Low	Minor
Displacement	Medium	Negligible	Negligible

4.1.5 Species Sensitivities

Qualifying species

There are twenty Special Protection Areas (SPA) in the UK for which whooper swan is a qualifying species, of which one is within an area of potential impacts from the proposed development:

- Loch of Strathbeg SPA & Ramsar (47.6 km).

Formerly whooper swan was also a qualifying feature for the Loch of Skene SPA and under the last review, the Loch of Skene held 307 whooper swan based on the 5 year peak mean from between 1991/92 and 1995/96 (Stroud *et al.* 2001). Recent counts at Loch of Skene indicate a decline in the use of the site by whooper swans with peak counts of 27 in 2007.

The Loch of Strathbeg review reported 183 whooper swans (3.3% of the wintering population in Great Britain) based on the 5yr peak mean from between 1991/92 and 1995/96 (Stroud *et al.* 2001). More recent data have recorded a five year peak mean of 333 whooper swans with the latest published counts being of 92 in 2008 (Calbrade *et al*. 2010).

Flight height

The median flight height for whooper swans across the Moray Firth is 1 m with 83% of flights at or below 20 metres and 100% of flights below 50 m. Elsewhere, recorded flight height have been higher, e.g. across the Wash the median flight heights are higher at 30 m with 22% below turbine height (Griffin, Rees & Hughes 2010).

Collision risk

Evidence from site specific monitoring from boat-based and land-based surveys indicate that whooper swans are infrequent within the area of the proposed development with no sightings within the footprint of the proposed development and only one sighting of five birds flying inland. Data from satellite tagging studies indicates a relatively low usage of the coast from North-east coast of Scotland by whooper swans, with the majority of birds flying overland (Griffin, Rees & Hughes 2010).

Evidence from other offshore wind farms indicate that migrating whooper swans will, if migrating along the coast, remain in nearshore waters. Nearly 90% of migrating whooper swans in Liverpool Bay were recorded within 2.5 km of the coast with 70% along the coastline (RBA 2005).

Flight height data obtained from radio tracking studies suggest that the majority of whooper swans fly below turbine height. Evidence from existing wind farms indicate that 70% of whooper swans fly below 30 m (RBA 2005).

Based on the evidence from existing offshore wind farms and site specific data indicating a very low, if any, usage of the area by whooper swans, the risk of any significant impact or adverse affect on whooper swans is negligible.

Barrier effect

Evidence from studies undertaken in Sweden suggests that Swans (including whooper swan) and geese may avoid flying into wind farms during migration (Pettersson 2005).

In order to avoid the turbines the birds may incur additional energetic expenditure. The proposed EOWDC is at its longest point approximately 4 km and at its widest 2 km. Assuming birds avoid the wind farm at 1,000 m then they may incur an overall increase in flight distance of 3.2 km. For whooper swans flying to or from Iceland the potential increase in distance flown in order to avoid the turbines is negligible.

Displacement

Whooper swans rarely settle on the sea surface and tend to do so only in poor weather during periods of migration. They do not forage offshore and therefore there will not be any potential displacement of whooper swans due to the proposed development.

Cumulative and in-combination

The very low level of usage of the site indicates that there will not be any cumulative or in-combination impacts.

4.1.6 Conclusions

Habitats Appraisal

Based on the available evidence from site specific surveys undertaken at the proposed development area and other offshore wind farms in particular, the very low usage of the site during migration and that the Loch of Strathbeg SPA is located to the north and therefore birds migrating from Iceland will not cross the proposed development area to and from their breeding grounds. It is concluded that the proposed development will not have an adverse effect on whooper swans as a qualifying feature for Loch of Strathbeg SPA.

Environmental Impact Assessment

Based on the apparently low numbers crossing the proposed development site and the known behaviour of Swans, it is predicted that there will not be a significant environmental impact arising from the proposed development on whooper swans.

4.2 Pink-footed goose (*Anser brachyrhynchus*)

4.2.1 Protection & Conservation Status

The Pink-footed goose is listed in Appendix II of the Bern Convention, Appendix II of the Bonn Convention and is on the Amber List of Species of Conservation Concern.

4.2.2 Background

Pink-footed goose		
GB Population	Winter – 340,000 ind.	Calbrade *et al.* 2010
Scotland Population	Winter – 200,000 ind.	Forrester *et al.* 2007
International threshold	2,700 ind.	Calbrade *et al.* 2010
GB threshold	2,400 ind.	Calbrade *et al.* 2010
Designated east coast sites where species is a noted feature	Ythan Estuary, Sands of Forvie and Meikle Loch – 16,300 (07/08 Loch of Strathbeg 53,454 (08/09) Firth of Forth: 3,220 (08/09) Firth of Tay & Eden Estuary: 2,704 (08/09) Montrose Basin: 38,911 (08/09)	Calbrade *et al.* 2010
European population estimate	Breeding 50,000 – 69,000 pairs Wintering – >290,000 ind.	Birdlife 2004
European population trend	Status 'secure' Trend 'large increase'	Birdlife 2004
World population	310,000 'adults'	Birdlife 2011

The pink-footed goose population that winters in the UK breed in Iceland and eastern Greenland. They migrate to the UK in the autumn in large numbers during September and October and winter in eastern Scotland, north-west England and Norfolk and start returning north in March and April. In North-east Scotland pink-footed geese are widespread occurring across the region from September through to April. Peak numbers occur in mid-October when pink-footed geese arrive from their breeding grounds during which time up to 25% of the British population may occur at the Loch of Strathbeg and Meikle Loch. Birds disperse southward for the winter and return again in March when birds overwintering to south of the region migrate northwards. Between October and March the number of pink-footed geese in the region is lower but those that remain feed on farmland and roost in large numbers on a few freshwater lochs, primarily Loch of Strathbeg and Meikle Loch.

Birds flying offshore peak during September and October with up to 800 birds per month past Peterhead with numbers dropping in November and December when less than 100 birds per month have been recorded. There is a smaller passage of pink-footed geese past Peterhead during April when 200 birds per month were recorded. Sightings were of birds out to 3 km from shore (Innes 1996).

The pink-footed goose population has increased substantially in recent decades from approximately 50,000 in the 1960's to a present day total of approximately 340,000 individuals and this increase has been reflected in the number of birds occurring in North-east Scotland where the use to be only 1,000 to 2,000 birds present to over 50,000 in recent years (Buckland, Bell & Picozzi 1990; Calbrade *et al.* 2010; NESBR).

Boat-based surveys

No pink-footed geese were recorded during any of the boat-based surveys undertaken between February 2007 and April 2008 and again from August 2010 and January 2011 (SMRU 2011b).

Vantage Point surveys

In Aberdeen Bay, pink-footed geese were recorded from four Vantage Point sites between October and March but none were recorded during 23 hours of survey undertaken during September and October 2005. There was only one record of three birds in September (Alba Ecology 2008a) and no records of pink-footed geese during April. Counts were of a relatively small number of skeins comprising of between 18 and 230 individuals and only three skeins of pink-footed geese were recorded between October and March 2006. The majority of sightings were of birds between 1-3 km from the coast and between 50% and 100% of were flying between 30 m–150 m.

Bird Detection Radar

During radar studies undertaken in October 2005 a total of 12 skeins of pink-footed geese were recorded totalling 858 birds. All sightings were made from Drums with no records from Easter Hatton (Walls *et al.* 2005). Birds were recorded out to 3.0 km with the majority within 500 m from shore (Figure 4-1).

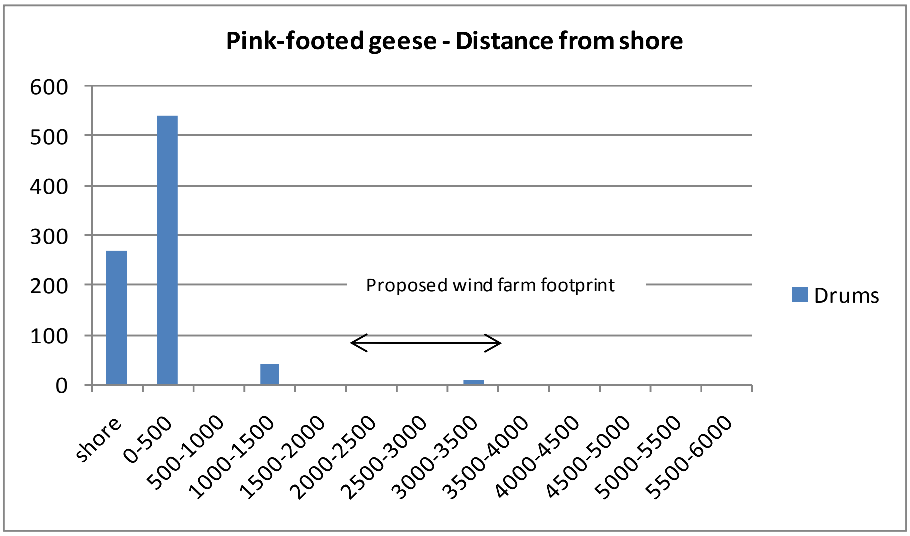

Figure 4-1: Number of pink-footed geese and distance from shore observed from surveys at Drums in October 2005 (Adapted from Walls *et al*. 2006).

Seventeen days of radar studies recorded 102 pink-footed geese in four skeins flying north between 11 April and 26 April 2007. All sightings were from between 0.5 km and 2 km from shore and below 30 m (Simms *et al.* 2007). A further radar study aimed to detect migrating geese across Aberdeen Bay during six days in April 2010 recorded three skeins of geese, one of which was confirmed to be pink-footed geese. All three skeins were moving northwards and the one skein that was visually observed was of 90 birds (Plonczkier & Simms 2010).

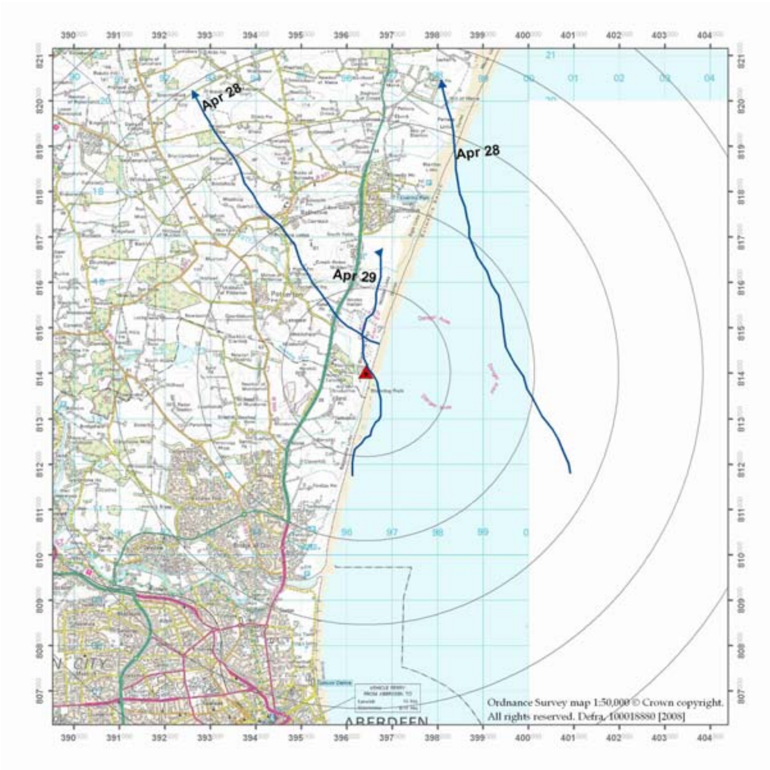

Figure 4-2: Flight directions of Geese sp. crossing Aberdeen Bay April 2010.

4.2.3 Summary of Results

Pink-footed geese were occasionally recorded in Aberdeen Bay during migration periods. Numbers recorded were generally low with no significant migration detected. The majority of birds were recorded flying above 30 m and most sightings were of birds within 2 km from shore.

Numbers of pink-footed geese recorded in Aberdeen Bay were below the threshold for a site of national importance.

4.2.4 Initial Assessment of Significance

Pink-footed goose	Overall sensitivity	Magnitude	Significance
Collision	Very High	Negligible	Minor
Barrier	High	Medium	Moderate
Displacement	High	Negligible	Negligible

4.2.5 Species Sensitivities

Qualifying species

The nearest SPAs to the proposed development for which the pink-footed goose is a qualifying species are the Ythan Estuary, Sands of Forvie and Meikle Loch SPA & Ramsar and the Loch of Strathbeg SPA & Ramsar. Elsewhere, the Montrose Basin, Firth of Forth and Firth of Tay & Eden Estuary SPA & Ramsar, also have pink-footed geese as qualifying species (SNH 2011).

Flight height

No pink-footed geese were recorded from boat-based surveys but flight heights from Vantage Point surveys indicated that between 50 – 100% of recorded flights were between 30 – 150 m above the sea surface and therefore at potential risk of collision.

Data from other offshore wind farms have recorded 46% of all flights as flying at potential rotor height (n=12,294).

Collision risk

Evidence from site specific surveys indicate that pink-footed geese occur in Aberdeen Bay particularly during the spring and autumn and are more frequently recorded within 2 km of the coast than further offshore (Figure 4-1).

Collision Risk Modelling undertaken for pink-footed goose is based on:

- Body length of 65 cm
- Wingspan of 153 cm
- Flight speed of 18.8 $m.s^{-1}$
- % at rotor height –46%
- Avoidance rate – 98, 99, 99.5%

(Koffijberg & Mennobart 1995; Gremillet, Schmid & Culik 1995)

The number of pink-footed geese recorded within the proposed development area was very low. Therefore, the collision risk modelling undertaken was based on a very precautionary ‘worst-case’ scenario using following assumptions:

1. The total number of pink-footed geese passing through North-east Scotland each autumn is 340,000. This is based on the entire UK wintering population occurring in North-east Scotland, which is not thought to be the case, as some but an unknown number of geese will arrive directly into the north-west England from their breeding grounds in Iceland (WWT 2007).
2. All pink-footed geese migrate south across a front of up to 5 km offshore and 5 km inland and therefore over a 10 km wide front. The maximum width of the proposed development is 3.6 km and therefore intercepts 36% of the potential flight path. This is precautionary as site specific data indicates that the majority of geese fly within 1 km from shore (Figure 4-1) and therefore do not interact with potential development. However, for the purposes of the collision risk modelling it assumed that 36% of the UK wintering population of pink-footed geese cross the proposed development area, i.e. 122,400 birds and that they pass through the site each autumn and spring, i.e. a total passage of 244,800 birds per year.
3. Those that do fly across the development area, 46% do so at turbine height and that there is no far field avoidance.
4. The same rate of passage occurs during the spring as it does during the autumn is also very precautionary as the numbers of pink-footed geese in the spring are always significantly lower than those in the autumn indicating that less pink-footed geese will pass through the region during the spring migration.

The Collision Risk Modelling has been undertaken on these precautionary assumptions using a range of avoidance rates: 98%, 99% and 99.5%.

Table 4-1: Results from collision risk modelling undertaken on pink-footed geese.

Collision probability	Avoidance rate (%)		
	98	99	99.5
8.4%	56	28	14

Based on the various very precautionary scenarios and using a precautionary avoidance rate of 99% as recommended by SNH, it is predicted that up to a total of 28 collisions per year may occur (Table 4-1).

The annual mortality rate for pink-footed goose is 13.7% (BTO 2011). Consequently, out of a population of 340,000 an annual mortality of 45,560 pink-footed geese may be predicted. Therefore, 1% of the baseline mortality is 4,556 birds per year.

Based on the results from the very precautionary Collision Risk Modelling undertaken, the number of pink-footed geese that may collide is lower than the rate of mortality which may cause concern of a potentially significant impact on pink-footed geese.

To assess whether there is the potential for an adverse effect on pink-footed geese as qualify species for the relevant regional SPAs, the assessment is based on the 5 year peak mean counts as opposed to numbers published at the time of SPA citation as the populations of pink-footed geese have increased significantly since the SPA citations were originally made. It is also assumed that each SPA population is separate from each other and any collision impacts relate to birds only associated with that SPA. This is known to be an incorrect and precautionary assumption as evidence from ringing studies indicates that pink-footed geese frequently move between sites during the winter period and that many birds migrate south-west from North-east Scotland to north-west England and are therefore not going to interact with the proposed development (WWT 2007; Mitchell & Hearn 2004). As the counts relate only to the autumn passage of geese the modelling is based on a similar rate of passage across each site in the spring.

Table 4-2: Predicted natural mortality rates of pink-footed geese at relevant SPAs.

Site SPA/Ramsar	Population	Natural Mortality	1% of Natural Mortality
Ythan Estuary, Sands of Forvie and Meikle Loch	16,300	2,233	22
Loch of Strathbeg	53,454	7,323	73
Firth of Forth	3,220	441	4
Firth of Tay and Eden Estuary	2,704	370	4
Montrose Basin	38,911	5,330	53

Based on the above and the precautionary guidance threshold of a 1% increase in baseline mortality, the results from the Collision Risk Modelling indicate that there is the potential for an adverse effect to occur should all the potential collisions relate to geese associated with three of the SPAs. However, this is based on the very precautionary assumptions made that the whole Icelandic population of pink-footed geese pass through the area and do so through a 10 km wide coastal corridor during both the autumn and spring migrations.

Intensive surveys have been undertaken at offshore wind farms to assess the potential collision risk of pink-footed geese. All studies undertaken to date have indicated a very high avoidance rate for pink-footed geese and very low risk of collision.

Studies undertaken at Barrow offshore wind farm in the East Irish Sea reported that pink-footed geese recorded flying in line of the wind farm adjusted their flight height to pass above the wind farm and continue their migration. Of the nine pink-footed geese recorded entering the wind farm at rotor height, all flew between the turbines without any collisions. No collisions were observed from a total of 16,542 observed passing birds of all species during the 21 days survey at Walney Island (BOW 2007).

The results from three years of studies assessing the potential impacts on birds in the Kalmar Sound from the two offshore wind farms of Utgrunden and Yttre Stengrund recorded very few collisions of any species. Although only a small proportion of the birds observed were pink-footed geese, nearly 120,000 other geese were recorded flying through the Sound. These were mainly barnacle, brent and white-fronted goose. Both prior and post construction the majority of the Geese flew along the shores of the Sound, with relatively few through the wind farm area. However, the number of geese migrating through the wind farm area increased from 6% of the total prior to construction to 13% of the total post construction. A total of 7,224 geese were recorded in the autumns of 2001 and 2002, all of which were seen to avoid the turbines.

At Nysted offshore wind farm in Denmark intensive radar studies undertaken tracked amongst other species (notably eider), approximately 10,000 geese each autumn and the results indicate that there was a significant decrease in the proportion of flocks entering the wind farm from between the pre-construction period and the current operational period. It reported that post construction, 9% of the birds entered the turbines compared with 40% crossing the same location before construction and no geese were recorded colliding with the turbines (Deshom & Kahlert 2005).

Similar results obtained from Horns Rev have also indicated that Geese, including pink-footed geese avoid operating offshore wind farms. A total of 11 flocks of geese observed on an intercept course with Horns Rev, one flock of 53 individuals was observed entering the wind farm area, without changing course, the remaining 10 flying past also without apparently altering course. Although course changes could have occurred before entering the radar area or due to their original line of approach they had no need to consider altering course. The flock that did alter course increased flight altitude when approaching the wind farm and when flying within the wind farm, ultimately flying at rotor height. Within the wind farm, the birds appeared to show less stability in flight resulting in a disrupted flock structure. The mean altitude of geese flocks was 64.2m and all flocks were within the rotor height (Christensen *et al.* 2004).

A total of 560 hours of observations undertaken at the eight turbines that make up the Rønland offshore wind farm in Denmark used both visual observations and radar to detect birds at night. Out of 30,977 birds recorded, 7,309 were Brent geese. Two collisions: one of a cormorant and the other of a pale bellied Brent goose were recorded during the study. This accounts for 0.07% of the total observations. Observations indicate that approximately 8% of all birds flew within 100 metres of the turbines and 4.5% of the flocks. But the risks of collision were much lower than those reported at other Danish wind farms (Jensen 2006).

Table 4-3 presents a summary of the data obtained on geese from existing constructed wind farms and the actual number of observed collisions. It is recognised that the total number of geese recorded includes geese observed that may not have had to take any avoidance behaviour as they were not originally flying in line with the turbines and also the observed collisions only occur during periods of daylight.

Table 4-3: Summary of data obtained on geese from constructed offshore wind farms.

Wind farm	No. of turbines	Length of study post construction	Species recorded	Total no. recorded	No of observed collisions
Utgrunden & Yttre Stergrund [1]	12	2 years	Bean goose	284	0

References - [1] Pettersson 2005, [2] Petersen *et al*. 2006, [3] Jensen 2006, [4] BOW 2007

Based on the above evidence and the highly precautionary nature of the Collision Risk Modelling undertaken and the site specific data indicating a low usage of the site by pink-footed geese it is concluded that risk of a significant or adverse effect is negligible.

Barrier effect

Although pink-footed geese may fly through wind farms (e.g. BOW 2007) they have also been recorded avoiding wind farms consequently there may be a barrier effect

Should a barrier effect occur then pink-footed geese will fly around the proposed development. By doing so, this could cause an overall increase in flying distance of up to approximately 3.2 km. For a bird migrating from Iceland to North-east Scotland, a distance of over 1,000 km then this will cause an increase of 0.3% in flight distance. This is considered to be a negligible impact and not cause any adverse effect.

Displacement

Pink-footed geese do not use Aberdeen Bay for feeding or roosting and therefore no displacement effects will occur.

Cumulative and in-combination

Potential cumulative and in-combination impacts on pink-footed geese have been addressed by many Round 1 and Round 2 offshore wind farms.

Cumulative collision risk totals based on Collision Risk Modelling are presented in Table 4-4. The collision risk modelling undertaken at the time was based on avoidance rates of 95%, 99% and 99.5%. Based on an avoidance rate of 99% a total of up to 167 pink-footed geese are predicted to be impacted from all the currently consented offshore wind farms. Based on the total UK population of 340,000 and 1%

baseline mortality rate of 4,556 individuals per year the cumulative impacts are therefore considered to be minor.

Table 4-4: Predicted potential collision mortality for pink-footed geese.

Site	Avoidance rate		
	95%	**99%**	**99.5%**
Ormonde	77	15	8
Walney	6	1	<1
West of Duddon Sands	5	1	<1
Barrow	15	15	8
Docking Shoal		15	8
Humber Gateway		48	24
Lincs	171 - 262	34 – 52	17 – 26
Lynn & Inner Dowsing	100 - 165	20 – 33	10 – 17
Total	**374 - 530**	**149 – 167**	**69 – 85**

Further evidence to support the conclusions that the potential impacts from collision risk are minor come from Population Viability Analysis (PVA) undertaken on pink-footed geese which indicate that the pink-footed goose population may be able to withstand an increase in mortality (from whichever source) of 5,000 birds per year (Trinder *et al.* 2005). Further PVA commissioned by DECC to model the possible effects of additional mortality on the pink-footed goose population over a 25 year period indicated that over a 25 year period there was a 2% chance of the pink-footed goose population decreasing to below 150,000 if, due to collisions, wind farms increase the annual mortality by more than 1,000 birds over and above current impacts, e.g. hunting. (Trinder 2008). The predicted level of mortality from all offshore wind farms based on precautionary collision risk modelling indicates that the level of mortality is below the threshold above which cumulative mortality rates could have an adverse effect.

4.2.6 Conclusions

Habitats Appraisal

Based on the site specific data indicating a low usage of the area by pink-footed geese and evidence from existing offshore wind farms indicating a very high avoidance rate; an adverse effect is not predicted to occur at any of the SPAs for which pink-footed goose is a qualifying species.

Environmental Impact Assessment

Based on the site specific data and data from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on pink-footed geese.

4.3 Greylag goose (*Anser anser*)

4.3.1 Protection & Conservation Status

The Greylag goose is listed in Appendix II of the Bern Convention, Appendix II of the Bonn Convention and is on the Amber List of Species of Conservation Concern.

4.3.2 Background

Greylag goose (Icelandic)		
GB Population	Winter – 85,000 ind.	Calbrade *et al.* 2010

European population trend	Status 'secure' Trend 'large increase'	Birdlife 2004
World population	1 – 1.100,000 'adults'	Birdlife 2011

Greylag geese breed in Iceland, north-west Scotland and many parts of Eurasia. They winter along the north-west and east coasts of Scotland particularly in Orkney where the population of over wintering birds has increased substantially in recent years from 3,000 in the 1990's to 43,000 in 2003 (Forrester *et al.* 2007). During the winter birds forage on farmland and are relatively sedentary until March when they start returning to their breeding grounds (Forrester *et al.* 2007).

In North-east Scotland greylag geese have been recorded passing Peterhead primarily in October with relatively few at other times of the year. In October up to 180 birds per month were recorded between 1978 and 1988 (Innes 1996). The wintering population of greylag geese in North-east Scotland has decreased in recent years as birds that used to winter in the region are now thought to do so in Orkney. Only relatively small numbers now winter at what used to be large winter roosts, particularly the Loch of Skene and Dinnet lochs that held up 15,000 and 30,000 birds each in the 1990's and now hold less than 1,000 birds each (Buckland, Bell & Picozzi 1990; NESBR).

The Greylag goose is notified feature for Corby Loch SSSI, which lies 4 km north of Aberdeen. Up until the early 1990's there was a winter roost of greylag geese of up to 2,600 birds but since then the numbers roosting there have declined and the loch is now only infrequently used by greylag geese (Hearn & Mitchell 2004, NESBR).

Boat-based surveys

No Greylag geese were recorded during any of the boat-based surveys undertaken between February 2007 and April 2008.

Vantage Point surveys

In Aberdeen Bay, greylag geese were recorded from Vantage Point sites during December and January 2006/2007 when four small skeins were recorded totalling 37 birds flying between 1-3 km from shore and none within the 30-150 m height band

(EnviroCenter 2007b). Further singles were recorded once in August 2006 and March 2008.

Bird Detection Radar

No positive sightings of greylag geese were made from the radar studies undertaken in October 2005, April 2007 or April 2010.

4.3.3 Summary of Results

Greylag geese were only occasionally recorded in Aberdeen Bay with the only records of note during December and January. The few sightings were of birds below 30 m and within 3 km from shore.

Numbers of greylag geese recorded in Aberdeen Bay were below the threshold for a site of national importance.

4.3.4 Initial Assessment of Significance

Greylag goose	Overall sensitivity	Magnitude	Significance
Collision	Very High	Negligible	Minor
Barrier	High	Low	Minor
Displacement	High	Negligible	Negligible

4.3.5 Species Sensitivities

Qualifying species

The nearest SPAs to the proposed development for which the Greylag goose is a qualifying species is the Loch of Skene SPA and the Loch of Strathbeg SPA & Ramsar. The greylag goose is also a qualifying species for Montrose Basin SPA & Ramsar and Firth of Tay SPA & Ramsar (SNH 2011).

Flight height

No greylag geese were recorded from boat-based surveys but flight heights from Vantage Point surveys indicated that none were flying between 30 m – 150 m and therefore not at potential risk of collision.

There is very limited data on flight heights of greylag geese from other offshore wind farms (Table 4-3). However, data from birds moving to and from roosts in North-east Scotland recorded 33% of flights as being between 50 m– 150 m (Patterson 2006).

Collision risk

Evidence from site specific surveys indicate that greylag geese occasionally occur in Aberdeen Bay particularly during the winter. However, as there were only six records of a total of 39 birds from all surveys and all were flying below turbine height the frequency of occurrence is low. Evidence from other offshore wind farms for all geese species indicate that they have a very high avoidance rate and even if the area is used more extensively than records suggest, this and low flight altitude indicate that the risk of collision is low and the impact on greylag geese should it occur, negligible.

Barrier effect

Although greylag geese may fly through wind farms they have also been recorded avoiding wind farms; consequently, there may be a barrier effect

Should a barrier effect occur then greylag geese will fly around the proposed development. By doing so this could cause an overall increase in flying distance of up to approximately 3.2 km. For a bird migrating from Iceland to North-east Scotland, a distance of approximately 1,000 km then this will cause an increase of 0.3% in flight distance. This is considered to be a negligible impact and will not cause any adverse effect.

Displacement

Greylag geese do not use Aberdeen Bay for feeding or roosting and therefore no displacement effects will occur.

Cumulative and in-combination

No cumulative or in-combination impacts on greylag geese have been recorded for any of the existing Round 1 or Round 2 offshore wind farms. There are no data available yet on whether greylag geese are being recorded during surveys being undertaken for the planned Round 3 offshore wind farms or those in Scottish Territorial Waters. However, the majority of greylag geese wintering in the UK are now doing so in Orkney and Caithness (Calbrade *et al*. 2010) and are therefore not at risk of potential risk with other offshore wind farms to the south.

On the basis that there is unlikely to be any substantial interaction with other offshore wind farms and that, as with other Geese, it is predicted that there will be a high avoidance rate, small potential of a barrier effect and no displacement, it is concluded that there will be a negligible adverse effect or cumulative impact.

4.3.6 Conclusions

Habitats Appraisal

Based on the site specific data indicating a low usage of the area by greylag geese and evidence from existing offshore wind farms indicating a very high avoidance rate for Geese as a whole an adverse effect is not predicted to occur at any of the SPAs for which greylag goose is a qualifying species.

Environmental Impact Assessment

Based on the site specific data and data from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on greylag geese.

4.4 Barnacle goose (*Branta leucopsis*)

4.4.1 Protection & Conservation Status

The barnacle goose is listed in Annex I of the Birds Directive, Appendix II of the Bern Convention, Appendix II of the Bonn Convention and is on the Amber List of Species of Conservation Concern.

4.4.2 Background

Barnacle goose (Svalbard)		
GB Population	Winter – 32,000 ind.	Calbrade *et al.* 2010
Scottish Population	Winter – 32,000 ind.	Calbrade *et al*. 2010
International threshold (Svalbard)	270 ind.	Calbrade *et al.* 2010
GB threshold	220 ind.	Calbrade *et al.* 2010
Designated east coast sites where species is a noted feature	Loch of Strathbeg	JNCC
European population estimate	Breeding 41 – 54,000 pairs Wintering – 370,000	Birdlife 2004
European population trend	Status 'secure' Trend 'large increase'	Birdlife 2004
World population (Svalbard)	32,000 ind.	Calbrade *et al.* 2010

Barnacle geese breed in the Arctic and winter in the UK and the mainland of Europe. They arrive in their UK wintering grounds during September and October and migrate north again during the spring. There are two distinct populations wintering in the UK. Birds from Svalbard occur in North-east Scotland as mainly passage migrants on their way to and from their main wintering site on the Solway Firth. Barnacle geese from Greenland winter along the west coast of Scotland and are not known to occur in the region.

The population of barnacle geese wintering in the Solway has increased considerably since the 1940's when there were 300 individuals. The wintering population has now increased to around 30,000 (Forrester *et al.* 2007).

Barnacle geese have been recorded passing Peterhead from late September through to late October when up to 400 birds per month have been recorded and again in the spring when up to 250 birds per month were recorded flying north during April and May. Birds were recorded out to a distance of 3 km (Innes 2006).

Peak counts at Loch of Strathbeg and elsewhere in North-east Scotland vary considerably across years but numbers have increased with up to 680 in October 2006 (NESBR 2007) and an exceptional 6,000 in September 2005. During the same period up to 2,270 were recorded flying south at Blackdog (Buckland, Bell & Picozzi 1990; NESBR 2006). The Loch of Strathbeg is an important staging post for barnacle geese from Svalbard and is one of only three sites in the UK that holds internationally important numbers; the others being the Solway Firth and Lindisfarne (Calbrade *et al.* 2010).

Boat-based surveys

A total of 831 barnacle geese were recorded from boat-based surveys undertaken between February 2007 and January 2008. All sightings were made on the 12 October 2007 when 14 skeins of barnacle geese were recorded ranging in size from 7 to 220 birds, the majority of which were recorded along a single transect (Figure 4-3) indicating a single 'pulse' of migrating barnacle geese occurred during that survey period. The majority of birds were flying in a southerly direction and 29%

were flying above 200 metres; 32% were between 15 m and 200 m and 6% between 25 m and 200 m.

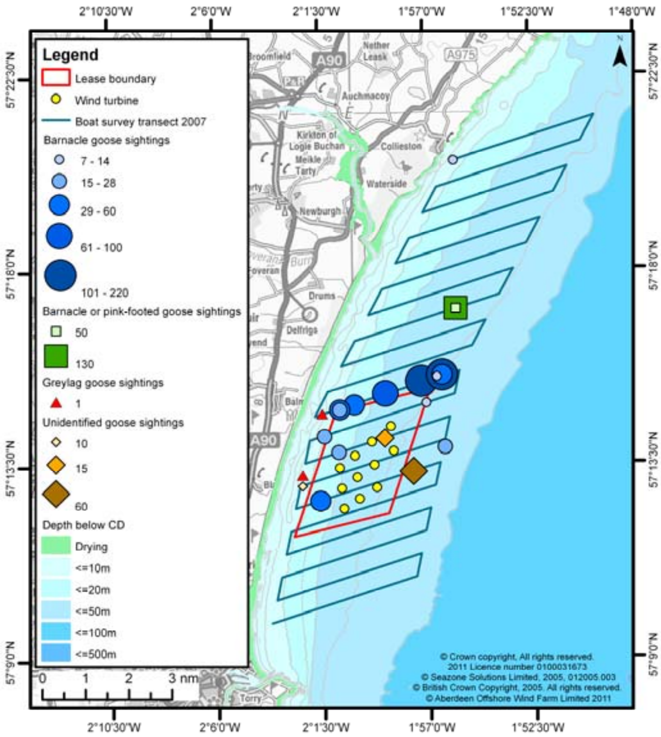

Figure 4-3: Geese distribution in Aberdeen Bay - February 2007 to April 2008 (all sightings).

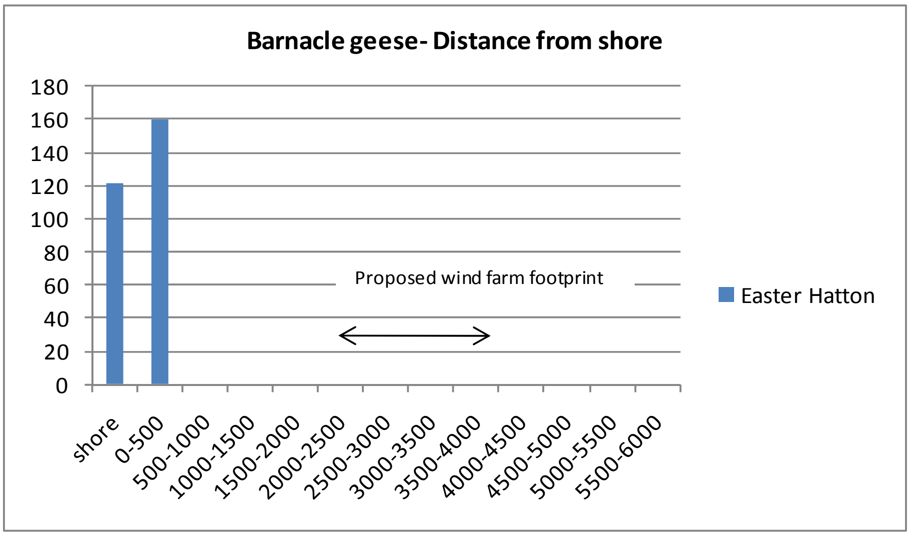
Vantage Point surveys

No Barnacle geese were recorded during the autumn of 2005 but up to 300 barnacle geese per hour were recorded past Drums in September 2006 and single skeins of 29 in December 2007 and 17 in January 2008 (Alba Ecology 2008b). Of the 300 birds recorded in 2006, nine birds per hour were recorded flying between 30 m and 150 m above sea surface. The majority of records were from between 1-2 km from shore with no sightings further offshore.

Bird Detection Radar

A total of five flocks of barnacle geese, comprising 281 birds were recorded during the Bird Detection Radar studies undertaken in October 2005. All sightings were of birds flying below 35 m and were within 500 m from shore (Figure 4-4) (Walls *et al.* 2006).



(Adapted from Walls *et al.* 2006, Simms *et al.* 2007)

Figure 4-4: Number of barnacle geese recorded and distance from shore at Easter Hatton during October 2005.

4.4.3 Summary of Results

Barnacle geese were the most frequently recorded goose in Aberdeen Bay where large numbers were recorded passing through the bay during September 2006 and on one date in October 2007. Relatively few barnacle geese were recorded outwith these peak periods. No geese were reported as having landed in the bay. Land based observations recorded the majority of birds within 2 km from shore but there were sightings out to at least 3 km. Of those birds recorded in flight from boat-based surveys 6 were flying above 25 m but below 200 m. Land-based observations recorded all barnacle geese as flying below 35 m.

The numbers of barnacle geese passing through Aberdeen Bay were above the threshold for a site of national and international importance.

4.4.4 Initial Assessment of Significance

Barnacle goose	Overall sensitivity	Magnitude	Significance
Collision	Very High	Negligible	Minor
Barrier	High	High	Major
Displacement	High	Negligible	Negligible

4.4.5 Species Sensitivities

Qualifying species

The nearest SPAs to the proposed development for which the Svalbard population of the Barnacle goose is a qualifying species are the Loch of Strathbeg and Solway Firth SPAs (JNCC 2011a, SNH 2011).

Flight height

Data from site specific boat-based studies recorded up to 6% of the barnacle geese as flying between 25 m and 200 m and therefore at turbine height.

There are currently no other data available on flight heights of barnacle geese from other UK offshore wind farms.

Collision risk

Evidence from site specific surveys indicate that barnacle geese occur in Aberdeen Bay particularly during the spring and autumn and are more frequently recorded within 2 km of the coast than further offshore.

Collision Risk Modelling undertaken for barnacle goose is based on:

- Body length of 64 cm
- Wingspan of 139 cm
- Flight speed of 18.0 $m.s^{-1}$
- Percentage at rotor height –100%
- Avoidance rate – 98, 99, 99.5%

(Patterson 2006)

As the number of barnacle geese recorded within the proposed development area was low, in order to undertake collision risk modelling based a potentially realistic ‘worst-case’ scenario the following assumptions were made:

1. The total number of barnacle geese passing through North-east Scotland each autumn is 2,200, based on the peak count at Loch of Strathbeg since 2004 (Calbrade *et al.* 2010).
2. All barnacle geese migrate south across a front of up to 5 km offshore and 5 km inland and therefore over a 10 km wide front. The maximum width of the proposed development is 3.6 km and therefore intercepts 36% of the potential flight path. This is precautionary as site specific data indicates that the majority of geese fly within 1 km from shore and therefore do not interact with potential development. However, for the purposes of the collision risk modelling it assumed that 36% of the total Svalbard population of barnacle geese pass through the offshore area, i.e. 23,040 birds per year.
3. That 46% of those that do fly across the development area do so at turbine height. This is based on data from pink-footed geese.
4. That a return passage during the spring occurs at the same level as in the autumn. This is highly precautionary as records of barnacle geese in North-east Scotland are relatively few compared to the autumn counts.

The Collision Risk Modelling has been undertaken on these precautionary assumptions using a range of avoidance rates: 98%, 99% and 99.5%.

Table 4-5: Results from collision risk modelling undertaken on barnacle geese.

Collision probability	Avoidance rate (%)		
	98	99	99.5
8.5%	5.3	2.6	1.3

Based on the various scenarios and using a precautionary avoidance rate of 99% as recommended by SNH, it is predicted that a total of 2.6 collisions per year may occur (Table 4-5).

The annual mortality rate for barnacle goose is 9% (BTO 2011). Consequently, out of a population of 32,000 an annual mortality of 2,880 barnacle geese may be predicted. Therefore, 1% of the baseline mortality is 28 birds per year.

Based on the results from the precautionary Collision Risk Modelling undertaken, the number of barnacle geese that may collide is lower than that that may cause concern of a potentially significant impact or adverse effect on the barnacle goose population as a whole.

To assess whether there is the potential for an adverse effect on barnacle goose as a qualifying species for the relevant regional SPAs the assessment is based on the 5 year peak mean counts as opposed to numbers published at the time of SPA citation as the populations of barnacle geese have increased significantly since the SPA citations were originally made. It also, incorrectly, assumes that each SPA population is separate from each other and any collision impacts relate to birds only associated with that SPA.

Table 4-6: Natural mortality rates for barnacle geese associated with relevant SPAs.

Site SPA	Population	Natural Mortality	1% of Natural Mortality
Loch of Strathbeg	726	65	0.6
Solway Firth	29,403	2,646	26

Based on the above, the results from the Collision Risk Modelling indicate that there is the potential for an adverse effect to occur should all potential collisions relate to geese associated with only the Loch of Strathbeg SPA.

As described in section 4.2.5 there are numerous studies indicating that Geese are at low risk of collision. Nearly 87,000 barnacle geese were recorded migrating past two offshore wind farms in Kalmar Sound and avoidance behaviour was observed and no collisions detected (Pettersson 2005). Similar results from other offshore wind farms for other similar species of geese support the findings of the study.

Based on the above evidence and the highly precautionary nature of the Collision Risk Modelling undertaken and the site specific data indicating a relatively low usage of the site by barnacle geese, it is concluded that risk of an adverse effect is negligible and the potential significance of any impact minor.

Barrier effect

Although barnacle geese may fly through wind farms they have also been recorded avoiding wind farms consequently there may be a barrier effect (Pettersson 2005).

Should a barrier effect occur then barnacle geese will fly around the proposed development. By doing so this could cause an overall increase in flying distance of up to approximately 3.2 km. For a bird migrating from Svalbard to North-east Scotland, a distance of approximately 2,500 km then this will cause an increase of 0.1% in flight distance. This is considered to be a negligible impact and not cause any adverse effect.

Displacement

Barnacle geese do not use Aberdeen Bay for feeding or roosting and therefore no displacement effects will occur.

Cumulative and in-combination

Barnacle geese migrating from Svalbard to the Solway Firth do so by travelling down the west coast of Norway before crossing to north-east and eastern Scotland and flying south-west to the Solway where they winter. Their return flights are similar but more direct and to the south of the proposed development area (Griffin, Rees & Hughes 2010). Consequently, there are little cumulative or in-combination impacts from existing offshore wind farms. There is the potential for cumulative impacts arising with planned developments in the Firth of Forth area. However, no data are available on the number or size of turbines being considered by the developments nor any data on whether barnacle geese have been observed from offshore surveys. Therefore no cumulative impact assessment is possible. However, the very high avoidance rates recorded for geese and the relatively low flight heights recorded indicate that the potential for a significant environmental impact or an adverse effect is unlikely.

4.4.6 Conclusions

Habitats Appraisal

Based on the site specific data indicating a low usage of the area by barnacle geese and evidence from existing offshore wind farms indicating a very high avoidance rate; an adverse effect is not predicted to occur at any of the SPAs for which barnacle goose is a qualifying species.

Environmental Impact Assessment

Based on the site specific data and data from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on barnacle geese.

4.5 Shelduck (*Tadorna tadorna*)

4.5.1 Protection & Conservation Status

The Shelduck is listed in Appendix II of the Bern Convention, Appendix II of the Bonn Convention and is on the Amber List of Species of Conservation Concern.

4.5.2 Background

Shelduck		
GB Population	Summer – 11,000 prs. Winter – 78,000 ind.	BTO 2011

Designated east coast sites where species is a noted feature	Montrose Basin: 988 (08/09) Firth of Forth: 3,166 (08/09) Forth of Tay and Eden Estuary 1,114 ind.	Calbrade *et al*. 2010 JNCC 2011a
European population estimate	Breeding: 41 – 54,000 pairs Wintering: 370,000 ind.	Birdlife 2004
European population trend	Status 'secure' Trend 'small decline'	Birdlife 2004
World population	580,000 – 710,000 'adults'	Birdlife 2011

Shelduck is a widespread coastal breeding species in the UK with a UK population of 11,000 pairs, of which 1,750 pairs breed in Scotland (Forrester *et al*. 2007). In winter they occur along coastal estuaries and mud flats. A proportion of Scottish breeding shelduck undertake a seasonal migration to Helgoland during July where they moult and return to eastern England in late August after which they then move north to their wintering grounds. There is also a moulting flock in the Firth of Forth.

In Eastern Scotland Shelduck occur widely in suitable coastal habitats with the main sites being the Firth of Forth and Montrose Basin where mean peak counts of up to 3,166 and 988 have been recorded between 2004 and 2009 (Calbrade *et al*. 2010).

Sightings of shelduck past Peterhead occurred throughout the year but with a distinct spring passage when up to 300 birds per month pass, predominantly northwards. The majority of sightings were within a few hundred metres from shore (Innes 2006).

In North-east Scotland Shelduck occur along all suitable coasts and in particular, the Ythan Estuary where up to 200 birds may occur in the spring and between 50 and 80 pairs breed on the adjacent Forvie nature reserve (Buckland, Bell & Picozzi 1990). During the autumn and winter numbers in the region are lower until March when birds start returning to the region.

Boat-based surveys

Seven Shelduck were recorded during boat-based surveys with two in April, four in May and one in January. The January bird was heading north while the spring birds were flying in a southerly direction. All records were of birds flying below 25 m.

Vantage Point surveys

Shelduck were recorded infrequently during vantage point surveys with a total of 37 individuals over the three years of surveys. Most records were between March and May, although the maximum count was in August when ten were seen in 2006.

There were two records during winter months with one in January 2008 and three in February 2007.

Bird Detection Radar

Five Shelduck were recorded, with one at Drums and four at Easter Hatton in five days of surveys during October 2005 (Walls *et al* 2005). A further 20 birds were seen during additional radar studies undertaken at Blackdog in April 2007 (Simms *et al.* 2007).

4.5.3 Summary of Results

Shelduck were regularly recorded in low numbers from shore based counts, particularly during the spring period. Of those for which flight heights were reported all Shelduck were flying below 25 m.

The numbers of shelduck recorded in Aberdeen Bay were below the threshold for a site of national importance.

4.5.4 Initial Assessment of Significance

Shelduck	Overall sensitivity	Magnitude	Significance
Collision	Very High	Negligible	Minor
Barrier	High	Negligible	Negligible
Displacement	Medium	Negligible	Negligible

4.5.5 Species Sensitivities

Qualifying species

There are three SPAs in the region for which shelduck are part of the qualifying assemblage: Montrose Basin, Firth of Forth and Forth & Tay Estuary SPA.

Flight height

Of those recorded in flight and for which flight heights were recorded all were flying below 25 m.

Elsewhere data from other offshore wind farms on flight heights for shelduck are limited with only eleven recorded flight heights from surveys undertaken at ten offshore wind farms. The few records recorded 36% of flights at rotor height.

Collision risk

Evidence from site specific monitoring indicate shelduck are scarce in Aberdeen Bay and those for which flight heights were recorded were below turbine height and most records were of birds within 2 km of the coast. Consequently the risk of significant environmental impact arising from collision is low and should it occur the significance on the regional population negligible. The SPAs for which shelduck are qualifying species as part of assemblages are over 60 km away and the likelihood of shelduck associated with these SPAs at risk of collision from the proposed development is remote. The risk of an adverse effect on the qualifying species being caused by collision mortalities arising from the proposed development is negligible.

Barrier effect

There is no evidence from existing offshore wind farms as to whether a barrier effect may occur. However, based on behaviour of other wildfowl it is predicted that at least some shelduck will avoid flying through the proposed development.

Should a barrier effect occur then shelduck may fly around the proposed development. This would incur an overall increase in flying distance of approximately 3.2 km. The movements of shelduck in Aberdeen Bay are not fully understood but there is no evidence of any regular feeding or roosting flights across the bay. Consequently, many flights are potentially *ad hoc* and or passage related; therefore, any additional energetic costs arising from the proposed development will not be regular but likely to be only occasional. The relatively small additional distance flown should shelduck fly around the proposed development will not be significant nor have an adverse effect.

Displacement

Shelduck do not use Aberdeen Bay for feeding or roosting and therefore no displacement effects will occur.

Cumulative and in-combination

The low level of usage of the site by shelduck indicates that there will not be any cumulative or in-combination impacts.

4.5.6 Conclusions

Habitats Appraisal

There are no SPAs for which shelduck is a qualifying species that will be effected by the proposed development.

Environmental Impact Assessment

Based on the relatively low numbers of shelduck recorded and their known behaviour it is predicted that there will not be a significant environmental impact arising from the proposed development on shelduck.

4.6 Eurasian Wigeon (*Anas Penelope*)

4.6.1 Protection & Conservation Status

The (Eurasian) wigeon is listed in Appendix II of the Bonn Convention, Appendix III of the Berne Convention and is on the Amber List of Species of Conservation Concern.

4.6.2 Background

Wigeon		
GB Population	Winter 359,236 ind.	Calbrade *et al*. 2010
Scottish Population	Summer – 240 – 400 prs. Winter 76,000 – 96,000 ind.	Forrester *et al* 2007
International threshold	15,000 ind.	Calbrade *et al*. 2010
GB threshold	4,060 ind.	Calbrade *et al*. 2010
Designated east coast sites where species is a noted feature	Montrose Basin: 3,944 ind. Firth of Forth: 2,139 ind.	Calbrade *et al.* 2010 JNCC 2011a
European population estimate	Breeding 85,000 – 100,000 pairs Wintering – >140,000 individuals	Birdlife 2004
European population trend	Status 'decreasing' Trend 'moderate decline	Birdlife 2004
World population	2,800,000 to 3,300,000	Birdlife 2011

Wigeon occur widely across northern Europe and Russia and there is a relatively small breeding population in the UK with between 48 and 124 pairs (Holling *et al*. 2010). In the autumn wigeon arrive from central and eastern Europe and Russia to winter in the UK where there is a large wintering population of 360,000 individuals of which between 76,000 and 96,000 winter in Scotland (Wernham *et al*. 2002, Forrester *et al*. 2007).

During the non-breeding season wigeon are mainly coastal, foraging on mudflats and coastal foreshores.

The main wintering sites in Scotland are the Moray Firth where up to 20,000 wigeon may winter and the Dornoch Firth with up to 15,000 wintering wigeon. In North-east Scotland wigeon occur with an average peak count in the region between 1992 and 2002 of 3,045 (Forrester *et al*. 2007). On the Ythan Estuary peak counts of wigeon occur during the winter months when up to 1,000 birds may be present, particularly during November and December (NESBR). Peak numbers of wigeon passing Peterhead occurred during September and October with few sightings during the winter. There is evidence of a small spring passage of birds heading north during March, April and May (Innes 1996). All sightings at Peterhead were of birds passing within a few hundred metres from shore.

Boat-based surveys

Twenty-eight wigeon were recorded during boat-based surveys with a flock of 20 birds in September 2007 and nine birds in three flocks in October. The only other record was of a single bird in April.

Vantage Point surveys

Wigeon were observed flying through Aberdeen Bay between April 2007 and March 2008 with up to seven birds per hour passing Blackdog during October 2007. The majority of sightings from the Donmouth were between 2–3 km from shore whereas those from Blackdog were predominantly 2 – 3 km from shore. All records were of birds flying below 30 metres.

Further records all of less than 20 birds were from Blackdog in August, September and December, Balmedie in September and Drums in December (EnviroCentre 2007b).

Bird Detection Radar

Sixteen wigeon were recorded, at Easter Hatton during the radar studies undertaken in October 2005 and 10 were seen from Blackdog during further radar studies undertaken in April 2007 (Walls *et al* 2005, Simms *et al.* 2007).

4.6.3 Summary of Results

Relatively few wigeon were recorded during surveys undertaken in Aberdeen Bay. Most records were obtained from Vantage Point surveys with birds recorded out to 3 km from shore. Of those for which flight height was reported, all wigeon were flying below 30 m.

4.6.4 Initial Assessment of Significance

Wigeon	Overall sensitivity	Magnitude	Significance
Collision	Medium	Negligible	Negligible
Barrier	High	Negligible	Negligible
Displacement	Medium	Negligible	Negligible

4.6.5 Species Sensitivities

Qualifying species

There are two SPAs in the region for which wigeon are part of the qualifying assemblage: Montrose Basin and Firth of Forth SPA & Ramsar.

Flight height

Observations made from site specific boat-based and land-based surveys recorded all but one wigeon as flying below 30 m in flight.

Elsewhere data from other offshore wind farms on flight heights for wigeon are limited with only 60 recorded flight heights from surveys undertaken at ten offshore wind farms. The few records recorded 38% of flights at rotor height.

Collision risk

Evidence from site specific monitoring indicate wigeon are regular in Aberdeen Bay but in relatively low numbers. Evidence from other offshore wind farms indicate that the majority of wigeon fly below 30 m. At Nysted offshore wind farm where 1% of all records were of wigeon and passage rates of up to 20 birds per hour were detected no collisions were recorded (Petersen *et al*. 2006). At Kalmar Sound 25,000 wigeon were counted during migration and no collisions observed (Pettersson 2005). Based on the relatively low numbers of wigeon recorded and evidence from offshore wind farms where wigeon are relatively common it is concluded that the risk of an adverse effect on wigeon from collision mortalities arising from the proposed development is negligible.

Barrier effect

Evidence from studies undertaken at Kalmar Sound suggest that there is the potential for some barrier effects as wigeon can avoid flying through offshore wind farms. Should a barrier effect occur then wigeon will fly around the proposed development. This may incur an overall increase in flying distance of approximately 3.2 km. There is no evidence of any regular feeding or roosting flights by wigeon across Aberdeen Bay and the seasonal occurrence of wigeon recorded suggest that the majority of birds are on migration. The relatively small additional distance flown should wigeon fly around the proposed development compared to the total distance of their migration will not be significant nor have an adverse effect.

Displacement

Wigeon do not use Aberdeen Bay for feeding or roosting and therefore no displacement effects will occur.

Cumulative and in-combination

The low level of usage of the site by wigeon and the relatively few recorded from other UK developments indicate that there will not be any cumulative or in-combination impacts.

4.6.6 Conclusions

Habitats Appraisal

There are no SPAs for which wigeon is a qualifying species that will be effected by the proposed development.

Environmental Impact Assessment

Based on the relatively low numbers of wigeon recorded and their known behaviour it is predicted that there will not be a significant environment impact arising from the proposed development on wigeon.

4.7 Eurasian Teal *(Anas crecca)*

4.7.1 Protection & Conservation Status

The (Eurasian) teal is listed in Appendix II of the Bonn Convention, Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.7.2 Background

Teal		
GB Population	Summer –155 – 2,600 prs. Winter – 192,000 ind.	BTO 2011
Scottish population	Summer – 1,950 – 3,400 prs Winter – 22,500 – 125,000 ind.	Forrester *et al.* 2007
International threshold	5,000 ind.	Calbrade *et al.* 2010
GB threshold	1,920 ind.	Calbrade *et al.* 2010
Designated east coast sites where species is a noted feature	Loch of Strathbeg: 504 ind.	SNH 2011 Calbrade *et al.* 2010
European population estimate	Breeding 920,000 – 120,000 ind. Wintering – >730,000 ind.	Birdlife 2004
European population trend	Status 'secure' Trend 'small decline'	Birdlife 2004
World population (Svalbard)	5,9 – 6,900,000 'adults'	Birdlife 2011

The teal is an uncommon breeding duck in the UK occurring on freshwater lochs and marshes. The majority of the UK population breed in Scotland where an estimated 3,400 pairs of teal breed (Forrester *et al*. 2007).

Following breeding, teal occur in both freshwater and coastal habitats feeding on seeds and grasses. There is a substantial increase in the numbers of teal in winter as migrants from northern Europe and Russia arrive during September and October and remain until March and April. About 6% of Scotland's wintering population of teal occur in North-east Scotland with most birds occurring on freshwater Lochs, e.g. Loch of Strathbeg and Loch of Skene. Elsewhere teal occur on the river Don where there may be up to 100 birds present.

Passage of teal past Peterhead occurs throughout the year but with a very distinct autumn passage with up to 550 birds during September. A smaller spring passage occurs during April and May. All sightings of teal made at Peterhead were of birds within a few hundred metres from the shore (Innes 1996).

Boat-based surveys

Three teal were seen from boat-based surveys with one in October and two in November.

Vantage Point surveys

Teal were infrequently recorded during the three years of Vantage Point surveys with a total of 43 birds recorded of which 26 were in September.

Bird Detection Radar

During the five days of observations undertaken at Easter Hatton and Drums during October 2005 as part of the Bird Detection Radar studies, 187 teal were recorded in seven flocks, all at Drums. (Walls *et al.* 2005). Additional radar studies undertaken over seventeen days in April 2007 recorded seven teal at Blackdog (Simms *et al.* 2007).

4.7.3 Summary of Results

Aside from birds recorded from land-based counts at Drums in October 2005 relatively few teal were recorded during surveys undertaken in Aberdeen Bay.

4.7.4 Initial Assessment of Significance

Teal	Overall sensitivity	Magnitude	Significance
Collision	Medium	Negligible	Negligible
Barrier	High	Negligible	Negligible
Displacement	Medium	Negligible	Negligible

4.7.5 Species Sensitivities

Qualifying species

The Loch of Strathbeg is the only SPA in the vicinity of the proposed development for which teal is a qualifying species.

Flight height

The only flight height recorded was of one bird flying at an altitude of greater than 30 m.

Elsewhere data from other offshore wind farms on flight heights for teal is very limited with records from a number of other offshore wind farms but the flight heights not being reported. There was one flock of 11 teal recorded at Beatrice Demonstration Project and all were flying at rotor height.

Collision risk

Teal were recorded across Aberdeen Bay in low numbers with peak counts occurring during periods of migration. Evidence from other offshore wind farms on the potential of collision risk is limited but a total of 2,300 teal were recorded during studies in Kalmar Sound and none were reported to collide. Evidence for other species of wildfowl indicate that wildfowl have high avoidance rates. Based on the low numbers of teal recorded within the proposed development area and the predicted high avoidance rates it is concluded that the risk of an adverse effect or significant environmental impact on teal from collision mortalities arising from the proposed development is negligible.

Barrier effect

Evidence from studies undertaken at Kalmar Sound suggest that there is the potential for some barrier effects as wildfowl avoid flying through wind farms. Teal may avoid flying through offshore wind farms and if so may incur an overall increase in flying distance of approximately 3.2 km. There is no evidence of any regular feeding or roosting flights by teal across Aberdeen Bay and the seasonal occurrence of teal recorded suggest that the majority of birds are on migration. The relatively small additional distance flown should teal fly around the proposed development compared to the total distance of their migration will not be significant nor have an adverse effect.

Displacement

Teal do not use Aberdeen Bay for feeding or roosting and therefore no displacement effects will occur.

Cumulative and in-combination

The low level of usage of the site by teal and the relatively few recorded from other UK developments indicate that there will not be any cumulative or in-combination impacts.

4.7.6 Conclusions

Habitats Appraisal

There are no SPAs for which teal is a qualifying species that will be adversely effected by the proposed development.

Environmental Impact Assessment

Based on the relatively low numbers of teal recorded and their known behaviour it is predicted that there will not be a significant environmental impact arising from the proposed development on teal.

4.8 Mallard (*Anas platyrhynchos*)

4.8.1 Protection & Conservation Status

The mallard is listed in Appendix II of the Bonn Convention Appendix III of the Bern Convention and is on the Green List of Species of Conservation Concern.

4.8.2 Background

Mallard		
GB Population	Summer – 48,000 – 114,000 prs. Winter – 352,000 ind.	BTO 2011
Scottish population	Summer – 17,000 – 43,000 prs Winter – 65,000 – 90,000 ind.	Forrester *et al.* 2007
International threshold	20,000 ind.	Calbrade *et al.* 2010
GB threshold	3,520 ind.	Calbrade *et al.* 2010
Designated east coast sites where species is a noted feature	Firth of Forth 2,546 ind (91/92-95/96)	SNH 2011
European population estimate	Breeding 920,000 – 120,000 ind. Wintering – >730,000 ind.	Birdlife 2004
European population trend	Status 'secure' Trend 'small decline'	Birdlife 2004
World population (Svalbard)	5,900,000 – 6,900,000 'adults'	Birdlife 2011

Mallard is the most common and widespread duck in Britain with a breeding population of up to 114,000 pairs and wintering population of approximately 352,000 individuals.

Mallard breed primarily on freshwater habitats but in winter occur widely on estuaries and shallow lochs (Forrester *et al.* 2007). Although the Scottish population is largely semi-resident, with only relatively localised movements, the wintering population is increased by migrants from Europe and Russia, which arrive during the autumn (Wernham *et al.* 2002). In North-east Scotland the main wintering areas are the Loch of Strathbeg and Loch of Skene with relatively small numbers of a hundred or less occurring on the Ythan Estuary (NESBR). Mallard were recorded throughout the year at Peterhead with a distinct peak in October and November when up to 500 birds were recorded (Innes 1996).

Boat-based surveys

Two mallard were recorded in January 2008, two in September 2010 and one in November 2010.

Vantage Point surveys

Mallard were infrequently recorded in Aberdeen Bay during the three years the Vantage Point surveys were undertaken with a total of 52 birds counted. There was no obvious seasonal variation in the small numbers of counts made, with 33 birds in June being the biggest count.

Bird detection Radar

No mallard were recorded from radar studies in October 2005 but nine were recorded at Blackdog during the radar surveys undertaken in April 2007 (Simms *et al.* 2007).

4.8.3 Summary of Results

Mallard were infrequently recorded in Aberdeen Bay with most sightings from Vantage Point surveys.

4.8.4 Initial Assessment of Significance

Mallard	Overall sensitivity	Magnitude	Significance
Collision	Medium	Negligible	Negligible
Barrier	High	Negligible	Negligible
Displacement	Medium	Negligible	Negligible

4.8.5 Species Sensitivities

Qualifying species

There is one SPA in the region for which mallard is part of the qualifying assemblage: Firth of Forth SPA.

Flight height

Very few records of mallard were made from site specific boat-based or land-based surveys and no records of their of flight heights were made.

Elsewhere there is very limited data from other offshore wind farms on flight heights for mallard with only six recorded flight heights from surveys undertaken at ten offshore wind farms. Of those recorded 33% of flights were at rotor height.

Collision risk

Evidence from site specific monitoring indicated that mallard are scarce in Aberdeen Bay and primarily occur in near-shore waters. Evidence from other offshore wind farms indicated that mallard are at low risk of collision from offshore wind farms. A total of nearly 5,500 mallard were recorded during studies undertaken in Kalmar Sound and no collisions were recorded (Pettersson 2005). Based on the relatively low numbers of mallard recorded and evidence of a potentially high avoidance rate from other developments where mallard are relatively more common, it is predicted that the risk of an adverse or significant environmental effect on mallard from collision mortalities arising from the proposed development is negligible.

Barrier effect

Evidence from studies undertaken at Kalmar Sound suggests that there is the potential for some barrier effects as mallard may avoid flying through offshore wind farms. Should a barrier effect occur then mallard will fly around the proposed development. This may incur an overall increase in flying distance of approximately 3.2 km. There is no evidence of any regular feeding or roosting flights by mallard across Aberdeen Bay nor any regular usage of the site itself. Any additional distance flown should mallard fly around the proposed development will be small compared to the total distance of their migration and will not be significant nor have an adverse effect.

Displacement

Mallard do not use Aberdeen Bay for feeding or roosting and therefore no displacement effects will occur.

Cumulative and in-combination

The low level of usage of the site by mallard and the relatively few recorded from other UK developments indicate that there will not be any cumulative or in-combination impacts.

4.8.6 Conclusions

Habitats Appraisal

There are no SPAs for which mallard is a qualifying species that will be effected by the proposed development.

Environmental Impact Assessment

Based on the relatively low numbers of mallard recorded and their known behaviour it is predicted that there will not be a significant environmental impact arising from the proposed development on mallard.

4.9 Common eider (Somateria mollissima)

4.9.1 Protection & Conservation Status

The (common) eider is listed in Appendix II of the Bonn Convention, Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.9.2 Background

Eider		
GB Population	Summer – 31,000 pairs Winter 73,000 ind.	BTO 2011
Scottish Population	Summer - 20,000 nesting females Winter – 64,500 ind.	Forrester *et al.* 2007
International threshold	12,850 ind.	Calbrade *et al.* 2010
GB threshold	730 ind.	Calbrade *et al.* 2010
Designated east coast sites where species is a noted feature	Ythan Estuary Montrose Basin Firth of Tay & Eden Firth of Forth	SNH 2011 JNCC 2011a
European population estimate	Breeding 840,000 – 1,200,000 prs Wintering – 1,700,000 individuals	Birdlife 2004
European population trend	Status 'secure' Trend 'small decline'	Birdlife 2004
World population	3.1 – 3,800,000 'adults'	Birdlife 2011

Eiders occur in coastal waters throughout northern Britain, particularly in areas where suitable prey of molluscs and crustaceans occur in shallow water of usually less than 3 metres. Breeding colonies are often large and flocks of many thousands of birds can occur in suitable nearshore areas. It is the commonest breeding seaduck in the UK with a breeding population of 31,000 pairs of which approximately 20,000 occur in Scotland.

Following breeding, eiders can congregate into large moulting flocks in specific areas with main areas being Firth of Forth, Shetland, Ythan, Aberdeen Bay and Montrose Basin (Cork Ecology 2004a). The largest moulting flock occurs off Murcar, in Aberdeen Bay, where up to 9,000 have been recorded (Forrester *et al.* 2007).

Although eiders in the UK are largely non-migratory there is some winter dispersal away from the breeding areas with a proportion of birds from North-east Scotland wintering in the Tay Estuary. The east coast of Scotland holds a substantial proportion of the UK wintering population with approximately 59,000 birds. The major wintering areas along the east coast of Scotland are the Tay Estuary, Firth of Forth, Montrose Basin, Orkney, Ythan and the Moray Firth (Cork Ecology 2004a). First winter birds remain near the Ythan Estuary (Baillie & Milne 1988).

The most important areas for eider in North-east Scotland are the Ythan Estuary, where up to 1,500 eider breed, and Aberdeen Bay where a large flock occurs during July and August when they undergo a post-breeding moult. Peak counts at the Ythan Estuary occur during May with maximum counts of up to 4,952 in 2004 and a five year peak mean of 3,333 individuals (NESBR, Calbrade *et al.* 2010). This is lower than the numbers present on the estuary during the 1980's when between 6,000 and 7,000 eider were recorded (Buckland, Bell & Picozzi 1990). Peak numbers in Aberdeen Bay are generally lower with generally between 1,000 – 2,000 birds present although a maximum count in recent years of 3,500 was in August 2002. However, numbers of eider present in Aberdeen Bay have also decreased since the peak counts in the 1980's when over 9,000 were recorded there every August (Buckland, Bell & Picozzi 1990; NESBR) (Figure 4-5).

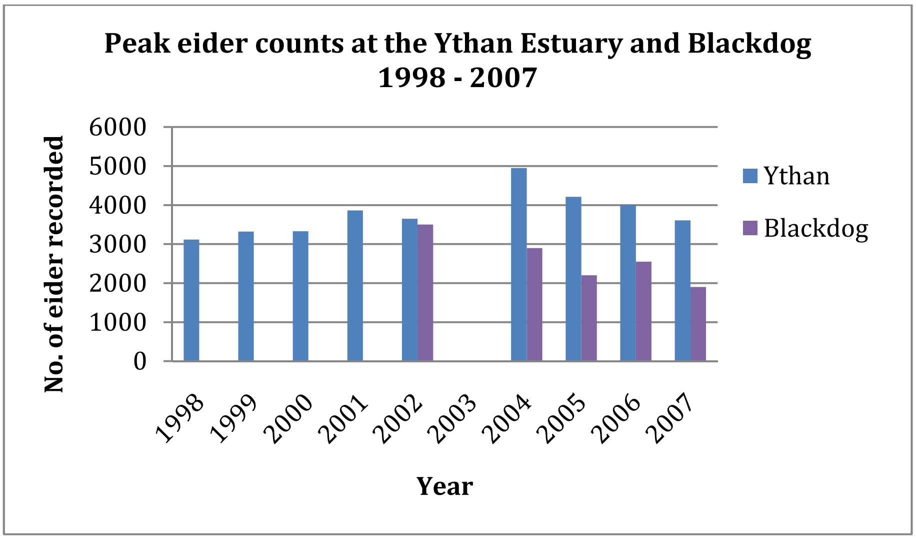

Figure 4-5: Peak eider counts at Ythan Estuary and Blackdog

Eiders are recorded passing Peterhead throughout the year but there is a strong seasonal variation with a marked spring passage of birds moving north of up to 175 birds per hour in March. The peak count was of 3,000 birds over three hours in April 1982 a year when over 30,000 eider were counted flying north between February and April (Buckland, Bell & Picozzi 1990; Innes 1996). There is a smaller movement of birds in the autumn of up to 100 birds per hour during October. Although eider occurred out to 3 km from shore, the majority of sightings were within several hundred metres from shore (Innes 1996).

Boat-based surveys

Common eiders were recorded throughout the year in inshore shallow waters predominantly in water depths of less than 10 metres (Figure 4-6, Figure 4-7, Figure 4-8). The majority of sightings were of birds outwith the 300 metre transect with only 77 birds ‘in transect’ and no records of eider ‘in transect’ during June, July and August. Consequently, the population estimates are under-representative to the total number of birds that may be present in the area. Maximum counts of common eider outwith the survey area were at Blackdog where 450 birds were present in September 2007 and 434 in September 2010 (SMRU 2011b).

The boat-based survey data indicate that the majority of eider occur in waters less than 20 m deep and in particular less than 10 m. There were no records of eider within the proposed development area with the majority of eider to the south-west in near-shore waters approximately 1 km from the nearest potential turbine location.

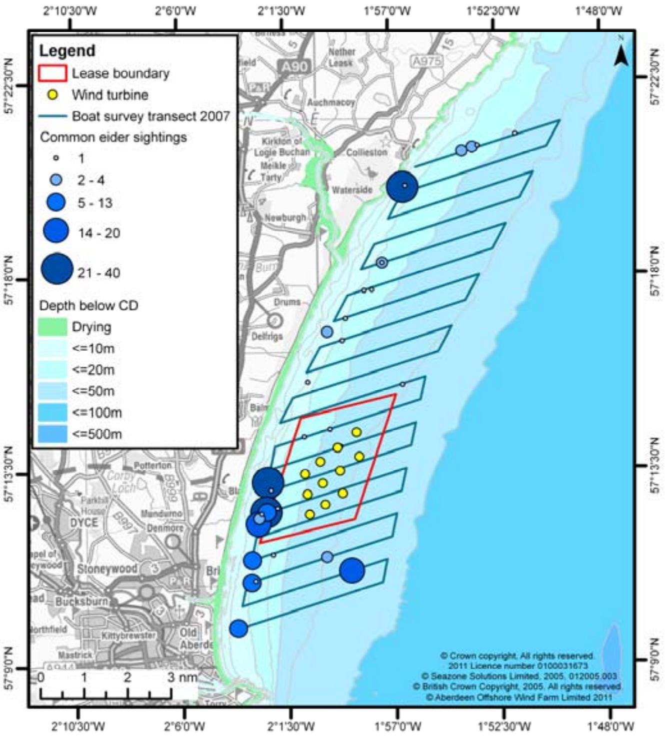

Figure 4-6: Common eider distribution in Aberdeen Bay during winter period: November to March (all sightings).

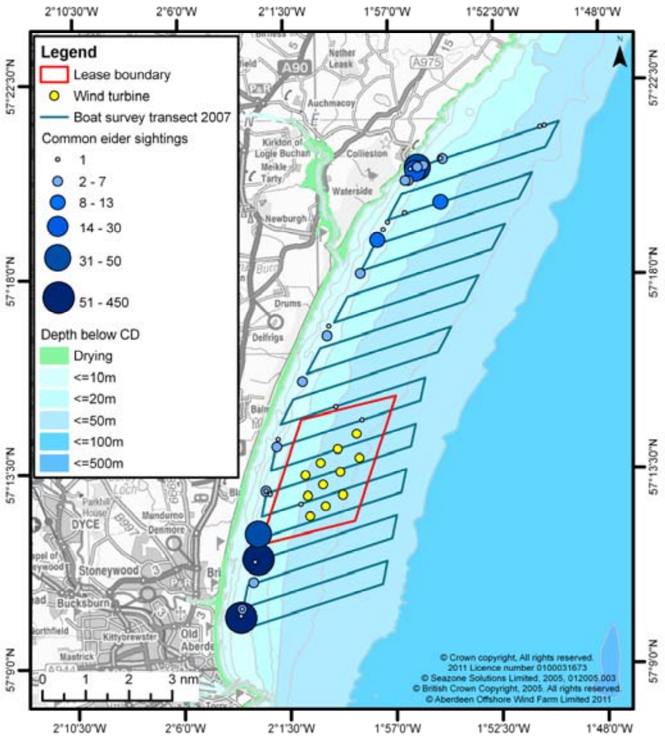

Figure 4-7: Common eider distribution in Aberdeen Bay during spring and autumn periods: April, May, September and October (all sightings).

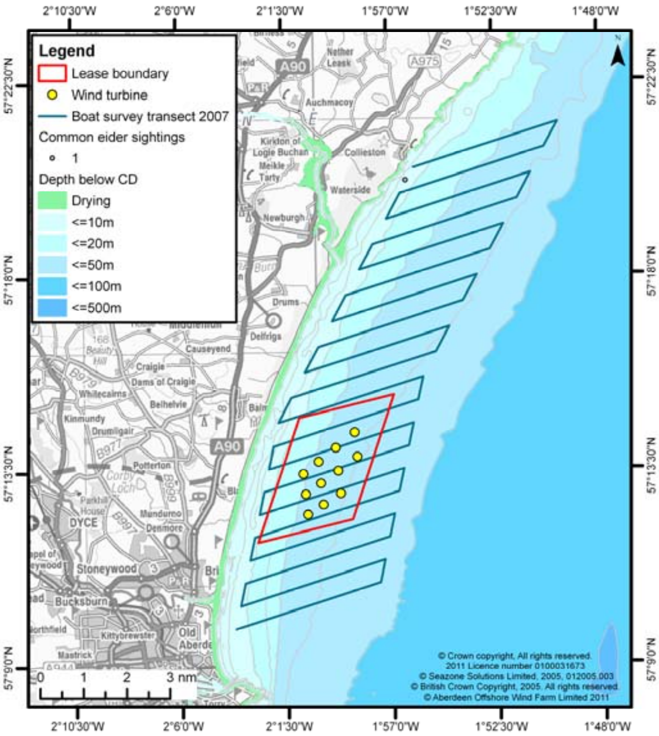

Figure 4-8: Common eider distribution in Aberdeen Bay during summer period: June, July, August (all sightings).

Vantage Point surveys

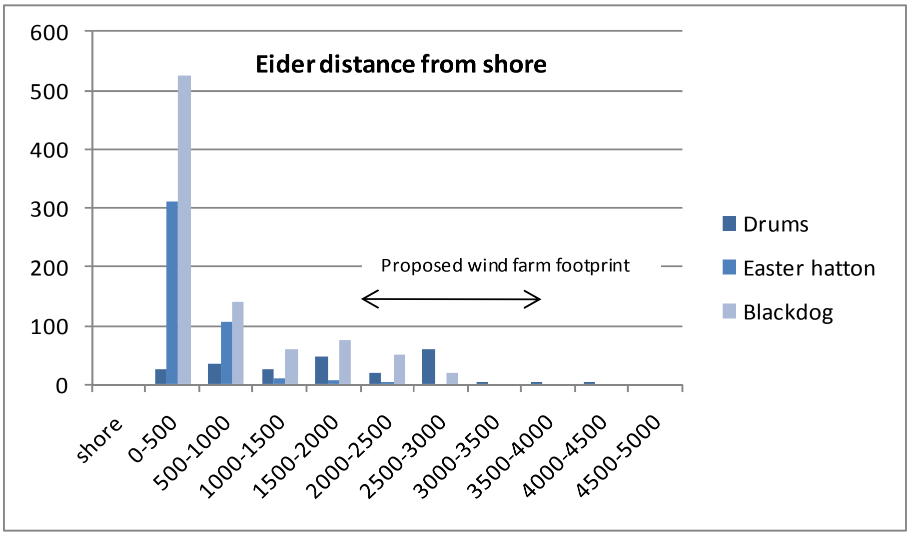
Peak movements of eider in Aberdeen Bay occurred during dawn and dusk with up to 10 birds per hour between December and March and increasing up to 32 birds per hour passing in April 2007 before decreasing to mainly less than 10 birds per hour from June through to August (EnviroCentre 2007a,b; Alba Ecology 2008a,b).

Between 96% and 98% of all flights were below 30 m with the majority of observations within 2 km of the coast and fewer between 2 km and 3 km away. Highest numbers were consistently recorded at Balmedie and Drums, which were the two closest Vantage Point sites to the Ythan Estuary.

Bird Detection Radar

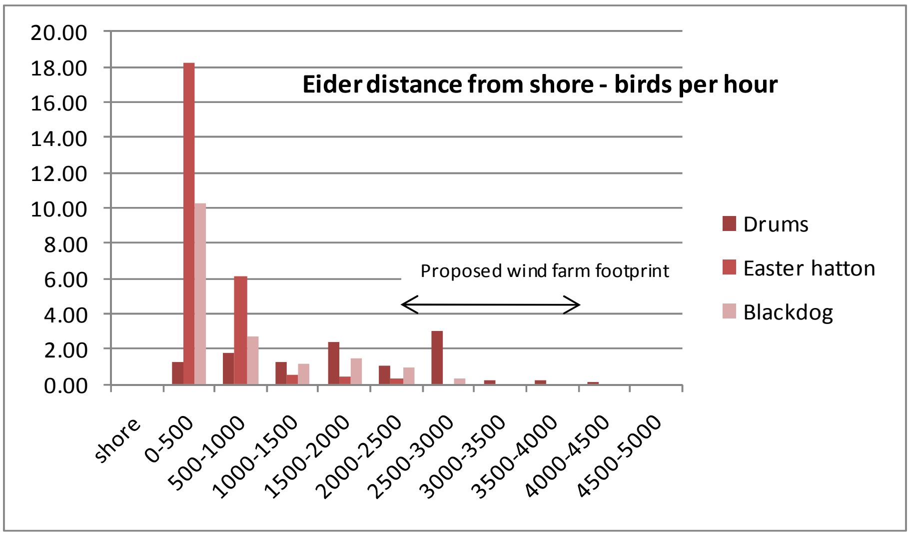
Eider were frequently recorded during the Bird Detection Radar studies undertaken in October 2005. A total of 680 birds were recorded, of which 449 were at Easter Hatton and 231 at Drums. Of those recorded in flight the maximum flight height was 10 m with the mean flight height of between 2 m and 3 m (Walls *et al*. 2006).

Additional radar studies undertaken in April 2007 recorded 855 eider at Backdog and of those recorded in flight, all were below 30 m. All sightings were of birds within 3 km from shore with the majority being within 500 m (Figure 4-12) (Simms *et al.* 2007).



(Adapted from Walls *et al.* 2006, Simms *et al.* 2007)

Figure 4-12: Distances from shore for common eider from three locations in Aberdeen Bay during surveys undertaken in October (Drums & Hatton) and April (Blackdog).



(Adapted from Walls *et al*. 2006, Simms *et al*. 2007).

Figure 4-13: Number of common eider per hour and distance from shore from three locations in Aberdeen Bay during surveys undertaken in October (Drums & Hatton) and April (Blackdog).

4.9.3 Summary of Results

The Ythan Estuary and Aberdeen Bay are both important areas for eider throughout the year. The Ythan Estuary is the largest breeding colony of eider in the UK and Aberdeen Bay holds nationally important numbers, particularly during the post-breeding period of July and August.

The results from boat-based surveys recorded relatively few eider with peak numbers during the winter and autumn periods. No eider were recorded within transect in either the proposed EOWDC area or the 'control' area between May and August. Data from land-based observations also recorded peak numbers of eider between December and April with a peak, in April, of up to 32 birds per hour. Eider were recorded out to at least 3 km from shore but as significant majority of sightings were within 1 km from shore.

All those recorded in flight from boat-based surveys were flying below 25 m and of those recorded from shore 96% and 98% were below 30 metres.

The breeding population on the Ythan Estuary and the number of birds using Aberdeen Bay are of national importance.

4.9.4 Initial Assessment of Significance

Eider	Overall sensitivity	Magnitude	Significance
Collision	Very High	Negligible	Minor
Barrier	High	Medium	Moderate
Displacement	High	High	Major

4.9.5 Species Sensitivities

Qualifying species

There are four SPAs in the region for which eider is a qualifying species as part of waterfowl assemblages: Ythan Estuary, Sands of Forvie and Meikle Loch SPA, Montrose Basin SPA & Ramsar, Firth of Forth SPA and Firth of Tay and Eden Estuary SPA.

Flight height

Flight heights obtained from boat-based surveys undertaken in Aberdeen Bay recorded all eiders in flight as being below 25 m and therefore not at risk of collision. Data obtained from land-based vantage point surveys recorded between 96% and 98% as being below 30 m.

Elsewhere in the UK there is very limited data from other offshore wind farms on flight heights for eider. Extensive studies undertaken in Denmark and Sweden have recorded significant numbers of eider. The proportion flying at rotor height is overall 26% with a mean flight height of 13.7 m (n=34,857).

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that eider are widespread and frequent within Aberdeen Bay. They occur widely with the majority of sightings occurring in nearshore waters within 1 km of the shore and in water depths of <20 m.

Studies undertaken in Denmark indicate that eider have a very high avoidance rate and that the majority of birds will detour around the wind farm. Birds flying within wind farms are unusual and when doing so 89% of all flights are below turbine height. Modelling undertaken for the significantly larger Nysted Offshore wind farm predicted that out of 235,000 passing eiders that between 0.018 and 0.02 birds might collide with a turbine (Petersen *et al*. 2006).

In Sweden at the two wind farms in the Kalmar Sound eiders are the most abundant species and over 1.2 million eider were recorded during the study period of which three were seen to collide with the turbines (Pettersson 2006).

Consequently there is substantial volume of evidence to indicate that the risk of collision by eider is extremely low.

The numbers of eider recorded in Aberdeen Bay are significantly lower than those studied in Denmark and Sweden and in neither of these studies was there any evidence of a significant impact from collision. Furthermore, site specific data indicates that relatively few eider in Aberdeen Bay occur beyond 2 km of the coast and therefore within the potential area of risk from the proposed development. Radar studies indicated up to six times more eider passing within 500 metres from shore compared to between 2.5 km and 3 km from shore.

Based on the results from other offshore wind farms that have demonstrated significant avoidance rate and very low risk of collision as well as the relatively low usage of the site due to its distance from shore it is concluded that the potential effect from collision risk is negligible.

Barrier effect

Studies undertaken in Sweden and Denmark have shown that there is the potential for significant barrier effect, with eiders changing flight directions at least 1 km from offshore wind turbines and flying around them. At Nysted offshore wind farm in Denmark radar studies undertaken tracked over 300,000 eider each autumn. The results indicated that there was a significant decrease in the proportion of flocks entering the wind farm from between the pre-construction period and the operational period. It was found that post construction, 9% of the birds entered the turbines compared with 40% crossing the same location before construction, i.e. there was a clear tendency for flocks to alter course and avoid the wind farm. Flocks that did continue into the wind farm adjusted their flight trajectories and tended to fly down the visually clear corridors between the rows of turbines (Deshom & Kahlert 2005). Further monitoring at Nysted reported a reduction of between 63%and 83% in the use of the wind farm airspace by migrating birds post construction compared to preconstruction (Petersen 2006), therefore providing evidence of large-scale avoidance behaviour of migrating birds.

Therefore it is predicted that the proposed development may cause a barrier effect to eiders in Aberdeen Bay.

There is no evidence of regular daily movements of eider within Aberdeen Bay to and from feeding or roosting areas. Should it occur with eider making daily movements from the Ythan Estuary to Aberdeen Bay to the south of the proposed development and the birds select to fly around the turbines up to 1 km away then they may incur an additional flight distance of up 3.2 km each way, or a total of 6.4 km. This may increase the daily energy expenditure to between 2.0% and 2.5% (Caldrow, Stillman & West 2007; Speakman, Gray & Furness 2009). This is a relatively small increase in daily energy expenditure and is unlikely to have an adverse effect on eiders in Aberdeen Bay.

The peak numbers of eider in Aberdeen Bay occur during July and August when the adult eider undergo a complete wing moult over a period of four weeks, during which time they become flightless. The daily energetic costs during this period increase but the birds remain within certain areas where they can forage and cannot undergo daily flight movements (Guillemette *et al.* 2007) Consequently, there is no incremental increase in daily energy expenditure due to the barrier effect during this period of higher energy expenditure.

Data obtained from three years of Vantage Point surveys did not detect any evidence to suggest that there are regular daily flights by eider across the proposed development area and so a regular barrier effect that may cause a long-term increase in daily energetic costs is not predicted. There is the potential for a relatively small *ad hoc* increase as birds move around the bay but as most movements are within 1 km of the coast regular barrier effects are unlikely. It is predicted that the possible impacts arising from a potential barrier effect will be minor and there will be no adverse effect or significant environmental impact.

Displacement

Based on the results from the monitoring data, the worst-case scenario is that should displacement occur, that no eider will be within the proposed development area and there will be 80% displacement out to a distance of 1 km and a further 50% decrease in abundance out to 2 km from the wind farm.

Based on the peak density obtained from boat-based surveys of 10.9 birds/km^2 during the winter period, should there be a total displacement of eider from within the proposed development area then it is predicted that up to 47 eider may be displaced during periods of peak density. Based on an 80% displacement out to 1 km (a total surface area of 12.3 km^2) from the proposed development area then it is predicted that a total of 154 eider may be displaced with a further 44 out to 2 km should there be 20% displacement. Therefore, the maximum number of eider potentially displaced is up to 198 birds based on the highest densities recorded from any survey within Aberdeen Bay and at least some displacement out to 2 km.

Based on the estimated total of 198 potentially displaced eider out of a peak reported count of 3,500 eider at Blackdog (Figure 4-5), it is predicted that up to 6% of the eider within Aberdeen Bay may be displaced. However, the distribution of eider within Aberdeen Bay is clustered with peak numbers occurring at various sites across the bay during different seasons (Sohle *et al*. 2006). The area off Blackdog regularly records the peak counts of eider in Aberdeen Bay (NESBR) and should displacement occur a greater proportion of eider might be affected than is estimated using densities obtained from boat-based surveys.

The Tuno Knob offshore wind farm in Denmark is a relatively small wind farm of ten turbines in an area that holds up to 5,800 eider. Post-construction monitoring at Tuno Knob has indicated that the distribution of eider is closely related to their prey and although there may be some displacement immediately post-construction there is unlikely to be any significant displacement of eider from the proposed development area as long as their prey remain available (Guillemette *et al.* 1999). Evidence from studies undertaken at Nysted offshore wind farm have indicated that although there was an avoidance of the area during construction there was a subsequent increase of 48% within the wind farm area post-construction but a decrease in numbers out to 2 and 4 km (Zucco *et al.* 2006).

These two studies demonstrate that eiders do not avoid wind farms post-construction and their distribution is closely aligned to the availability of prey. The main prey items for eider are mussels (*mytilus edulus*). Evidence from constructed wind farms indicates that there is likely to be an increase in mussels around the base of turbines and that no significant impacts have been detected on mussels from the construction of wind farms. Consequently, there is unlikely to be a negative impact on prey availability for eiders within Aberdeen Bay.

Based on the evidence from existing offshore wind farms it is predicted that the potential impact from displacement is minor.

Calculations used for displacement	
Area	*Peak density of eider – 10.9 birds/km^2*
Area of EOWDC – 4.3 km^2	4.3 * 10.9 = 47
Area of EOWDC 1 km buffer – 12.3 km^2 @ 80%	(12.3 * 10.9)*0.8 = 107
Area of EOWDC 2 km buffer – 20.3 km^2 @ 20%	(20.3 * 10.9)*0.2 = 44
Total predicted displacement	47+107 + 44 = 198

Disturbance

Eiders may be disturbed by vessels both during the construction phase and during operations from maintenance vessels. Studies have indicated that there may be displacement from large vessels out to 1,000 m (Larsen & Laubek 2005).

During construction there may be a number of vessels operating within the area but they will likely be focussed around a single point where the turbine is being installed. Consequently, eider may be displaced from within 1 km radius of the installation; an area of 3 km^2. Based on the highest recorded density of 10.9 birds/km^2, it is therefore predicted that up to 33 eider may be displaced from the vicinity during construction. This equates to approximately 1% of the peak eider population within Aberdeen Bay based on the peak estimated figure of 3,500 individuals. The construction period will be of short duration and the impacts from construction vessels temporary. Consequently, any potential impact is predicted to be negligible.

Displacement by service boats may diminish the re-population potential of the EOWDC. It is not known how many service vessels may be required but based on the scale of the proposed development there is unlikely to be frequently more than one vessel on any one occasion. The presence of the proposed development in the vicinity of the intensively used Aberdeen Harbour means that the potential increase of one vessel movement on a regular basis will not have any noticeable difference to the number of vessels already using Aberdeen Bay. Any specific displacement caused by the service or construction boats will be temporary as eiders will be able to move into the area once the vessels leave.

It is concluded that the effect of disturbance from construction or service boats is negligible.

Cumulative and in-combination

The potential future Ocean Pod will require additional vessel movements within the proposed development area. Should this occur then there is the potential for a cumulative effect on eider. It is not yet known what type of structure the Ocean Pod may be or how it will be installed or the number of vessel movements will be required. However, it is a single structure and it is predicted that the level of disturbance will be no greater than that arising from the installation of a single wind turbine. The scale of disturbance is therefore predicted to be localised and of short duration.

Aside from the historical and on-going levels of shipping, there are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts. The eiders present are known to travel to the Tay during the winter and have the potential to interact with other offshore wind farm planned in the area. However, the location of the wind farms in the Firth of Forth area, in particular their distance from shore, are such that eiders are unlikely to be frequently recorded in any of the areas of the proposed developments. Consequently there are unlikely to be any cumulative or in-combination impacts.

4.9.6 Conclusions

Habitats Appraisal

Based on the evidence from existing offshore wind farms indicating both a very low collision risk and little, if any, displacement and that there are not expected to be any significant barrier effects; it is predicted that there will not be any adverse effects on the SPAs for which eider is a qualifying species.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on eider.

4.10 Long-tailed duck (*Clangula hyemalis*)

4.10.1 Protection & Conservation Status

Long-tailed duck is listed in Appendix II of the Bonn Convention, Appendix III of the Bern Convention and is on the Green List of Species of Conservation Concern.

4.10.2 Background

Long-tailed duck		
GB Population	Winter – 16,000 ind.	BTO 2011
Scottish Population	Winter – 15,000 ind.	Forrester *et al* 2007

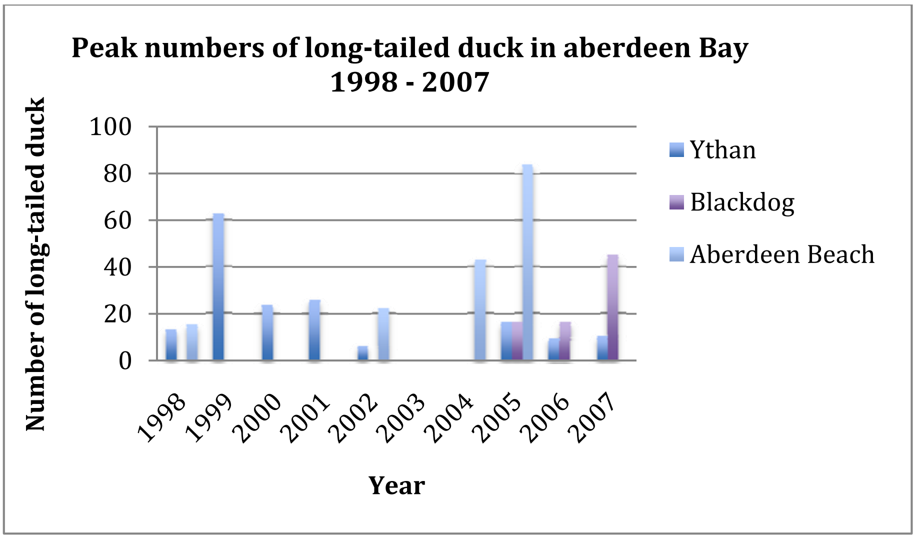
GB threshold	160 ind.	1% of GB Pop[n]
Designated east coast sites where species is a noted feature	Firth of Forth Firth Tay & Eden	SNH 2011
European population estimate	Breeding 7,669 – 17,294 pairs Wintering – 4,700,000 individuals	Hagemeijer & Blair 1997
European population trend	Status 'decreasing' Trend 'moderate decline	Birdlife 2004
World population	6.2 to 6,800,000 ind.	Birdlife 2011

Long-tailed duck breed in the high Arctic with significant breeding population in Russia where up to 5 million pairs are estimated to breed. In north-west Europe, breeding populations are considerably smaller with less than 18,000 pairs in Sweden, Iceland and Finland. Long-tailed duck do not breed in the UK but an estimated 16,000 winter in the UK of which 15,000 winter in Scottish waters, primarily in Shetland, Orkney and the Moray Firth (Forrester *et al.* 2007). Outwith the breeding season long-tailed duck occur along sheltered coasts, often with soft sandy sediments and can dive to depths of up to 60 metres so can occur further offshore than many other species of seaduck.

In North-east Scotland long-tailed duck are an uncommon winter visitor with most sightings and peak numbers occurring in Aberdeen Bay where less than a hundred birds may occur (Figure 4-14). Passage of birds passing Peterhead occurred from September to May with peak counts of up to 14 birds per hour during March. Although most sightings at Peterhead were within a few hundred metres from the shore long-tailed duck were seen as far out as 3 km (Innes 1996).



(Source NESBR)

Figure 4-14: Peak numbers of long-tailed duck recorded at the Ythan, Blackdog and Aberdeen Beach 1998 – 2007.

Boat-based surveys

A total of 33 long-tailed duck were recorded from ship-based surveys in January, April, October, and November. All sightings were of birds close inshore, flying parallel to the coast (Figure 4-15) (IECS 2008, SMRU 2011b).

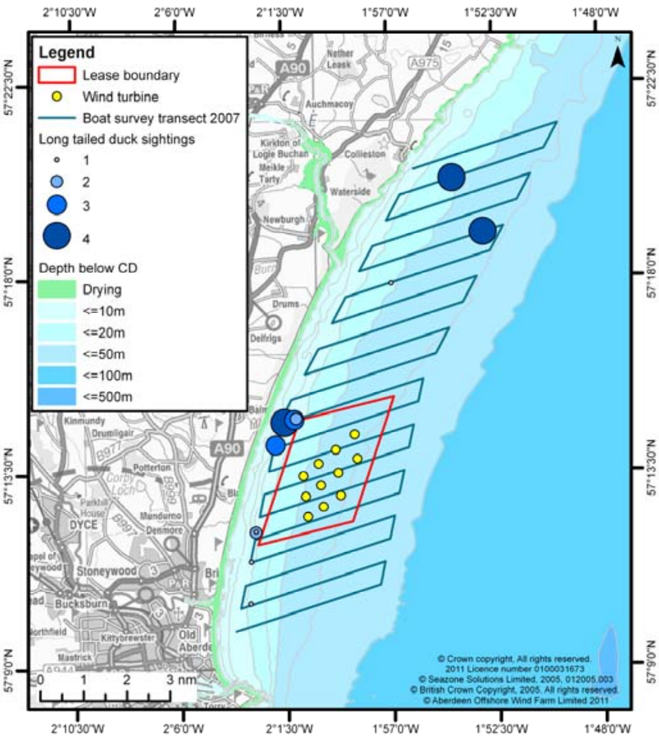


Figure 4-15: Long-tailed duck distribution in Aberdeen Bay (all sightings).

Point surveys

Long-tailed duck were regularly recorded in low numbers within Aberdeen Bay, primarily between December and March with a peak count of up to 25 birds per hour passing Blackdog in November 2007. However, numbers passing were usually less than five birds per hour at other sites (Alba Ecology 2008b). All birds were recorded flying below 30 metres with the majority of sightings between 1 km to 3 km from shore.

Bird Detection Radar

A total of 17 long-tailed duck were recorded during the radar studies in October 2005 with seven at Drums and ten at Easter Hatton. Although long-tailed duck were recorded out to 2.7 km from shore the majority of sightings were within 2 km from the coast. The mean flight heights were 2 m above sea surface with the maximum height of 4 m (Walls *et al.* 2005). Forty-seven birds were recorded during radar studies undertaken at Blackdog in April 2007. All birds were flying below 30 m and 90% of sightings were within 1.5 km of the coast (Simms *et al.* 2007).

4.10.3 Summary of Results

Relatively small numbers of long-tailed duck occur in Aberdeen Bay with peak counts of usually less than 50 birds, occurring in any month between November and March. Although long-tailed duck can occur throughout the bay the main areas are the Ythan mouth, Blackdog and the Donmouth. The majority of sightings are of birds within 2 km of the shore and at least 90% of the birds recorded in flight were flying below 30 m.

No counts of long-tailed duck within Aberdeen Bay were of national importance.

4.10.4 Initial Assessment of Significance

Long-tailed duck	Overall sensitivity	Magnitude	Significance
Collision	Medium	Negligible	Negligible
Barrier	High	Low	Minor
Displacement	Very High	Low	Moderate

4.10.5 Species Sensitivities

Qualifying species

There are two SPAs in the region for which long-tailed duck is a qualifying species as part of waterfowl assemblages: Firth of Forth SPA and Firth of Tay and Eden Estuary SPA.

Flight height

Flight heights obtained from boat-based surveys undertaken in Aberdeen Bay recorded all seventeen long-tailed ducks for which flight heights were recorded as flying below 25 m. Data from site specific radar studies recorded a mean flight height of 2 m and a maximum of 4 m.

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that long-tailed duck occur in relatively low numbers within Aberdeen Bay. Studies undertaken in Sweden indicate that long-tailed duck have a very high avoidance rate and that the majority of birds will either detour around the wind farm or fly below turbine height (Pettersson 2006). Consequently, there is evidence to indicate that the risk of collision by long-tailed duck is extremely low.

The numbers of long-tailed duck recorded in Aberdeen Bay were significantly lower than those studied in Denmark and Sweden and in neither of these studies was there any evidence of a significant impact from collision.

Based on the results from site specific study indicating the low altitude at which long-tailed duck fly and evidence from other offshore wind farms it is predicted that there is a very low risk of collision and that the potential effect from collision is negligible.

Barrier effect

Studies undertaken in Sweden and Denmark have shown that there is the potential for a barrier effect, with long-tailed duck changing flight directions at least 1 km from offshore wind turbines and flying around them. Therefore, it is predicted that the proposed development may cause a barrier effect to long-tailed duck in Aberdeen Bay.

Data obtained from nearly three years of Vantage Point surveys plus additional radar studies and boat-based surveys did not detect any evidence to suggest that there are regular daily flights by long-tailed duck across the proposed development area and so a regular barrier effect that may cause a long-term increase in daily energetic costs is not predicted. There is the potential for a relatively small *ad hoc* increase as birds move around the bay but as most movements are within 2 km of the coast regular barrier effects are unlikely. It is predicted that the potential impacts arising from barrier effect will be minor and there will be no adverse effect or significant environmental impact.

Displacement

Based on the results from the monitoring data, the worst-case scenario is that should displacement occur, that no long-tailed duck will be within the proposed development area out to a distance of 1 km and a further 50% decrease in abundance occurs out to 2 km from the wind farm. However, very few long-tailed duck were recorded from any surveys and any displacement will impact on a relatively low number of birds and any that are displaced will be able to re-locate if needed to alternative areas. Data from aerial surveys identify Cruden Bay to the North and Bridge of Don to the south of the proposed development as being the main areas for long-tailed duck (Sohle *et al*. 2006).

Based on the low numbers of long-tailed duck recorded in the vicinity of the proposed development and that alternative areas of Aberdeen Bay are known to be suitable for long-tailed it is predicted that the potential impact from displacement is negligible.

Disturbance

Long-tailed ducks may be disturbed by vessels both during the construction phase and during operations from maintenance vessels. Studies have indicated that there may be displacement from supply vessels (Pettersson 2006).

During construction there may be a number of vessels operating within the area but will likely be focussed around a single point where the turbine is being installed. The numbers of long-tailed duck present in the vicinity of the proposed development are relatively low. Evidence from existing wind farms indicates that long-tailed duck may fly up to 2 km from the vessel once disturbed and return once the vessel departs (Pettersson 2006).

It is not known how many service vessels may be required but based on the scale of the proposed development there is unlikely to be frequently more than one vessel on site at any one time. The presence of the proposed development in the vicinity of the intensively used Aberdeen Harbour means that the potential increase of one vessel movement on a regular basis will not make any noticeable difference to the number of vessels already using Aberdeen Bay. Any specific displacement caused by the service boats will be temporary as long-tailed duck will be able to move into the area once the vessels leave.

It is concluded that the effect of disturbance from construction or service boats is negligible.

Cumulative and in-combination

The potential future Ocean Pod will require additional vessel movements within the proposed development area. Should this occur then there is the potential for a cumulative effect on long-tailed duck. It is not yet known what type of structure the Ocean Pod may be or how it will be installed or the number of vessel movements will be required. However, it is likely to be a single structure and it is predicted that the level of disturbance arising from the installation of it will be no greater than that arising from the installation of a single wind turbine. The scale of disturbance is therefore predicted to be localised and of short duration.

Aside from the historical and on-going levels of shipping, there are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts. Based on the numbers present and the low risk of any adverse effect from the proposed development on its own there are no known potential cumulative or in-combination impacts.

Habitats Appraisal

Based on the evidence from existing offshore wind farms indicating both a very low collision risk, little displacement and that there are not expected to be any significant barrier effects; it is predicted that there will not be any adverse effects on the SPAs for which long-tailed duck is a qualifying species.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on long-tailed duck.

4.11 Common scoter (*Melanitta nigra*)

4.11.1 Protection & Conservation Status

Common scoter is listed in Schedule I of the Wildlife and Countryside Act, Appendix II of the Bonn Convention Appendix III of the Bern Convention and is on the Red List of Species of Conservation Concern for a breeding species and Amber List for wintering species.

4.11.2 Background

Common scoter		
GB Population	Breeding 9 – 52 pairs Winter – 50 – 65,000 ind.	Holling 2010 Cranswick 2001
Scottish Population	Breeding – 9 – 52 pairs Winter – 25,000 – 30,000 ind.	Holling 2010 Forrester *et al.* 2007
International threshold	16,000 ind.	Calbrade *et al*. 2010
GB threshold	500 ind.	Calbrade *et al*. 2010
Designated east coast sites where species is a noted feature	Firth of Forth Firth of Tay & Eden	SNH 2011
European population estimate	Breeding 100,000 – 130,000 pairs Wintering – 610,000 individuals	Birdlife 2004
European population trend	Status 'secure' Trend 'small decline'	Birdlife 2004
World population	2,100,000 – 2,400,000 'adults'	Birdlife 2011

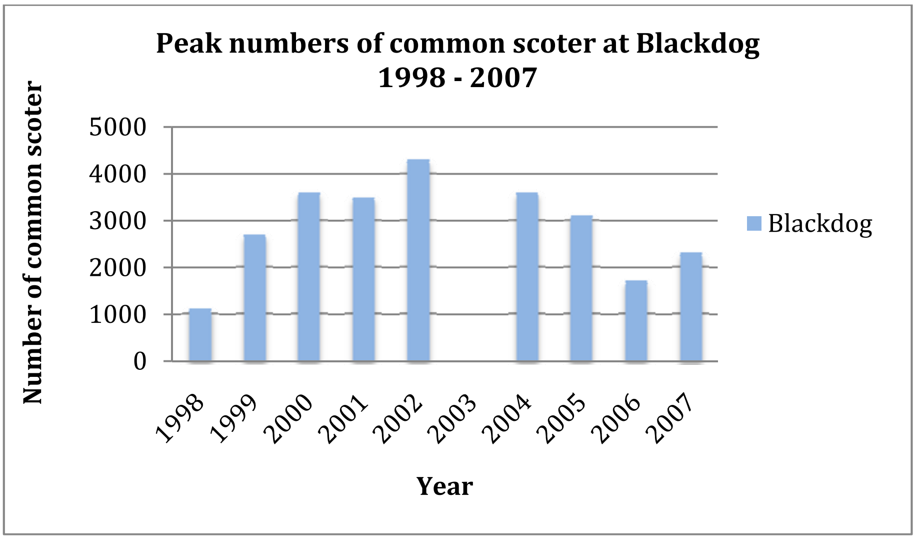
Common scoter breeds across the boreal and subarctic zones of Eurasia and has a European breeding population of up to 130,000 pairs. There is a small breeding population in the UK with between 9 and 52 pairs breeding in Scotland (Holling 2010).

Common scoter is a common winter visitor occurring in waters predominantly less than 20 m deep where they forage on benthic mussels and crustaceans. They are generally gregarious and form large flocks in suitable areas. In eastern Scotland the main wintering areas are the Moray Firth, Firth of Forth, St Andrews Bay, Carnoustie, Lunan Bay and Aberdeen Bay where a combined total of c.9,000 individuals winter (based on 5 year peak mean counts) (Calbrade *et al.* 2010).

Common scoters also occur during the summer months at regular 'moult' sites where flocks of up to 3,000 individuals may occur (Cork Ecology 2004a). The main summering sites are Aberdeen Bay, Firth of Forth, St Andrew's Bay, St Cyrus and Lunan Bay where a combined total across all sites total of c.6,500 birds may summer (Cork Ecology 2004a)

In North-east Scotland common scoter occur regularly in large numbers in a few preferred areas; particularly Aberdeen Bay. Numbers are lowest during the winter months when there are usually less than 200 birds present (Wilson *et al*. 2006). During the summer months a 'moult' flock of common scoter is present in Aberdeen Bay, primarily between the Donmouth and Balmedie to the south and west of the proposed development, with peak counts of up to 4,750 birds occurring (Buckland, Bell & Picozzi 1990; NESBR) (Figure 4-16).

Common scoter were recorded passing Peterhead throughout the year with a strong seasonal variation. Numbers passing Peterhead were generally low during the winter months with less than four birds per hour. There is a peak spring passage during April when up to 13 birds per hour were recorded with a decrease thereafter. Most sightings were of birds between 300 to 500 metres from shore but some were out to 3 km (Innes 1996).



(Source NESBR)

Figure 4-16: Peak numbers of common scoter recorded at Blackdog between 1998 and 2007.

Boat-based surveys

Common scoters were recorded in coastal waters of Aberdeen Bay throughout the year with peak counts during June and July. All records were of birds in water depths of less than 20 m with the majority of sightings within 2 km of the coast and in water depths of less than 10 m. There were relatively few records of common scoter within the proposed development area with small numbers present during the spring and autumn migration periods. The largest flocks were recorded between Donmouth and Balmedie with a cluster of flocks totalling 1,200 common scoter in July 2007 (Figure 4-17, Figure 4-18, Figure 4-19) (IECS 2008).

Additional surveys undertaken between August 2010 and January 2011 recorded common scoter within the proposed development area. Peak totals occurred in September and January when approximately 100 birds were present (Figure 4-20) (SMRU 2011b).

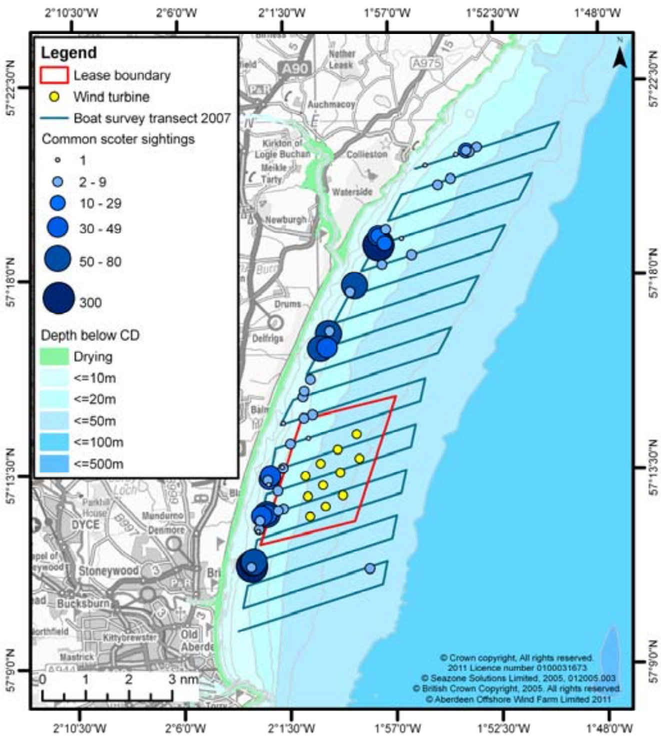


Figure 4-17: Common scoter distribution in Aberdeen Bay during winter period: November to March (all sightings).

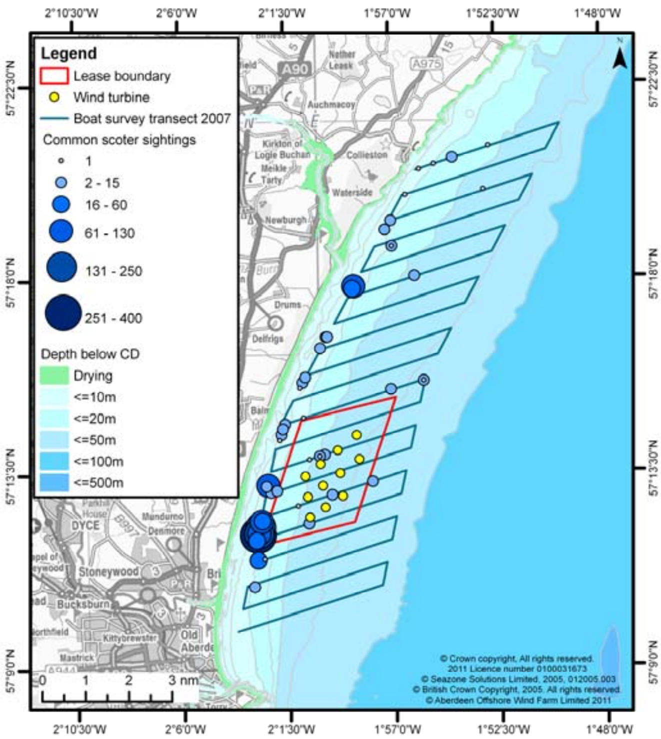

Figure 4-18: Common scoter distribution in Aberdeen Bay during spring and autumn periods: (all sightings).

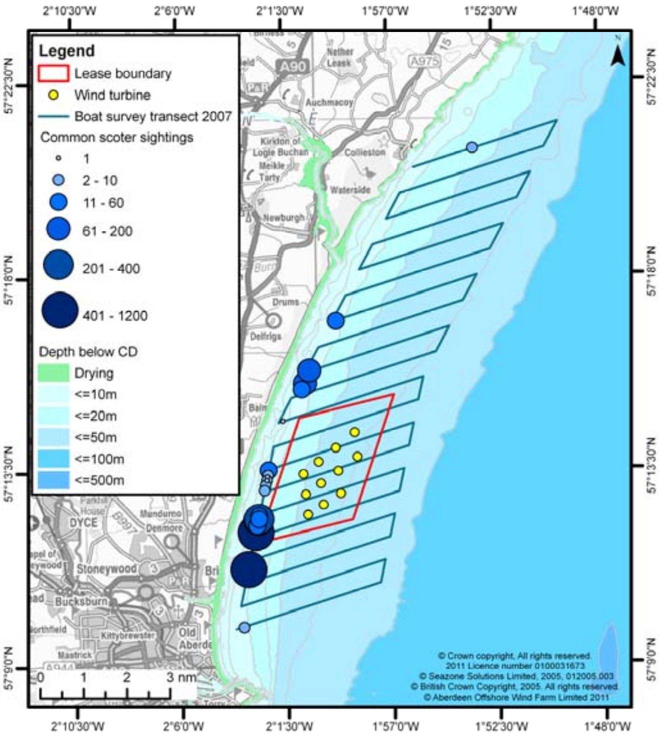

Figure 4-19: Common scoter distribution during summer period: June to August (all sightings).

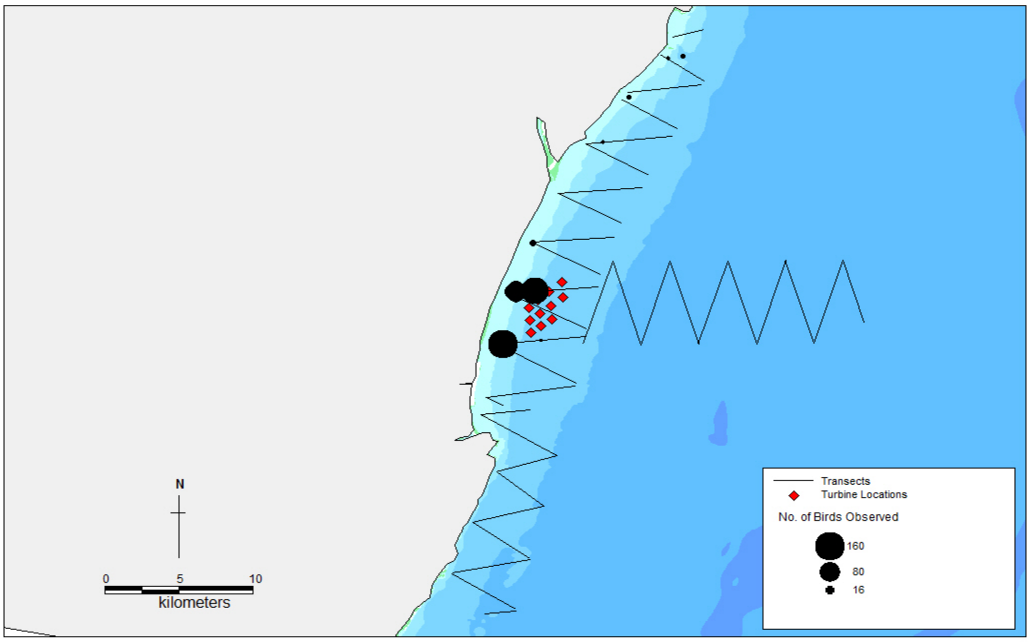

Figure 4-20: On-effort observations of all species of seaduck (Common Scoter, Unidentified Scoter species, Common Eider and Long-tailed Duck) along transects during August, September and November 2010 and January 2011.

Most sightings from boat-based surveys were of birds when not on transect and outwith the 300 m transect width. Consequently, the number of birds recorded for population estimates were relatively low. Greatest numbers were recorded within the wider proposed EOWDC development area but not within the footprint of the proposed development; with seasonal estimates using *Distance* sampling indicating peak numbers in the proposed EOWDC development area of 1,175 individuals and 442 individuals in the summer period (Table 4-9, Figure 4-21,Figure 4-22).

Table 4-9: Seasonal estimates of density and abundance of Common Scoters in the proposed EOWDC and 'control' Areas

	Density Estimate (km^2)	S.E	Estimated Abundance	SE	Number of Observations
EOWDC - winter	0.23	0.15	12	7.7	4
Control -winter	0.09	0.09	5	4.6	2
EOWDC - Spring	23.1	45.48	1,157	2,310	4
Control - Spring	0.39	0.11	20	5.9	5
EOWDC - Summer	8.69	18.62	442	946	5
Control - Summer	1.55	1.58	79	80	1

.

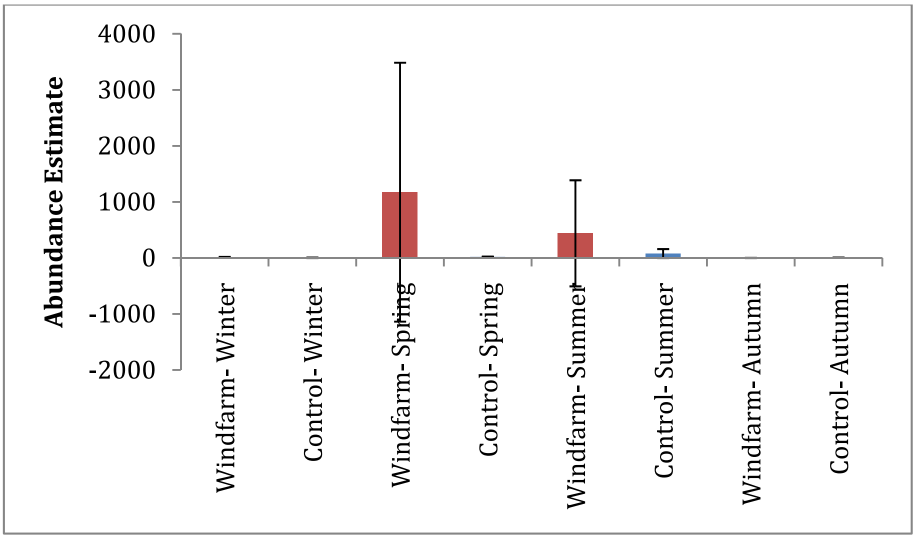

Figure 4-22: Seasonal estimates (+/- SE) of abundance of Common Scoters in the proposed EOWDC and 'control' Areas.

Vantage Point surveys

Results from monthly vantage point counts undertaken in Aberdeen Bay throughout the year recorded relatively low numbers of common scoter between December and February with numbers increasing from March onwards and peak movements between June and September when up to nearly 200 birds per hour were recorded passing in July 2007 (Alba Ecology 2008a,b). This is in contrast to the records from Peterhead where most sightings occurred during the spring and relatively few sightings during the summer. Birds were recorded at all Vantage Point sites with peak numbers at Balmedie, Murcar and the Promenade during June. Of those for which flight heights were recorded at least 95% were flying below 30 m with the majority of those recorded at greater than 30 m being at Donmouth. Most records were within 1 km and 2 km from shore, with relatively few between 2-3 km.

Bird Detection Radar

Common scoter were frequently recorded during the Bird Detection Radar studies undertaken during October 2005 with a total of 1,054 sightings of which 911 were at Easter Hatton and 143 at Drums. Common scoter recorded at Easter Hatton were generally less than 2 km from shore with those at Drums between 4 km and 4.5 km from shore. Of those recorded in flight all were flying below 5 m. (Walls *et al.* 2006).

A seventeen day radar study was undertaken at Blackdog between 11 and 26 of April 2007. During this survey a total of 1,872 common scoter were recorded in relatively small flocks of no more than 60 birds (Simms *et al.* 2007). Unlike the surveys undertaken in October 2005, approximately 50% of all common scoter were between 2 km and 4 km from shore (Figure 4-23). Although April is a period of spring migration for common scoter, there was no clear difference between the numbers of birds heading north as opposed to flying south, which indicates that the movements of birds during this period may have related to foraging movements as opposed to migrating individuals. As the majority of sightings were during the first two hours of dawn the movements recorded may also relate to birds redistributing after night time drifting (Figure 4-24).

4.11.3 Summary of Results

Common scoters were frequently recorded throughout the year during surveys undertaken across Aberdeen Bay. Peak numbers recorded during boat-based surveys were during the spring and summer months with most records from within the proposed EOWDC survey area. Land based surveys recorded peak numbers of common scoter during the summer months with most birds being recorded off Blackdog. Most common scoter were recorded with 2 km of the coast and in waters of less than 10 m. However, a survey undertaken in April recorded the majority of common scoter off Blackdog as being between 1 km and 3 km from shore.

Of those recorded in flight at least 95 of common scoter were recorded flying below 30 m.

Peak counts of common scoter recorded within Aberdeen Bay are of national importance but are not of international importance.

4.11.4 Initial Assessment of Significance

Common scoter	Overall sensitivity	Magnitude	Significance
Collision	Medium	Negligible	Negligible
Barrier	High	Medium	Moderate
Displacement	Very High	High	Major

4.11.5 Species Sensitivities

Qualifying species

There are two SPAs in the region for which common scoter is a qualifying species as part of waterfowl assemblages: Firth of Forth SPA and Firth of Tay and Eden Estuary SPA.

Flight height

Flight heights obtained from boat-based surveys undertaken in Aberdeen Bay recorded 377 common scoter in flight of which 1% were recorded as flying above 25 m and therefore at risk of collision.

Extensive studies undertaken, particularly in the East Irish Sea have recorded large numbers of common scoter of which 4.0% have been recorded at rotor height and mean flight height of 9.3 m.

Collision risk

Evidence from site specific monitoring using boat-based and land-based surveys and other data sources indicate that common scoter are widespread and frequent within Aberdeen Bay and occur in large flocks in certain areas. They occur widely with the majority of sightings occurring in nearshore waters within 3 km of the shore and in water depths of <20 m.

Collision Risk Modelling undertaken for common scoter is based on:

- Body length of 49 cm
- Wingspan of 84 cm
- Flight speed of 20.9 $m.s^{-1}$

Avoidance rates ranging from between 98%, 99% and 99.5% have been used.

As no common scoters were recorded in flight from boat-based surveys undertaken within the proposed development area, the collision risk calculation is based on the maximum number of birds recorded in flight from within the 'control' area to the north. This is a precautionary assumption as the proposed development area is in water depths greater than typical foraging depths for common scoter and is therefore infrequently used but it does take into account the possibility that birds may potentially fly through the area to other feeding locations.

Table 4-10: Predicted number of potential collisions for common scoter.

Collision probability	Avoidance rate (%)		
	98	99	99.5
6.6	0.27	0.13	0.06

Based on the precautionary avoidance rate of 98% it is predicted that a total of 0.27 collisions per year may occur (Table 4-10).

The annual mortality rate for common scoter is 22.7% (BTO 2011). Consequently, out of a peak regional population of 4,300 individuals an annual mortality of 976 common scoter, may be predicted. Therefore, 1% of the baseline mortality is 10 birds per year.

Based on the results from collision risk modelling, which predicts a total of 0.27 collisions per year there will not be a significant impact on the common scoter due to collisions.

The Firth of Forth SPA is approximately 134 km away and has a five year peak mean population of 1,070 individuals. Therefore an annual mortality rate of 243 scoter. Should the whole of the wintering population in the Firth of Forth SPA fly through the proposed development area then the collision risk modelling predicts there will not be an adverse effect on the population due to collision.

The Firth of Tay & Eden Estuary SPA lies approximately 96 km away from the proposed development and has a five year peak mean population of 1,037 scoters. Therefore, an annual mortality rate of 235. Should the whole of the wintering population in Firth of Tay & Eden Estuary SPA fly through the proposed development area the collision risk modelling predicts that there will not be an adverse effect on the population due to collision.

No collisions have been reported from post-construction monitoring studies undertaken in Denmark and Sweden indicating that common scoter have a very high avoidance rate and that the majority of birds will detour around the proposed development.

Based on the results the very low risk of collision and results from operating wind farms that have demonstrated significant avoidance rates by common scoter it is concluded that the potential effect from collision risk is negligible.

Barrier effect

Studies undertaken in Sweden and Denmark have shown that there is the potential for a barrier effect on common scoter with changes flight directions up to 1 km from offshore wind turbines and flying around them (Christensen & Hounisen 2004, 2005). Therefore it is predicted that the proposed development may cause a barrier effect to common scoter in Aberdeen Bay.

There is no evidence of regular daily movements of common scoter within Aberdeen Bay to and from feeding or roosting areas. However, most flight activity at Blackdog was recorded at dawn and these may be birds moving from a roost site to feeding areas (Figure 4-24). Should a barrier effect occur with common scoter making daily movements from one location to another around the proposed development area then they may incur an additional flight distance of up 3.2 km each way, or a total of 6.4 km. This may increase the daily energy expenditure to between 2.2% and 2.6% (Speakman, Gray & Furness 2009). This is a relatively small increase in daily energy expenditure and is unlikely to have an adverse effect on common scoter in Aberdeen Bay.

As with eider, the peak numbers of common scoter in Aberdeen Bay occur during July and August when the adults undergo a complete wing moult over a period of four weeks, during which time they become flightless. The daily energetic costs during this period may increase but the birds remain within certain areas where they can forage and cannot undergo daily flight movements, consequently, there is no incremental increase in daily energy expenditure due to the barrier effect during this period of higher energy expenditure.

Data obtained from nearly three years of Vantage Point surveys did not detect any evidence to suggest that there are regular daily flights by common scoter across Aberdeen Bay, although the increased frequency in flights at dawn indicates that these may occur. Should they do so then there may be a relatively small increase in energetic expenditure.

The incremental increase in the distance migrating common scoter from their breeding grounds in Scandinavia or Russia may incur should they be displaced during their migration to or from the Firth of Forth or Firth Tay & Eden Estuary SPAs will be negligible and not cause an adverse effect.

Displacement

Based on the results from the monitoring data, the worst-case scenario is that should displacement occur, that no common scoter will be within the proposed development area and there will be 80% displacement out to a distance of 1 km and a further 50% decrease in abundance out to 2 km from the proposed development.

Based on the peak density obtained from boat-based surveys of 23.1 birds/km^2 during the spring period, should there be a total displacement of common scoter from within the proposed development area then it is predicted that up to 99 common scoter may be displaced during periods of peak density. Based on an 80% displacement out to 1 km from the proposed development area it is predicted that up to a further 227 common scoter may be displaced and an additional 94 out to 2 km should there be 20% displacement between 1 km and 2 km from the proposed development. Therefore, the maximum number of common scoter potentially displaced is up to 420 birds based on the highest densities recorded from any survey within Aberdeen Bay and displacement out to 2 km.

Based on the estimated total of 420 potentially displaced common scoter out of a peak reported count of 4,300 common scoter at Blackdog (Figure 4-16), it is predicted that up to 10% of the common scoter within Aberdeen Bay may be displaced. However, the distribution of common scoter within Aberdeen Bay is clustered with peak numbers occurring at various sites across the bay during different seasons (Sohle *et al*. 2006). The area off Blackdog regularly records the peak counts of common scoter in Aberdeen Bay (NESBR) and should displacement occur, a greater proportion of common scoter may be affected than is estimated using densities obtained from boat-based surveys alone.

However, intensive post-construction monitoring undertaken at Horns Rev offshore wind farm has indicated that displacement of common scoter may not occur and that birds will occur within an operating wind farm with a similar frequency as outwith (Petersen & Fox 2007). Similar results have suggested that this may also be the case at UK wind farms, e.g. Rhyl Flats.

These studies indicate that common scoter do not avoid wind farms post-construction.

Based on the evidence from existing offshore wind farms it is predicted that the potential impact from displacement is minor.

Calculations used for displacement	
Area	*Peak density of common scoter – 23.1 birds/km^2*
Area of EOWDC – 4.3 km^2	4.3 * 23.1 = 99
Area of 1 km buffer at 80% displacement = 12.3 km^2	(12.3 * 23.1)*0.8 = 227
Area of 2 km buffer at 20% displacement = 20.3 km^2	(20.3 * 23.1)/0.2 = 94
Total displaced	99+227+94 = 420

Disturbance

Common scoter may be disturbed by vessels, both during the construction phase and during operations from maintenance vessels. Studies have indicated that there may be displacement from large vessels out to 1,000 m (Larsen & Laubek 2005).

During construction there may be a number of vessels operating within the area but these will likely be focussed around a single point where the turbine is being installed. Consequently, common scoter may be displaced from within 1 km radius of the installation; an area of 3 km^2. Based on the highest recorded density of 23.1 birds/km^2, it is predicted that up to 69 common scoter may be displaced from the vicinity during the construction period. This equates to approximately 1.5% of the peak common scoter population within Aberdeen Bay based on the peak estimated figure of 4,300 individuals. The construction period will be of short duration and the displacement impacts from construction vessels temporary. Consequently, any potential impact is predicted to be negligible.

Displacement by service boats may reduce the re-population potential of the proposed development area. It is not known how many service vessels may be required but based on the scale of the proposed development there is unlikely to be more than one vessel at the site on any one occasion. The presence of the proposed development in the vicinity of the intensively used Aberdeen Harbour means that the potential increase by vessel movement will not have any noticeable difference to the number of vessels already using Aberdeen Bay. Any specific displacement caused by the service or construction boats will be temporary as common scoter will be able to move into the area once the vessels leave.

It is concluded that the effect of disturbance from construction or service boats is negligible.

Cumulative and in-combination

The potential future Ocean Pod will require additional vessel movements within the proposed development area during the installation and maintenance of it. Should this occur then there is the potential for a cumulative effect to common scoter. It is not yet known what type of structure the Ocean Pod may be or how it will be installed or the number of vessel movements will be required. However, it is a single structure and it is predicted that the level of disturbance will be no greater than that arising from the installation of a single wind turbine. The scale of disturbance is therefore predicted to be localised and of short duration.

Aside from the historical and on-going levels of shipping, there are no other additional activities within Aberdeen Bay that may cause either cumulative or in-combination impacts. There is not predicted to be any cumulative or in-combination impacts arising at other planned developments as their locations offshore and their water depths indicate that common scoter may not regularly occur in these areas. Studies undertaken at the Beatrice demonstrator wind farm have recorded one flock of 13 common scoter (Talisman 2005). Consequently there are unlikely to be any cumulative or in-combination impacts.

4.11.6 Conclusions

Habitats Appraisal

Based on the evidence from existing offshore wind farms indicating both a very low collision risk and little, if any, displacement and that there are not expected to be any significant barrier effects; it is predicted that there will not be any adverse effects on the SPAs for which common scoter is a qualifying species.

Environmental Impact Assessment

Based on evidence from existing offshore wind farms it is predicted that there will not be a significant environmental impact arising from the proposed development on common scoter.

4.12 Velvet scoter (*Melanitta fusca*)

4.12.1 Protection & Conservation Status

Velvet scoter is listed in Appendix II of the Bonn Convention, Appendix III of the Bern Convention and is on the Amber List of Species of Conservation Concern.

4.12.2 Background

Velvet scoter		
GB Population	Winter – 3,000 ind.	BTO 2011
Scottish Population	Winter – 2,500 – 3,500	Forrester *et al*. 2007
International threshold	10,000 ind.	Calbrade *et al.* 2010
GB threshold	30 ind.	Calbrade *et al.* 2010
Designated east coast sites where species is a noted feature	Firth of Forth Forth of Tay & Eden Estuary	SNH 2011
European population estimate	Breeding 85,000 – 100,000 pairs Wintering – >140,000 individuals	Birdlife 2004
European population trend	Status 'declining' Trend 'moderate decline'	Birdlife 2004
World population	1,700,000 – 3,000,000	Birdlife 2011

Velvet scoters do not breed in the UK but are a regular but uncommon winter visitor with an estimated wintering population of approximately 3,000 individuals along the east coast of the UK (Wernham *et al*. 2002). The main areas for velvet scoter along the east coast of Scotland are the Moray Firth, St Andrew's Bay and the Firth of Forth with a total of about 2,000 birds wintering (Calbrade *et al.* 2010).

During the late summer, small numbers of velvet scoter occur amongst the larger flocks of moulting common scoter and numbers increase for the rest of the year with peak wintering numbers in February.

During the winter months velvet scoter are uncommon in North-east Scotland with ones and twos being reported around the coasts. Peak numbers occur during July and August when velvet scoter occur amongst the moulting common scoter flock in Aberdeen Bay. Peak numbers vary considerably across years but up to 600 individuals have been recorded (Buckland, Bell & Picozzi 1990; NESBR) (Figure 4-25).
