Preface

In 2009-2011 ship-based surveys following the European Seabirds at Sea (ESAS) methodology have been carried out as part of the baseline study for wind farm initiatives at Neart na Gaoithe off the east coast of Fife, Scotland.

Mainstream has commissioned Bureau Waardenburg to calculate population estimates and bird densities based on the data collected during the above-mentioned surveys. In addition, collision rate modelling was carried out based on the densities of flying birds recorded during the surveys. This report presents the analysis and results of the population, density and collision rate estimates for birds at Neart na Gaoithe.

The project team of Bureau Waardenburg consisted of and was responsible for:

R.C. Fijn	distance analysis, report
M.P. Collier	collision rate modelling, report
R-J. Jonkvorst	distance analysis, report
M. Japink	database management
M.J.M. Poot	project management, distance analysis, collision rate modelling, report

Cork Ecology, Colin Barton and Claire Pollock, have been particularly helpful with providing their databases and answering questions. This project was commissioned by Mainstream Renewable Energy and coordinated by Zoe Crutchfield, who also ensured that data for the collision rate modelling were available.

Louise Burt from the Centre for Research into Ecological and Environmental Modelling of the University of St. Andrews provided advice and made useful suggestion on the Distance modelling in this project.

Theo Boudewijn provided comments on previous versions of this report. The authors thank everyone who has contributed during discussions over these analyses for their contribution, particularly Colin Barton and Claire Pollock (both Cork Ecology), Digger Jackson (Natural Research), Phil Bloor (Pelagica) and Phil Whitfield (Natural Research).

1 Introduction

In 2009-2011 ship-based surveys following the European Seabirds at Sea (ESAS) methodology have been carried out as part of the baseline study for wind farm initiatives at Neart na Gaoithe (NnG) off the east coast of Fife, Scotland.

Mainstream has commissioned Bureau Waardenburg to calculate population estimates and bird densities based on the data collected during the above-mentioned surveys. In addition, collision rate modelling was carried out based on the densities of flying birds recorded during the surveys.

In this report, the analysis and results of the population, density and collision rate estimates for birds at Neart na Gaoithe are presented as determined following the 'Distance methodology' (see §2.2). This report should be regarded as background document to support the understanding of the population, density and collision rate estimates for Neart na Gaoithe. The main goal of this report is to provide a clear overview of the analyses carried out and present the results in a comprehensive and accessible form. The data presented within this report are delivered as electronic data files, enabling the data to be easily processed for presentation in final documents.

2 Methods

2.1 Base Material

In this section we describe the procedures carried out during the handling of ESAS data collected at Neart na Gaoithe. The data analysed in this report were collected according to ESAS ship-based survey methodology (Tasker *et al.* 1984; Camphuysen *et al.* 2004). Monthly surveys at Neart na Gaoithe were carried out from November 2009 until October 2011 (with the exception of November 2010). Survey conditions and observations *etc.* are given in Mainstream Renewable Power (2012).

Preparation of database (ESAS model)

The physical data model was built on a PostgreSQL database server and was based on the 'SAST Coding Manual v 6.pdf' along with some additions (see figure 2.1). All coding lists were imported in tables and survey data from Neart na Gaoithe were imported to the database. Geometric fields for spatial querying of the data are non-projected in WGS84.

During the uploading of the data some fundamental checks were carried out using a Microsoft (MS) Access database as a front-end to the PostgreSQL database. Therefore, all PostgreSQL tables are ODBC-linked in MS Access and the data table-structures for trips, environment, bird and base data are hard copied.

Processing data (trip, environment, bird, base) ready for analysis

The different steps of how the base data were processed are described below. The different steps indicated are presented schematically in figure 2.2.

Formatting paradox export files

Paradox exports are required to be in text format. In this case files were delivered in csv format, therefore, the following steps were undertaken:

- replacing spaces with underscores in column names in the csv files;
- replacing all ',' with ';' as field delimiter.

Read into MS Access front-end

- All formatted files were read in hard copied MS Access native tables prior to adding to PostgreSQL.
- A record count was made to ensure all data were successfully imported.

Check against coding lists

- Each field was checked against its coding list to find missing values *etc.*

Upload in database

During the import some fields were recalculated.

- Latitude and longitude minutes were changed back to '.' separated values.

Corrections

The only corrections made to the data were in the field 'distance'.

- a new field 'flight_altitude' was populated with the numeric information from the 'distance' field.
- all 'distance' fields with numeric data were replaced with 'F' to indicate flying birds.

Additions

The ESAS database structure has been extended with some extra fields and an extra table.

- a geometry field in the base table was updated with point locations based on the coordinates in latitude and longitude.
- an 'in_out' field in the base table was updated with a 'study area' number, see figure 2.3 for a visible representation.
- an extra survey table was populated with lines calculated from base points with the following criteria 'count_type' =1 AND key fields from the Neart na Gaoithe survey data AND 'in_out' is not null'.
- line lengths were calculated in UTM 30N projection.
- *N.B.* For Distance analyses, line lengths were halved as Distance software assumes that observations along transects are made on two sides.

SELECT and analyse

Following loading and checking the data were ready for use in analysis.

- selection of major sea state, wind direction and observer for each survey for each transect.
- selection of flying or 'distance birds'.
- export of required data for Distance and density calculations.

Data used in the collision rate modelling were based on:

- flying birds in transect (in the 'snapshot' count);
- birds not associated with the observer base or similar vessels;
- only birds within the area of interest, *i.e.* Neart na Gaoithe development area.

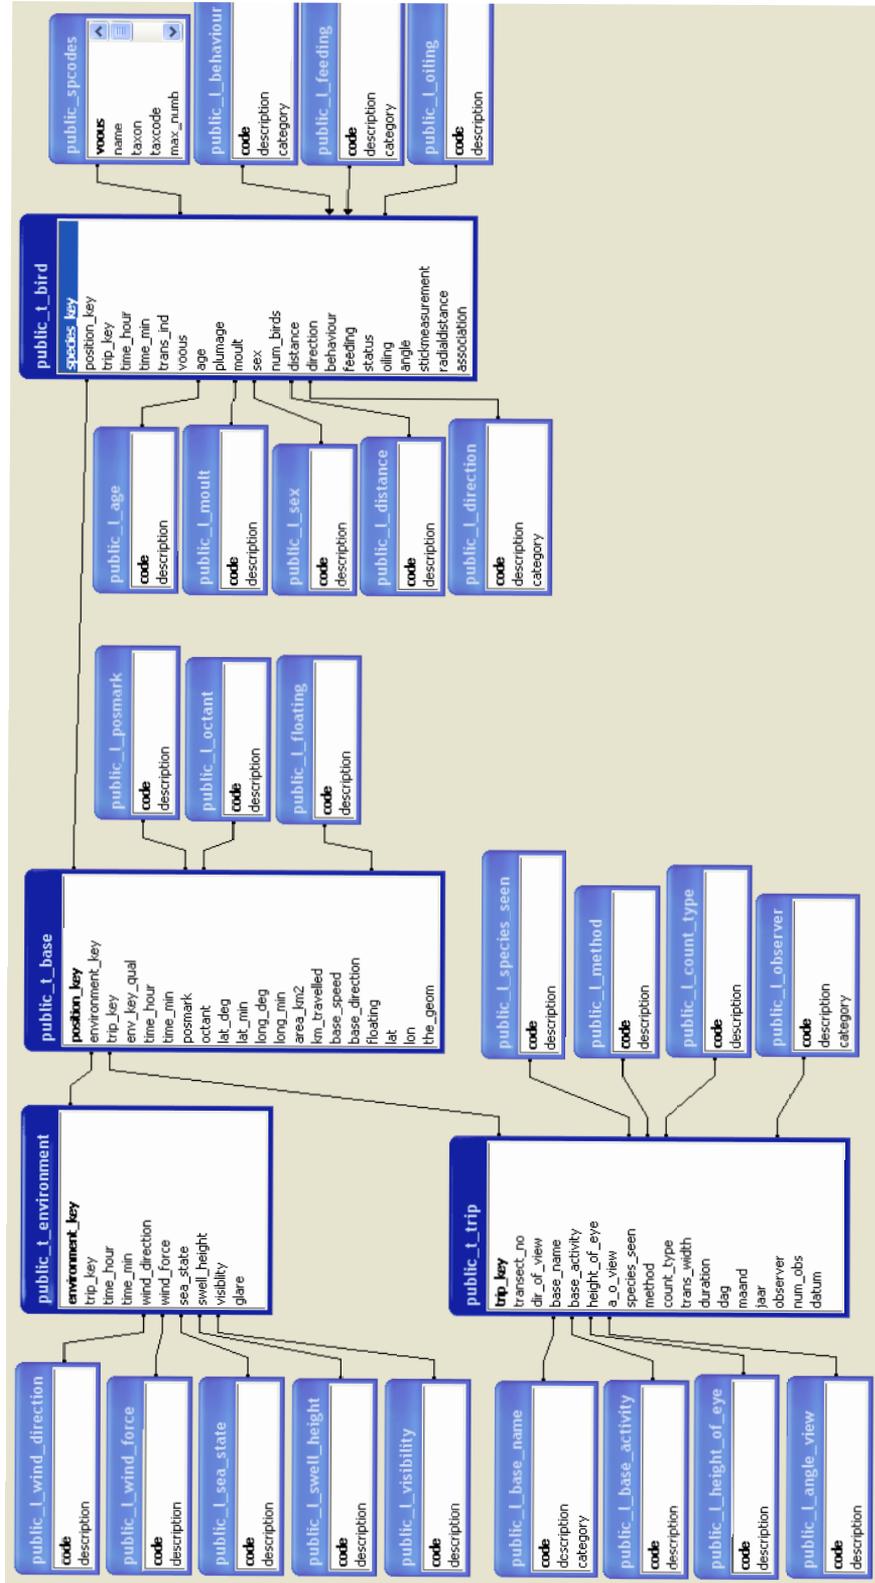

Figure 2.1 Overview of the database according the ESAS data model.

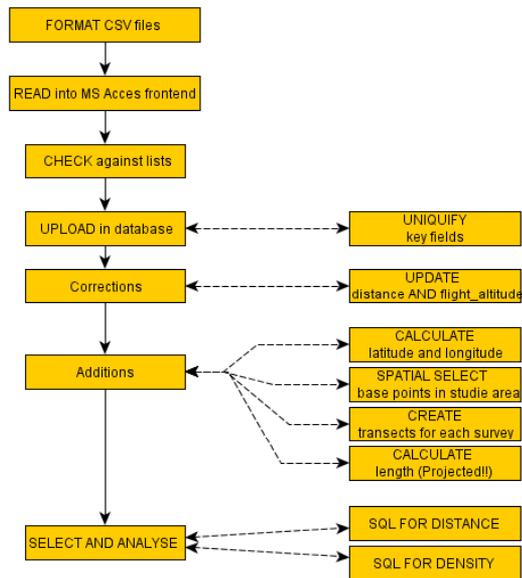

Figure 2.2 Overview of the processing steps to make the data ready for analysis.

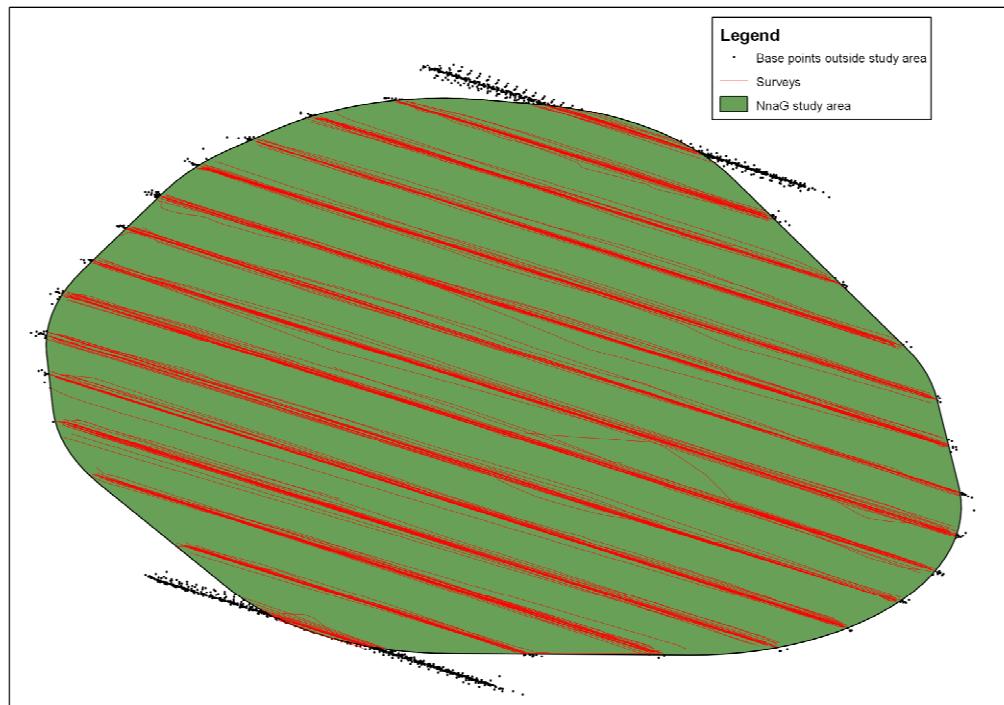

Figure 2.3 For the Distance analysis the observations outside the delimited study area of Neart na Gaoithe (here NnaG) were excluded. The transect lengths were amended accordingly.

2.2 Distance analysis

The data collected during the ship-based surveys at Neart na Gaoithe formed basis for estimating population sizes and densities of seabirds in the area (see 2.1 for an explanation of data collection and handling). Birds were recorded while steaming along pre-defined transects within the Neart na Gaoithe study area using the ESAS methodology (chapter 1 and 2.1). The detection probability of birds decreases with increasing distance from the transect line. Therefore, reliable estimates of the densities and population sizes of birds can only be estimated with the application of the Distance Sampling Technique (Buckland *et al.* 1993, 2001, 2004). Distance 6.0 software, developed by the Centre for Research into Ecological and Environmental Modelling at the University of St. Andrews (CREEM), uses this technique to fit a species-specific detection curve through the data collected to determine the width of the strip in which species were effectively recorded (Thomas *et al.* 2010). Subsequently, the densities of birds in the study area can be calculated based on those within the area covered (transect line multiplied with the effective strip width).

A key assumption of this technique is that all birds along the transect line ($g(0) = 1$) are detected. This assumption is not always valid due to disturbance of the survey ship causing birds to either dive, swim or fly away from the transect line to more distant transect bands. Furthermore, the calculated densities for species that regularly undertake long dive must be regarded as a lower limit as the proportion under the water remains unknown. In seabirds, the species with potentially lower detection rates ($g(0) \neq 1$) is likely to include auks, and in particular the smaller species. If not all individuals of a certain species are detected ($g(0) \neq 1$), several analytical techniques can be used to correct for this imperfect detection.

The distance analysis included all observations of birds that were not in flight (either swimming or sitting on floating objects) and within transect (up to 300 m) and categorised in one of four observation bands (0-50 m, 50-100 m, 100-200 m and 200-300 m). These four observation bands give average perpendicular distances (used by the Distance 6.0 software) of 25, 75, 150 and 250 m. So, automatically a 'right truncation' of the data was performed at the outer boundary of band D (300 m).

As a robust, conservative approach, hazard-rate detection curves were always chosen first, unless half normal curves would give a more smooth detection curve with a realistic decrease in numbers at larger distance. Model selection was mainly based on the Akaike Information Criteria (AIC), with lower AIC values resembling models with a better fit. In each species account in this report, our assessment of distance curves is explained.

As a general rule at least 60 positive observations are needed in order to be able to fit a reliable detection function. In order to correct for loss of detection due to factors such as sea state *etc.* the number of observations needed increases with a multiple of the number explanatory parameters, including covariates in Distance analysis models.

Therefore, in order to determine the most reliable detection function especially applicable for the scarce species, all available data were used to estimate the detection functions. For Neart na Gaoithe survey data from over a two year period were available and were used to determine a global detection function.

Detection of seabirds on the water surface is influenced by observation conditions due to weather and sea state. The Distance 6.0 software allows the analysis of sea state data as covariates during the modelling process. Also here, model selection was mainly based on the Akaike Information Criteria (AIC) with lower AIC values representing models with a better fit. By applying this criterion, better models could be used to correct population estimates for the effect of sea state, resulting in better estimates with smaller confidence intervals.

2.3 Collision rate modelling

For various bird species, the level of collision-related mortality was estimated by collision rate modelling. The model used was that published by the Crown Estate Strategic Ornithological Support Services group in November 2011 (Band 2011; available from <http://www.bto.org/science/wetland-and-marine/soss/projects>). This model, based on the SNH/Band collision risk model (Band *et al.* 2007; available from <http://www.snh.gov.uk/planning-and-development/renewable-energy/onshore-wind/assessing-bird-collision-risks/>), has been extended to allow the direct input of density data and to allow the comparison of various avoidance rates on the estimated collision rates.

Based on the physical characteristics of both the turbine and species of bird, a turbine/species-specific probability of collision for a single bird crossing the rotor-swept area can be calculated. This probability is then applied to the number of birds crossing the rotor-swept area of an entire wind farm, which is estimated based on the density of flying birds and the size and number of turbines. Finally, an avoidance factor is applied that accounts for birds avoiding turbines, were they present. The model also allows a correction factor for large arrays, which assumes a decreasing density of birds across the wind farm that is relative to numbers of birds that have been assumed to collide. For the current wind farm scenarios, this correction factor has the effect of reducing the estimates of the numbers of collisions by a fraction of a percent, and has therefore not been applied.

The collision risk model makes a number of assumptions and is further sensitive to changes in avoidance rates (Chamberlain *et al.* 2006), which urge caution when interpreting the results. Here, four different avoidance rates have been applied: 95%, 98%, 99% and 99.5%.

Data for the various wind farm variants and turbine-specific data were provided by Mainstream and are given in section 6.1. Data for species-specific parameters, such

as length, wingspan and flight speed, were obtained from literature. These are also given in section 6.1. Not all data were available for all wind farm scenarios or for all species modelled. Missing data were estimated based on similar turbines or on similar species.

The proportions of each species flying at rotor height were calculated from data recorded during the ship-based surveys (see section 2.1). The heights of flying birds were recorded in 5m categories. For each turbine variant, the proportions of birds recorded in the height categories of the rotor tip at its lowest point to the rotor tip at its highest point were taken as the proportion flying at rotor height.

Only flying birds recorded as 'in transect', thus within the snapshot count, were included in when calculating species-specific densities (see sections 2.1 and 2.2). Monthly densities, and therefore monthly collision rates, were calculated, which were summed to provide annual collision rates.

An additional 22 species were assessed based on a fixed number of passages per year (flux), from which areal densities were calculated. This flux was based on 1,000 birds passing through the development area in a north-south/south-north direction two times a year. The width of the development area was taken as 10km. Areal density was calculated following Annex 2 of the guidance published by the Crown Estate Strategic Ornithological Support Services group. The assumption was made that 1,000 individuals of each species assessed passed through the development area during April and then again in September. This would yield the same results if these birds passed during any time frame within the year. The results of the collision rate modelling for the additional species are given in section 6.5.

3 Population estimates and densities at Neart na Gaoithe - Year 1

3.1 Introduction

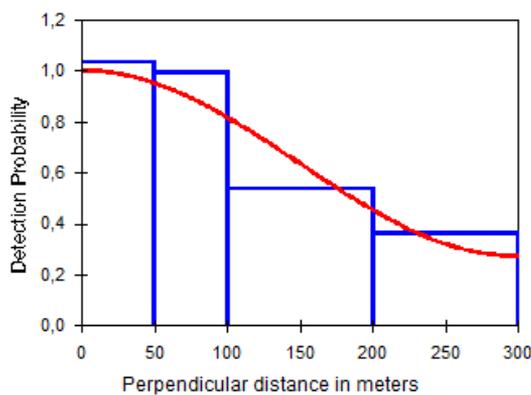

In the species accounts below we present the population estimates and densities at Neart na Gaoithe on a monthly basis for the first year of the study period (November 2009 - October 2010). Figures presented are for birds sitting on the water and are based on calculations with the Distance Analysis software (CREEM). Detection functions were built for species or species-groups with at least 60 different sightings (Buckland *et al.* 1993). In every species account rationale is given for the model chosen for use in Distance. Data from the second year of study were also incorporated to strengthen the detection functions. Estimates of population sizes are accompanied by confidence intervals. The average density of flying birds as determined by the snapshot method is also presented along with a population estimate based on this density and the total surface cover of the study area. The two population estimates together provide the estimated total population for the area. In every species account rationale is given for the model chosen for use in Distance.

3.2 Northern Fulmar *Fulmarus glacialis*

Observations:

A total of 87 individual Northern Fulmars were recorded divided over 49 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. The lowest numbers of Northern Fulmars were recorded in late spring and summer. Most sightings of Northern Fulmars were recorded in spring and summer (March/April and September).

Model selection:

Model function: Uniform (1)

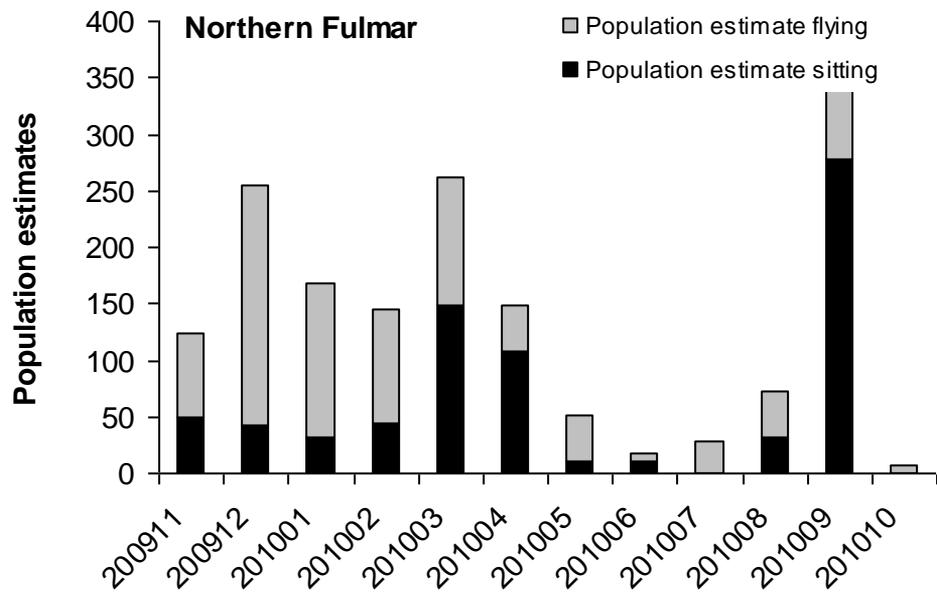

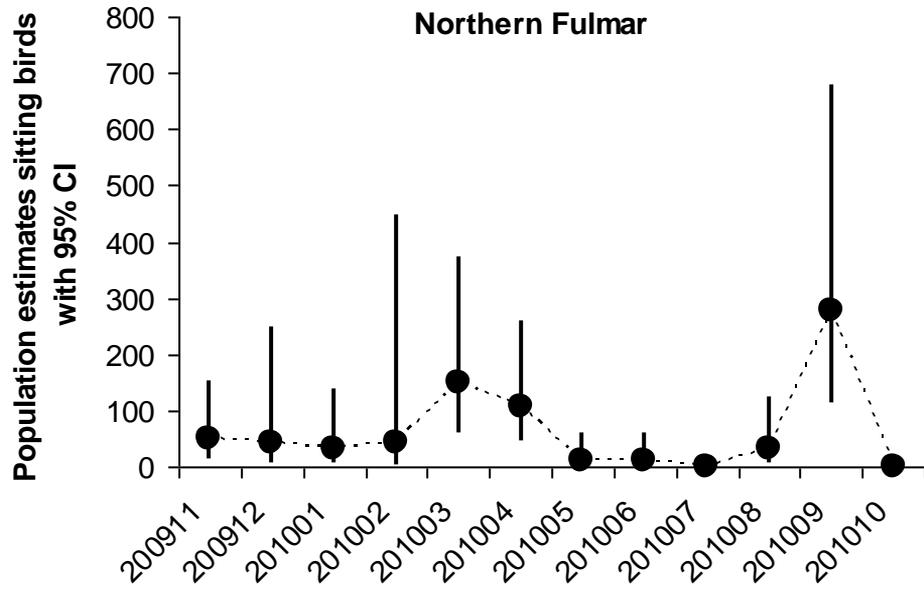

Covariates: n.a.

Remarks: A uniform function with one cosine adjustment term was chosen to build the detection function of Northern Fulmar based on lowest AIC. Hazard rate or half-normal functions including sea state as covariate did not lead to a better model and caused wider confidence intervals.

Effective strip width (\pm SE): 190.92 ± 11.643
 CI: $169.30 <> 215.31$

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

Survey (yyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
200911	0.12	75	0.08	49	16	153
200912	0.34	212	0.07	43	7	249
201001	0.22	136	0.05	32	7	139
201002	0.16	101	0.07	44	4	448
201003	0.18	114	0.24	149	59	374
201004	0.06	41	0.17	108	45	261
201005	0.06	41	0.02	11	2	62
201006	0.01	7	0.02	11	2	62
201007	0.04	27	0.00	0	0	0
201008	0.06	41	0.05	32	8	125
201009	0.12	75	0.44	277	114	678
201010	0.01	7	0.00	0	0	0

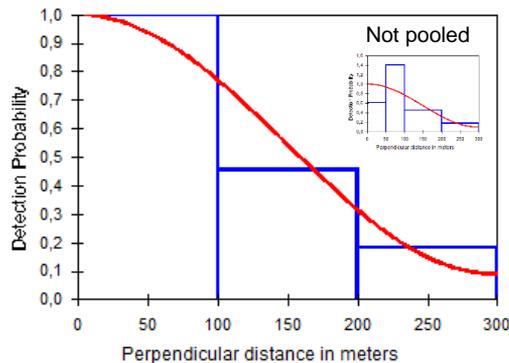

3.3 Sooty Shearwater *Puffinus griseus*

Observations:

A total of 85 individual Sooty Shearwaters were recorded divided over 39 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. Sooty Shearwaters were only present in the autumn. The majority of the sightings were made during the October survey (N = 28) but Sooty Shearwaters were also recorded in August and September.

Model selection:

Model function: Uniform (1)

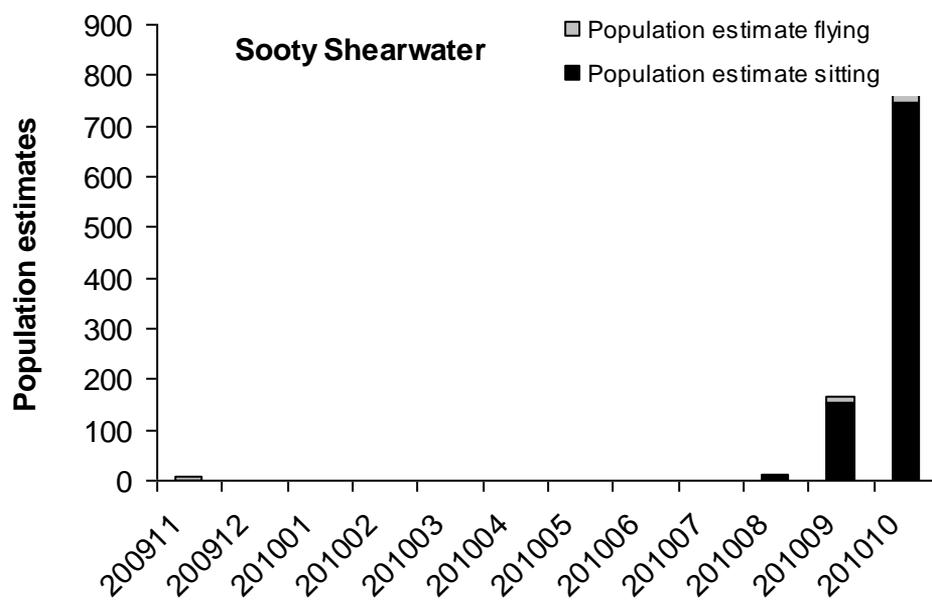

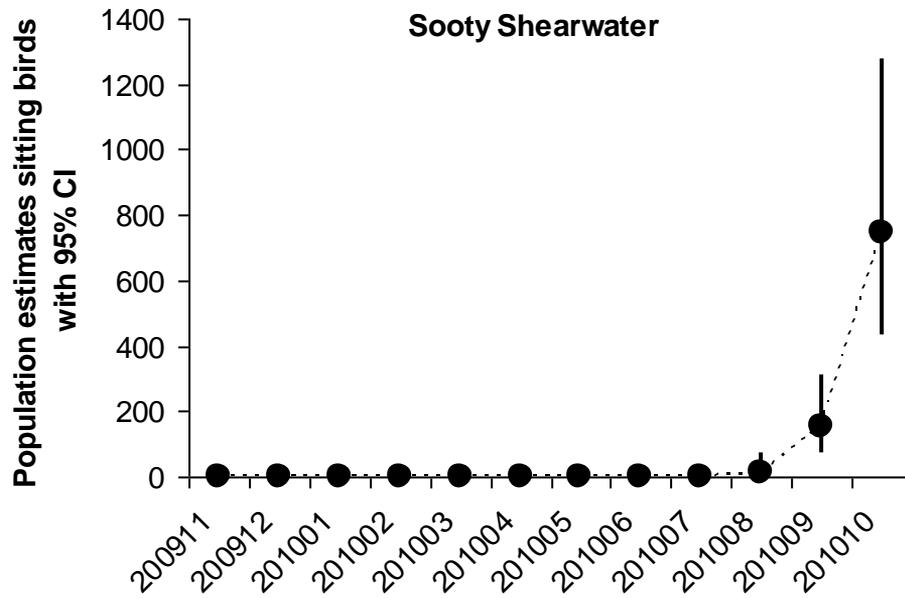

Covariates: n.a.

Remarks: In this species avoidance behaviour of birds swimming out of transect A caused by disturbance of the approaching survey ship, was reflected heavily in the detection function. It was therefore decided to pool strip A and B. Then, a half-normal function would have the lowest AIC but overestimated the numbers of birds in the first transect band. A uniform function with one cosine adjustment proved to be the best detection function of Sooty Shearwater.

Effective strip width (\pm SE): 163.31 \pm 12.927 CI: 139.37 <> 191.36

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

Survey (yyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
200911	0.01	7	0.00	0	0	0
200912	0.00	0	0.00	0	0	0
201001	0.00	0	0.00	0	0	0
201002	0.00	0	0.00	0	0	0
201003	0.00	0	0.00	0	0	0
201004	0.00	0	0.00	0	0	0
201005	0.00	0	0.00	0	0	0
201006	0.00	0	0.00	0	0	0
201007	0.00	0	0.00	0	0	0
201008	0.00	0	0.02	13	2	73
201009	0.02	14	0.24	153	75	311
201010	0.05	34	1.18	746	435	1280

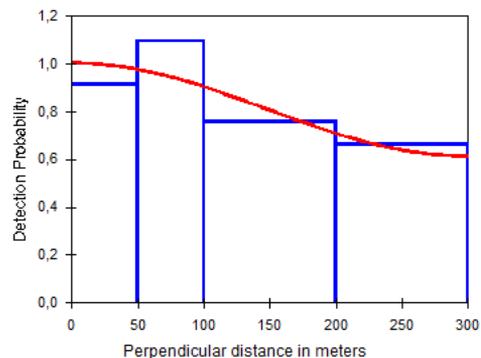

3.4 Northern Gannet *Morus bassanus*

Observations:

A total of 540 individual Northern Gannets were recorded divided over 374 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. Northern Gannets were scarce during winter. Most sightings were recorded during the September survey of 2010 (N = 189) and to a lesser extent during the spring, summer and autumn surveys.

Model selection:

Model function: Uniform (1)

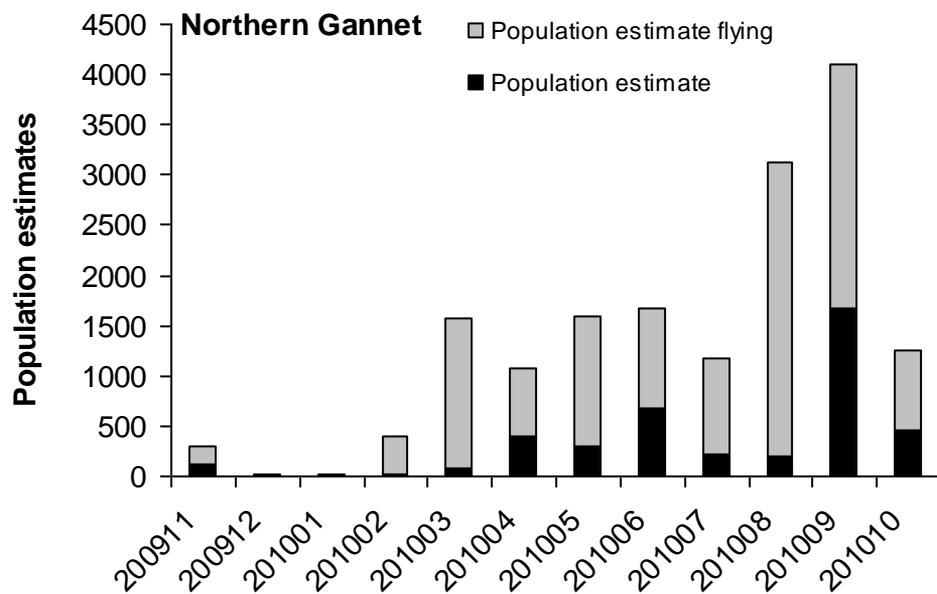

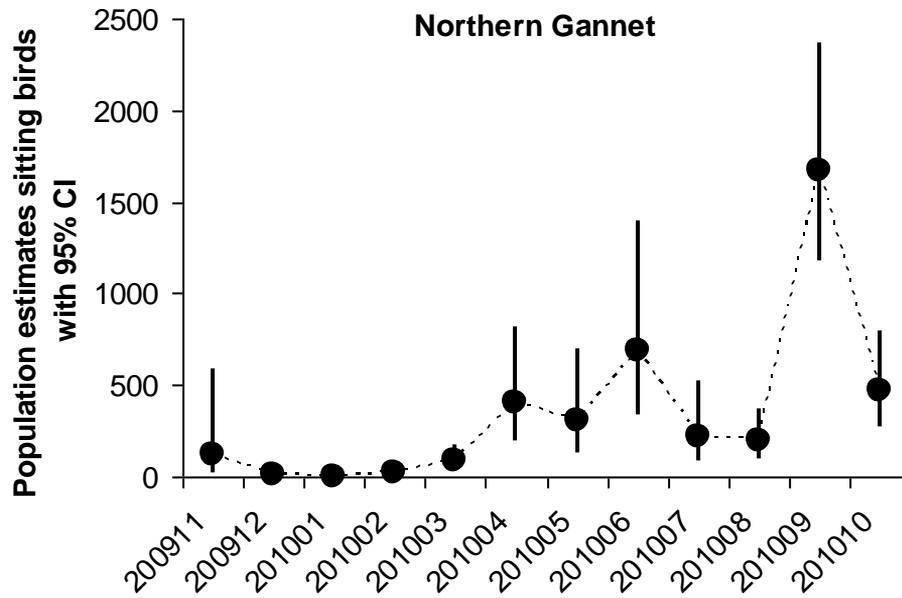

Covariates: n.a.

Remarks: A uniform detection function with one cosine adjustment was chosen (lowest AIC) to predict the detection of Northern Gannets. This model corrects for the disturbance of birds in transect A (0-50 m) caused by the survey ship. Due to their size these birds are better detected at larger distances of the transect line, which means that half normal and hazard rates function are less applicable.

Effective strip width (\pm SE): 241.82 \pm 8.395
CI: 225.90 <> 258.86

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

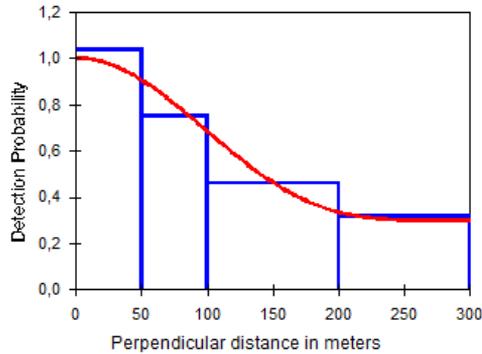

Survey (yyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
200911	0.29	183	0.18	116	23	594
200912	0.03	21	0.01	8	1	50
201001	0.03	20	0.00	0	0	0
201002	0.60	377	0.03	17	4	65
201003	2.35	1485	0.13	83	38	179
201004	1.08	681	0.64	401	197	818
201005	2.04	1287	0.49	307	136	697
201006	1.58	996	1.08	685	336	1397
201007	1.51	955	0.34	216	88	527
201008	4.64	2930	0.31	193	102	366
201009	3.86	2437	2.64	1668	1174	2370
201010	1.25	787	0.74	466	273	795

3.5 Herring Gull *Larus argentatus*

A total of 1,065 individual Herring Gulls were recorded divided over 64 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. On average Herring Gulls were mainly present in winter. Most sightings were during the January survey of 2010 (N = 14) and to a lesser extent during the November survey of 2009.

Model selection:

Model function: Uniform (1)

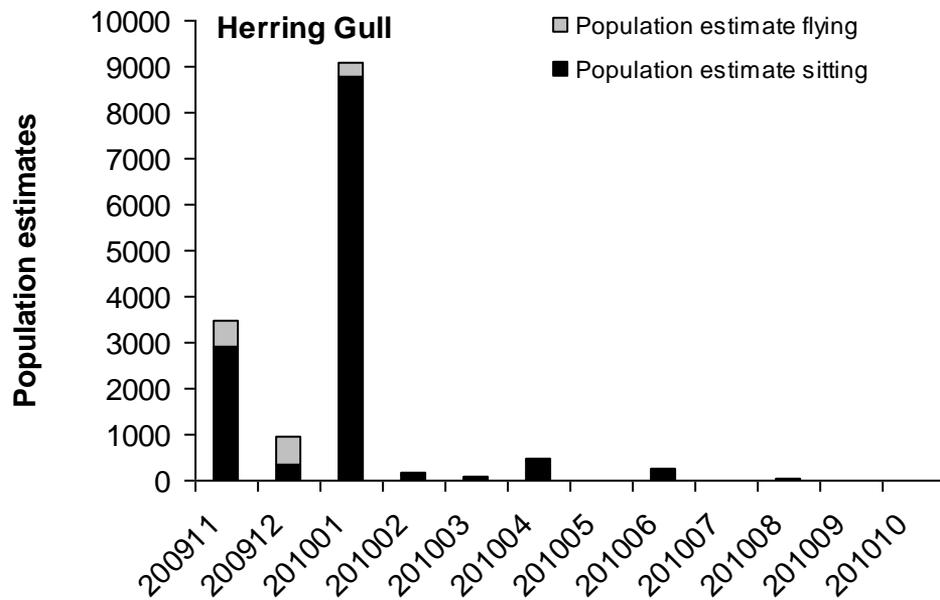

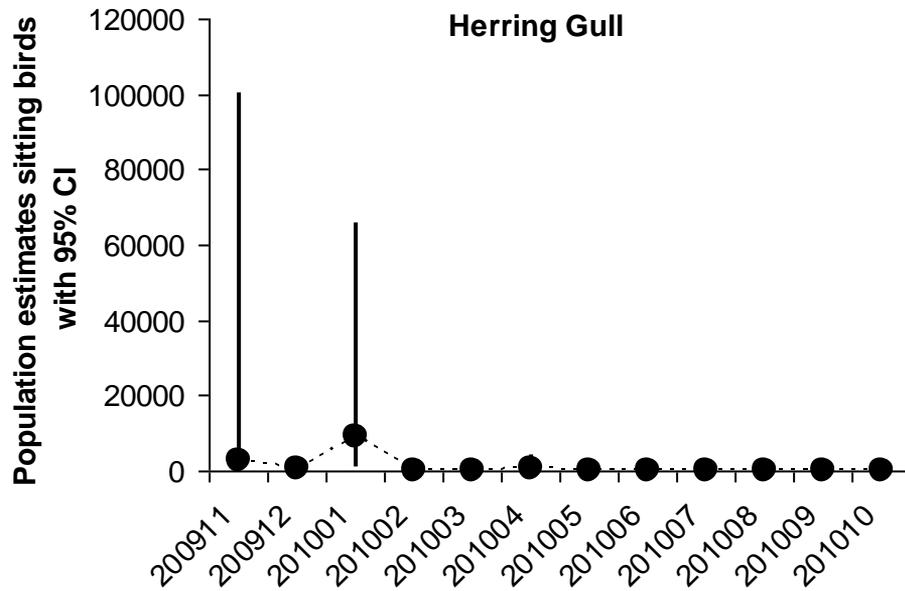

Covariates: n.a.

Remarks: A hazard rate detection function had the lowest AIC, however, this function overestimated the numbers of birds on the transect line considerably. A uniform function with one cosine adjustment had a marginally higher AIC but fitted the data better and was chosen based on the detection function plot.

Effective strip width (\pm SE): 167.08 \pm 20.410 CI: 131.29<> 212.64

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

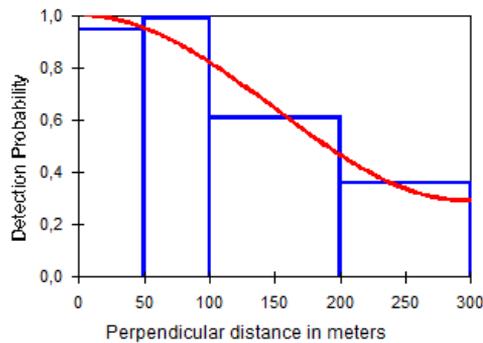

Survey (yyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
200911	0.89	563	4.60	2909	85	100120

3.6 Great Black-backed Gull *Larus marinus*

A total of 320 individual Great Black-backed Gulls were recorded divided over 51 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. Great Black-backed Gulls were largely absent during most of the surveys. Most sightings were recorded during the January survey of 2010 (N= 17) and to a lesser extent during the November survey of 2009 and the October survey of 2010.

Model selection:

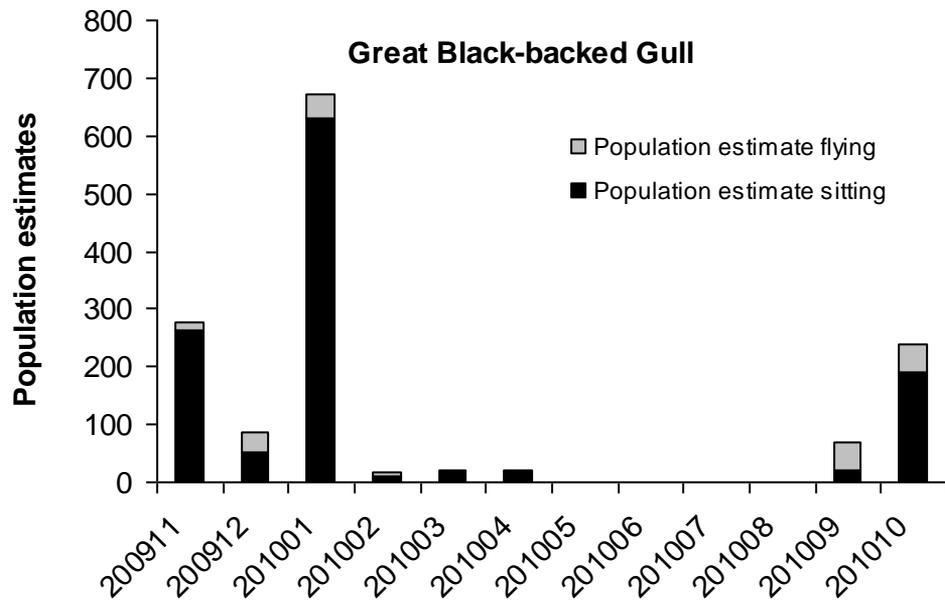

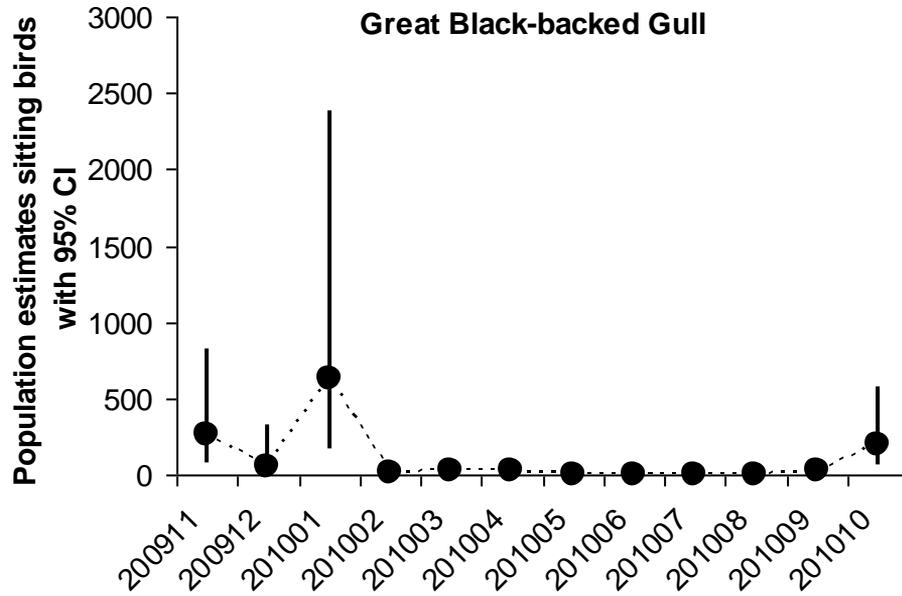

Model function: Uniform (1)
Covariates: n.a.

Remarks: A uniform detection function with one cosine adjustment was chosen based on the lowest AIC criterion.

Effective strip width (\pm SE): 193.59 \pm 17.741
CI: 161.41 <> 232.19

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

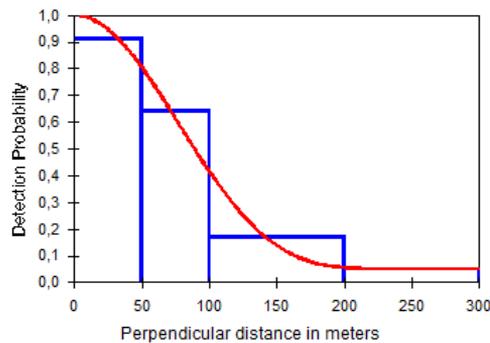

Survey (yyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
200911	0.02	14	0.42	263	84	824
200912	0.05	34	0.08	53	9	322
201001	0.06	41	1.00	631	167	2388
201002	0.01	7	0.02	10	2	62
201003	0.00	0	0.03	21	5	80
201004	0.00	0	0.03	21	5	81

201007	0.00	0	0.00	0	0	0
201008	0.00	0	0.00	0	0	0
201009	0.08	48	0.03	21	5	81
201010	0.08	47	0.30	192	65	573

3.7 Little Gull *Larus minutus*

A total of 106 individual Little Gulls were recorded divided over 45 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. Little Gulls were largely absent during most of the surveys. Most sightings were recorded during the October survey of 2010 (N = 40) and some low numbers of sightings during the November survey of 2009 and the July survey of 2010.

Model selection:

Model function: Uniform (1) *
Covariates: n.a.

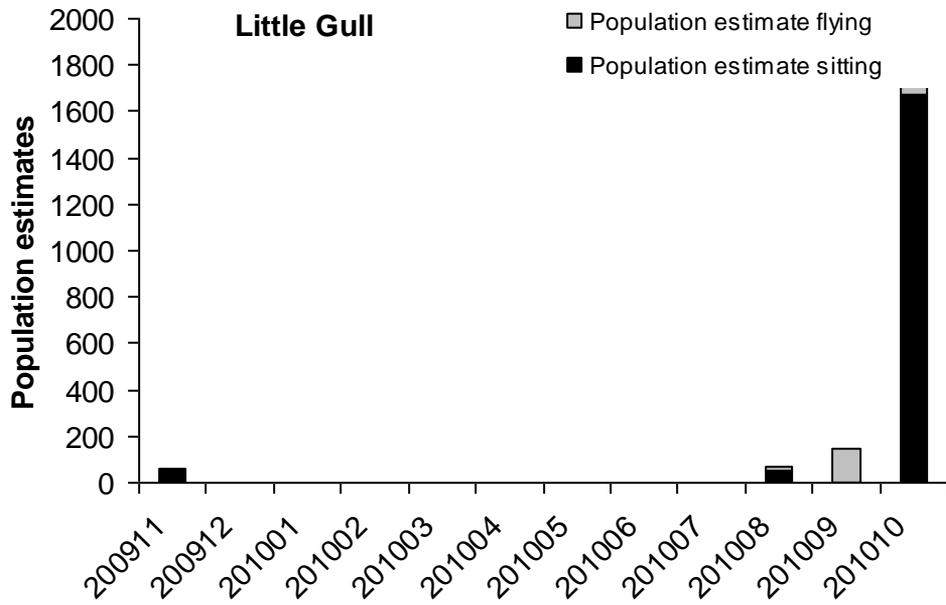

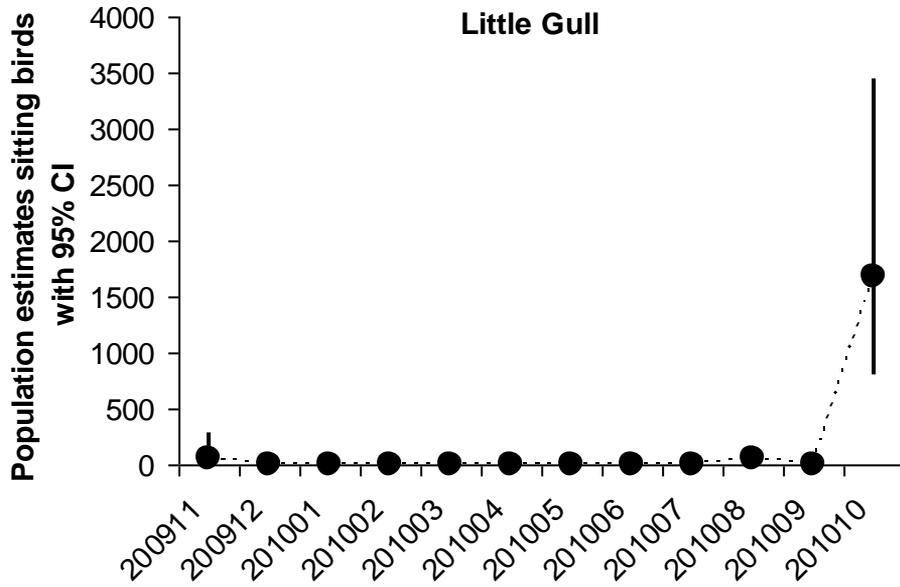

Remarks: A hazard rate detection function had the lowest AIC, however, this overestimated greatly the numbers in the transect bands A and B. Some avoidance might be expected for this species but overestimation in the first band should be limited. Therefore, a uniform detection function with one cosine adjustment term was chosen.

Effective strip width (\pm SE): 190.92 \pm 11.643
CI: 169.30 <> 215.31

* The number of sightings for which this detection curve was built was 59 groups; where a minimum of N = 60 for sample size is usually regarded as a general requirement, however, the detection curve conforms to expectations and shows no abnormal characteristics.

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

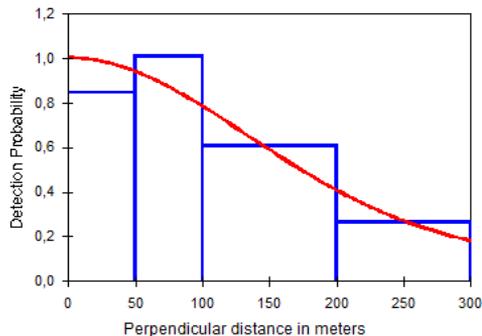

Survey (yyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval

201010	0.17	109	2.65	1672	811	3444

3.8 Kittiwake *Rissa tridactyla*

A total of 1,826 individual Kittiwakes were recorded divided over 173 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. Kittiwakes were largely absent during most of the surveys. Most sightings were recorded during the autumn surveys of 2010, with a peak in October (N= 63).

Model selection:

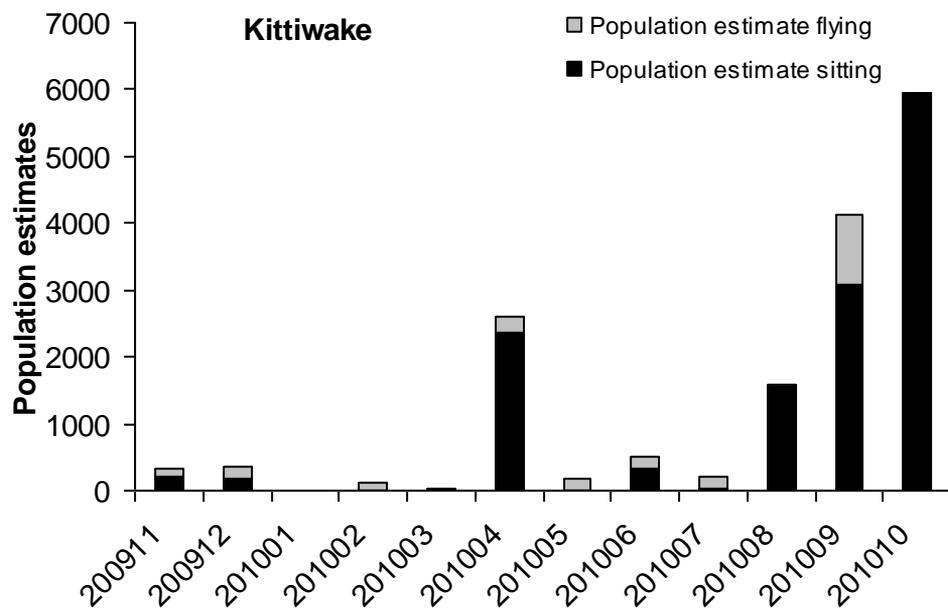

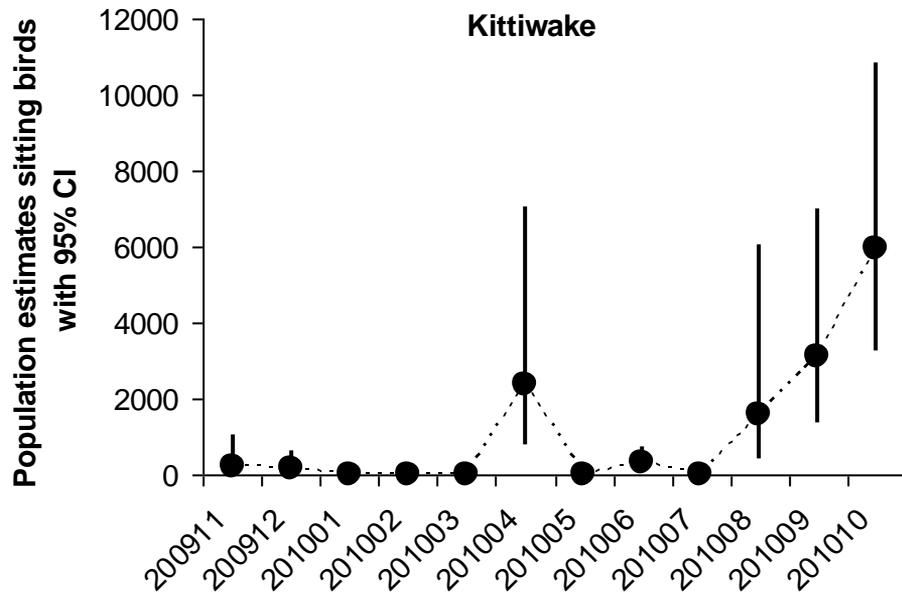

Model function: Half-normal
Covariates: Sea state (Variate)

Remarks: A half-normal detection curve without cosine adjustments but with sea state as covariate yielded the best fit for Kittiwake (lowest AIC). This model corrects for the expected effects of disturbance of birds in transect A caused by the survey ship.

Effective strip width (\pm SE): 181.13 \pm 6.184
CI: 169.37 <> 193.71

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

201010	1.04	658	9.44	5967	3282	10849

3.9 All gull species

A total of 3,344 individual Gulls were recorded divided over 344 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. This group comprises all species of gull (Herring, Great Black-backed, Lesser Black-backed, Common and Little Gulls) as well as unidentified gulls (Black-backed Gull spp. and Large gull spp.). Gulls show an erratic abundance pattern. Most sightings of gulls were recorded during autumn 2010 with a peak in October.

Model selection:

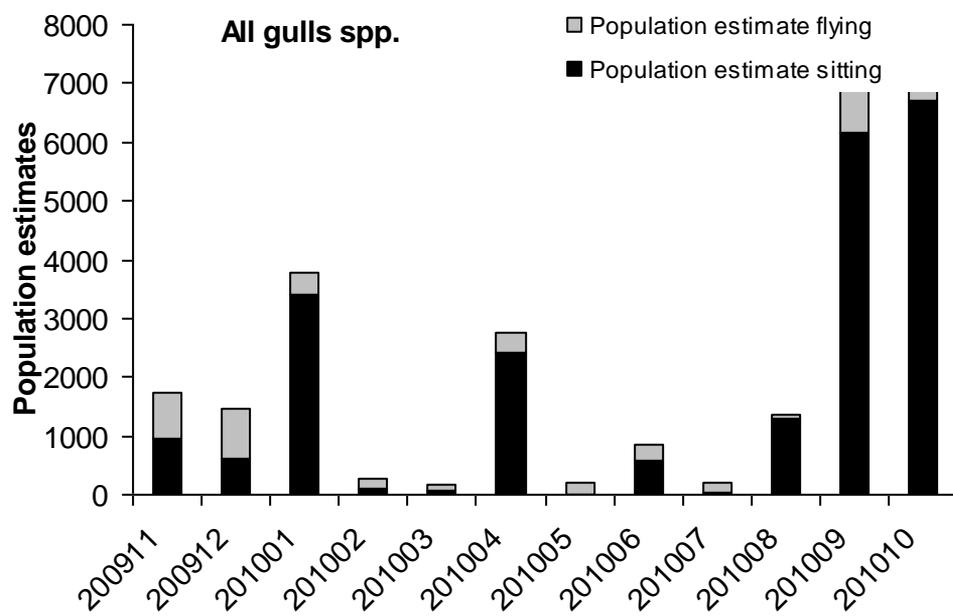

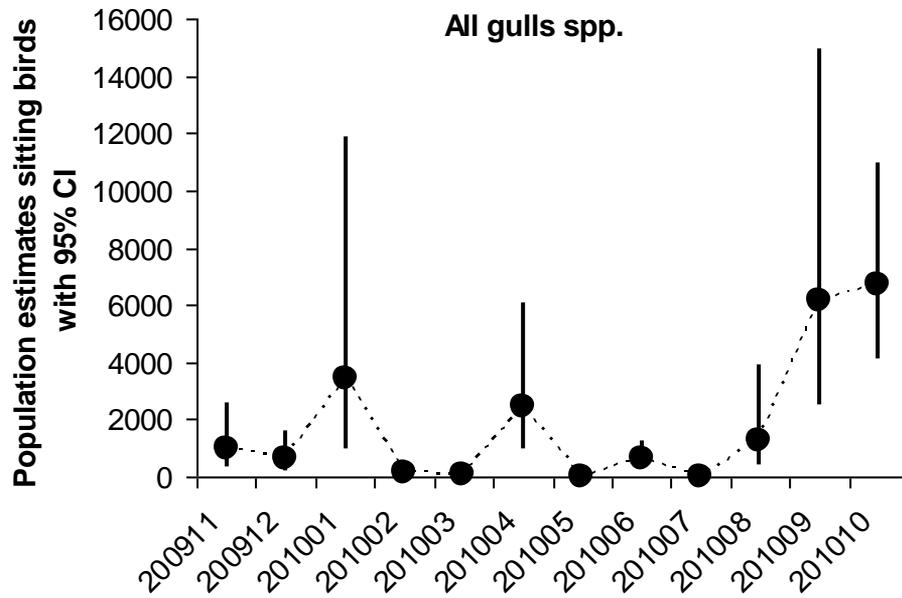

Model function: Hazard Rate (0)
Covariates: Sea state (Factor)

Remarks: A hazard rate detection curve without cosine adjustments but with sea state as covariate yielded the best fit for all gull species together (lowest AIC). This model corrects for the expected effects of disturbance of birds in transect A caused by the survey ship.

Effective strip width (\pm SE): 184.19 \pm 4.710
CI: 175.17 <> 193.68

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

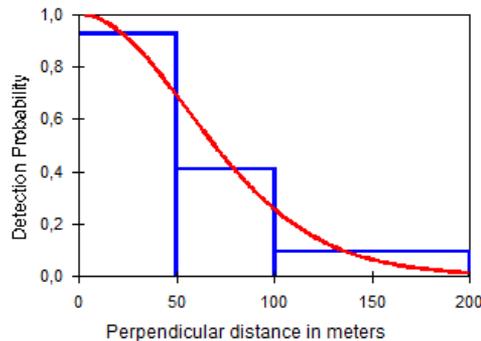

Survey (yyyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
200911	1.23	780	1.53	967	365	2565
200912	1.34	848	0.95	600	220	1639
201001	0.58	367	5.40	3412	982	11856

201009	1.96	1236	9.75	6158	2538	14945
201010	1.38	875	10.62	6712	4099	10992

3.10 Little Auk *Alle alle*

A total of 117 individual Little Auk were recorded divided over 71 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. Little Auks were absent during most of the surveys being recorded only in winter. Most sightings were recorded during the November survey of 2009 (N = 34) and February survey of 2010.

Model selection:

Model function: Half-normal (0)

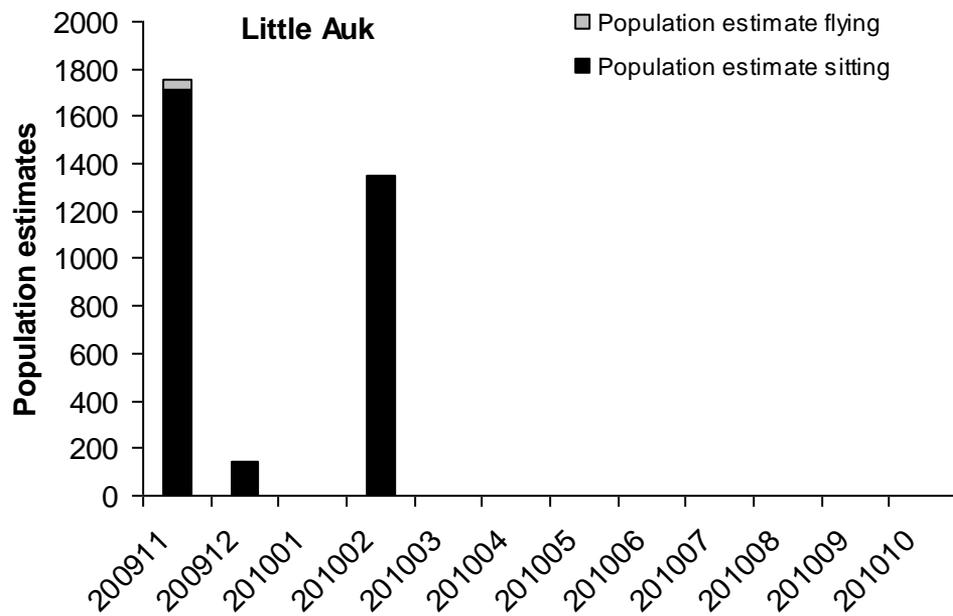

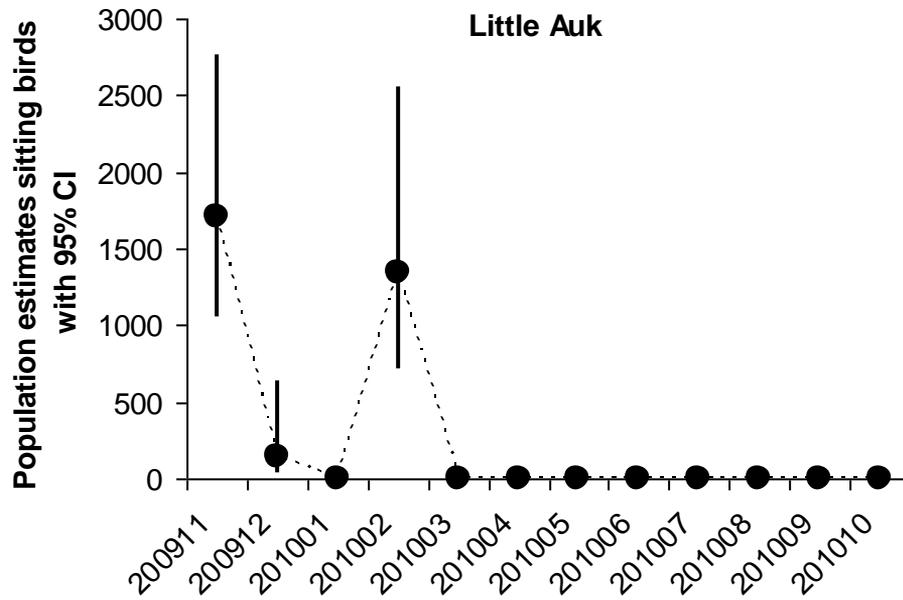

Covariates: Sea state (Variate)

Remarks: A half-normal detection curve without cosine adjustments but with sea state as covariate yielded the best fit for Little Auk (lowest AIC). Also a right truncation was performed as no observations beyond 200 m were in the database. This model corrects for the expected effects of disturbance of birds in transect A caused by the survey ship. In this small diving species $G(0)$ is expected to be less than 1. Sea state was included as covariate as detection of this small species is heavily influenced by sea state.

Effective strip width (\pm SE): 76.28 ± 6.154 CI: $65.02 <> 89.45$

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

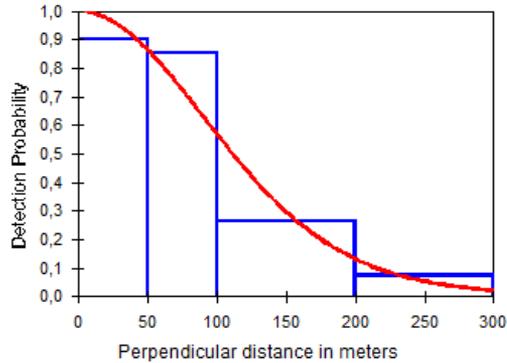

Survey (yyyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval

3.11 Puffin *Fratercula arctica*

A total of 7,147 individual Puffins were recorded divided over 1,338 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. Puffins were most common in summer and autumn. Most sightings were recorded during the autumn of 2010 with a peak in October (N = 410).

Model selection:

Model function: Hazard rate (0)

Covariates: Sea state (Factor)

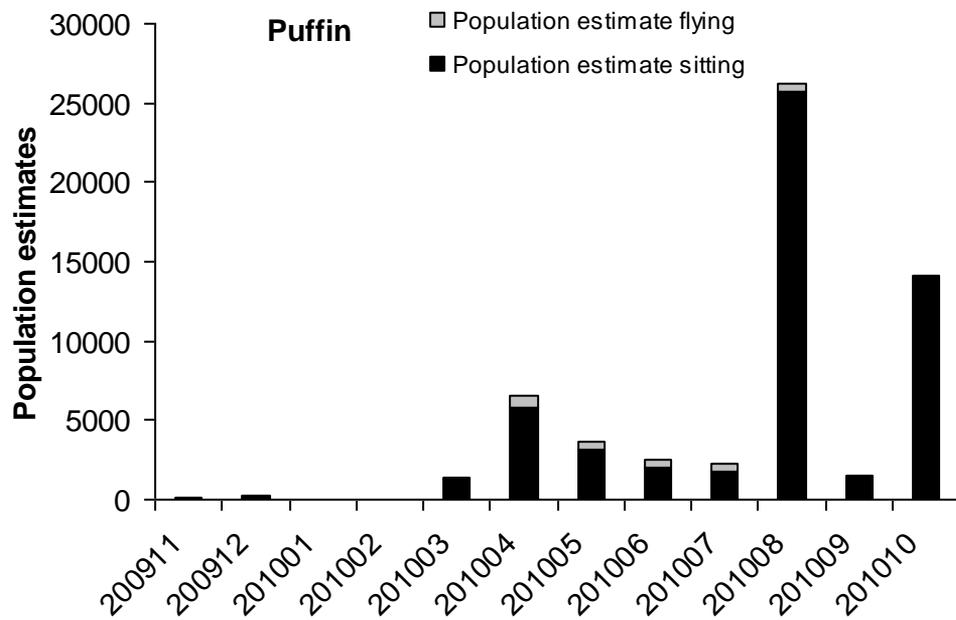

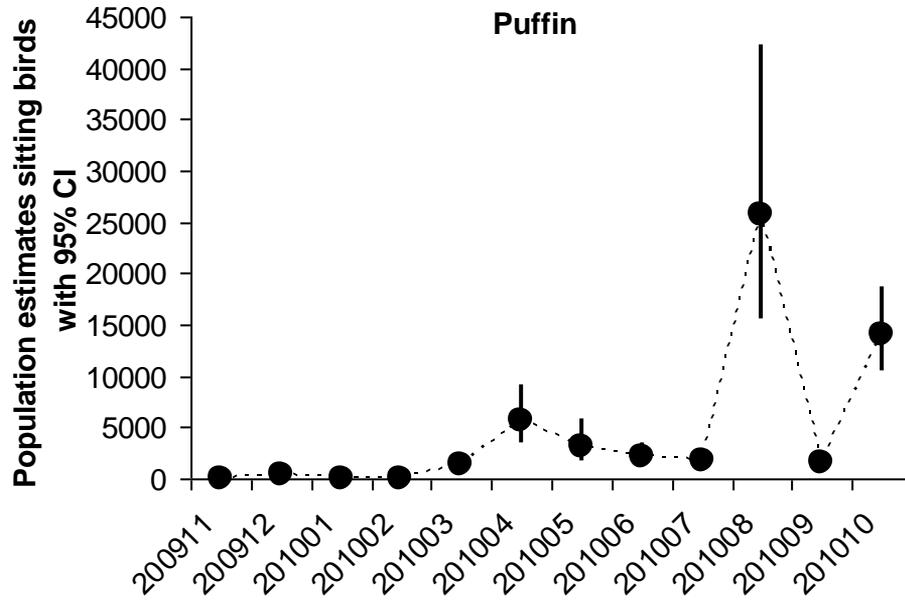

Remarks: A hazard rate function with sea state (factor) as covariate has the lowest AIC. This model corrects for the expected $G(0) < 1$ effect in this small diving species. Sea state was included as covariate as detection of this small species is heavily influenced by sea state.

Effective strip width (\pm SE): 131.59 ± 1.794

CI: $128.12 <> 135.15$

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

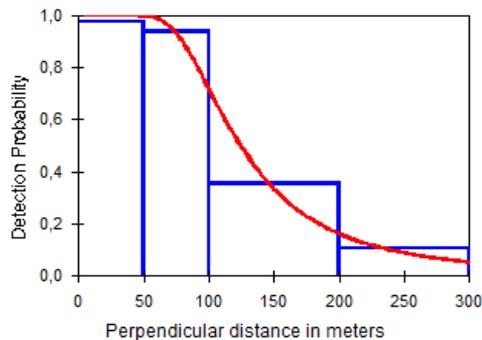

Survey (yyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval

201010	0.00	0	22.27	14067	10530	18790

3.12 Guillemot *Uria aalge*

A total of 5,558 individual Guillemots were recorded divided over 1,972 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. Guillemots were present almost year-round but with fewest sightings in winter. Most sightings were recorded during the autumn with a peak in the October survey of 2010 (N = 611).

Model selection:

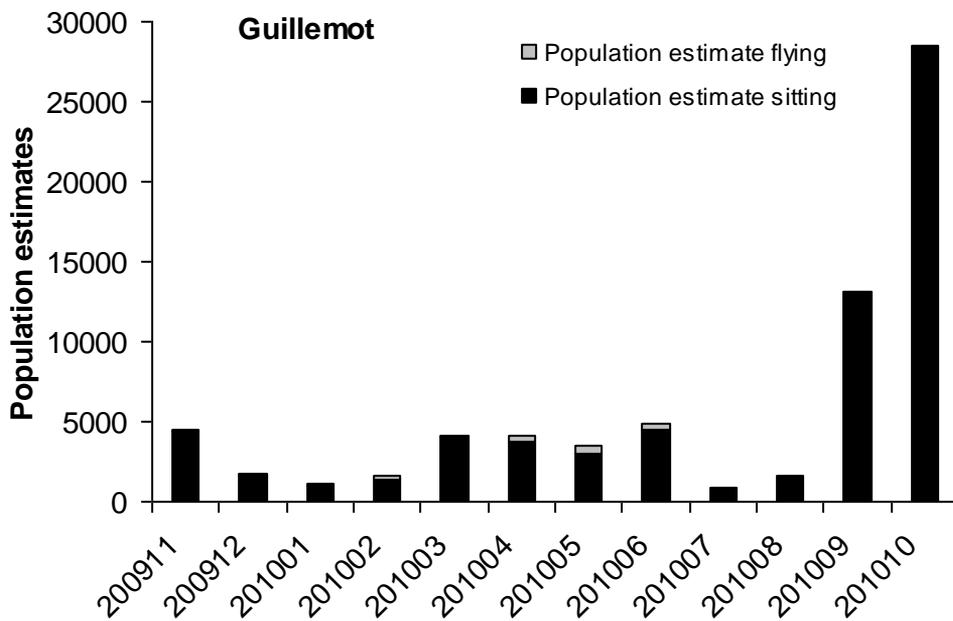

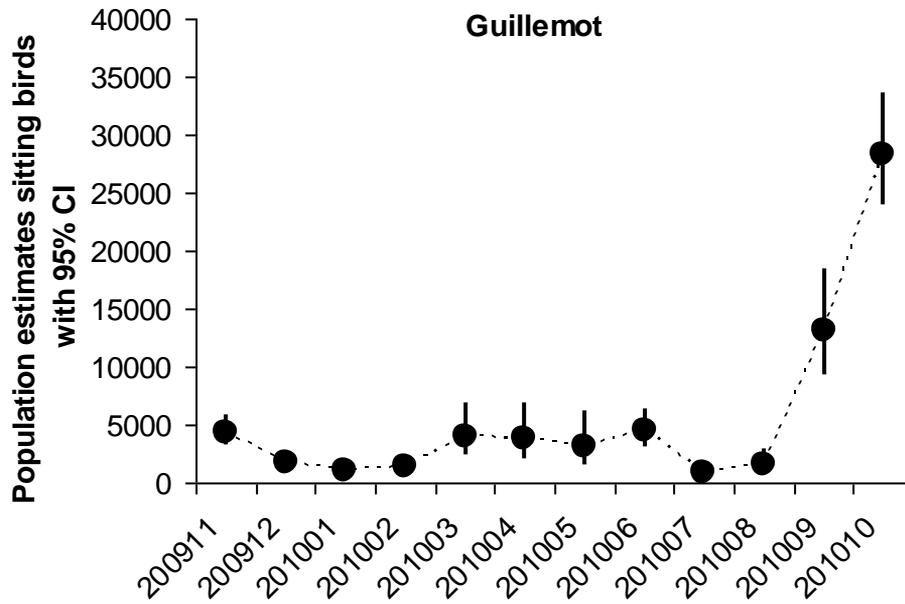

Model function: Hazard Rate
Covariates: Sea state (Factor)

Remarks: A hazard rate function with no adjustment terms was chosen (lowest AIC) for the detection probability of Guillemot. Sea state was included as covariate as detection of this species is influenced by sea state in more distant strips. Including sea state as a factor the model corrects for the effect of sea state.

Effective strip width (\pm SE): 142.34 \pm 1.529
CI: 139.38 <> 145.37

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

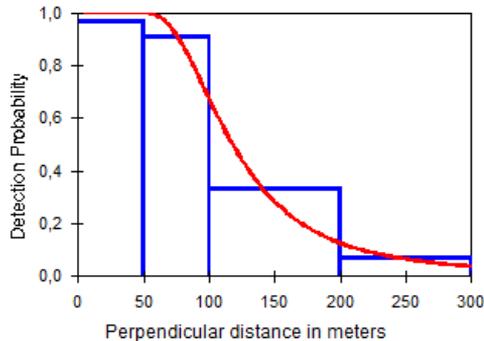

Survey (yyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
200911	0.13	81	6.92	4374	3253	5883
200912	0.08	48	2.61	1652	1026	2660

201008	0.00	0	2.50	1579	828	3014
201009	0.00	0	20.72	13093	9299	18437
201010	0.17	109	44.86	28342	23951	33538

3.13 Razorbill *Alca torda*

A total of 3,018 individual Razorbills were recorded divided over 795 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. Razorbills were largely absent throughout the year with the exception of autumn. Most sightings were recorded during the October survey of 2010 (N = 310).

Model selection:

Model function: Hazard Rate (0)

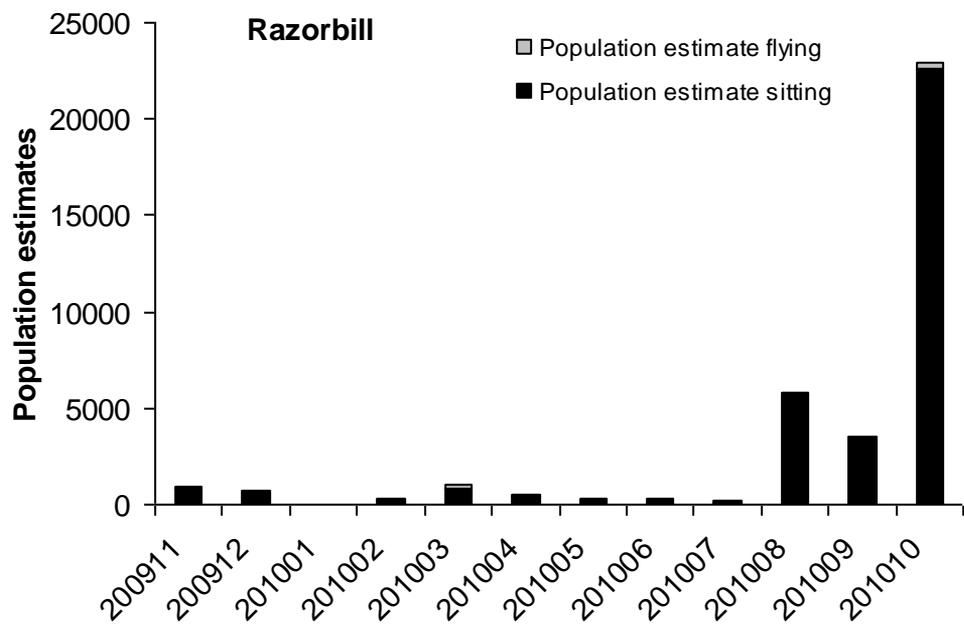

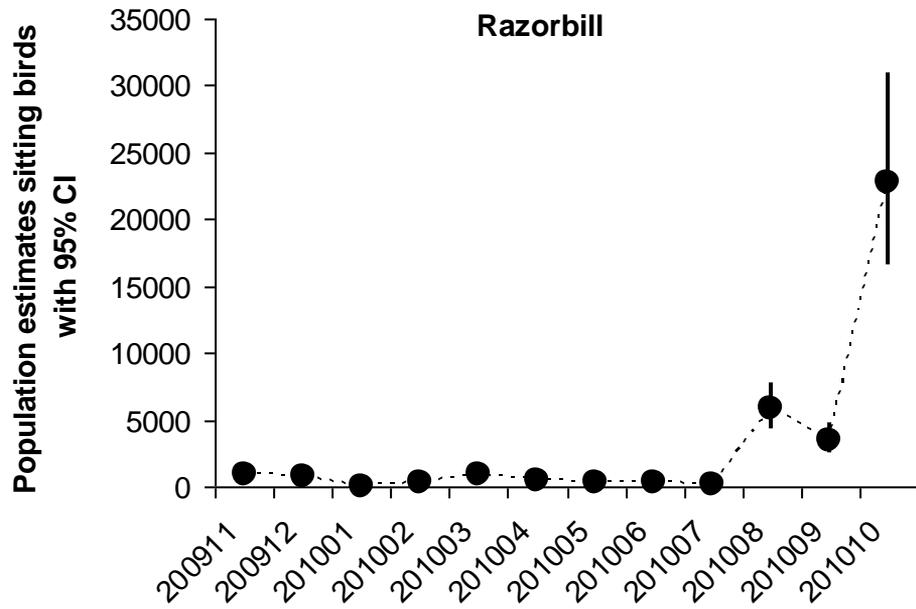

Covariates: Sea state (Factor)

Remarks: A hazard rate function with no adjustment terms was chosen (lowest AIC) for the detection probability of Guillemot. Sea state was included as covariate as detection of this species is influenced by sea state in more distant strips. Including sea state as a factor the model corrects for the effect of sea state.

Effective strip width (\pm SE): 135.14 \pm 2.698
CI: 129.95 <> 140.54

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

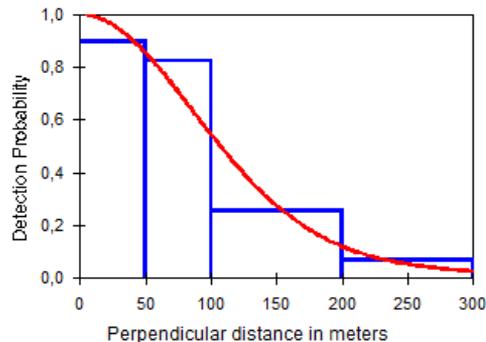

Survey (yyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
200911	0.10	61	1.38	873	541	1408
200912	0.02	14	1.10	695	358	1352
201001	0.02	14	0.02	15	3	90
201002	0.16	101	0.38	241	108	534

201008	0.03	20	9.24	5839	4397	7755
201009	0.02	14	5.56	3511	2572	4793
201010	0.45	285	35.87	22661	16562	31007

3.14 Small auk species

Small auks as a species group consist of unidentified small auks, Little Auk and Puffin. A total of 7,267 individual small auks were recorded divided over 1,411 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. Small auks were fairly common throughout the year with the exception of winter. Most sightings were recorded during the August and October surveys of 2010.

Model selection:

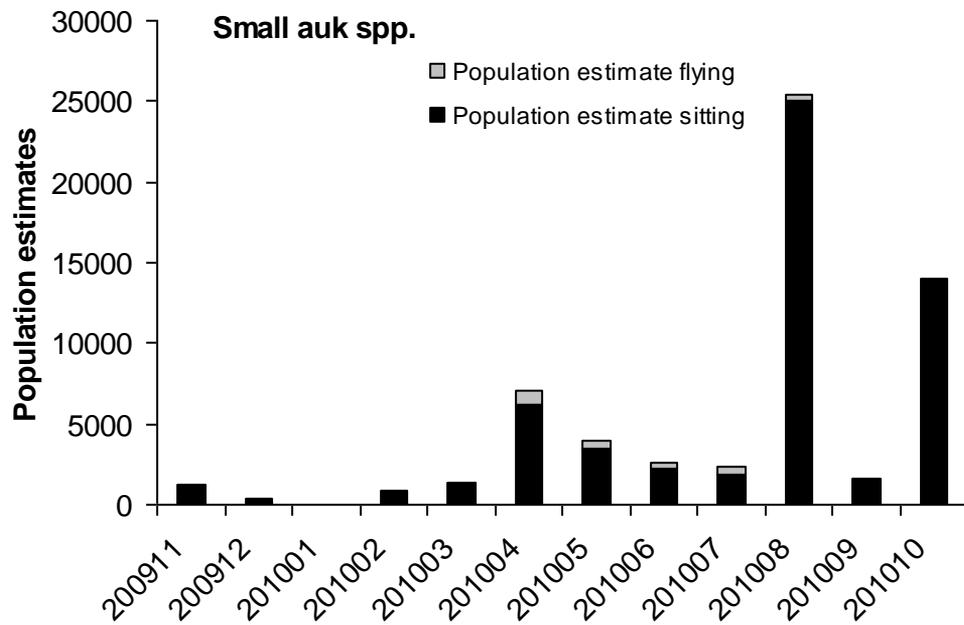

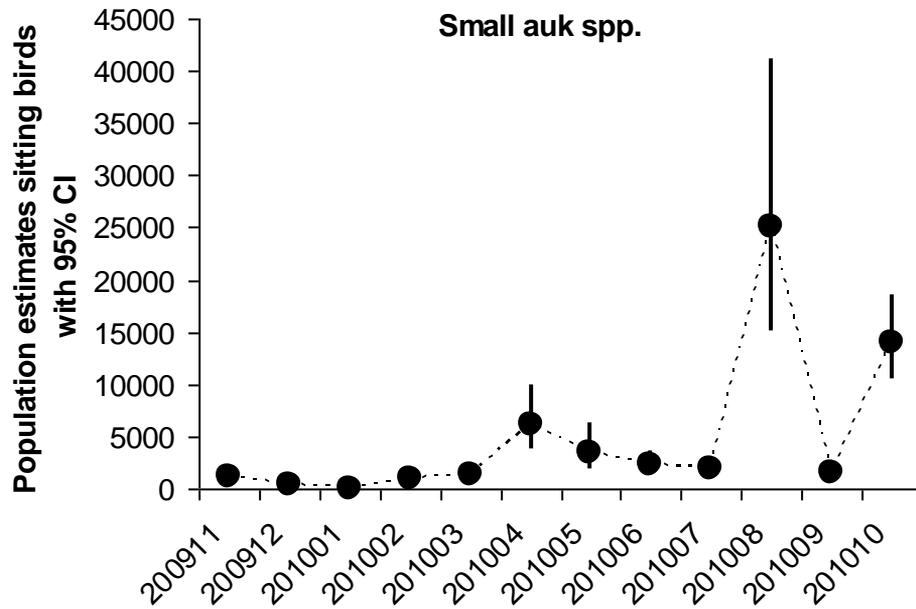

Model function: Half normal (3)
Covariates: Sea state (Factor)

Remarks: A half normal detection function with 3 cosine adjustment terms was chosen based on lowest AIC and it corrects in the first surveyed strip for the expected $G(0)$ to be smaller than 1. Sea state was included as covariate as the detection of small auk species is heavily influenced by sea state.

Effective strip width (\pm SE): 120.11 \pm 1.660
CI: 116.90 <> 123.41

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

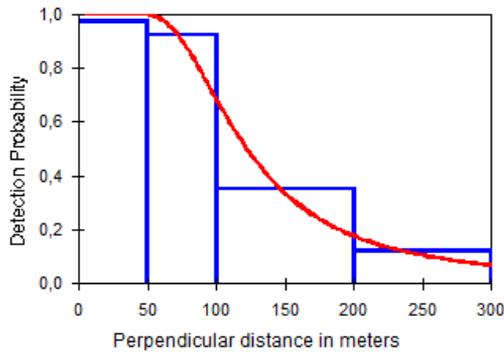

Survey (yyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
200911	0.08	47	1.89	1195	802	1780
200912	0.00	0	0.64	402	129	1250
201001	0.00	0	0.00	0	0	0
201002	0.00	0	1.38	873	483	1577
201003	0.04	27	2.19	1386	987	1946

201008	0.71	450	39.57	25000	15206	41102
201009	0.00	0	2.50	1580	1072	2329
201010	0.00	0	22.08	13953	10445	18639

3.15 Large auk species

The species group large auks consist of birds recorded as guillemot/razorbill, Guillemots and Razorbills. A total of 11,681 individual Large auks were recorded divided over 2,916 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. Large auks were seen throughout the year with a peak in autumn. Most birds were recorded during the October survey of 2010.

Model selection:

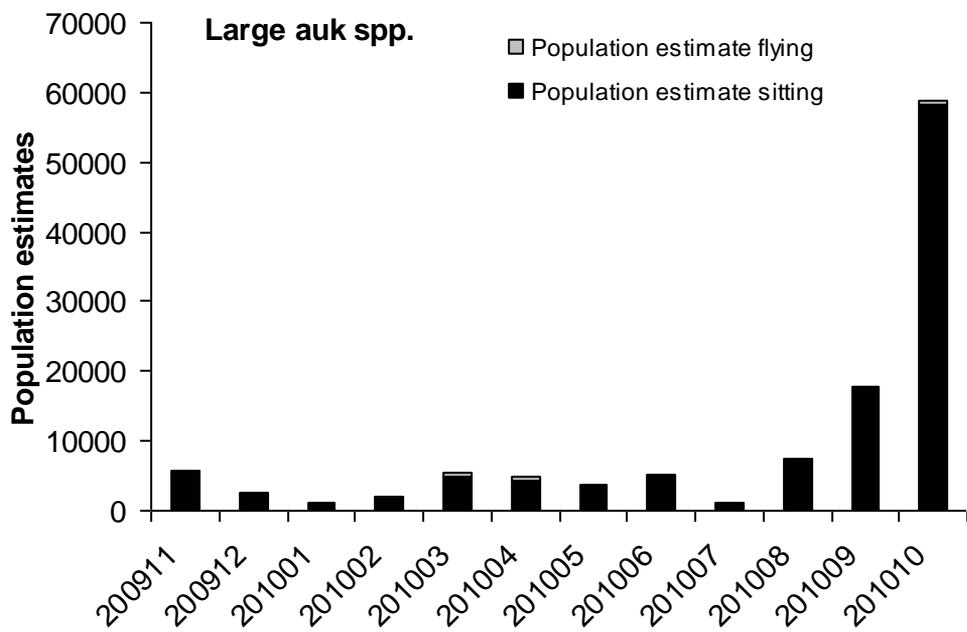

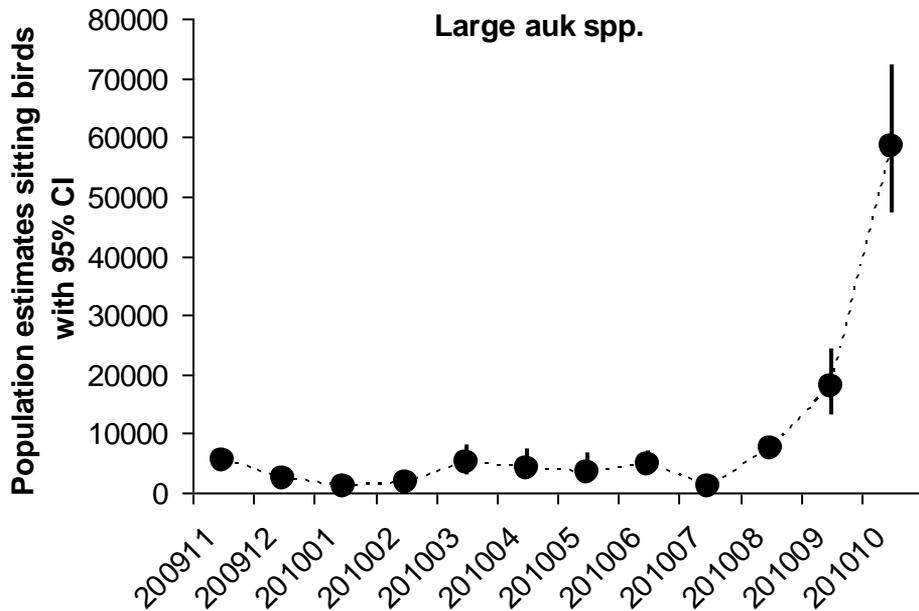

Model function: Hazard Rate (0)
Covariates: Sea state (Factor)

Remarks: A half normal detection probability would yield the lowest AIC, however, the detection function shows an abnormal shape ('hump' at greater distances) and was therefore rejected. Instead a plain hazard rate function was chosen. Sea state was included as covariate as detection of auk species is influenced by sea state. Including sea state as a factor the model corrects for the effect of sea state.

Effective strip width (\pm SE): 140.45 ± 1.312
CI: $137.91 <> 143.05$

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

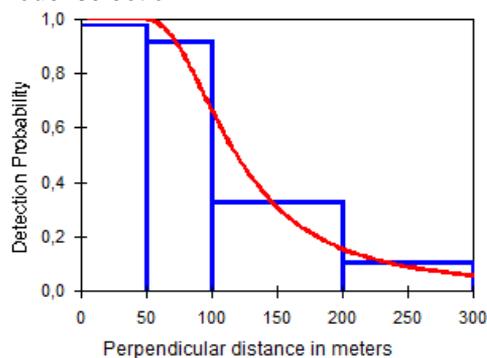

Survey (yyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval

201010	0.74	468	92.41	58381	47163	72268

3.16 All auk species

The species group all auk species consist of all categories of species in the groups Small auk species and Large auk species as well as the category ‘unidentified auks’ (of which observers did not give an indication that the birds either belonged to the group of small or large auks). A total of 18,948 individual auks were recorded divided over 4,327 sightings during the ship-based surveys in the first study year at Neart na Gaoithe. Auks were common throughout the year with a peak in autumn. Most sightings were recorded during the October survey of 2010.

Model selection:

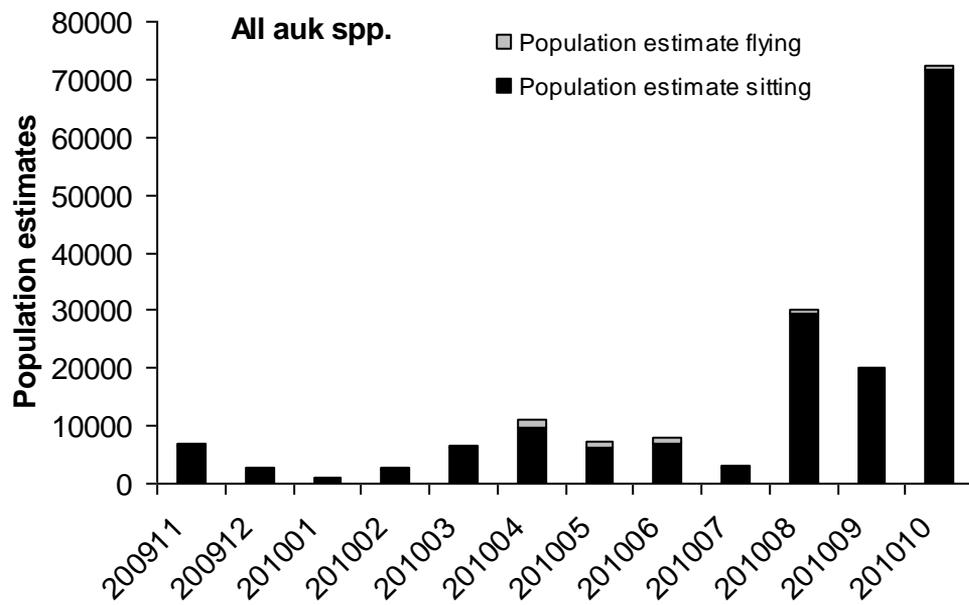

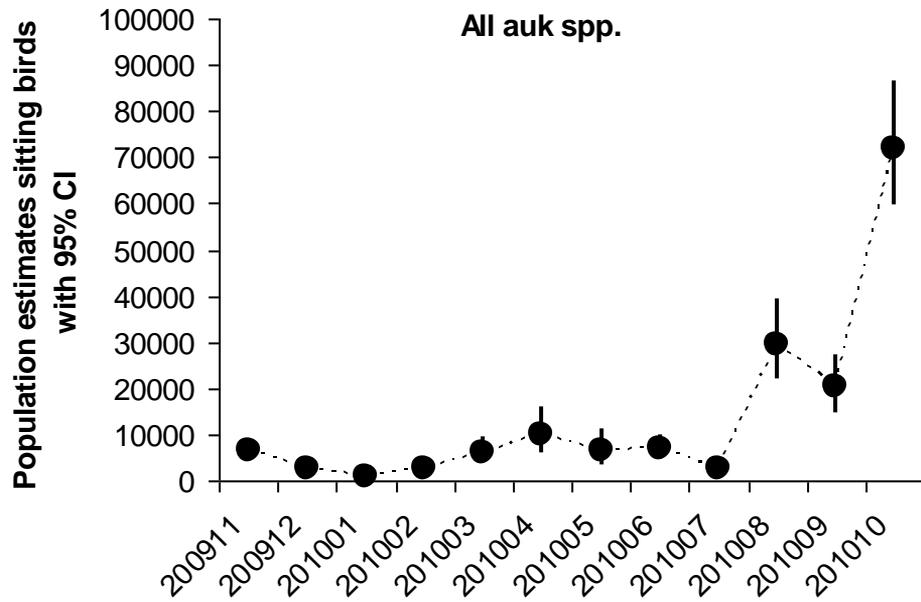

Model function: Hazard rate (0)
Covariates: Sea state (Factor)

Remarks: A half normal detection probability would yield the lowest AIC, however, the detection function shows an abnormal shape (‘hump’ at greater distances) and was therefore rejected. Instead a plain hazard rate function was chosen. Sea state was included as covariate as detection of auk species is influenced by sea state. Including sea state as a factor the model corrects for the effect of sea state.

Effective strip width (\pm SE): 139.41 \pm 1.056
CI: 137.35 <> 141.49

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

4 Population estimates and densities at Neart na Gaoithe - Year 2

4.1 Introduction

In the species accounts below we present the population estimates and densities at Neart na Gaoithe on a monthly basis for the second year of the study period (December 2010 - October 2011). Figures presented are for birds sitting on the water and are based on calculations with the Distance Analysis software (CREEM). Detection functions were built for species or species-groups with at least 60 different sightings (Buckland *et al.* 1993). In every species account rationale is given for the model chosen for use in Distance. Data from the second year of study were also incorporated to strengthen the detection functions. Estimates of population sizes are accompanied by confidence intervals. The average density of flying birds as determined by the snapshot method is also presented along with a population estimate based on this density and the total surface cover of the study area. The two population estimates together provide the estimated total population for the area. In every species account rationale is given for the model chosen for use in Distance.

4.2 Northern Fulmar *Fulmarus glacialis*

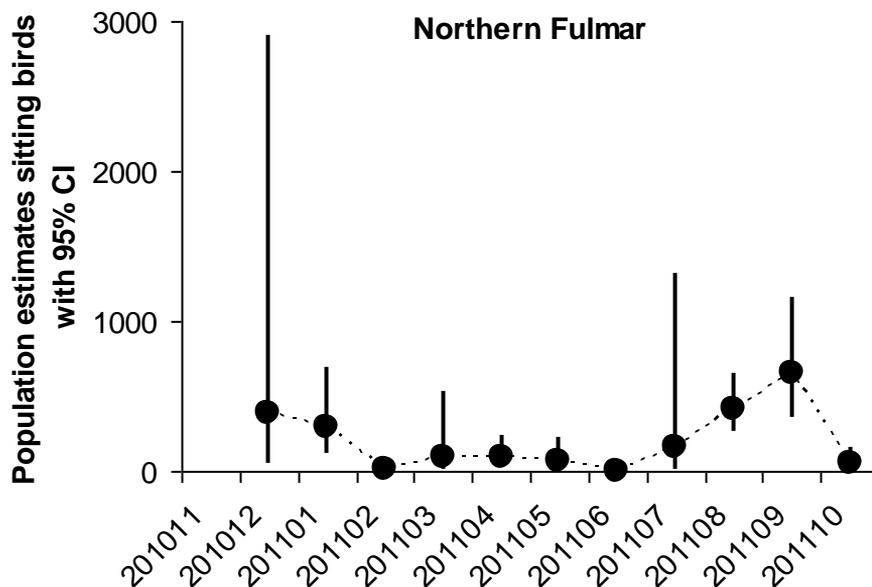

Observations:

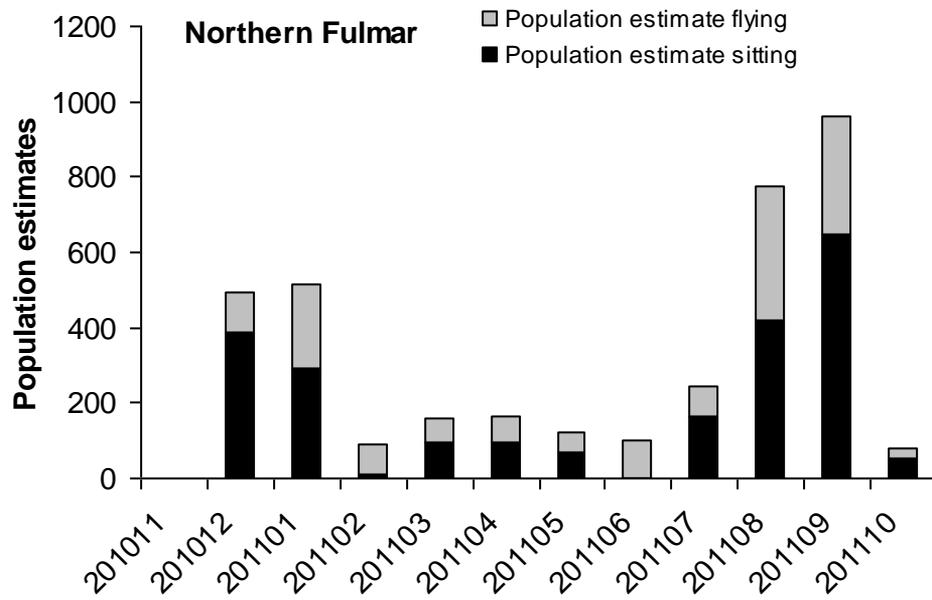

A total of 196 individual Northern Fulmars were recorded divided over 136 sightings during the ship-based surveys in the second study year at Neart na Gaoithe. Fulmars were recorded throughout the year with highest numbers in spring, autumn and winter.

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

Survey (yyyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
201011						
201012	0.17	105	0.61	388	52	2904
201101	0.36	224	0.46	292	123	697

201107	0.13	81	0.26	165	20	1321
201108	0.56	355	0.66	420	267	659
201109	0.49	311	1.03	648	362	1160
201110	0.04	27	0.08	53	18	156

Monthly population estimates of sitting and flying birds:

4.3 Sooty Shearwater *Puffinus griseus*

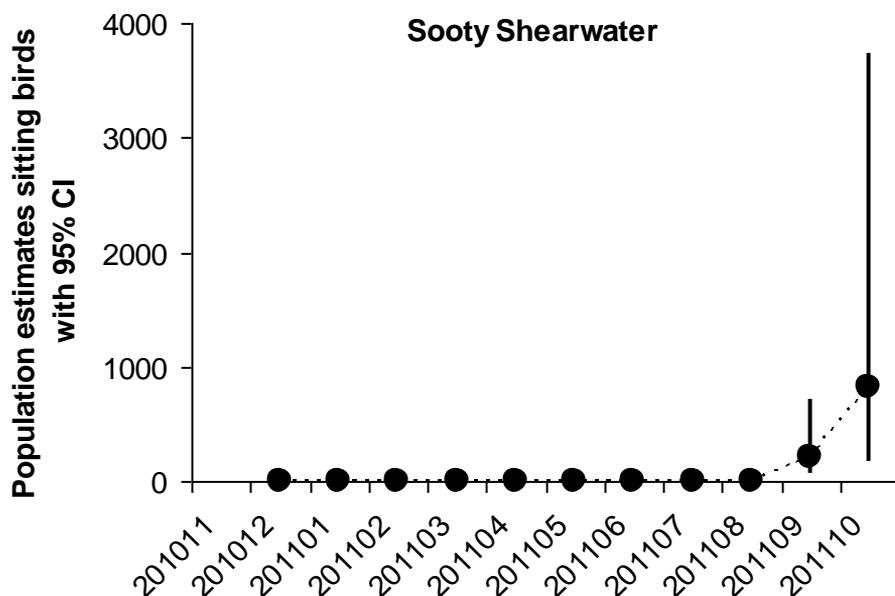

Observations:

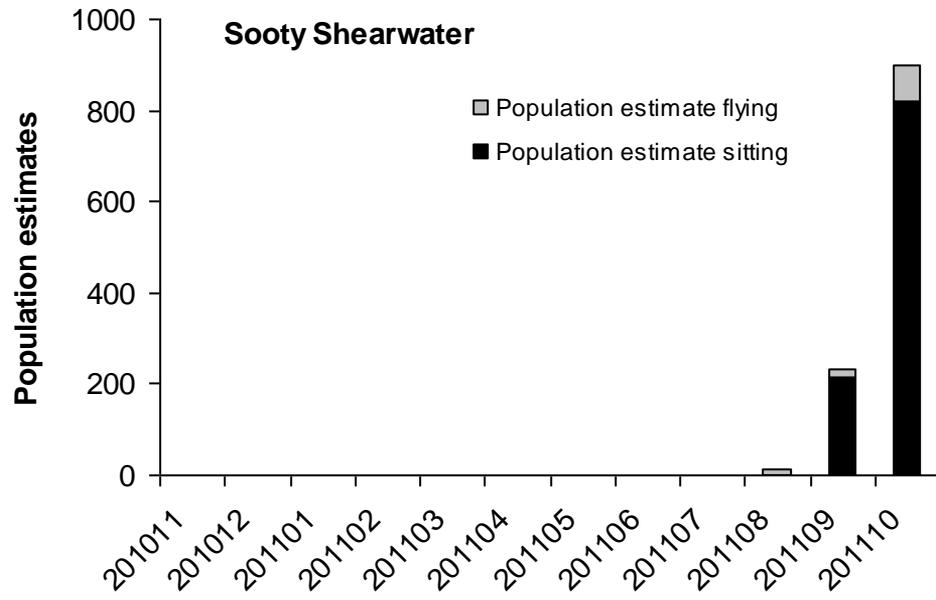

A total of 67 individual Sooty Shearwaters were recorded divided over 15 sightings during the ship-based surveys in the second study year at Neart na Gaoithe. Sooty Shearwaters were only recorded in September and October.

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

Survey (yyyymm)	Density flying birds per km2	Population estimate flying	Density sitting birds per km2	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
201011						
201012	0.00	0	0.00	0	0	0

Monthly population estimates of sitting and flying birds:

4.4 Northern Gannet *Morus bassanus*

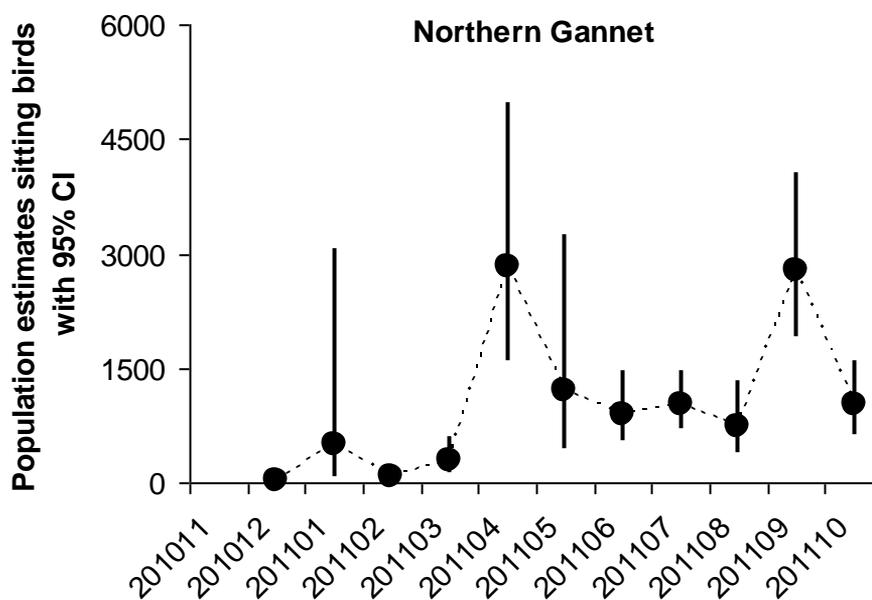

Observations:

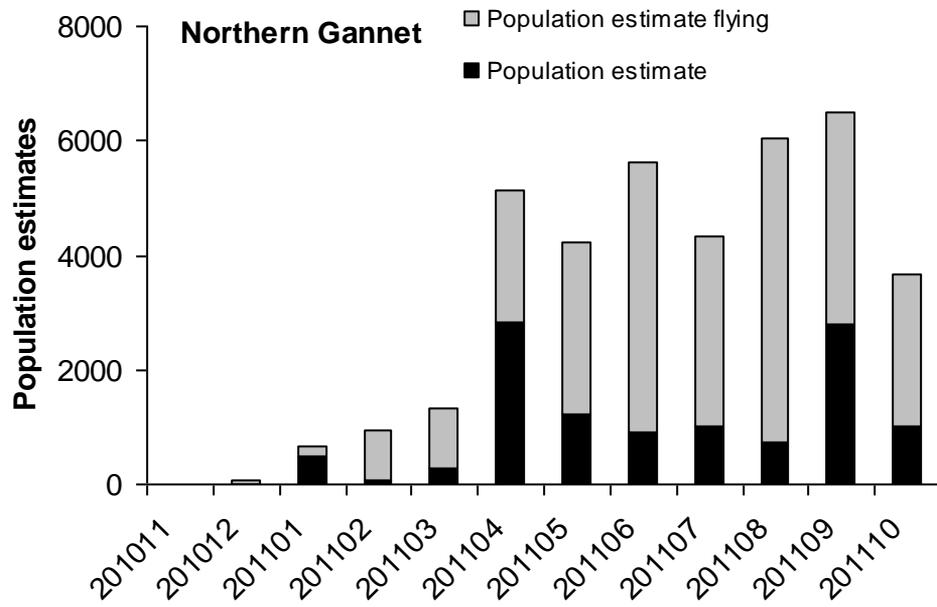

A total of 1,729 individual Northern Gannets were recorded divided over 756 sightings during the ship-based surveys in the second study year at Neart na Gaoithe. Northern Gannets were scarce during winter and most abundant during spring, summer and autumn.

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

Survey (yyymm)	Density flying birds per km2	Population estimate flying	Density sitting birds per km2	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
201011						
201012	0.10	63	0.03	17	3	100
201101	0.28	177	0.77	488	77	3078
201102	1.39	878	0.12	76	32	179
201103	1.63	1031	0.45	285	134	607

201110	4.23	2675	1.60	1010	634	1606

Monthly population estimates of sitting and flying birds:

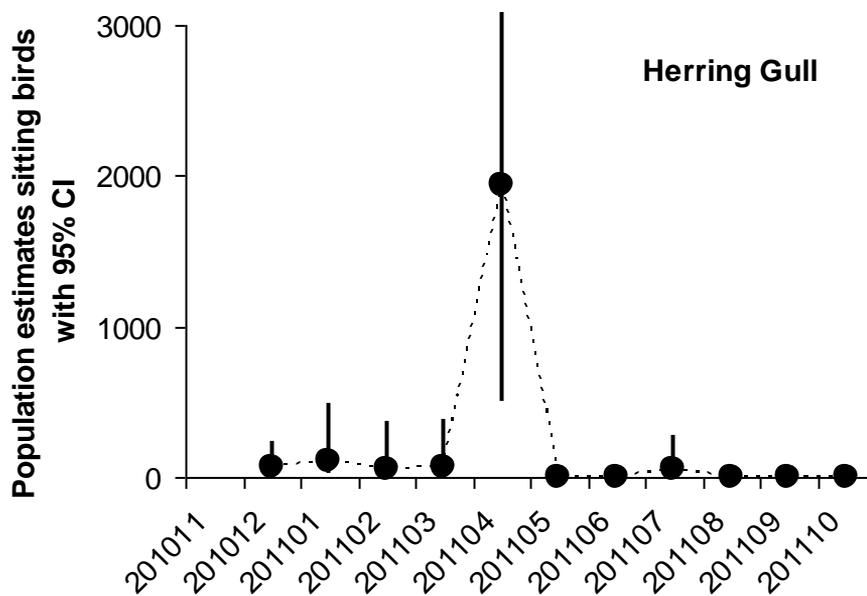

4.5 Herring Gull *Larus argentatus*

A total of 608 individual Herring Gulls were recorded divided over 53 sightings during the ship-based surveys in the second study year at Neart na Gaoithe. On average, Herring Gulls were mostly present in winter. Most sightings were during the January survey of 2010 (N = 14) and to a lesser extent during the November survey of 2009.

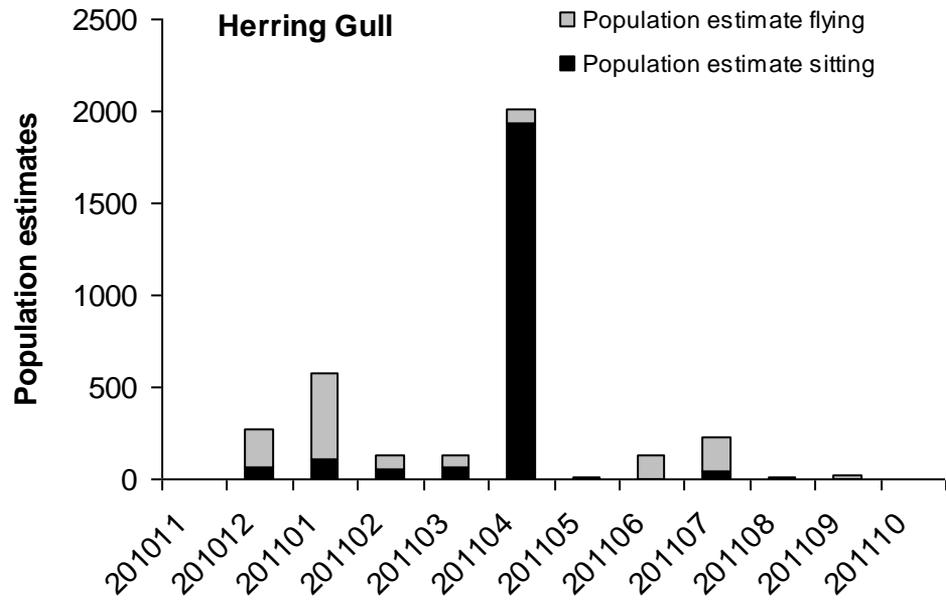

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

Survey (yyyymm)	Density flying birds per km ²	Population estimate flying	Density sitting birds per km ²	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
201011						
201012	0.33	210	0.10	66	19	234

Monthly population estimates of sitting and flying birds:

* Note that for clarity reasons the Y-axis has been truncated.

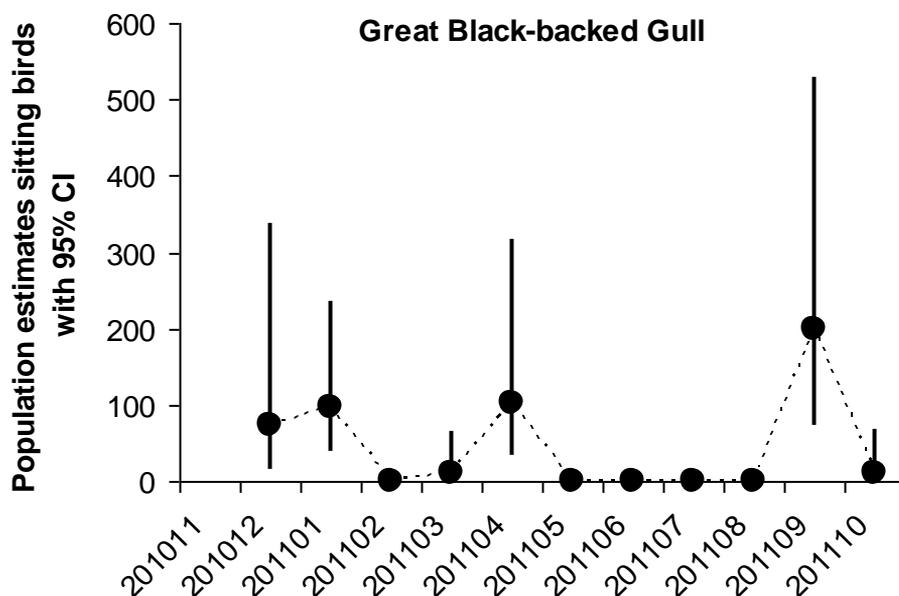

4.6 Great Black-backed Gull *Larus marinus*

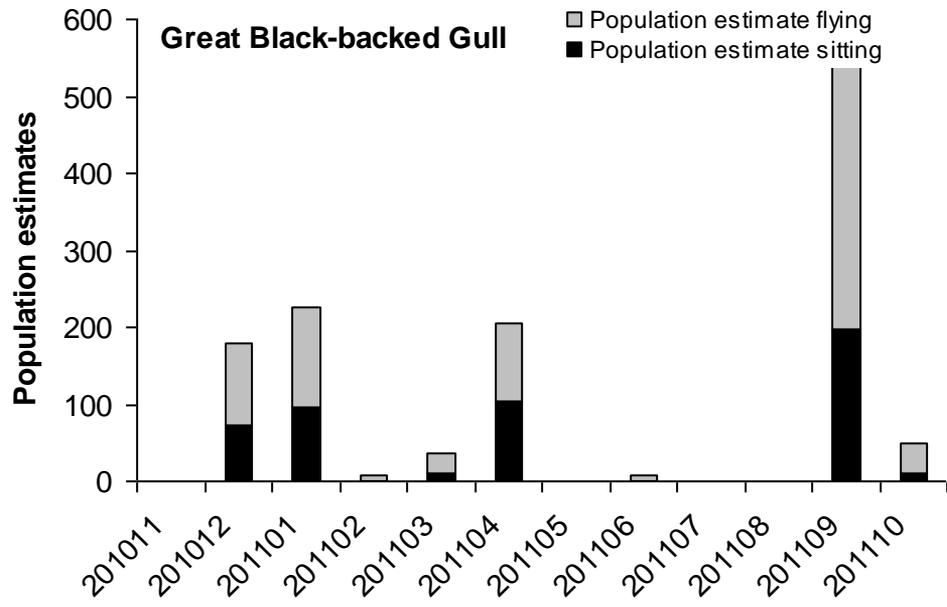

A total of 102 individual Great Black-backed Gulls were recorded divided over 35 sightings during the ship-based surveys in the second study year at Neart na Gaoithe. The highest numbers of Great Black-backed Gulls were recorded in September. Great Black-backed gulls were largely absent in late spring and summer.

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

Survey (yyyymm)	Density flying birds per km2	Population estimate flying	Density sitting birds per km2	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
201011

201110	0.25	156	4.38	2767	970	7893

Monthly population estimates of sitting and flying birds:

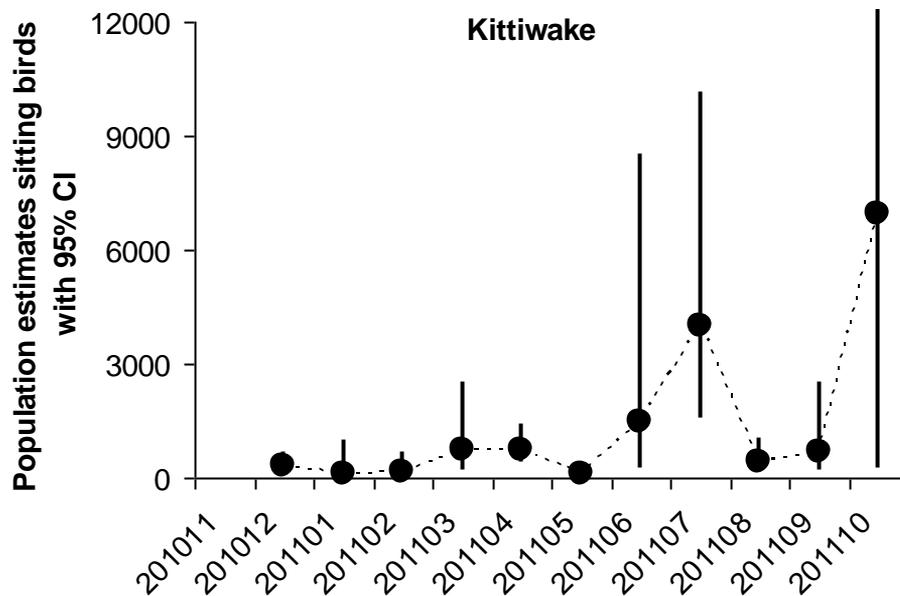

4.8 Kittiwake *Rissa tridactyla*

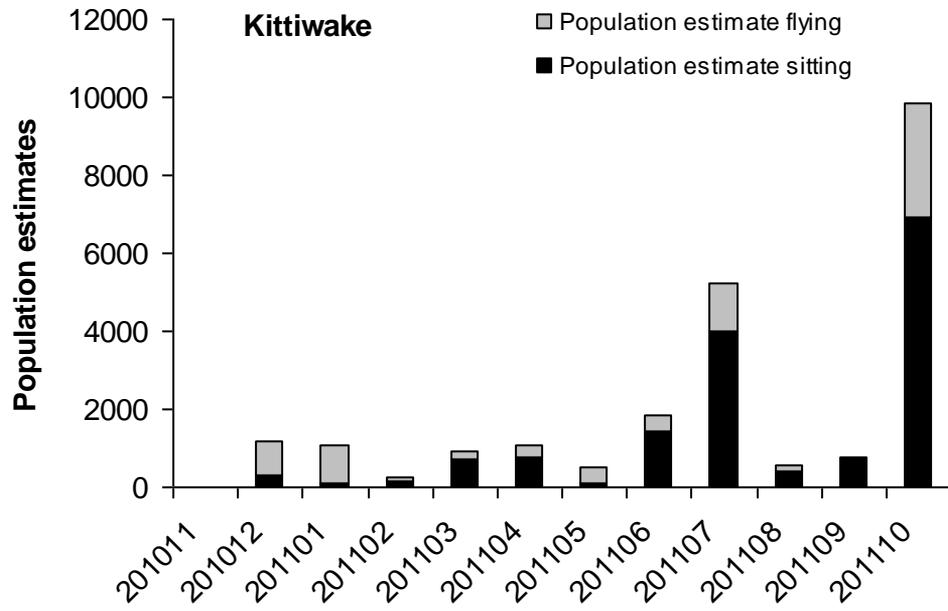

A total of 1,055 individual Kittiwakes were recorded divided over 180 sightings during the ship-based surveys in the second study year at Neart na Gaoithe. Most Kittiwakes were recorded in summer and autumn although the species was present year-round.

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

Survey (yyyymm)	Density flying birds per km2	Population estimate flying	Density sitting birds per km2	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
201011						
201012	1.40	883	0.49	310	139	691
201101	1.56	986	0.18	112	12	1025

201110	4.63	2925	10.96	6926	267	179930

Monthly population estimates of sitting and flying birds:

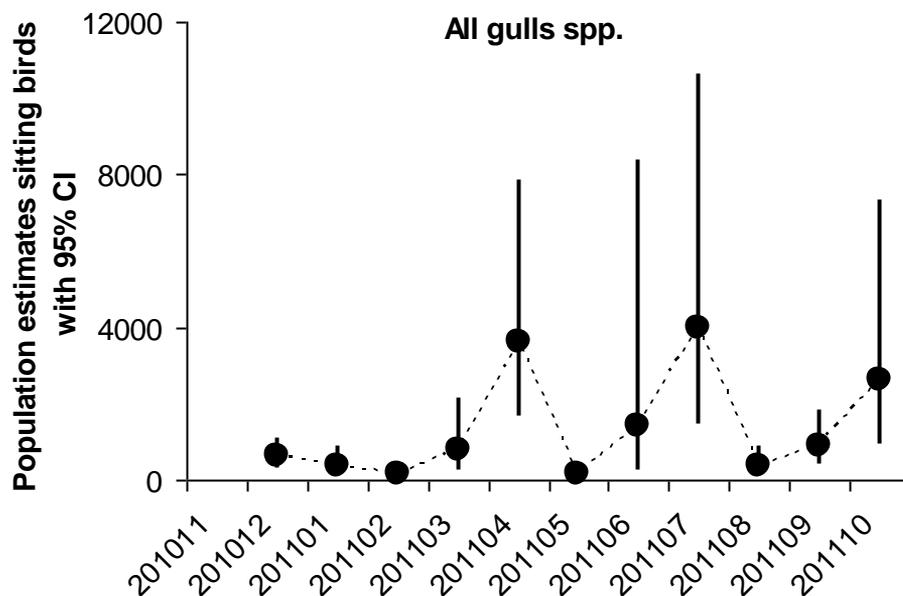

4.9 All gull species

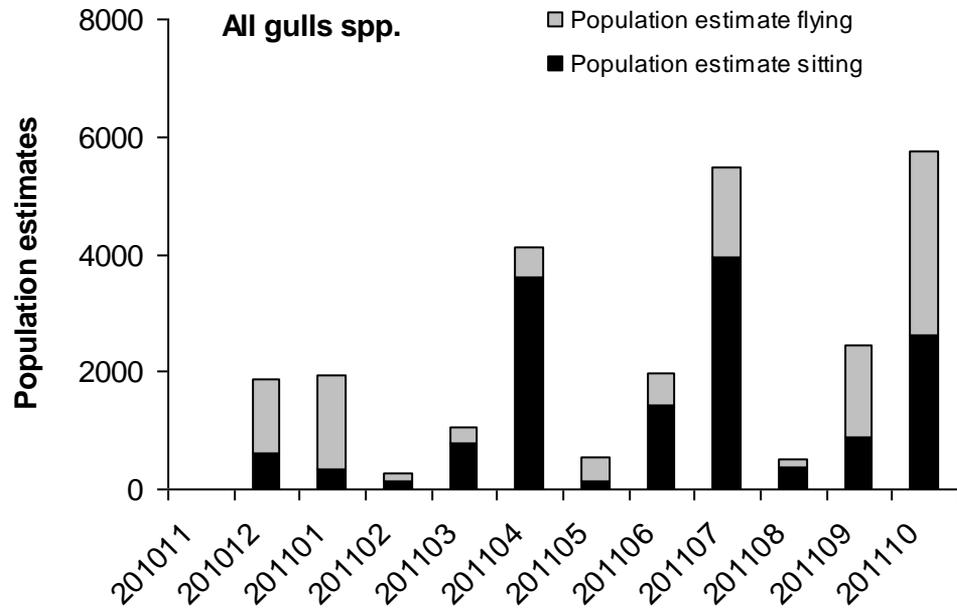

A total of 1,925 individual gulls were recorded divided over 297 sightings during the ship-based surveys in the second study year at Neart na Gaoithe. This group comprises all gull species (Herring, Great Black-backed, Lesser Black-backed, Common and Little Gulls) as well as unidentified gulls (Black-backed Gull spp. and Large gull spp.). Gulls show an erratic abundance pattern. Most gulls were recorded in spring and summer .

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

Survey (yyymm)	Density flying birds per km2	Population estimate flying	Density sitting birds per km2	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval

201110	0.01	7	26.70	16869	13724	20734

Monthly population estimates of sitting and flying birds:

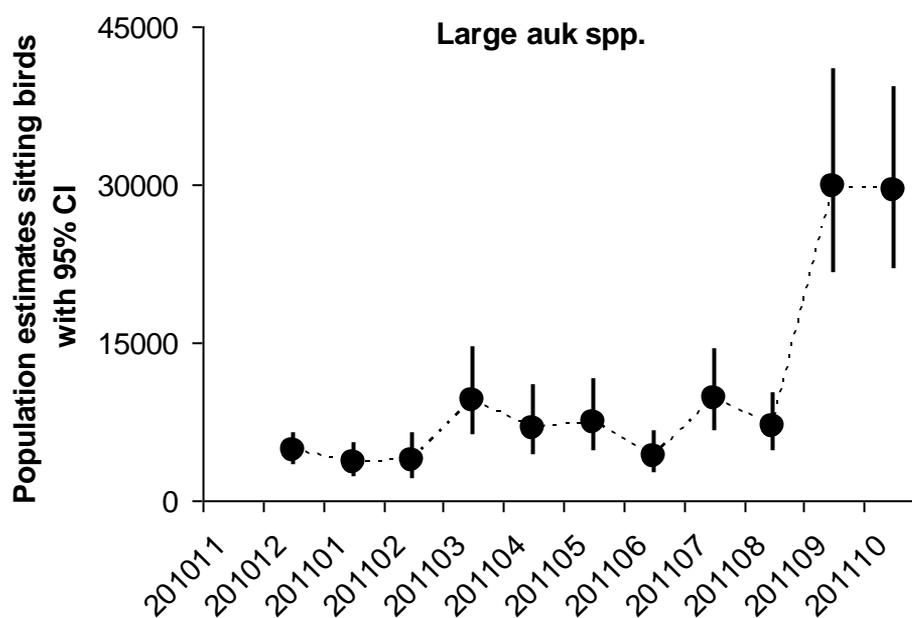

4.15 Large auk species

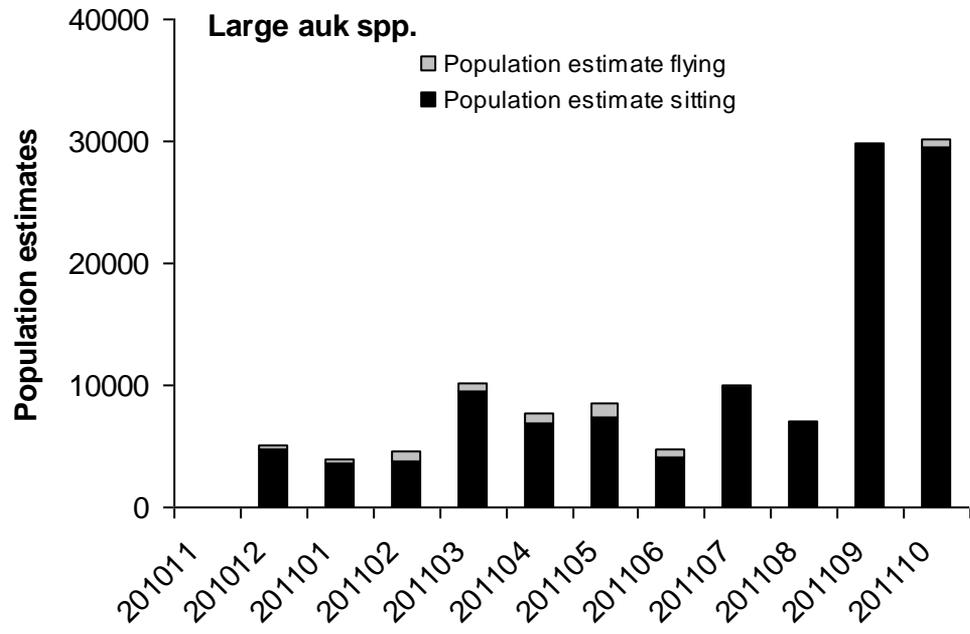

The species group Large auks consist of birds recorded as guillemot/razorbill, Guillemots and Razorbills. A total of 11,161 individual Large auks were recorded divided over 3,561 sightings during the ship-based surveys in the second study year at Neart na Gaoithe. Large auks were present year-round and high numbers were recorded in autumn

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

Survey (yyyymm)	Density flying birds per km2	Population estimate flying	Density sitting birds per km2	Population estimate sitting	Lower 95% Confidence interval	Higher 95% Confidence interval
201011						
201012	0.65	413	7.51	4744	3450	6524
201101	0.57	360	5.66	3573	2344	5447
201102	1.48	932	5.86	3705	2152	6379
201103	0.86	545	15.12	9552	6213	14687
201104	1.31	830	10.89	6880	4289	11035
201105	1.75	1109	11.70	7392	4688	11655
201106	1.01	636	6.59	4161	2593	6677

201108	0.04	27	11.09	7006	4805	10214
201109	0.00	0	47.14	29784	21642	40991
201110	1.21	765	46.60	29443	22100	39227

Monthly population estimates of sitting and flying birds:

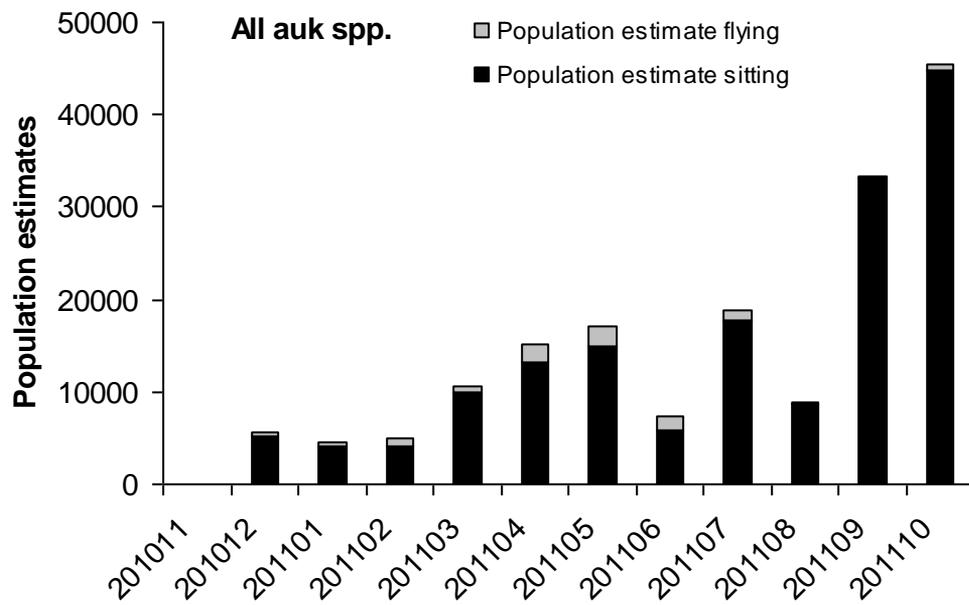

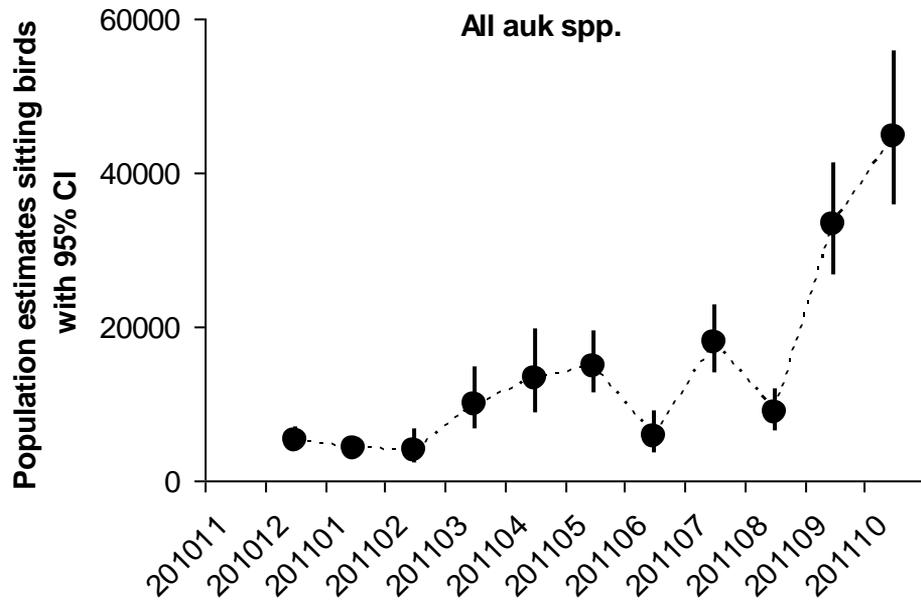

4.16 All auk species

The species group All auk species consist of all categories of species in the groups Small auk species and Large auk species as well as the category 'unidentified auks' (of which observers did not give an indication that the birds either belonged to the group of small or large auks). A total of 14,700 individual auks were recorded divided over 5,489 sightings during the ship-based surveys in the second study year at Neart na Gaoithe. Auks were common throughout the year with a peak in autumn.

Density and population estimates of flying and sitting birds (including confidence intervals for the sitting birds):

Monthly population estimates of sitting and flying birds:

5 Populations estimates in predefined sub-zones at Neart na Gaoithe

5.1 Introduction and methods

In this chapter population estimates have been derived for different sub-zones at Neart na Gaoithe on a monthly basis for both study years (23 surveys in the period November 2009 - October 2011). These figures, presented in the following paragraphs (5.1 - 5.16), are birds sitting on the water and are based on calculations with the Distance Analysis software (CREEM).

Distance analysis yielded population estimates for the whole study area Neart na Gaoithe. Within this study area a development area (DA) was defined (Figure 5.1). Around this DA four buffers were created, each at a distance of 1 km from the last. All individual sightings of birds within the different sub-zones (DA, DA+1, DA+1+2, DA+1+2+3, DA+1+2+3+4 and Neart na Gaoithe) were identified in the database. Population sizes for each sub-zone were calculated as a proportion of the population of the entire area based on the ratios of observed numbers of the different sub-zones. The population sizes for each sub-zone are presented along with lower and upper ranges, which are based on the confidence intervals determined in chapters 3 and 4. These have also been calculated proportionally to the relative sighted numbers of each sub-zone. Accordingly these intervals have lost their strict statistical meaning, so that these should be regarded as ranges and treated as indicative only.

Legend

- Development Area (DA)

6 Collision rate modelling

6.1 Introduction

Below the results of the collision rate modelling are presented for year 1 (November 2009 to October 2010), year 2 (November 2010 to October 2011) and on the basis of both years of data. A total of four wind farm variants were modelled. The parameters of each variant that were used in the collision rate modelling are given in table 6.1.1. For each of the wind farm variants a monthly operating time was provided by Mainstream (table 6.1.2).

Table 6.1.1 *Parameters used in collision rate modelling, for four wind farm variants at Neart na Gaoithe.*

Variant	Number of blades	Rotation speed (rpm)	Rotor radius (m)	Minimum rotor height	Maximum blade width (m)	Pitch (°)	Number of turbines	Latitude (DD)
128 x 3.6MW	3	13	60	24	4.2	15 ²	128	56.25
109 x 4.135MW	3	18	56.25	24	4.2 ¹	15 ²	109	56.25
75 x 6MW	3	13	60.5	24	4.2 ¹	15 ²	75	56.25
64 x 7MW	3	12.1	82	24	5.4	15 ²	64	56.25

¹ Data estimated based on other turbine models. ² Data based on nominal value.

Table 6.1.2 *Monthly operating times as used in collision rate modelling, for four wind farm variants at Neart na Gaoithe. Figures were provided by Mainstream.*

Variant	Proportion of time in operation											
	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
128 x 3.6MW	0.88	0.89	0.89	0.88	0.87	0.86	0.86	0.86	0.88	0.89	0.89	0.89
109 x 4.135MW	0.88	0.89	0.89	0.88	0.87	0.86	0.86	0.86	0.88	0.89	0.89	0.89
75 x 6MW	0.88	0.89	0.89	0.88	0.87	0.86	0.86	0.86	0.88	0.89	0.89	0.89
64 x 7MW	0.85	0.85	0.84	0.82	0.80	0.80	0.78	0.79	0.82	0.84	0.85	0.85

For each of the four wind farm variants, collision rate modelling was carried out for a total of 34 species or species-groups. For 12 species this was based on recorded densities and for the 22 additional species on a predefined flux of 1,000 bird passages occurring twice a year. The parameters of each species that were used in the collision rate modelling are given in table 6.1.3.

Table 6.1.3 *Parameters used in collision rate modelling for twelve bird species.*

Species	Length ¹ (m)	Wingspan ¹ (m)	Flight speed (m/s)	Flapping (0) or gliding (1)	Nocturnal activity factor ⁵ (1-5)	Proportion at rotor height ⁶

¹ Taken from Cramp & Perrins (1974-1994) or Snow & Perrins (1997)

² Taken from Alerstam et al. (2007).

³ Taken from Pennycuik (1997).

⁴ Taken from Pennycuik (1987).

⁵ Taken from Garthe & Hüppop (2004).

⁶ Based on observed flight heights from ship-based surveys carried out at Neart na Gaoithe between November 2009 and October 2011.

⁷ Taken as the mean values of Herring Gull, Lesser Black-backed Gull and Great Black-backed Gull.

⁸ Taken from Wakeling & Hodgson (1992).

⁹ Taken from Cook et al. (in prep).

Results of the collision rate modelling are given in sections 6.2 to 6.5. Firstly, data based on the densities of birds recorded during the first study year are presented, followed by those based on densities during the second study year and then the mean densities from both years. Finally the results for the additional species are presented, which are based on densities calculated from fluxes of 1,000 in the month of April and 1,000 in September (see 2.3). Note that results for Pink-footed Goose and Great Skua in 6.2 to 6.4 are based on recorded densities and use the recorded proportions at rotor height.

6.2 Results Year 1

Table 6.2.1 Densities of flying birds at Neart na Gaoithe development area between November 2009 and October 2010. Data gathered during ship-based surveys, see section 2.1.

7 Discussion

7.1 Distance analysis

Choice of models for Distance analysis calculations

In the species accounts the rationale is given for every species why a certain model was chosen. The main issues for improving models concerned the type of detection function, the inclusion or not of covariates (either as a variate or factor), the application of size bias regression or mean size in the cluster size analysis. This latter issue turned out to lead potentially to relatively large differences in final population estimates, the reason this aspect is discussed more elaborately below.

Generally, the data of the Neart na Gaoithe surveys were such that a variety of competing models could be fitted that produced similar results. Thus, fitting a variety of models and using AIC to objectively choose between models seemed in principle a sensible approach for most species. However, as reported in several individual species accounts, selecting the model with the lowest AIC was not always applied to all species. Most of the exclusions have been made on the basis of the knowledge of birds and survey experience. Especially in case the detection function overestimated the density on the track line, we have chosen an alternative function. Most of the time this was in situations that birds were being detected disproportionately in the second band (due to birds diving under water or birds flying up in the A band and pop up in the second band unnoticed). As a robust, conservative approach, hazard-rate detection curves can then be chosen. Alternatively pooling the two bands also can reveal a smooth distance detection curve. Only sea state has been included in some species models as a covariate in some detection functions when on the basis of AIC it would be included. Mostly sea state was included as a non-factor variable as it used fewer parameters and enforced a monotonic relationship between detectability and sea state. The Distance analysis program uses a size bias regression for each survey to obtain estimates of cluster size. For some species the numbers of sightings in a survey were small and so in these cases the size bias regression failed to come up with reliable estimates of expected cluster size. In the following paragraph this issue is further discussed as it turned out to be that applying a mean cluster size instead could reveal far too high population estimates.

Size bias regression vs Mean cluster size analysis

In some cases during the population size modelling in Distance, the created models encounter problems with the clustered distribution of certain species. Distance uses size-bias regression models to calculate population estimates based on the assumption that larger groups are more easily observed further away from the transect line than individual birds at a similar distance. With the size-bias regression, the assumption is made that all cluster sizes are observed on, or close to, the track line. So, in case more large clusters are observed close to the line than one would expect the size-bias estimate is larger than the mean estimate. The question is why the observed groups on the track line can consist of more large groups than

expected? Often this is the case when numbers per survey are low and thus the potential influence of a large group near the transect line is large. In certain species, like gulls and Northern Fulmar, this phenomena can occur due to groups of birds related to fishery activities, that are still present long after fishing activity was undertaken at that location. Also clustered presence of foraging Little Gulls along lines or fronts at sea might give problems.

This size-bias regression gives problems when the expected cluster size ($E(s)$ as determined by Distance) is larger than the mean cluster size. This problem mainly occurs when population estimates are given per survey and thus based on a cluster size per survey as well (in Distance terms: "Cluster Size per 'stratum' instead of 'global'"). Only in one extreme case size-bias regression was less likely to be the preferred method and possible consequences are described in the example below of the Great Black-backed Gull.

Great Black-backed Gull

The greatest influence of shifting from size bias regression to mean cluster size would have occurred when analysing Great Black-backed Gull. In 3 out of the 23 surveys (implying 35% of the total number of observations) $E(s)$ was larger than the Mean Cluster Size and a warning is given by the model. Although the problem only occurred in a limited number of surveys the implications could be great for the final outcomes of the estimates sizes of the populations (table 7.1). In these surveys population estimates are indeed slightly smaller when mean cluster size is used, however, in cases when the size bias regression properly reveals that $E(s) < \text{Mean CS}$, and rigorously the mean cluster size approach is applied to all surveys the population estimates can rise up to 5.43 times as high.

In this report, size-bias regression has been chosen as the preferred method for estimating populations based on several reasons. Problems with the size-biased regression do not occur frequently (only in 12% of all surveys (41 out of 345 (15 species, 23 surveys) surveys) and in most cases $E(s)$ only slightly larger than the mean cluster size. Also the surveys with these problems are almost exclusively surveys with low numbers of the particular species so the overall influence on population estimates is small.

Table 7.1 Comparison of Size bias regression and Mean Cluster Size population estimates during individual surveys.

Species	Survey	Warning	Population estimate based on Size-bias Regression	Population estimate based on Mean Cluster Size	Correction factor when using Mean Cluster Size approach

7.2 Collision rate modelling

The results of the collision rate modelling for four wind farm variants in the Neart na Gaoithe development area are presented in chapter 6. For the 12 main species, these results are presented on the basis of densities of flying birds recorded in the area during a two-year period. In addition, a further 22 species were assessed based on a fixed number of passages per year; these results are discussed at the end of this chapter. The differences between the estimated collision rates between year 1 and year 2 are due to differences in recorded bird densities. In general, the recorded densities of flying birds in the Neart na Gaoithe development area were slightly higher in year 2. On average, monthly densities for the 12 species assessed in the collision rate modelling (excluding additional species) differed by 3.82 birds/km². The results based on the mean density across the two years are also presented (6.4) and are discussed here in relation to the modelled estimates in order to prevent repetition.

A total of four wind farm variants were modelled. These variants differed in the type, size and operating characteristics of turbines as well as the numbers of turbines. These differences translate into differing collision risk for a single transit across the rotor-swept area and also the total number of transits through this area. In terms of the model used, in general a larger turbine relates to a lower collision risk per transit but a greater potential number of transits through the rotor-swept area for any given species. The total number of transits per wind farm is also influenced by the total number of turbines. For the variants modelled, the highest collision risk per transit was for the smallest turbine (4.135MW GE) and the lowest collision risk was for the largest turbine (7MW Vestas). The total number of transits per year was lowest for the variant

with the second-fewest turbines (75 x 6MW Siemens NG5) and highest for the variant with the most turbines (128 x 3.6MW Siemens).

For the model used, and for any given turbine, collision risk is related to the size and flight speed of the bird in question. Of the 12 species assessed, the largest, Northern Gannet, had the highest collision risk and the smallest, Puffin, the lowest. Collision risk per transit varied from 4.7% for Puffin with a 7MW (Vestas) turbine to 8.4% for Northern Gannet with a 4.135MW (GE) turbine. The combination of this collision risk and the potential number of transits resulted in the species-specific and variant-specific collision rates to which various avoidance factors were applied. This avoidance factor reduces the estimated numbers of collisions proportionately. Here avoidance rates of 95%, 98%, 99% and 99.5% were applied, which reduced the estimated numbers of collisions correspondingly.

The application of avoidance rates reduced the estimated number of collisions per year. For the highest collision rate calculated before avoidance (appendix 1), for Northern Gannet and the 128 x 3.6MW Siemens variant, an avoidance rate of 99% reduced the estimated number of collisions to 451 per year; for a rate of 99.5% this was 225 estimated collisions per year.

The estimated numbers of collisions for the 22 additional species are fairly similar between species. This is a consequence of the identical fluxes and similar proportions flying at rotor height used. The latter value was taken from literature and for many species was a generic value leading to identical values being used for all species within a group, *i.e.* geese. The differences in results are therefore mainly due to bird characteristics (size and flight speed) and are relatively small compared. The numbers of birds used in the model is directly proportional to the estimated numbers of collisions. Therefore, increasing the flux by two would double the numbers of collisions. In this respect the results for these additional species, which are based on a known number of flights, provide a useful reference for species seldom recorded during the field surveys.

The estimates of collision rates for birds at Neart na Gaoithe development area were produced using the extended Band model, which makes a number of assumptions and simplifications of birds, turbines and their interactions. Furthermore, simplification of input data adds to the variability and uncertainty of output values. The main sources of uncertainty are outlined in Band (2011) and include, amongst others, the use of fixed parameters for dynamic variables like wingspan, flight speed, flight direction, turbine speed, wind speed and bird abundance. Uncertainty also exists in the data for bird abundance, which often shows high variability, both spatially and temporally. These factors influence the uncertainty surrounding estimates to varying degrees, however, it is arguably avoidance behaviour that has most influence on this uncertainty. Currently, few published figures exist for the level of avoidance exhibited by birds in relation to wind turbines, certainly for the offshore environment. This, coupled with the strong influence of the avoidance rate on the modelled results,

means that the uncertainty arising from avoidance rates used are likely to overshadow any uncertainty resulting due to other factors. Band (2011) outlines the uncertainty surrounding the modelled results should be expressed numerically. For most factors, however, these cannot be assessed empirically and would therefore be an ambiguous appraisal of the error involved.
