1. Introduction

1.1 Project Background

Green Volt Offshore Wind Limited ('the Applicant') is proposing to develop the Green Volt Offshore Wind Farm (OWF) (from here on referred to as 'Green Volt') as a proposed floating offshore wind farm. The proposed site is approximately 75 kilometres (km) northeast of the Aberdeenshire coast in northern North Sea, Scotland (**Figure 1**). The proposed array area covers an area of 116 km², whilst the survey area included a 4 km buffer surrounding the array area providing coverage of the total study area of approximately 391 km². Green Volt will comprise both offshore and onshore infrastructure, including an offshore generating station (the wind farm), export cables to landfall and an onshore substation for connection to the electricity transmission network (please see **Green Volt Offshore Wind Farm Environmental Impact Assessment Report Chapter 5: Offshore Project Description** for full details on the Project Design).

APEM Ltd (hereafter APEM) was commissioned by the Applicant to undertake a study of offshore ornithology that characterise the area that may be influenced by Green Volt. A separate report (**Appendix 12.1: Offshore and Intertidal Ornithology Baseline Technical Report**) provides the findings from offshore and intertidal ornithology data to determine the receptors that characterise the baseline and are of relevance to the assessment of potential impacts from Green Volt. This technical annex has been produced to support **Green Volt Offshore Wind Farm Environmental Impact Assessment Report Chapter 12: Offshore and Intertidal Ornithology**.

The consideration of offshore ornithology for Green Volt has been discussed with consultees through the Green Volt Stakeholder Ornithology Meetings; of which Nature Scot, Marine Scotland Science (MSS), Marine Scotland Licensing Operations Team (MS-LOT) and the Royal Society for the Protection of Birds (RSPB) are members. Agreements made with consultees within the Green Volt Stakeholder Ornithology meeting process are set out in Section 12.3 Consultation and Engagement within **Chapter 12: Offshore and Intertidal Ornithology**.

1.2 Displacement Analysis

The presence of Wind Turbine Generators (WTGs) in the marine environment has the potential to directly disturb and displace seabirds that would normally reside within and around the area of sea where Green Volt is proposed. This in effect represents indirect habitat loss, potentially reducing the area available for those seabirds that are sensitive to disturbance to forage, loaf and/or moult in the way that they are currently able to within and around Green Volt. There is also the potential for the construction and decommissioning of WTGs, substations and cable laying to directly disturb and displace seabirds, though the nature of such potential impacts is more restricted spatially and temporally by virtue of the nature of those phases of the development.

Following consultation in the Green Volt Stakeholder Ornithology meetings, five seabird species have been identified for which potential disturbance and displacement should be considered in relation to Green Volt. These are:

- Gannet, *Morus bassanus*;
- Kittiwake *Rissa tridactyla*;
- Guillemot *Uria aalge*;
- Razorbill, *Alca torda*; and
- Puffin, *Fratercula arctica*.

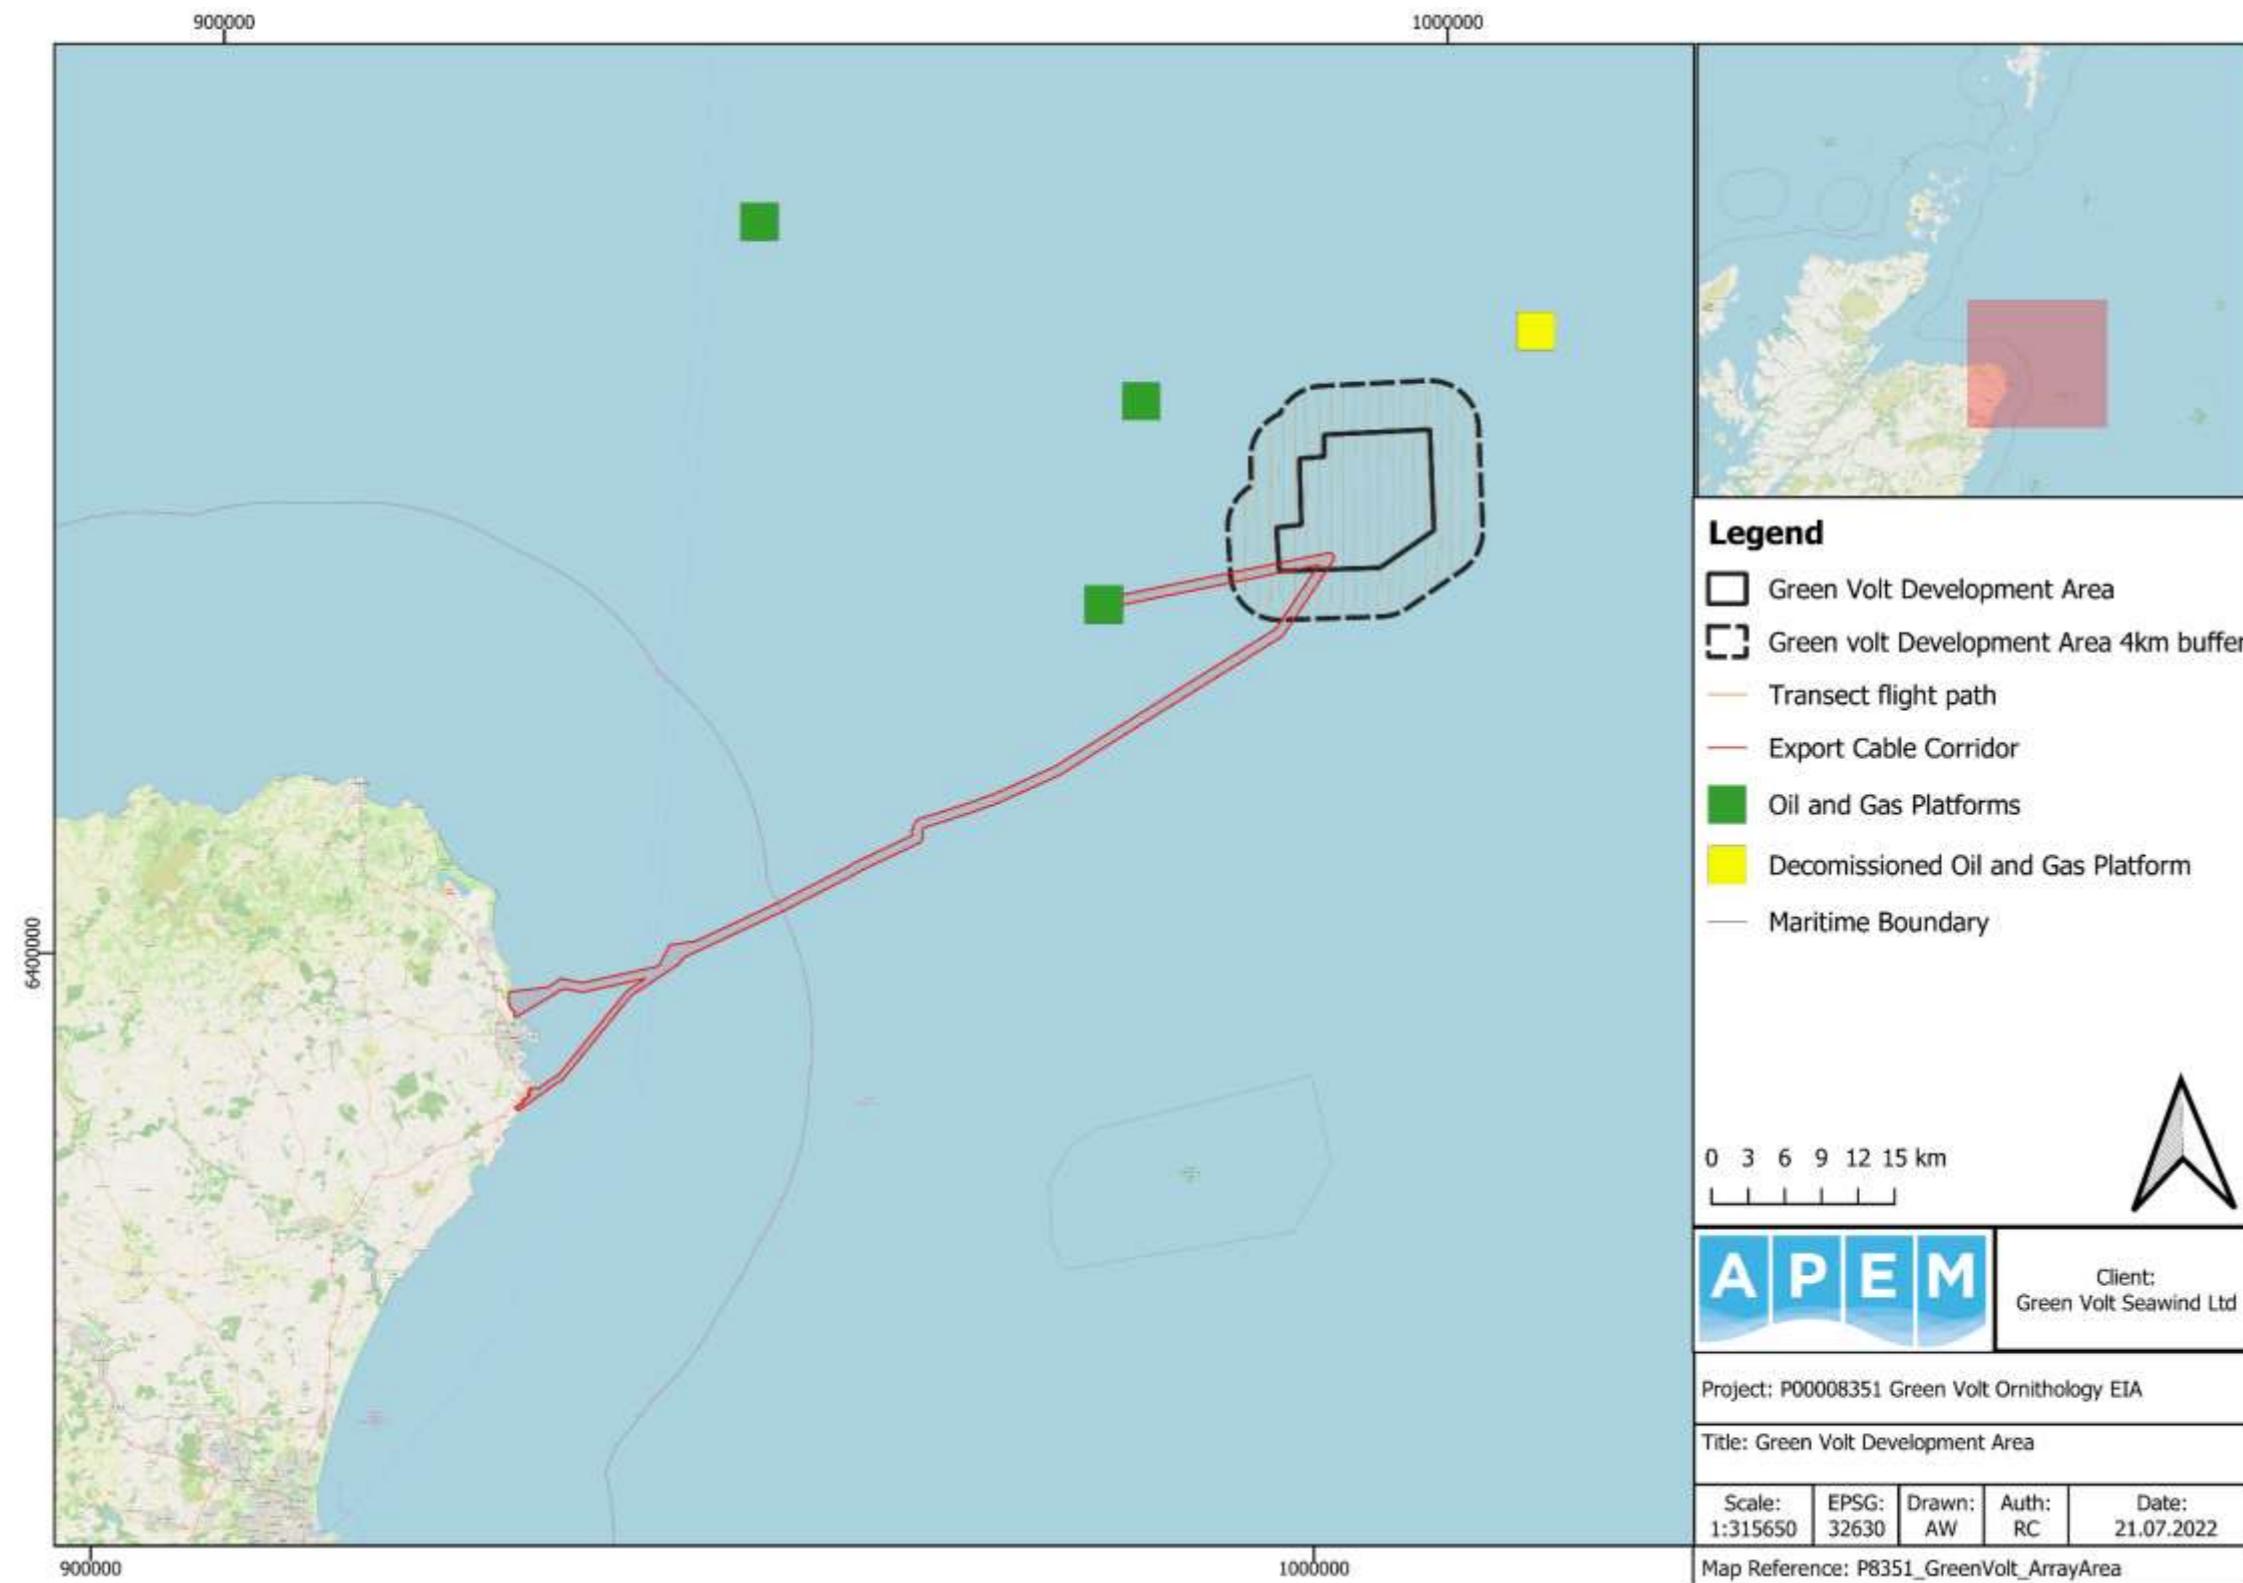

2. Methods

2.1 Buffers for Displacement

The main assessment on disturbance and displacement is found within **Chapter 12: Offshore and Intertidal Ornithology**. The scale of the potential displacement applied in this report is in response to guidance in the literature (SNCBs, updated 2022), comments received to date from the Green Volt Stakeholder Ornithology meetings (see **Section 12.3 in Chapter 12**) and supporting evidence from post-construction monitoring reviews and other seabird behaviour studies related to offshore wind farms.

With consideration of the generic guidance (SNCBs, updated 2022), this report presents displacement matrices that consider gannet, kittiwake, guillemot, razorbill and puffin. These matrices present abundances for gannet, kittiwake, guillemot and razorbill and puffin within the Green Volt array area plus a 2 km buffer during different bio-seasons.

Figure 1 Location of Green Volt array area (and 4 km buffer zone) used for estimating abundances for displacement analysis.

2.2 Data sources for displacement matrices

The data contributing to this annex are taken from the 24 months of aerial digital surveys undertaken across the Green Volt study area, which comprised the proposed array area and a 4 km buffer, from May 2020 to April 2022, inclusive. Full details of the site-specific surveys can be found in Appendix 12.1: **Offshore and Intertidal Ornithology Baseline Technical Report**. These data are inclusive of apportionment of unidentified birds and corrections for availability bias, where appropriate.

Displacement matrices are presented for each of the five species (gannet, kittiwake, guillemot, razorbill and puffin) separately for each bio-season. For all species, displacement matrices are presented for the array area and the array area plus 2 km buffer. For all species both flying and 'sitting' (including birds observed diving, landing and taking off) abundances were included in the displacement analysis, as agreed in the Green Volt Stakeholder Ornithology meetings, to allow for an account of barrier effect to be incorporated into the displacement assessments for each species. Note that barrier effects are considered separately in **Chapter 12: Offshore and Intertidal Ornithology**.

2.3 Data limitations

The data within this annex for all five species are reliant upon site-specific high-resolution aerial digital video surveys undertaken across the Green Volt study area. These data are considered to be the most reliable source for characterising the baseline environment for offshore ornithology for Green Volt. However, using these data to characterise the abundances for each species within individual bio-seasons (as described in Section 2.5) is subject to interpretation, given variation in migratory movements between species and between years, the age classification of birds within each bio-season, connectivity to breeding colonies and other factors. Therefore, these data may be used for the assessments within the Environmental Impact Assessment report (EIAR) Chapter and the Report to Inform Appropriate Assessment (RIAA) in differing manners, depending upon additional factors considered when assessing the potential impacts and / or effects of displacement on these species.

2.4 Presentation of displacement by bio-seasons

Bird behaviour and abundance is recognised to differ across a calendar year dependent upon the bio-season. Separate bio-seasons are recognised in **Appendix 12.1: Offshore and Intertidal Ornithology Baseline Technical Report** in order to establish the level of importance any seabird species has within the Green Volt study area during any particular period of time. Species-specific seasons for the Green Volt study area (**Table 1**) have been defined primarily referring to the guidance note from NatureScot, who have provided suggested definitions for all regularly occurring birds in the Scottish marine environment (NatureScot, 2020). Additional consideration was also provided to the UK bio-seasons compiled in Furness (2015), where appropriate.

The bio-seasons are defined for the Green Volt study area as breeding and non-breeding following NatureScot guidance and pre-breeding migration, migration-free breeding, post-breeding migration, migration-free winter, bio-seasons following (Furnace, 2015). The use of either two separate or over two bio-seasons for different species are used to understand the relevance of the Green Volt study area during different periods within the annual cycle of seabirds. It should be noted that bespoke bio-

seasons are applicable for each seabird species considered for this project based on site-specific evidence in support of the guidance from NatureScot (2020) and Furness (2015), with different combinations used depending on the biology and life history of a species within this study area.

NatureScot (2020) advise two main bio-seasons are proposed for use, which include a breeding bio-season when birds are strongly associated with their nest site / colony and a non-breeding bio-season when birds are on migration or reside in their wintering locations.

Furness (2015) advises that there are multiple different components, where some species are recommended to consider two bio-seasons (similar to NatureScot, 2020), whilst others are determined to have up to four different bio-seasons (e.g. razorbill), which include a pre-breeding migration bio-season (when birds are migrating to breeding colonies), a migration-free breeding bio-season (when birds are attending colonies, nesting and provisioning young), a post-breeding migration bio-season (when birds are migrating to wintering areas or dispersing from colonies) and a migration-free winter bio-season (when non-breeding birds are over-wintering in an area).

For the Green Volt study area both methods were considered alongside site-specific evidence on seabird behaviour to assigned the most appropriate bio-seasons for the baseline characterisation for use in impact assessment and subsequently for use in displacement analysis in **Table 1**.

For kittiwake a number of options are presented for consideration at this stage, with two and three bio-season options; using two bio-seasons defined by NatureScot guidance and three bio-seasons by incorporating the migratory periods pre- and post-breeding defined in Furness (2015). These options are provided to maximise interpretation of peak abundance estimates and behaviour over the Green Volt study area of this species. Gannet is presented with three bio-seasons to account for extensive population movements occurring during migratory periods.

Table 1 Bio-season colour coding.

Bio-season	Gannet	Kittiwake	Guillemot	Razorbill	Puffin
Return Migration (Green)	Dec – Mar	Jan-(mid) Apr	N/A	N/A	N/A
Migration-free Breeding (Purple)	Apr – Sep	(mid) Apr-Aug	N/A	N/A	N/A
Post-breeding Migration (Orange)	Oct – Nov	Sep-Dec	N/A	N/A	N/A
Migration-free Winter (Grey/Blue)	N/A	N/A	N/A	N/A	N/A
Breeding (Pink)	N/A	(mid) Apr-Aug	Mar – (mid) Aug	Apr-(mid) Aug	Apr- (mid) Aug
Extended Non-breeding (Yellow)	N/A	Sep-(mid) Apr	(mid) Aug-Feb	(mid) Aug-Mar	(mid) Aug- Mar

2.5 Bio-season mean peak abundances

As per the SNCBs joint interim advice note (SNCBs, updated 2022), data considered within displacement assessments are to be based on bio-season mean peak abundances. The bio-season mean peak abundances are calculated as the highest recorded monthly abundance within each bio-season averaged across the two years' worth of data. It should be noted that calculating bio-season abundance in such a way can be considered precautionary, as it is highly unlikely that the abundance within a given bio-season remains at such a high abundance, especially when considering the non-breeding bio-season. The calculated bio-season mean peak abundances used for these analyses are presented in **Table 2**.

Table 2 Bio-season mean peak abundances in the Green Volt array area and corresponding buffers (all behaviours).

Bio-Season	Survey Area	Gannet	Kittiwake	Guillemot	Razorbill	Puffin
Return Migration	Green Volt array area	49	31	N/A	N/A	N/A
	Green Volt array area plus 2 km buffer	102	83	N/A	N/A	N/A
Migration-free Breeding	Green Volt array area	120	143	N/A	N/A	N/A
	Green Volt array area plus 2 km buffer	198	183	N/A	N/A	N/A
Post-breeding Migration	Green Volt array area	16	76	N/A	N/A	N/A
	Green Volt array area plus 2 km buffer	24	149	N/A	N/A	N/A
Breeding	Green Volt array area	N/A	143	2,480	183	134
	Green Volt array area plus 2 km buffer	N/A	183	4,429	457	250
Non-breeding	Green Volt array area	N/A	76	9,676	42	20
	Green Volt array area plus 2 km buffer	N/A	149	16,105	58	41
