1. INTRODUCTION

1.1. Background

Aberdeen Harbour is the major port serving the North East of Scotland. There are approximately 8,000 vessel arrivals and 5 million tonnes of cargo handled each year, with the harbour supporting 10,000 full time equivalent jobs. It is also the mainland port for the lifeline service to the Northern Isles and as well as general cargo and passengers. Aberdeen is the largest support harbour for the North Sea Energy Industry.

As a statutory harbour authority, Aberdeen Harbour Board (AHB) is required to carry out maintenance dredging of the main navigation channels and berths (shown on Figure 1) to maintain safe navigable depths and support customers' business needs. Clause 72 of the Aberdeen Harbour Order (Confirmation) Act 1960 gives AHB powers to dredge within its statutory harbour limits.

This report presents the Best Practicable Environmental Option (BPEO) assessment for the fate of maintenance dredged material from Aberdeen Harbour. BPEO assessment is a method for identifying the option that provides the *most environmental benefit* or *least environmental damage*. It assesses the performance of different options using a range of criteria such as environmental impact, technical feasibility and cost.

1.2. Source of Materials

Aberdeen Harbour has been built on the former delta at the mouth of the River Dee. Both the harbour and the entrance channel are susceptible to continued progressive natural infilling from two sources:

- a) River-borne silts and muds; and
- b) Sea-borne sands

In 1986, AHB commissioned HR Wallingford Ltd to study the siltation at the harbour entrance (see Appendix 1). The results concluded that the sediment transport is due to a complex action of tides, currents and wave action and consequently cannot be controlled.

In addition, the siltation of harbour berths is caused by the river silt being carried down the River Dee to the harbour. There the natural current takes some of this material anticlockwise around the Point Law headland where it is deposited at the harbour berths.

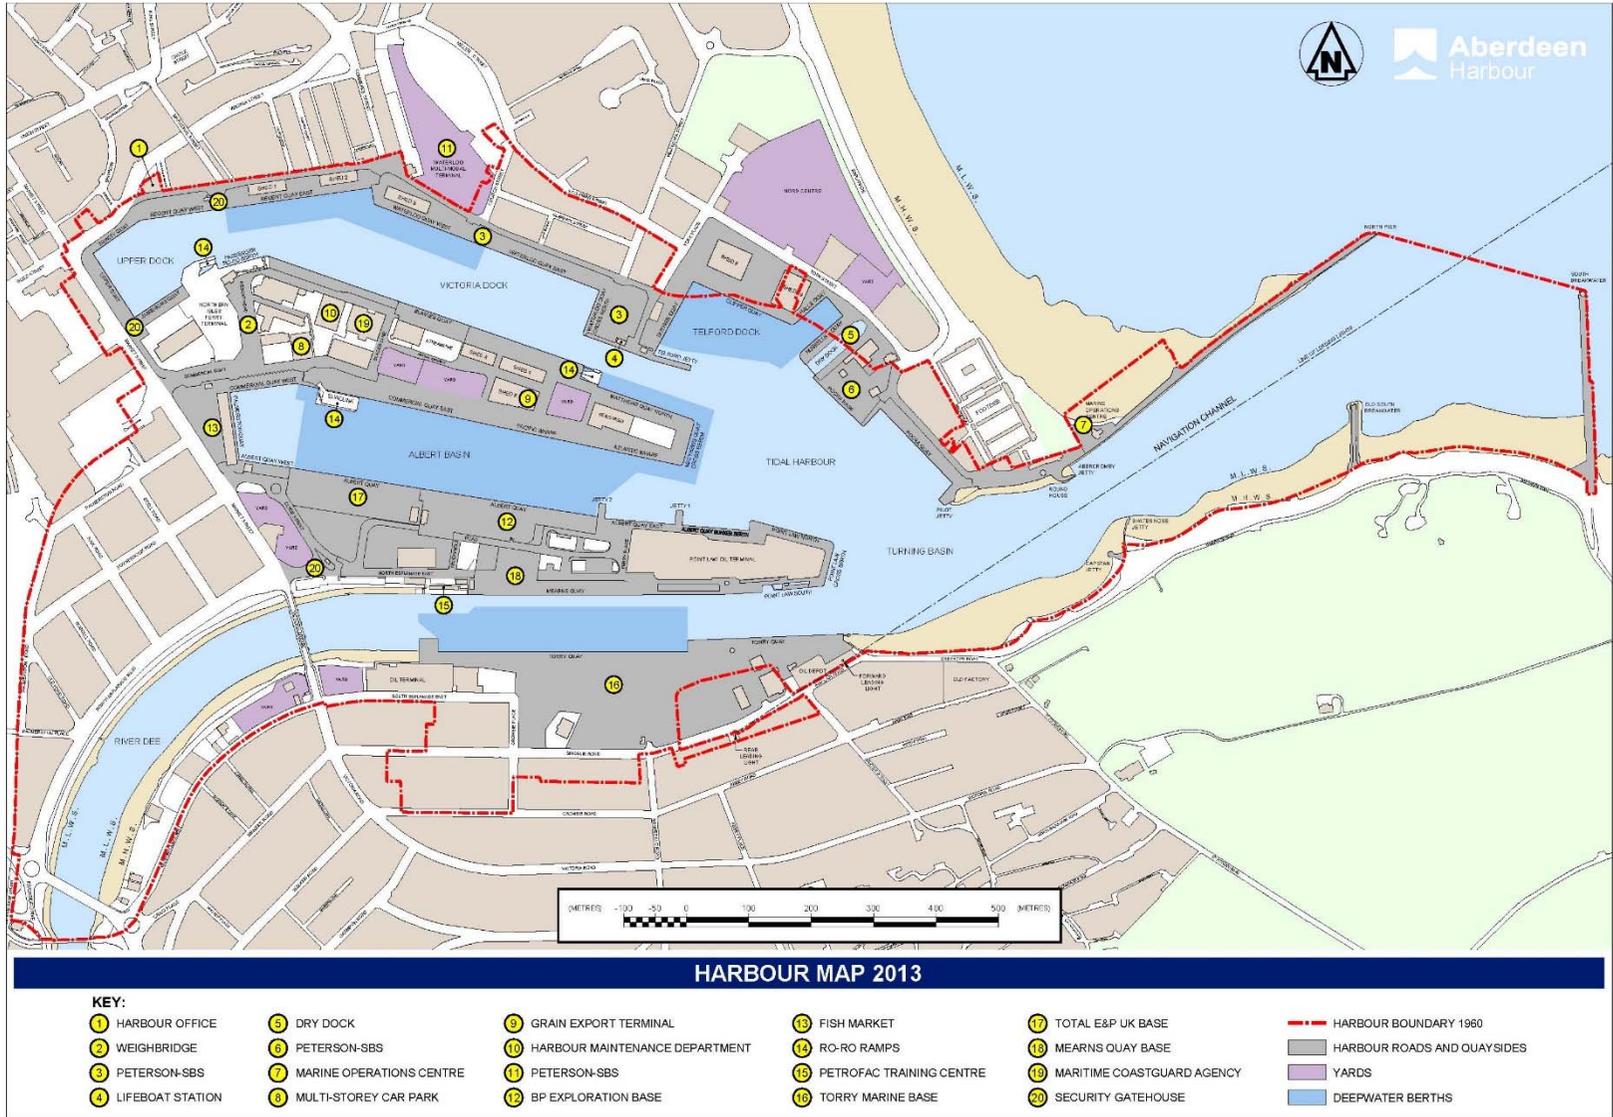

Figure 1 Aberdeen Harbour

2. DESCRIPTION OF PROPOSED DREDGING

2.1. Dredging Methodology

AHB has a recorded history of almost 900 years and a record of dredging going back almost 200 years. In recent years, maintenance dredging has been carried out mainly with a trailer suction hopper dredger, working in conjunction with a bed levelling tug. The latter is used to smooth out any high spots left by the suction dredger. The dredged material is taken by the trailer suction hopper dredger to the designated offshore disposal site Aberdeen CR110, approximately 2.5 nautical miles to the southeast of the harbour entrance, as shown in Figure 2.

The annual maintenance dredging campaign is typically carried out once a year within the areas shown in Figure 3; however, there have been occasions in the past where an additional winter dredging campaign has been required due to inundated accretion of material in the navigation channel and River Dee caused by severe winter storms.

The annual maintenance dredging campaign is typically carried out in spring/summer each year, after any winter storms, depending on the availability of dredging plant. The duration of the campaign will vary from one to four weeks depending on the dredge volumes.

The combined volume of material removed annually from the harbour and channel varies between 100,000 to 200,000 m³ in-situ volume of sand and silt.

Occasionally, deepening of sections of the harbour beyond the maintained depth is carried out to improve the facilities available to shipping; however, any such capital dredging is subject to a separate marine licence application and is outside the scope of this BPEO Assessment.

2.2. Material to be dredged

In October 2017, 10 surface grab samples were collected from the areas to be dredged, as agreed with Marine Scotland. Sediment samples were analysed for the Marine Scotland suite of parameters. A summary of the results is presented in this section and the full report is provided in Appendix 2.

2.2.1 Comparison with Marine Scotland Revised Action Levels

The results have been compared to the Marine Scotland Revised Action Levels, which are used to determine the contaminant loading of the material and its suitability for disposal at sea. Levels of some heavy metals (cadmium, copper, lead and zinc) were elevated above Marine Scotland Revised Action Level 1 in four of the samples analysed. In all cases the levels were well below Action Level 2.

Levels of polychlorinated biphenyls and tributyl tin were below Action Level 1 in all samples.

Levels of polycyclic aromatic hydrocarbons (PAHs) were elevated above Action Level 1 in nine of the samples analysed; however, levels did not exceed (and in many cases were lower than) the PAH levels observed in the samples collected in 2014 for the previous marine licence application for disposal of dredged material 2015 – 2017 (see Appendix 3).

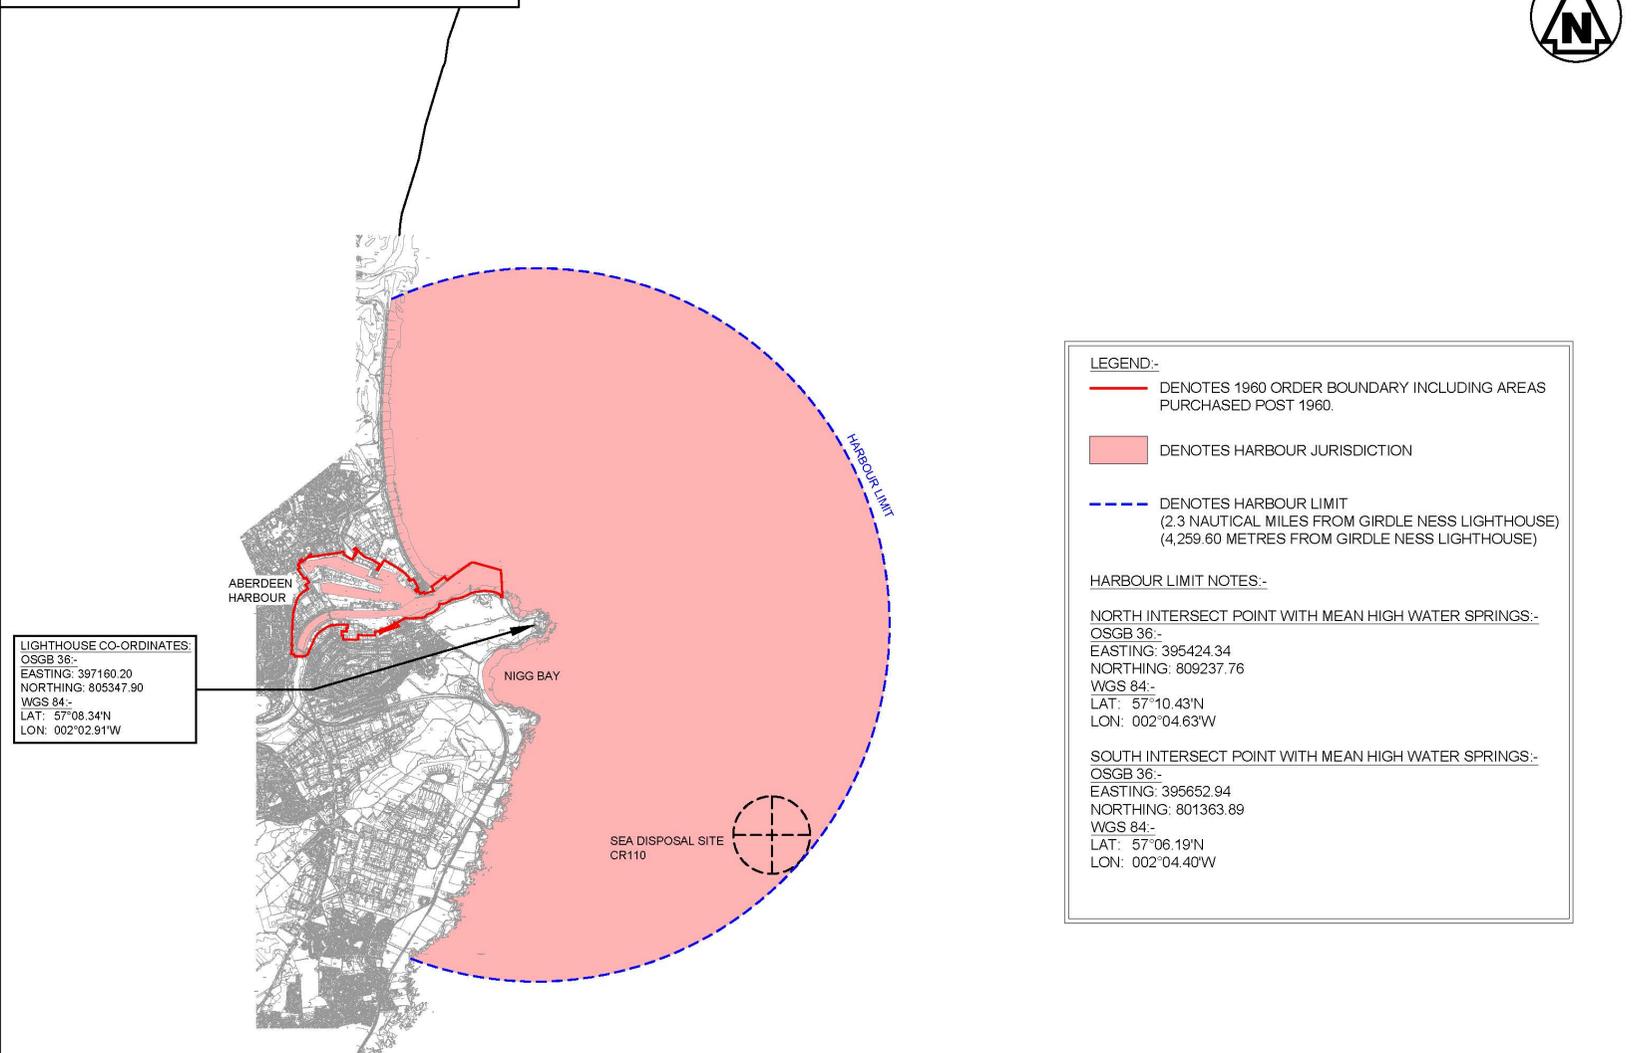

Figure 2 Offshore disposal site Aberdeen CR110

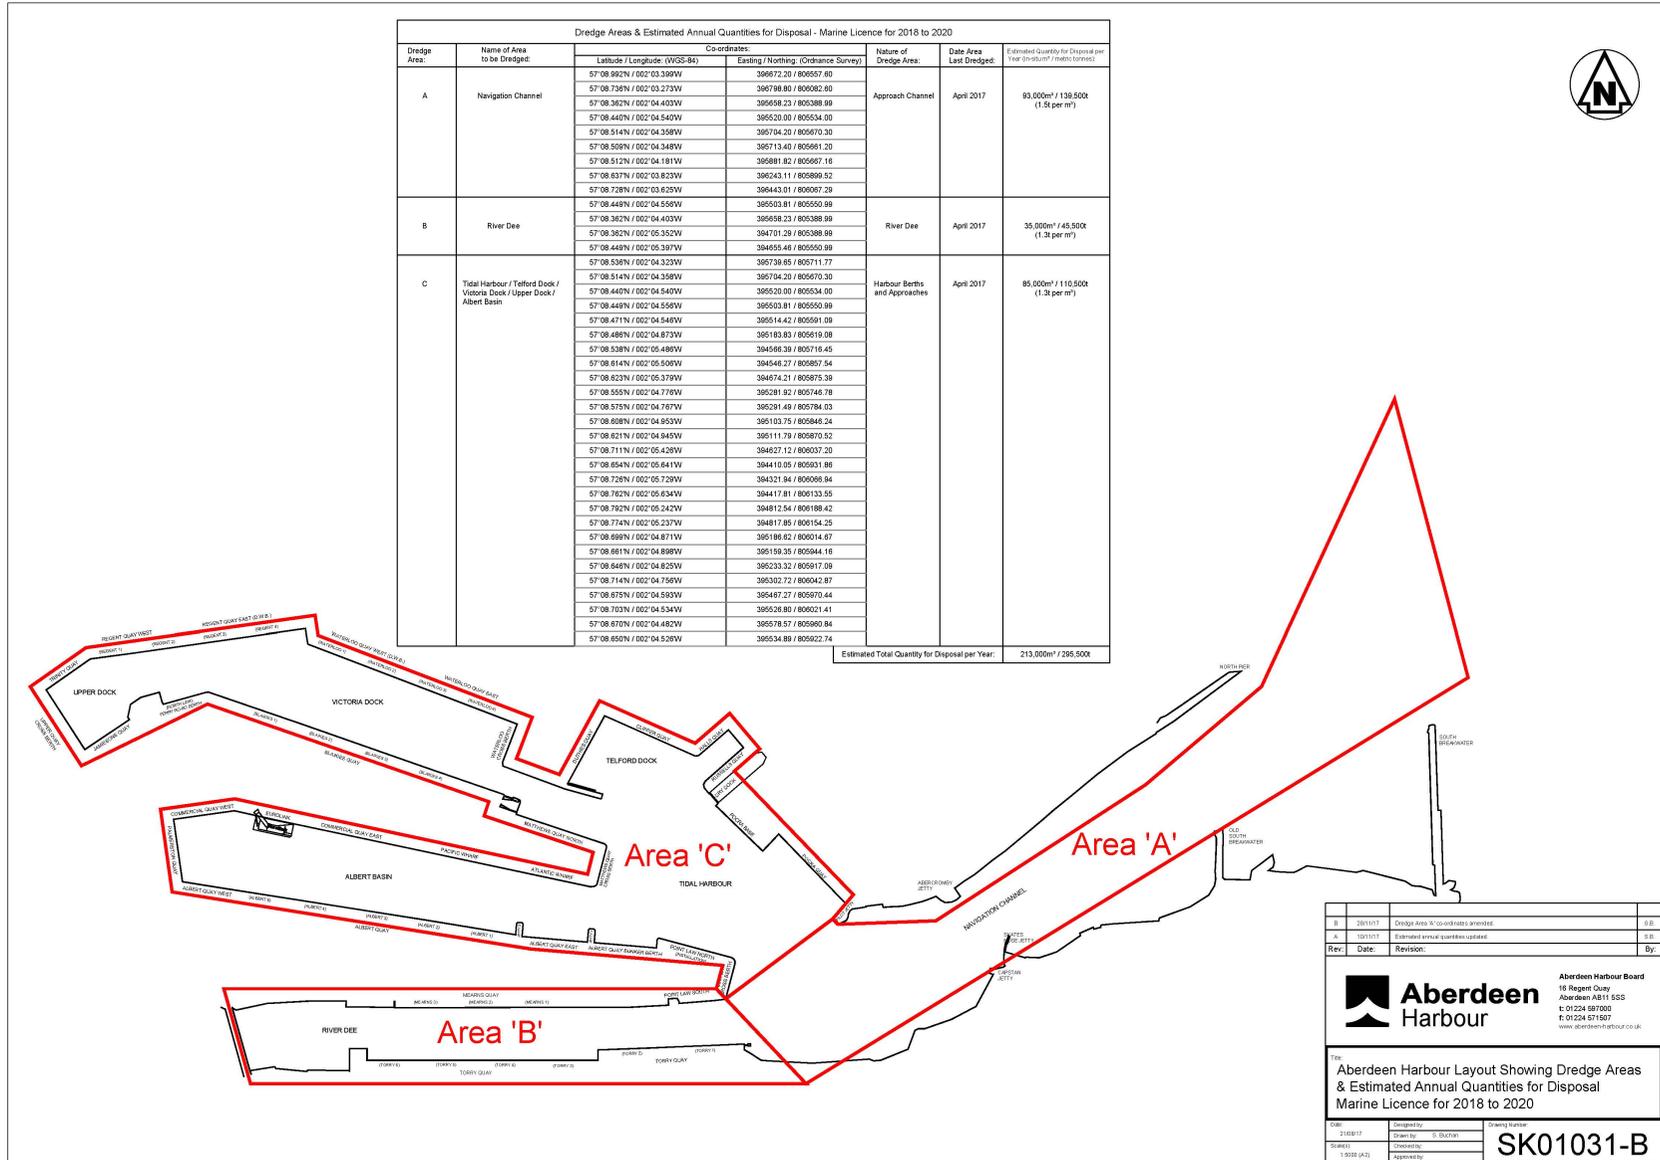

Figure 3 Areas to be dredged

To set the results into context, Marine Scotland has undertaken regular analysis of the material from the dredge hopper during AHB's maintenance dredging campaigns as far back as 1988, and the results of the analysis are provided in Appendix 4. The levels of heavy metals range between below the detection limit to above Revised Action Level 2. For example, a set of samples collected in 1998 and 1999 show elevated levels of copper, zinc, nickel and cadmium above Action Levels 1 and 2, and there are notable samples that are far in excess of Action Level 2. It should be noted that the licensing regime for dredging and disposal activities has changed substantially since 1988 and that disposal activities were carried out in accordance with the regulations of the time.

A report by the Marine Laboratory (Hayes *et al.*, 2005) examined the concentration of heavy metals at the Aberdeen offshore disposal site CR110, along with a number of other disposal sites off the east coast of Scotland. The majority of samples were collected from surveys undertaken in 2002 and 2003; however, historical data collected and analysed in a similar manner was also included. Table 1 presents the average and maximum concentrations of heavy metals.

In addition to the Hayes *et al.* study (2005), additional sampling was undertaken by Marine Scotland at disposal site CR110 between 1995 and 2011: the results are presented in Appendix 5, and the average concentrations of heavy metals are presented in Table 2. The results from this dataset and the study by Hayes *et al.* (2005) show that levels of heavy metals at the disposal site are consistently below Action Level 1, even during times when material above Action Level 1 (and in some cases above Action Level 2) was disposed at the site. As the average levels are considerably lower in the sediments at the disposal site than at the source of dredging, there is no evidence of an accumulation of heavy metals at the disposal site at levels that could cause biological harm. As such, the disposal of material at the offshore site that is either below Action Level 1, or between Action Level 1 and 2, is considered to have a negligible effect on water quality or biological receptors.

Table 1 Concentrations of heavy metals at Aberdeen offshore disposal site (~2003)

Metal	Average (mg/kg dry weight)	Maximum (mg/kg dry weight)
Arsenic	6.1	14.0
Cadmium	0	0.2
Chromium	13.1	32.5
Copper	7.9	34.9
Mercury	0.1	0.3
Nickel	7.8	21.2
Lead	13.6	28.5
Zinc	35.9	75.8

(Reproduced from Hayes et al. (2005))

Table 2 Average concentration of heavy metals at Aberdeen offshore disposal site (1995 – 2011)

Metal	Average concentration (mg/kg dry weight)
Arsenic	5.65
Cadmium	0.07
Chromium	12.78
Copper	6.17
Mercury	0.07
Nickel	7.19
Lead	10.93
Zinc	35.95

2.2.2 Comparison with Sediment Quality Guidelines

Sediment quality guidelines (SQGs) developed by Long et al. (1998) utilise the 'Effects Range Low'/'Effects Range Median' (ERL/ERM) methodology which is founded on a large database of sediment toxicity and benthic community information. They were derived based upon empirical analyses of data compiled from numerous field and laboratory studies, including chemistry data and a variety of different types of biological data for numerous taxa derived from either bioassays of field- collected samples, laboratory toxicity tests of clean sediments spiked with specific toxicants, benthic community analyses, or equilibrium-partitioning models. The ERL/ERM methodology derives SQGs representing, respectively, the 10th and 50th percentiles of the effects dataset and can be derived for heavy metals and individual PAH compounds. This method is adopted by the Centre for Environment, Fisheries and Aquaculture Science (Cefas) in their monitoring of dredged material disposal sites in England (e.g. Bolam *et al.*, 2014).

Adverse biological effects are rarely observed when concentrations are below the ERL; the ERM represents concentrations toward the middle of the effects ranges and above which effects are more frequently observed (Gorham-Test, 1998; Long *et al.*, 1998).

Table 3 presents the results of the sediment analysis, and exceedances of the ERL and ERM are identified using colour-coding. The results are summarised below.

Heavy metals

- No exceedances of the ERM in any samples.
- Arsenic: ERL is marginally exceeded in 6 samples. The highest concentration is 12.5 mg/kg, which is well below the ERM of 70 mg/kg.
- Copper: ERL is exceeded in 5 samples. The highest concentration is 80.7 mg/kg, which is well below the ERM of 270 mg/kg.
- Lead: ERL is exceeded in 2 samples. The highest concentration is 62.9 mg/kg, which is well below the ERM of 218 mg/kg.
- Nickel: ERL is marginally exceeded in 1 sample, at a concentration of 22.6 mg/kg, which is well below the ERM of 52 mg/kg.
- No exceedances of the ERL for cadmium, chromium, mercury or zinc.

PAHs

- No exceedances of the ERM in any samples.
- Acenaphthene: ERL is exceeded in 3 samples. The highest concentration is 40 µg/kg, which is well below the ERM of 500 µg/kg.
- Fluorene: ERL is exceeded in 2 samples. The highest concentration is 43 µg/kg, which is well below the ERM of 540 µg/kg.
- Phenanthrene: ERL is exceeded in 1 sample, at a concentration of 259 µg/kg, which is well below the ERM of 1,500 µg/kg.
- No exceedances of the ERL for the remaining PAHs.

As there are no exceedances of the ERM, and only limited exceedances of the ERL for some heavy metals and PAHs (which are in many cases only marginally exceeded, and in all cases are far closer to the ERL than the ERM), the material to be dredged is not considered to pose a significant risk to the marine environment. As such, the material to be dredged is considered suitable for disposal at sea and use on land. If material is disposed at sea, sampling and testing of material within the hopper will be carried out during the dredging campaign, in accordance with Marine Scotland's requirements.

Parameter	Units (dry weight)	ERL	ERM	Sample number and location									
				CL/1778 079	CL/1778 080	CL/1778 081	CL/1778 082	CL/1778 083	CL/1778 084	CL/1778 085	CL/1778 086	CL/1778 087	CL/1778 088

Table 3 2017 sediment sample analysis: comparison with ERL and ERM

3. SCOPING OF POTENTIAL DISPOSAL OPTIONS

3.1. Introduction

This section describes all potential disposal options for the dredged material. When an option is not considered feasible, the reason is given and it is not taken forward to the assessment stage. Those options which are considered to be practicable are considered in Section 4 of this report.

3.2. Option 1: Landfill

The most common use of dredged material within landfill sites is as capping or restoration material. Material would need to be brought ashore within the existing harbour and dewatered before being transported to trucks and taken to the landfill site by road.

There are no suitable sites in the immediate vicinity of the harbour that could cope with a large quantity of material on an annual basis. The closest operational landfill sites to Aberdeen Harbour are approximately 9 km to the south and 12 km to the north by road from Aberdeen Harbour (SEPA, 2016a). Existing sites must cope with large volumes of domestic and industrial requirements, and marine dredgings on the present scale would place an intolerable burden on these sites. Dredged material is relatively inert, so disposal to landfill is not usually necessary or recommended unless dredged material is significantly contaminated, which it is not in this case (see Section 2.2).

Prior to landfill, dredged material would have to be dried in lagoons before being transported by road to a distant site. Suitable land for drying lagoons is not available within the harbour estate.

Transportation of material from the harbour to the landfill would generate significant vehicle movements on local roads, contributing to congestion and generating air and noise pollution, as well as road safety concerns.

On these grounds this option for disposal has been discounted.

3.3. Option 2: Agriculture Use

The North East of Scotland is a rural farming area with an abundance of good arable land and there is therefore no requirement for a supplement of imported material. The dredged material would have to be de-watered and desalinated to make it suitable for soil conditioning or spreading, and no land is available to locate a drying lagoon. This option for disposal has been discounted.

3.4. Option 3: Reclamation

Dredged material can be suitable for land reclamation and other construction works. The material grade and quality are critical: material suitable for reclamation is generally medium to coarse sands and gravel fractions. As the material to be dredged is variable and cannot easily be dredged according to material type, use in reclamation projects is not considered appropriate. This option for disposal has been discounted.

3.5. Option 4: Beach Recharge

The use of dredged material for beach recharge is a sustainable beneficial use: it generates a purpose for the material that benefits a local amenity. Material is typically deposited direct

from the dredging vessel via a pipeline or by ‘rainbowing’ onto the beach, where it is reprofiled using land-based plant. This option is considered in detail in Section 4.

3.6. *Option 5: Other uses for Dredged Material*

The saline content of the material makes it unsuitable as a construction material. The grading and washing required coupled with the drying and storage previously identified makes this option uneconomical. This disposal option has been discounted.

3.7. *Option 6: Sea Disposal*

The present sea disposal site for dredged material from Aberdeen Harbour (CR110 - shown on Figure 2) is approximately 20 minutes’ sailing time from the harbour. The site is located far enough from the shore and harbour so as not to have any visual or operational effects or impact at the shore line of the harbour. It is a long-established disposal site.

The nature of the dredged material and the proximity of the suitable licensed disposal site makes disposal at sea a viable option which will be considered in detail in Section 4.

3.8. *Summary of options scoping*

The identification of available disposal options concludes that Options 1 (landfill), 2 (agricultural use), 3 (reclamation) and 5 (other uses) are not viable for the reasons described above. The following options will be taken forward to assessment:

- Option 4: Beach recharge
- Option 6: Sea disposal

4. ASSESSMENT OF OPTIONS

In this section, Options 4 and 6 are considered in greater detail. The BPEO assessment comprises three aspects: strategic, environmental and cost considerations.

4.1. *Option 4: Beach Recharge*

4.1.1. Strategic Considerations

Operational Aspects

Beach recharge (sometimes called beach nourishment) requires clean, sandy material. Such material is typically found in the outer part of the entrance channel; the remaining mixed silty material from the berths would be unacceptable (see Appendix 6 showing areas of sand and mixed clays/silts/sands). A volume computation based on the 2017 post-dredge survey versus the pre-dredge survey revealed that just over 20,000 m³ of the 93,610 m³ dredged was likely to be sandy material. For this BPEO the proportion of material that is potentially suitable for beach recharge is estimated at 20%, but this will vary annually.

The material is typically dredged using a trailer suction hopper dredger. However, since the material has to be deposited on an exposed open beach, the dredger could not sail close to the beach and strong pipelines through the breaker zone would be required to deposit sand on the beach. Once ashore, the material would be stockpiled in a bund and recovered and spread during low water.

The sediment transport study completed by HR Wallingford in 1989 (see Appendix 1) concluded that the beach material from Aberdeen Bay moves in a cyclical motion; thus, with this type of motion and the groyne located on the beach there has never been a regular need for beach recharge in the area.

The following points have emerged from recent studies of beach recharge projects:

- 1) Replenishment sand should have a medium grain size 1½ to 2 times that occurring naturally on the beach. A high content of fine particles should be avoided since this will lead to initial instability and rapid loss of the fine fraction.

As described above, the particle size of maintenance dredged material is unlikely to be suitable in this case.

- 2) About 20 to 30% of the bulk replacement volume is normally lost during the process.

As stated in Section 2.1, the overall dredge volume may vary from 100,000 m³ to 200,000 m³ per annum, so the volume of material suitable for beach recharge may vary from 20,000 m³ out of 100,000 m³, to 40,000 m³ out of 200,000 m³. Therefore, with a 20% loss this drops to 16,000 m³ – 32,000 m³.

Availability of Suitable Sites/Facility

In response to the previous marine licence application for disposal of dredged material in 2015, Scottish Natural Heritage suggested that AHB liaise with Aberdeen City Council (ACC) to determine whether they are considering further beach recharge in Aberdeen and whether the quantities of sand would be of use.

In November 2017, AHB contacted Aberdeen City Council (ACC) to enquire whether there were any opportunities for using dredged material for beach recharge. ACC confirmed that they have no plans to do any beach recharge works in Aberdeen in the next 3 years so there would be no potential to use dredged material (see correspondence in Appendix 7). There are no beach recharge sites available within a reasonable sailing distance of Aberdeen.

Analysis of the Coastal Erosion Susceptibility Model, an output of the Dynamic Coast (Coastal Change Assessment) project, reveals that areas of erosion are predicted in the 'Future Look (2050)' condition along the sandy coastline between the Bridge of Don and Newburgh. AHB contacted Aberdeenshire Council in 2015 and again in 2018 to establish any plans for beach recharge; as demonstrated in the correspondence in Appendix 8, there are no projects planned that would make use of dredged material.

General Public Acceptability

The pipework and bunds required to pump the dredged material ashore would create a temporary barrier along the beach. This would prevent the public from accessing parts of the beach in the spring/summer months when the dredging would take place.

Legislative Implications

Standing advice from the Scottish Environment Protection Agency (SEPA) states that waste material, which includes dredged material, deposited above the low water mark is subject to Waste Management Licensing controls regulated by SEPA unless it is subject to a licence issued under Part 4 of the Marine (Scotland) Act 2010, in which case it is excluded from such controls (SEPA, 2016b), provided that it does not constitute a landfill, which is not applicable

to this project. As beach recharge would require a marine licence, it is assumed that a separate Waste Management Licence would not be required.

Section 34 of the Environmental Protection Act 1990 (as amended) makes it a duty to take all measures available as are reasonable in the circumstances to apply the waste hierarchy set out in Article 4(1) of the Waste Directive. The waste hierarchy ranks waste management options according to the best environmental outcome taking into consideration the lifecycle of the material. In its simplest form, the waste hierarchy gives top priority to preventing waste. When waste is created, it gives priority to reuse, then recycling, then other recovery, and last of all disposal (i.e. landfill). The option to reuse the material for beach recharge ranks highly on the waste hierarchy; it negates the need to otherwise dispose of the material.

4.1.2. Environmental Considerations

Safety Implications

A pipeline over a beach could pose a tripping hazard or falling from height hazard and would have to be cordoned off. The construction plant required to spread the material would present a small risk to users of the beach.

Public Health Implications

There is no public health risk given that the dredged material is naturally occurring sands that is suitable for disposal at sea (see Section 2.2).

Pollution/Contamination

There would be little or no risk of pollution or contamination resulting from the inert material.

Amenity/Aesthetic Implications

The temporary stockpiling of the dredged material would not be aesthetically pleasing, but otherwise of little implication. There would be temporary access restrictions on the beach whilst the recharge activity was on-going.

4.1.3. Cost considerations

Estimated annual cost of dredging 100,000 m³ of sand, of which 20,000 m³ is used for beach recharge.

Lag Pipeline	£400,000
Dismantle Pipeline	£100,000
Hire of Plant	£ 50,000
Pumping Costs @ £1/m ³	£ 20,000
Dredger Mobilisation	£ 50,000
Dredge Costs @ £2.50/m ³	<u>£250,000</u>
TOTAL	£870,000

4.2. Option 6: Sea disposal

Dredging and disposal to sea has been carried out at Aberdeen Harbour throughout its history. For the past 80 years at least, the material has been deposited at the same offshore site used solely by the harbour: Aberdeen CR110, as shown on Figure 2.

4.2.1. Strategic considerations

Operational Aspects

The practicalities of disposing of dredged material at the Aberdeen CR110 designated disposal site are straightforward: it is likely that a split hopper barge would be used, which would discharge directly at the disposal site. No preparation of the material is required prior to disposal.

The option to dispose of the material at an offshore site ranks poorly on the waste hierarchy (see Section 4.1.1 for details); however, for various reasons, including waste reduction but also the high cost and the logistical challenges of accommodating a dredger in the harbour, AHB dredges only the volume of material required to maintain the navigation channel and berths at the published depths. Applying for a marine licence to dispose of the maximum volume reduces the risk of breaching the marine licence by exceeding our licensed disposal volume, and/or having to re-apply for a licence to amend the volume.

Availability of Suitable Sites/Facility

The licensed disposal site is available for the acceptance of dredged material and has been used for many years by the harbour.

General Public Acceptability

The disposal site has a long history of use for disposal of dredged material. As there is no requirement for the dredged material to come ashore for onward transportation, there is no associated impact on the local road network.

Local Acceptability

There are no anticipated local acceptability issues associated with the continuation of a long-standing method of disposing of dredged material. AHB has never received a complaint or enquiry from a member of the public regarding the disposal of maintenance dredged material at sea. No known objections have been received from members of the public relating to previous marine licence applications.

Legislative Implications

The existing disposal site Aberdeen CR110 has received dredged material from Aberdeen Harbour for many years. Clause 72 of the Aberdeen Harbour Order (Confirmation) Act 1960 gives Aberdeen Harbour Board powers to dredge provided that the activity is approved by the Scottish Ministers before it is carried on. A marine licence would be required from Marine Scotland to dispose of material at the site.

4.2.2. Environmental considerations

Safety Implications

Disposal to sea would have negligible implications for safety providing that normal navigational and maritime procedures are observed.

Public Health Implications

There are no known threats to public health associated with sea disposal.

Pollution/Contamination Implications

As presented in Section 2.2, the material to be dredged contains isolated elevations above Marine Scotland Revised Action Level 1, but not to an extent that would prevent disposal of the material in the marine environment. The risk of pollution/contamination is very low.

Interference with other Legitimate Activities

There is the potential for interference between the dredging vessel and other users of the sea (e.g. fishing vessels); however, this can be managed through compliance with harbour byelaws and good communication between the dredging crew, AHB and other users.

Amenity/Aesthetic Implications

There are no amenity or aesthetic implications of disposing of material at a designated offshore site.

4.2.3. Cost Considerations

Estimated cost of sea disposal of 100,000m³

Dredger Mobilisation	£50,000
Dredger Costs @ £2.50/m ³	<u>£250,000</u>
TOTAL	£300,000

5. BEST PRACTICABLE ENVIRONMENTAL OPTION

Table 2 summarises the BPEO assessment presented in Section 4 by allocating a relative score of 0 or 1 for each option in each of the three areas considered, where a score of 0 is the least favourable option.

	Option 4: Beach recharge	Option 6: Sea disposal
Strategic considerations	0	1
Environmental considerations	1	0
Cost considerations	0	1
Total	1	2

Table 2: Relative scoring of BPEO assessment

It is concluded that the best practicable environmental option is sea disposal. Whilst beach recharge is a more environmentally sustainable option as it uses a material that would otherwise be disposed of, there are no known suitable beach recharge schemes, and it is a significantly more expensive option.

ABERDEEN HARBOUR
An Investigation of Wave Effects
in the Harbour Entrance

Report No EX 1475
August 1986

Extract from Report (Ex 1475)

Summary and Recommendations

This preliminary study has investigated the siltation of the navigation channel at Aberdeen, in particular reviewing the link between infill and wave action. Analysis was based on the recorded changes of a single cross-section, because of the time and cost restraints of the study, but it is felt that the observed behaviour of that section gives a good indication of the channel infill as a whole.

Apart from some infill soon after maintenance dredging, which is tentatively attributed to slumping of the channel side-slopes, the majority of siltation seems to travel into the channel from the north. In addition, periods of rapid infill appear to be strongly linked with heavy wave activity.

However, the siltation of the channel cannot be explained by wave effects alone. Calculations of along shore drift for the beaches north of the harbour indicate a strong sediment transport from south to north, and this is confirmed both by the spit and the mouth of the Rive Don, and the reported build-up of material on the southern side of groynes along this frontage. This direction of sediment transport therefore opposes the observed direction causing infill in the channel.

Although this may be partially explained by a long-term onshore movement of sand from deep water, a more satisfactory explanation involves the tidal currents.

Because of the generally southward set of the tidal currents from about 4¼ hours before to 1¼ hours after high-water, it seems likely that sand on the sea bed is stirred during heavy wave action by the oscillating currents, and then advected into the harbour entrance by the admittedly rather weak tidal currents. Once reaching the channel, the material is deposited in the area sheltered by the breakwaters. On the ebb tide, when at lower water levels this shelter is increased, the wave action cannot stir the sediment quite so vigorously. In addition, the ebb current has to flow up the channel side-slope (near the sea bed) and is therefore less able to flush material out of the channel entrance. This wave-stirring/tidal advection process will occur whatever the wave direction, and will also produce the observed infill pattern in the channel.

In addition to this combined tidal current/wave action mechanism, there is also the infill due to wave action alone when the wind direction is from north of east. Although these conditions occur much more infrequently than waves from the south-east sector, they will be much more efficient, hour for hour, in causing channel infill.

Sediment sampling results 2017

PR Details

Total amount to be dredged (wet tonnes) 295,500

Explanatory Notes:

The values entered for each determinand should be an average wet weight concentration from all the samples representing the material to be disposed to sea. They should be entered in the units stated in the Unit of measurement column in the table below.
Results above Action Level 1 will be highlighted in blue and above Action Level 2 in red.

Average for the total dredge area:

Laboratory Details

Explanatory Notes
Please complete a separate worksheet for each laboratory (e.g. complete 'Laboratory_1' worksheet for 1 laboratory and complete 'Laboratory_2' worksheet for a second laboratory). If there are more than 3 laboratories then please contact MS-LOT.

Laboratory 1 Details
Laboratory name: Environmental Scientific Group Limited
Year: 2017

LabRefMat	Q1	Does the laboratory carrying out the analyses undertake the analysis of blank samples and laboratory reference materials with each batch of samples of waste and other material dumped in the maritime area that is analysed by that laboratory?	Yes
CompAnal	Q2	Does the laboratory carrying out the analyses undertake periodic comparative analysis of laboratory reference materials and certified reference materials?	Yes
QAQC	Q3	Does the laboratory carrying out the analyses undertake the compilation of quality control charts based upon the data resulting from the analyses of the laboratory reference materials and certified reference materials, and the use of those quality control charts to monitor analytical performance in relation to all samples of dumped wastes or other materials?	Yes
InterlabCaleb	Q4	Does the laboratory carrying out the analyses undertake periodic participation in interlaboratory comparison exercises, including, where possible, international comparison exercises?	Yes
InternatCaleb	Q5	Does the laboratory carrying out the analyses undertake periodic participation in national and, where possible, international laboratory proficiency schemes?	Yes
SpikedSamples	Q6	If the answer to questions 4 or 5 is 'Yes' then does the laboratory analyse samples of substances which are provided by the organisers of the scheme?	Yes
BlindSamples	Q7	If the answer to questions 4 or 5 is 'Yes' then does the laboratory confirm that the composition of those samples is not disclosed in advance?	Yes
Ranking	Q8	If the answer to questions 4 or 5 is 'Yes' then does the laboratory confirm that the results of the scheme for each participating laboratory are made available to all participating laboratories?	Yes
FracAnal	Q9	Enter the size fraction that is analysed i.e. Whole or less than 63µm etc.	<63µm(metals)
GranMeth	Q10	PSA method	NMBAQC
OCMeth	Q11	Organic Carbon method	carbonate removal and sulfurous acid/combustion at 800°C/ND R,
MetExtrType	Q12	Method of extraction used for metal analysis	Aquaregia
MethOfDetMetals	Q13	Method of detection used for metal analysis	ICP-MS
PAHExtrType	Q14	Method of extraction used for poly aromatic hydrocarbon analysis	Methanol/DCM solvent extraction with silica clean up and copper clean up stages
MethOfDetPAH	Q15	Method of detection used for poly aromatic hydrocarbons analysis	GCMS
OHExtrType	Q16	Method of extraction used for organohalogens inc PCBs, pesticides, flame retardants etc analysis	Ultrasonic acetone/hexane solvent extraction
MethOfDetOH	Q17	Method of detection used for organohalogens inc PCBs, pesticides, flame retardants etc analysis	GCMSMS
OTExtrType	Q18	Method of extraction used for organotin analysis	derivatisation and solvent extraction
MethOfDetOT	Q19	Method of detection used for organotin analysis	GCMS

Methods

Methods
Heavy metals by ICP-MS
ICES 7 Polychlorinated Biphenyls (PCBs) by GC-MS
Brominated Flame Retardants (PBDEs) by GC-MS
Total Petroleum Hydrocarbons by GC-FID
US EPA 16 Polycyclic Aromatic Hydrocarbons (PAHs) by GC-MS
Tributyltins (TBT) by GC-MS
Total Organic Carbon by Dumas Combustion Elemental Analyser
Particle Size by Laser Diffraction

Analytical Procedures

Heavy metals by ICP-MS

The samples were air dried at 30°C and sieved to <63µm. This fraction was subjected to a strong acid digestion and the digests analysed for selected heavy metals by ICP-MS.

Tributyltins by GC-MS

The samples were air dried at 30°C and sieved to <63µm. This fraction was extracted, the extract derivatised and the TBT derivatives analysed by GC-MS in the single ion mode. TBTs were quantified with reference to an added internal standard.

US EPA 16 PAHs

The samples were freeze dried and sieved to <2mm. This fraction was extracted and the extract analysed for the US EPA 16 PAHs by GC-MS in the single ion mode. PAHs were quantified with reference to a series of 7 deuterated PAH internal standards.

ICES 7 PCBs

The samples were freeze dried and sieved to <2mm. This fraction was extracted and the extract analysed for the ICES 7 PCBs by GC-MS in the single ion mode. PCB congeners were quantified with reference to an added internal standard.

Brominated Flame Retardants (PBDEs)

The samples were freeze dried and sieved to <2mm. This fraction was extracted and the extract analysed for the PBDEs by GC-MS in the single ion mode. PBDE congeners were quantified with reference to an added internal standard.

Total Petroleum Hydrocarbons

The as received samples were extracted and the extracts treated with Florisil. The extracts were then analysed for total petroleum hydrocarbons using GC-FID. The hydrocarbons were quantified by comparison with an added internal standard.

Particle Size

Material <2mm was suspended in a dispersant and the particle size distribution measured using a Malvern laser diffractometer.

Total Organic Carbon

The dried material was pre-treated with acid to remove inorganic carbon and the remaining carbon measured using a Dumas combustion elemental analyser.

9/ABZ/14	1165423	6

Note:

Samples will be stored for a period of eight weeks following completion of analysis and acceptance of analytical report(s) at no extra cost after which samples will be disposed of unless a specific instruction is given (with the sample analysis request/order) to store the sample beyond this period. Extended storage charges will apply.

Sent: 13 November 2017 11:13
To: [Redacted]
Subject: RE: Beach recharge in Aberdeen

[Redacted]

Thanks for your message. Unfortunately we have no plans to do any beach recharge works in Aberdeen in the next 3 years so there would be no potential to use dredged material. If there are any changes to these plans I will let you know.

Regards,

[Redacted]

Dear [Redacted]

[Redacted] has passed me your contact details - a few months ago I spoke to [Redacted] about the potential for using dredged material within the Aberdeen area – see email exchange below for details.

Are you able to confirm whether any beach recharge is planned/likely over the next 3 years?

Many thanks,
[Redacted]

[Redacted]

Sorry for taking so long to get back to you on this, my understanding is the Aberdeen City Council is looking at a beach recharge scheme but that this would be out with the timeframe you set out. The best person to talk to for more detail is [Redacted] berdeencity.gov.uk).

I am hoping to meet him to discuss these proposals and will let you know the outcome of these discussions.

All the best

Subject: Beach recharge in Aberdeen

Dear [Redacted]

Good to talk to you just now. As discussed, we're preparing the marine licence renewal for our annual maintenance dredging campaign. We've been asked to explore whether there are any opportunities for using the dredged material for beach recharge/nourishment within the Aberdeen area. Could you please let me know whether any projects are planned over the next 3 years (the duration of the licence)?

The material is typically silts and fine sands so may not be suitable for recharge in any event; however, if there are projects in the pipeline (excuse the pun...) then we can discuss further whether the material is suitable.

I'll be out of the office for the next few days so if you have any questions please feel free to email or call my mobile.

Many thanks,
[Redacted]

Attachments: Keith Young re Aberdeen harbour dredge material use.doc

Dear [Redacted]

Further to our telephone conversation earlier today, I would confirm that we have no change in opinion from that stated in our previous letter dated 15th July 2015. We currently have no use for any dredged material.

Thank you for contacting us again regarding this matter.

Regards,

Subject: Aberdeen Harbour Board - dredged material

Dear [Redacted]

Good to talk to you just now. As discussed, I'd be grateful if you could confirm by return of email that Aberdeenshire Council's position has not changed since [Redacted] attached letter dated 15 July 2015 – i.e. you do not have any current plans that would make use of dredged material.

Many thanks,

Dear [Redacted]

Coast Protection and Beach Recharge

Thank you for your letter dated 11 June 2015 regarding the potential use of dredged sand and silt from various activities taking place in Aberdeen Harbour.

I can confirm that we do not have any current plans which would make use of dredge material. However, there may be opportunities for mutually convenient options as we investigate and develop future flooding and coast protection and schemes along the Aberdeenshire coast.

Please do not hesitate to contact me should you wish to discuss this any further.

Yours sincerely
