## 1. Introduction

APEM Ltd has been commissioned to undertake a survey of the subtidal benthic ecological habitats and species present in Tarbert Harbour on the Isle of Harris, on behalf of Aspect Land & Hydrographic Surveys (ALHS) and Caledonian Maritime Assets Ltd (CMAL). Tarbert Ferry Terminal is located in a sheltered bay on the east coast of the Isle of Harris, and provides a direct ferry link to the Isle of Skye. This survey will provide data to enable an Environmental Impact Assessment (EIA) of proposed improvements to Tarbert Ferry Terminal (the proposed development) to be conducted.

In accordance with Saunders et al. (2011), this survey will gather information for the EIA process by identifying whether there are any benthic habitats or species of note present (i.e. priority, rare, protected or invasive) and identify the spatial distribution and abundance of these species in the area. This will allow an assessment to be conducted of how these habitats or species will be affected by the proposed development and the significance or implications of any damage or loss incurred, which is beyond the scope of this survey report but it is understood will be conducted by CMAL and Affric Ltd. for the proposed development.

The aim of the survey was to collect underwater video and grab samples to provide data on the subtidal benthic ecology habitats, community composition and sediment composition within the area of the proposed development, to enable the subtidal benthic ecology of Tarbert Harbour to be characterised, and the effect of the improvements to Tarbert Ferry Terminal to be assessed.

This report provides a full description of the survey and analysis conducted by APEM Ltd. to obtain the data for characterisation, and the complete datasets for use along with a summary description of the datasets obtained.

## 2. Methodology

### 2.1 Field survey

All survey permissions, including a Marine Licence Exemption and Crown Estate Consent, were obtained by CMAL prior to the survey commencing.

The survey operations were conducted in December 2017 from the vessel Remote Sensor, operated by ALHS and shown in Figure 2-1 below. Remote Sensor is an 8.4m catamaran survey vessel (MCA Cat III) with high manoeuvrability, which was an essential requirement due to the constrained characteristics of the survey area.

The survey was overseen by an attending marine ecologist from Affric Ltd., on behalf of CMAL, who conducted quality assurance during the survey and specified grab sample locations whilst on-site using the footage from the underwater video.

The methodologies for collection of the underwater video and grab samples are provided in Sections 2.1.1 and 2.1.2 below respectively.

**Figure 2-1 The survey vessel Remote Sensor used for the Tarbert Ferry Terminal subtidal benthic ecology surveys**

#### 2.1.1 Underwater video survey

The underwater video survey was conducted on the 12<sup>th</sup> December 2017 in daylight hours.

Although not yet operational at the time of the survey, a new floating pontoon had been installed shortly prior to the survey. The pontoon anchorage and other entanglement hazards likely to be present in the area as a result of the new pontoon were considered in the survey design phase, leading to the requirement for use of a Remote Operated Vehicle (ROV) for the underwater video survey, rather than a Drop Down Video (DDV) camera.

APEM's methodology was discussed with Scottish Natural Heritage (SNH), who confirmed that they were content with the use of a video system, and that there was not a requirement to use a camera system capable of taking independent still photographs. Instead, SNH requested pauses in the transects to allow capture of the seabed:

*"The proposed benthic baseline monitoring grid at Tarbert looks suitable and I'd be content that the transects are taken between the months you have indicated - please ensure there is sufficient lighting and the operator makes frequent 'pauses' in the footage to allow the camera to capture a 'still' of the seabed (approximately every 20-30 metres). The pauses should be long enough to let any sediment plume disperse and allow the camera focus (if on auto) to perform. Should the survey discover any sensitive habitat or species of conservation interest it'd be helpful to chart its full character and extent by adapting the methodology at the time of survey. This would avoid any possible requirement to re-survey should anything of conservation importance be found (unlikely as that may be)."*

APEM was provided with a specification of transect routes for the underwater video survey, shown in Figure 2-2, which had been discussed and agreed with Scottish Natural Heritage (SNH) by CMAL and Affric Ltd. prior to the pontoon being constructed. APEM was therefore allowed dispensation to adapt the transect routes whilst on-site to avoid the pontoon and pontoon anchorage if required due to accessibility or entanglement risk, whilst still maintaining a series of transects across the site (approximately south west to north east) and a single transect down the site and seabed contours (approximately south east to north west).

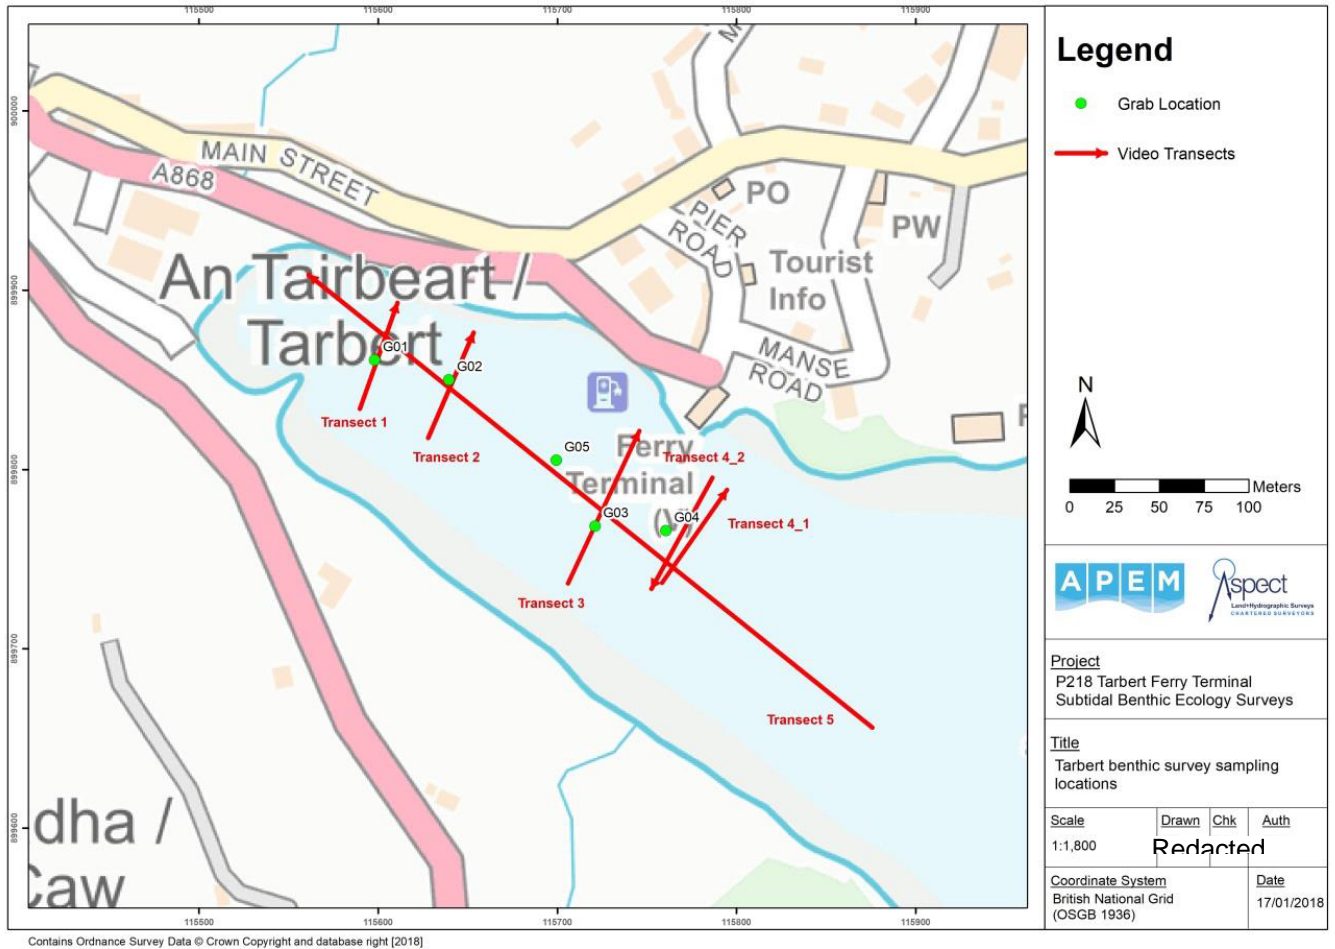

**Figure 2-2 Tarbert Ferry Terminal transect location specification for underwater video survey**

The underwater video transects were completed using Subsea Technology and Rental's (STR) "BlueROV2", a small hand-launch 6-thruster ROV with a high-definition 1080p resolution camera. The ROV was flown by a trained ROV pilot provided by STR, and the transect routes flown are shown in Figure 2-3, with grid coordinates of the start and end points of each transect given in Table 2-1. Whilst APEM had to make small adjustments to the transect routes to avoid entanglement, these were limited given the choice of a manoeuvrable vessel and ROV system, and so the transects were obtained in a similar layout to the required specification.

Although most of the underwater video transects were conducted from south west to north east, Transect 4 was repeated in the opposite direction due to some bottom low visibility on the first attempt. The second attempt collected enough data to integrate with the first passage.

**Figure 2-3 Location of the underwater video transect routes, with arrows indicating the transect direction flow, and location of the grab sampling stations.**

**Table 2-1 Start and end point coordinates for each underwater video transect. Coordinates are presented in the Ordnance Survey/British National Grid Project Coordinate System format.**

Underwater video transect	Start coordinates		End coordinates	
	X	Y	X	Y
Transect 1	115589	899833	115611	899893
Transect 2	115628	899818	115653	899876
Transect 3	115706	899736	115746	899821
Transect 4_1 (original)	115758	899737	115795	899789
Transect 4_2 (repeated)	115787	899785	115752	899733
Transect 5	115788	899656	115561	899908

### 2.1.2 Grab sampling survey

The subtidal grab sampling survey was conducted on the 13<sup>th</sup> December 2017 in daylight hours.

No specification for the number or location of the grab sampling stations was provided by CMAL or Affric Ltd. prior to the survey, as the grab sampling stations were to be sited by Affric Ltd.'s attending marine ecologist based on the findings of the underwater video survey conducted on 12<sup>th</sup> December 2017.

During the survey design phase, it was specified by CMAL and Affric Ltd. that there was no requirement to obtain replicate grab samples for macrobenthic analysis. It was stated that the purpose of the survey was to characterise the subtidal benthic ecology habitats, community composition and PSD to assess the habitat and species types that may be lost as a result of the proposed development. As the habitats surveyed will be lost under the footprint of the proposed development they will be subject to a direct effect, and so there is no requirement to obtain replicate grab samples for compilation of a baseline dataset upon which a future monitoring programme for indirect effects could be defined. This also meant that there was no requirement to conduct formal *a priori* statistical power analysis to define the number of samples required by the survey, as the data collected prior to construction would not be quantitatively compared to any data collected post-construction and as such the statistical power of the survey design was not a relevant consideration.

Following review of the underwater video survey outputs, APEM proposed five grab sampling station locations within Tarbert Harbour that were agreed with Affric Ltd., and these are shown on Figure 2-3 with coordinates provided in Table 2-2. At each of these stations, grab samples were collected for macrobenthic and Particle Size Distribution (PSD) analysis using a 0.1 m<sup>2</sup> Day Grab. A single grab sample was obtained for macrobenthic analysis, and a further separate single grab sample was obtained for PSD analysis as close as possible to the original macrobenthic grab sample location.

**Table 2-2 Coordinates for each grab sample station. Coordinates are presented in the Ordnance Survey/British National Grid Project Coordinate System format.**

Grab sample station	Site code	X	Y
Station 1	G01	115598	899861
Station 2	G02	115640	899850
Station 3	G03	115721	899768
Station 4	G04	115761	899766
Station 5	G05	115700	899805

Whilst conducting the grab sampling, a minimum sediment volume limit of 5 litres was defined as an acceptable size for a grab sample to be considered successful. If this minimum volume was not obtained then a further two attempts were to be made at the same location, followed by three attempts at a different location at least 50m from the original target. At station 3, the first PSD grab attempt was rejected due to a stone blocking the grab jaws. The second attempt retrieved a suitable size sample (>7l).

For each grab attempt the following information was recorded on the survey log-sheet:

- Survey name, location and project code;
- Survey Date;
- Survey Team staff;
- Site information including: site/replicate, sample position (lat/lon; WGS84), collection time, water depth, weather conditions;
- Sampling equipment including sieve mesh size;
- Salinity for later use in the WFD IQI calculation
- Sample description, including sediment description, grab depth in cm, volume, type, profile, concretions, surface features, burrows, algae, colour and colour changes, smell, etc.;

- Any obvious or notable (e.g. Annex 2 species) taxa observed;
- Notes (e.g. anoxia, anthropogenic debris, any problems encountered, etc.);
- Photograph of the unsieved sample (an example is presented in Figure 2-4 below).

**Figure 2-4 Unsieved grab sample from Station 4 in Tarbert Harbour.**

Biological samples were sieved on board through a 1.0mm sieve as is standard for subtidal surveys in marine conditions. All material retained on the sieves was fixed with 4% buffered formaldehyde solution in seawater and stored in sealed crates.

## **2.2 Sample analysis**

### **2.2.1 Macrobenthic analysis of grab samples**

Samples were processed according to APEM's in-house Standard Operating Procedures (SOP's) and in full compliance with North East Atlantic Marine Biological Analytical Quality Control Scheme (NMBAQC) guidance (Worsfold and Hall, 2010). To standardise the sizes of organisms and improve sorting efficiency, samples were sieved through a stack of sieves of 4.0, 2.0 and 1.0 mm meshes in a fume cupboard following UKTAG guidance for benthic invertebrate sample analysis for coastal waters (WFD-UKTAG, 2014). All biota retained in the sieves were then extracted under low power microscopes, identified and enumerated, where applicable.

Taxa were identified to the lowest possible practicable taxonomic level using the appropriate taxonomic literature. For certain taxonomic groups (e.g. nemerteans and, nematodes), higher taxonomic levels were used due to the widely acknowledged lack of appropriate identification tools for these groups. The NMBAQC Scheme has produced a Taxonomic Discrimination Protocol (TDP) (Worsfold and Hall 2010) which gives guidance on the most appropriate level to which different marine taxa should be identified, and this guidance was adhered to for the laboratory analysis. Where required, specimens were also compared with material maintained within the laboratory reference collection. Nomenclature followed the World Register of Marine Species (WoRMS), except where more recent revisions were known to supersede WoRMS.

At least one example of each taxon recorded from the surveys was set aside for inclusion in APEM's in-house reference collection. This collection acts as a permanent record of the biota recorded.

### 2.2.2 PSD analysis of grab samples

PSD analysis was performed in accordance with NMBAQC Scheme best practice guidance for PSA for supporting biological analysis (Mason, 2016). A combination of dry sieving and laser diffraction was used due to the range of particle sizes present in the samples.

The PSA data were entered into GRADISTAT (Blott and Pye, 2001) to produce sediment classifications, following Folk (1954) (Figure 2-5). Summary statistics were also calculated including mean particle size, sorting, skewness and kurtosis (following Blott and Pye, 2001).

Figure 2-5 Folk sediment classification pyramid (Folk, 1954).

### 2.2.3 Imagery analysis of underwater video capture

The underwater video was analysed by an experienced marine benthic taxonomist and image analyst to provide habitat/biotope extent and transition data and enable the identification of any small-scale habitats outside the subtidal grab sampling target habitats (such as rock outcrops).. The video captures for each transect were re-played in the laboratory and the biotopes and notable taxa along each transect identified and recorded.

The timing of the transitions between each habitat along the transects in the underwater video were also noted, and these were then related to the ROV and vessel position within the survey logs to identify the position of habitat transitions.

### 3. Results

#### 3.1 Macrobenthic analysis data

The full suite of enumerated macrobenthic data from each grab sample is provided in Appendix 1. A summary of the prevailing conditions at the time of each macrobenthic grab sample is provided in Table 3-1 below, and the biotopes assigned to each grab sample are provided in Table 3-2. The most abundant species was the Polychaete *Lumbrineris cingulata* agg. with more than 300 individuals across 5 samples and an abundance peak of more than 160 individuals in Station 3. The most abundant Mollusc was the Gastropod *Philine quadripartita* with 82 individuals in Station 2.

**Table 3-1 Prevailing water depth and salinity conditions at the time of collection of each macrobenthic grab sample**

Grab sample station	Collection time	Water depth (m)	Volume (l)	Salinity (ppm)
Station 1	10:06	0.7	10	35.66
Station 2	13:05	1.5	9.8	35.94
Station 3	12:19	4.2	10	35.96
Station 4	11:35	5.2	10	35.48
Station 5	13:46	3	7	35.67

**Table 3-2 Biotopes assigned to macrobenthic grab samples**

Grab sample station	Biotope	Description
Station 1	SS.SMu.ISaMu	Infralittoral sandy mud
Station 2	SS.SMu.IFiMu.PhiVir	<i>Philine aperta</i> and <i>Virgularia mirabilis</i> in soft stable infralittoral mud
Station 3	SS.SCS.CCS.MedLumVen	<i>Mediomastus fragilis</i> , <i>Lumbrineris</i> spp. and venerid bivalves in circalittoral coarse sand or gravel
Station 4	SS.SCS.CCS.MedLumVen	<i>Mediomastus fragilis</i> , <i>Lumbrineris</i> spp. and venerid bivalves in circalittoral coarse sand or gravel
Station 5	SS.SCS.CCS.MedLumVen	<i>Mediomastus fragilis</i> , <i>Lumbrineris</i> spp. and venerid bivalves in circalittoral coarse sand or gravel

#### 3.2 PSD analysis data

The full suite of PSD analysis data from each grab sample is provided in Appendix 2. A summary of the prevailing conditions at the time of each PSD grab sample is provided in Table 3-3 below and the Folk (1954) classifications provided in Table 3-4. Finally, histograms of particle size classifications are presented in Figure 3-1 for each PSD grab sample.

**Table 3-3 Prevailing water depth and salinity conditions at the time of collection of each PSD grab sample**

Grab sample station	Time	Water depth (m)	Volume (l)	Salinity (ppm)
Station 1	10:37	0.7	10	35.66
Station 2	14:16	1.5	10	35.94
Station 3	12:55	4.2	7	35.96
Station 4	12:10	5.3	10	35.48
Station 5	14:07	3	9.8	35.67

**Table 3-4 Visual descriptions and Folk (1954) classifications of PSD grab samples**

Grab sample station	Visual description of >1 mm fraction	Folk (1954) classification
Station 1	Slag/cinders, shell and organics including peat	Gravelly Mud
Station 2	Very minor shell	Slightly Gravelly Sandy Mud
Station 3	Degraded shell, gravel/slag	Muddy Gravel
Station 4	Largely shell	Gravelly Mud
Station 5	Largely shell	Gravelly Mud

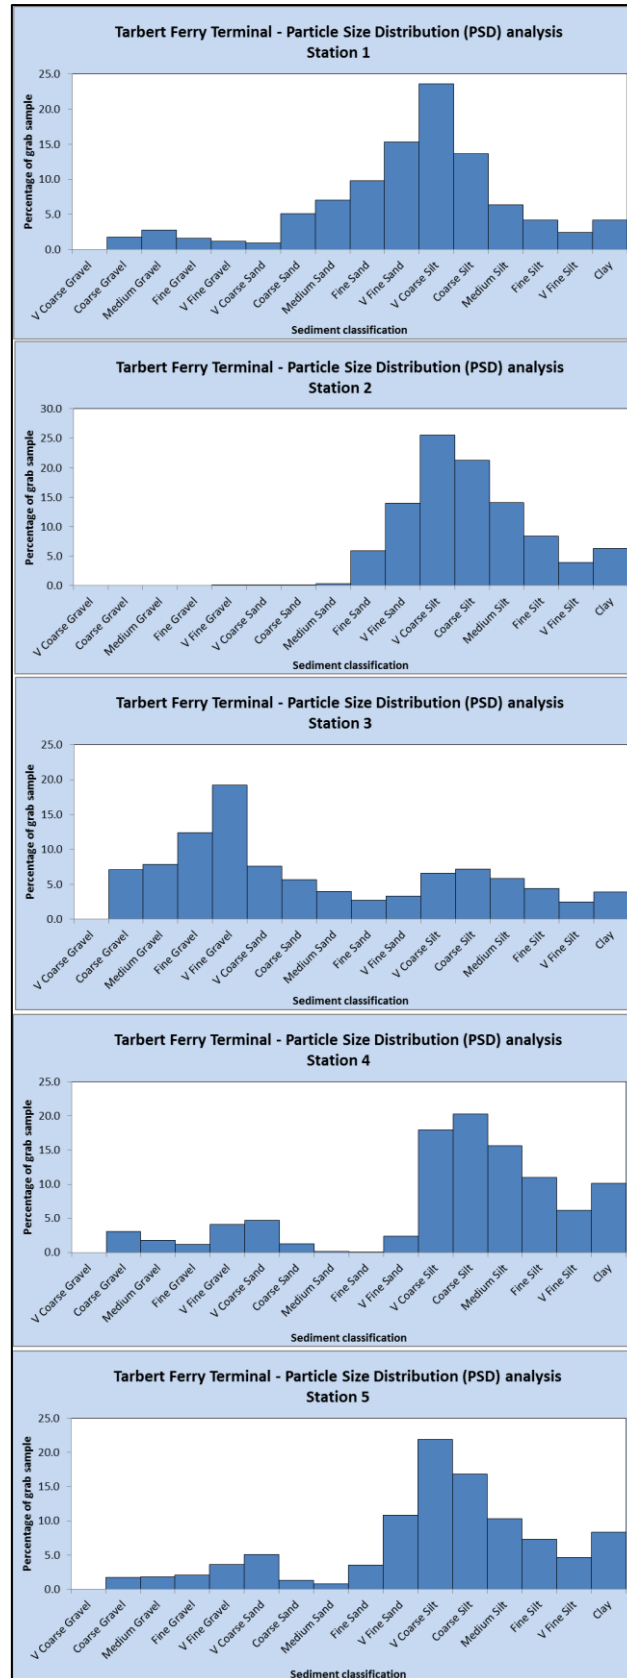

Figure 3-1 Sediment classification distribution graphs for each sample station

### 3.3 Underwater video data

The full suite of habitat classification data for each transect is provided in Appendix 3. The biotopes found to be present in Tarbert Harbour, with example images of each biotope from the underwater video survey, are provided in Figures 3-2, 3-3 and 3-4. The biotopes identified by the underwater video imagery have been mapped along each of the transect routes in Figure 3-5.

Figure 3-2 SS.SMu.IFiMu – Infralittoral fine mud

Figure 3-3 SS.SMx – Sublittoral mixed sediment

Figure 3-4 LR.LLR.F.Fser.X – *Fucus serratus* on full salinity lower eu-littoral mixed substrata

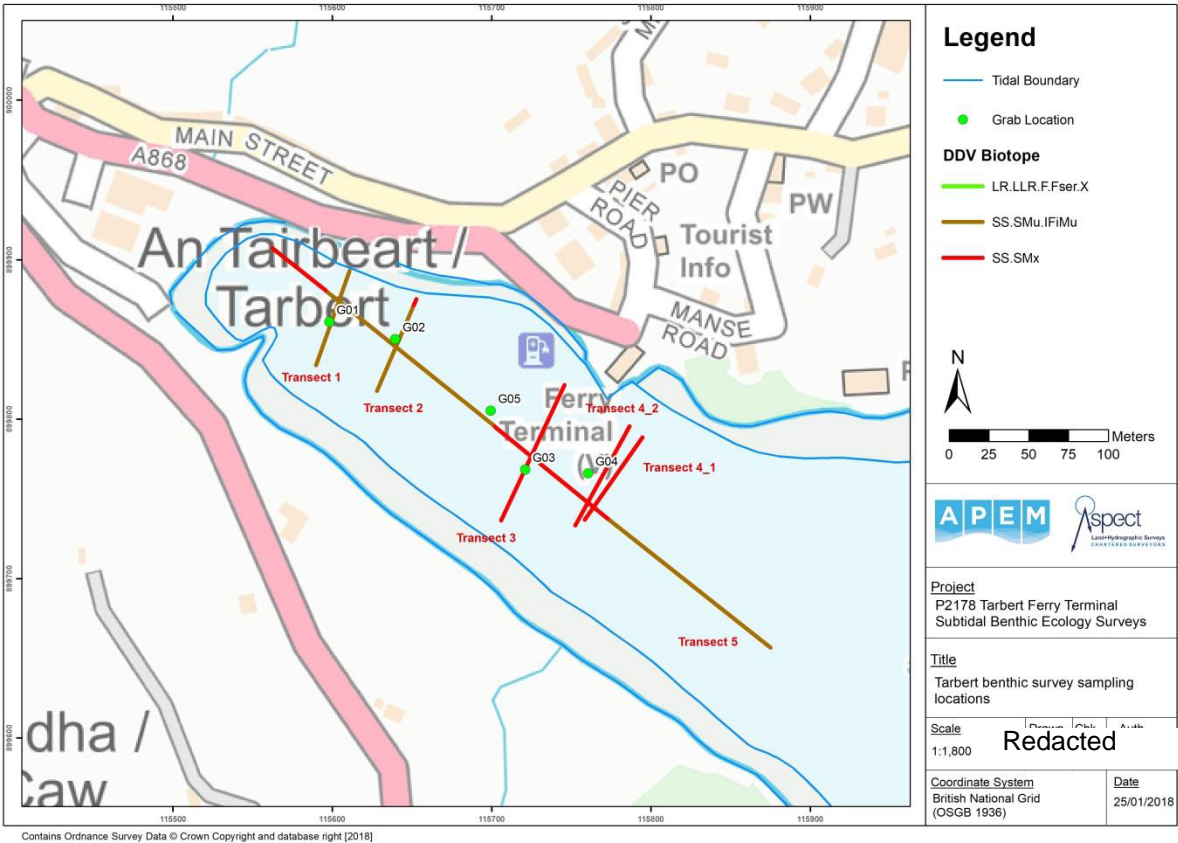

Figure 3-5 Transect routes with mapped biotopes overlaid

### 3.4 Tarbert Harbour biotope mapping

The macrobenthic count data, PSA data and underwater video biotope classification data has been compiled to allocate biotopes to each point along the underwater video transects and at the grab sample stations. Biotopes were allocated following JNCC's National Marine Habitat Classification for Britain and Ireland: Version 04.05 (Connor *et al.* 2004). EUNIS codes corresponding to each biotope have also been provided (JNCC 2010, Parry 2015).

As the survey coverage across Tarbert Harbour has transects running across the harbour and down the full length of the shore and at various depths, it has been possible to extrapolate between the known biotopes along the transects to provide a more complete biotope map of the harbour. This plan is shown in Figure 3-6. It is acknowledged that this is an extrapolation of the known data and so the biotope assignment away from the transects and grab sample locations is with a lower level of confidence to the biotope assignment at the grab sample stations and transects.

The biotope map presented in Figure 3-6 is an interpretive map based on an extrapolation of the raw data collected in the grab samples and along the underwater video transects, to delineate approximate habitat biotope boundaries within Tarbert Harbour. Following the approach set out by Saunders *et al.* (2011) the confidence in this biotope map would be enhanced by conducting a geophysical survey of the harbour to allow the grab sample point data and underwater video line data to act as reference points for the habitats in the rest of the harbour defined using the geophysical survey.

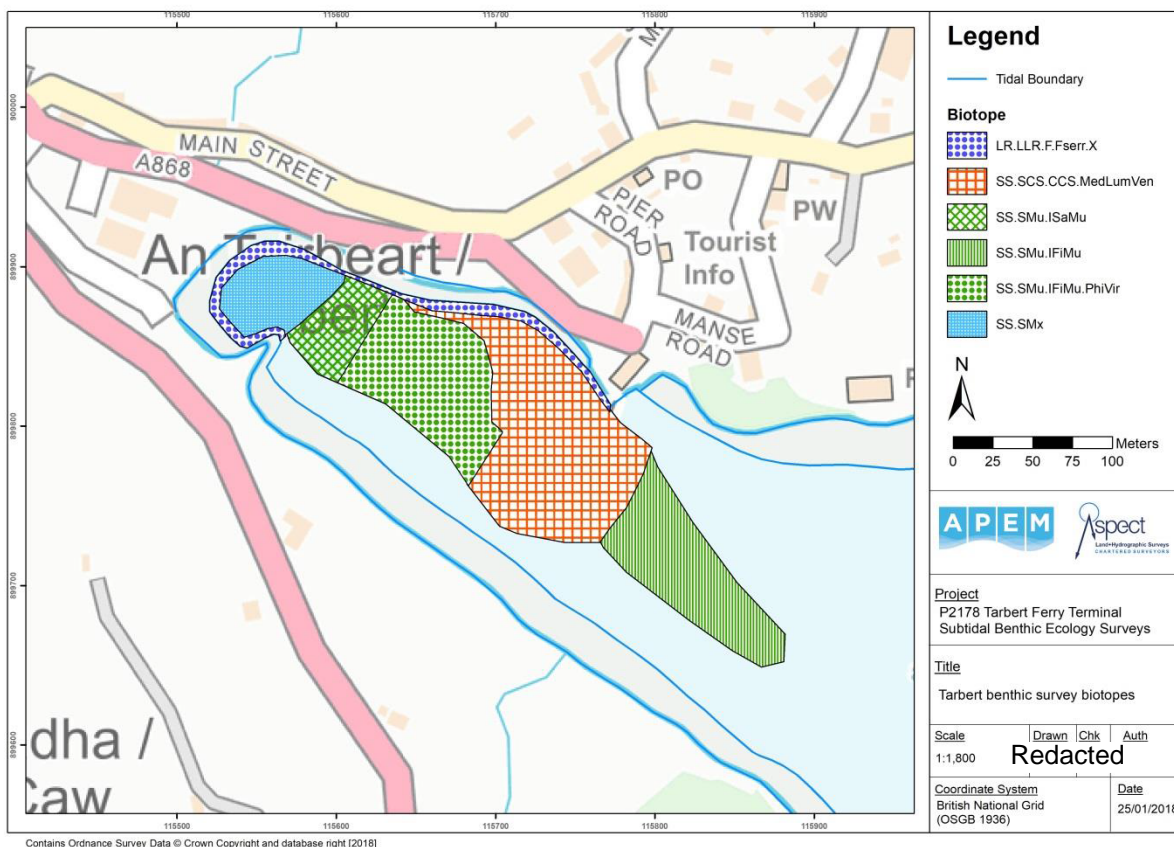

Figure 3-6 Tarbert Harbour mapped subtidal benthic biotopes

## 1. Introduction

APEM Ltd has been commissioned to undertake a further survey of the subtidal benthic ecological habitats and species present in Tarbert Harbour on the Isle of Harris, on behalf of Aspect Land & Hydrographic Surveys (ALHS) and Caledonian Maritime Assets Ltd (CMAL). This survey is of an area to the east of the original survey conducted by APEM in December 2017 (APEM, 2018). Tarbert Ferry Terminal is located in a sheltered bay on the east coast of the Isle of Harris, and provides a direct ferry link to the Isle of Skye. The aim of this survey is to provide data to enable an Environmental Impact Assessment (EIA) of proposed improvements to Tarbert harbour to be conducted.

In accordance with Saunders et al. (2011), this survey will gather information for the EIA process by identifying whether there are any benthic habitats or species of note present (i.e. priority, rare, protected or invasive) and identify the spatial distribution and abundance of these species in the area. This will allow an assessment to be conducted of how these habitats or species will be affected by the proposed development and the significance or implications of any damage or loss incurred, which is beyond the scope of this survey report but it is understood will be conducted by CMAL and Affric Ltd. for the proposed development.

The aim of the survey was to collect underwater video and grab samples to provide data on the subtidal benthic ecology habitats and community composition within the area of the proposed development, to enable the subtidal benthic ecology of Tarbert Harbour to be characterised, and the effect of the improvements to Tarbert Ferry Terminal to be assessed.

This report provides a full description of the survey and analysis conducted by APEM Ltd. to obtain the data for characterisation, and the complete datasets for use along with a summary description of the datasets obtained.

## 2. Methodology

### 2.1 Field survey

All survey permissions, including a Marine Licence Exemption and Crown Estate Consent, were obtained by CMAL prior to the survey commencing.

The survey operations were conducted in April 2018 from the vessel Remote Sensor, operated by ALHS and shown in Figure 2-1 below. Remote Sensor is an 8.4m catamaran survey vessel (MCA Cat III) with high manoeuvrability.

The survey was overseen by an attending marine ecologist from Affric Ltd., on behalf of CMAL, who conducted quality assurance during the survey and specified grab sample locations whilst on-site using the footage from the underwater video.

The methodologies for collection of the underwater video and grab samples are provided in Sections 2.1.1 and 2.1.2 below respectively.

**Figure 2-1** The survey vessel Remote Sensor used for the Tarbert Ferry Terminal subtidal benthic ecology re-visit survey (Photo from APEM's survey at Tarbert Ferry Terminal in April 2018)

#### 2.1.1 Underwater video survey

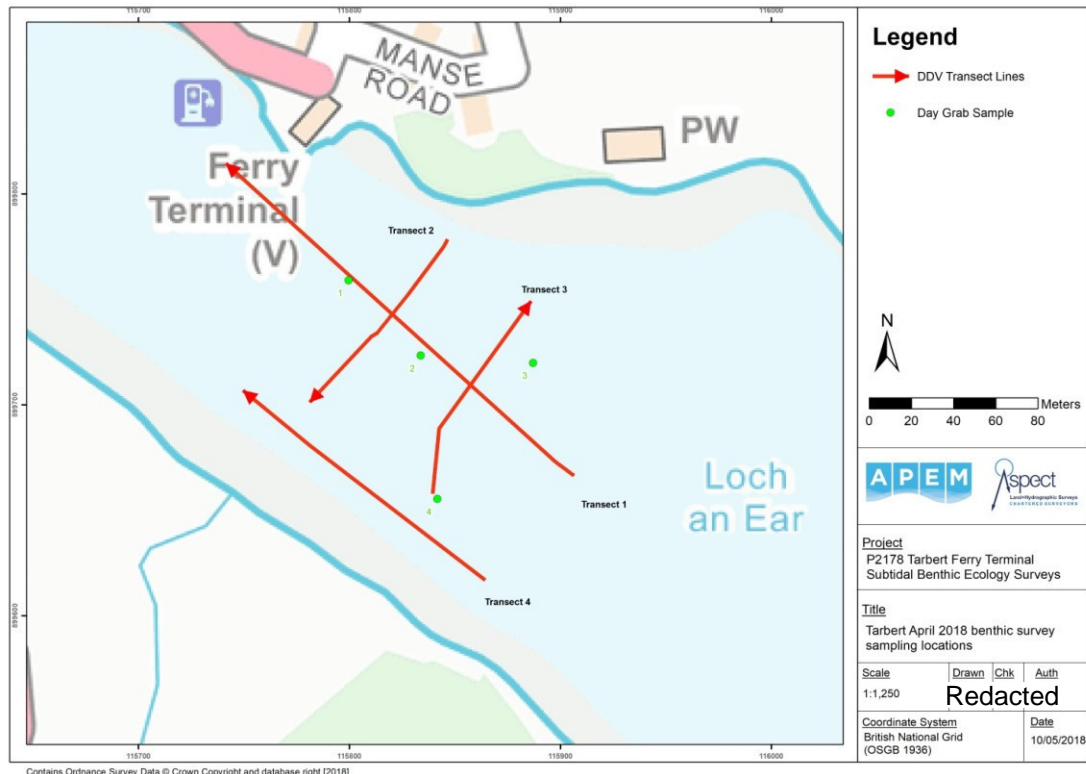

The underwater video survey was conducted on the 9<sup>th</sup> April 2018 in daylight hours.

APEM was provided with a specification of three transect routes for the underwater video survey by CMAL. These transect routes were not in the vicinity of the new pontoon in Tarbert Harbour and therefore a Drop Down Video (DDV) camera system could be used.

The three underwater video transects (plus an additional fourth transect) were completed using an Imenco 'Tiger Shark' underwater stills camera. This was mounted onto a frame along with a flash, lighting and multiplexer equipment as shown in Figure 2-2. A video recording device was used on the vessel to capture the video outputs of the DDV camera. The DDV camera was deployed from the Remote Sensor and captured imagery of the seabed looking vertically downward as the Remote Sensor navigated along the transects. The transects, as shown in Figure 2-3 and Table 2-1, are considered to provide a good coverage of the area of interest.

**Figure 2-2** The Imenco 'Tiger Shark' subsea camera and Imenco 'Lantern Shark' flash as mounted onto the ALHS frame which was deployed from the davit of the Remote Sensor.

**Figure 2-3 Location of the underwater video transect routes, with arrows indicating the transect direction flow, and location of the grab sampling stations.**

**Table 2-1 Start and end point coordinates for each underwater video transect. Coordinates are presented in the Ordnance Survey/British National Grid Projected Coordinate System format.**

Underwater video transect	Start coordinates		End coordinates	
	X	Y	X	Y
Transect 1	115906.47	899669.87	115741.40	899817.97
Transect 2	115846.54	899781.97	115781.11	899704.72
Transect 3	115839.41	899661.32	115886.08	899752.73
Transect 4	115864.39	899620.48	115749.51	899710.32

### 2.1.2 Grab sampling survey

The subtidal grab sampling survey was conducted on the 10<sup>th</sup> April 2018 in daylight hours.

Four pre-defined grab sample station locations were specified by CMAL prior to the survey, as shown in Figure 2-3 and Table 2-2. At these sample stations, it was specified that macrobenthic samples were to be taken but there was no requirement to obtain samples for Particle Size Distribution (PSD) analysis. At each of these stations, grab samples were collected for macrobenthic analysis using a 0.1m<sup>2</sup> Day Grab.

**Table 2-2 Coordinates for each grab sample station. Coordinates are presented in the Ordnance Survey/British National Grid Projected Coordinate System format.**

Grab sample station	Site code	X	Y
Station 1	G01	115793.66	899768.33
Station 2	G02	115826.98	899728.55
Station 3	G03	115892.46	899729.18
Station 4	G04	115844.14	899662.19

Whilst conducting the grab sampling, a minimum sediment volume limit of 5 litres was defined as an acceptable size for a grab sample to be considered successful. If this minimum volume was not obtained then a further two attempts were to be made at the same location, followed by three attempts at a different location at least 50m from the original target. The first two attempts at station 1 collected an insufficient volume due to the presence of cobbles causing incomplete closure of the grab's jaws. Furthermore, the first attempt at station 3 captured large debris but no sediments and so the sample was discarded. Subsequent attempts at both station 1 and station 3 successfully collected an appropriate sample.

For each grab attempt the following information was recorded on the survey log-sheet:

- Survey name, location and project code;
- Survey Date;
- Survey Team staff;
- Site information including: site/replicate, sample position (lat/lon; WGS84), collection time, water depth, weather conditions;
- Sampling equipment including sieve mesh size;
- Salinity for later use in the WFD IQI calculation
- Sample description, including sediment description, grab depth in cm, volume, type, profile, concretions, surface features, burrows, algae, colour and colour changes, smell, etc.;
- Any obvious or notable (e.g. Annex 2 species) taxa observed;
- Notes (e.g. anoxia, anthropogenic debris, any problems encountered, etc.);
- Photograph of the unsieved sample (an example is presented in Figure 2-4 below).

**Figure 2-4 Unsieved grab sample from Station 3 in Tarbert Harbour (attempt 2).**

Biological samples were sieved on board through a 1.0mm sieve as is standard for subtidal surveys in marine conditions. All material retained on the sieves was fixed with 4% buffered formaldehyde solution in seawater and stored in sealed crates.

## 2.2 Sample analysis

### 2.2.1 Macrobenthic analysis of grab samples

Samples were processed according to APEM's in-house Standard Operating Procedures (SOP's) and in full compliance with North East Atlantic Marine Biological Analytical Quality Control Scheme (NMBAQC) guidance (Worsfold and Hall, 2010). To standardise the sizes of organisms and improve sorting efficiency, samples were sieved through a stack of sieves of 4.0, 2.0 and 1.0 mm meshes in a fume cupboard following UKTAG guidance for benthic invertebrate sample analysis for coastal waters (WFD-UKTAG, 2014). All biota retained in the sieves were then extracted under low power microscopes, identified and enumerated, where applicable.

Taxa were identified to the lowest possible practicable taxonomic level using the appropriate taxonomic literature. For certain taxonomic groups (e.g. nemerteans and, nematodes), higher taxonomic levels were used due to the widely acknowledged lack of appropriate identification tools for these groups. The NMBAQC Scheme has produced a Taxonomic Discrimination Protocol (TDP) (Worsfold and Hall 2010) which gives guidance on the most appropriate level to which different marine taxa should be identified, and this guidance was adhered to for the

laboratory analysis. Where required, specimens were also compared with material maintained within the laboratory reference collection. Nomenclature followed the World Register of Marine Species (WoRMS), except where more recent revisions were known to supersede WoRMS.

At least one example of each taxon recorded from the surveys was set aside for inclusion in APEM's in-house reference collection. This collection acts as a permanent record of the biota recorded.

### *2.2.2 Imagery analysis of underwater video capture*

The underwater video was analysed by an experienced marine benthic taxonomist and image analyst to provide habitat/biotope extent and transition data and enable the identification of any small-scale habitats outside the subtidal grab sampling target habitats (such as rock outcrops). The video captures for each transect were re-played in the laboratory and the biotopes and notable taxa along each transect identified and recorded. The timing of the transitions between each habitat along the transects in the underwater video were also noted, and these were then related to the vessel position within the survey logs to identify the position of habitat transitions.

### 3. Results

#### 3.1 Macrobenthic analysis data

The full suite of enumerated macrobenthic data from each grab sample is provided in Appendix 1. A summary of the prevailing conditions at the time of each macrobenthic grab sample is provided in Table 3-1 below, and the biotopes assigned to each grab sample are provided in Table 3-2. The most abundant species (> 100 individuals) were Polychaetes *Lumbrineris cingulata* agg. (n=166) and *Kurtiella bidentate* (n=118) recorded across stations 1 to 3; and *Capitella* (n=106) only recorded at station 4. Other species present in appreciable numbers included *Spirobranchus lamarcki* (n=43), *Melinna palmate* (n=42), *Nematoda* (n=32), *Mediomastus fragilis* (n=32), *Polycirrus* (n=23), *Leptochiton asellus* (n=20), *Dodecaceria* (n=19) and *Magelona allenii* (n=11).

**Table 3-1 Prevailing water and depth conditions at the time of collection of each macrobenthic grab sample**

Grab sample station	Collection time	Water depth (m)	Volume (l)	Salinity (ppm)
Station 1	9:37	9.3	5	26.17
Station 2	10:14	10.9	9	26.40
Station 3	10:51	11.6	8	26.66
Station 4	11:05	10.5	9	27.45

**Table 3-2 Biotopes assigned to macrobenthic grab samples**

Grab sample station	Biotope	Description
Station 1	SS.SMp.KSwSS.LsacR	<i>Laminaria saccharina</i> and red seaweeds on infralittoral sediments
Station 2	SS.SMp.KSwSS.LsacR	<i>Laminaria saccharina</i> and red seaweeds on infralittoral sediments.
Station 3	SS.SMp.KSwSS.LsacR.Mu	<i>Laminaria saccharina</i> with red and brown seaweeds on lower muddy mixed sediments.
Station 4	SS.SMu.IFiMu	Infralittoral fine mud.

#### 3.2 Underwater video data

The full suite of habitat classification data for each transect is provided in Appendix 2. The biotopes found to be present in Tarbert Harbour, with example images of each biotope from the underwater video survey, are provided in Figures 3-1, 3-2, 3-3 and 3-4. The biotopes identified by the underwater video imagery have been mapped along each of the transect routes in Figure 3-5.

**Figure 3-1 SS.SMx.CMx.OphMx: *Ophiothrix fragilis* and/or *Ophiocomina nigra* brittlestar beds on sublittoral mixed sediment**

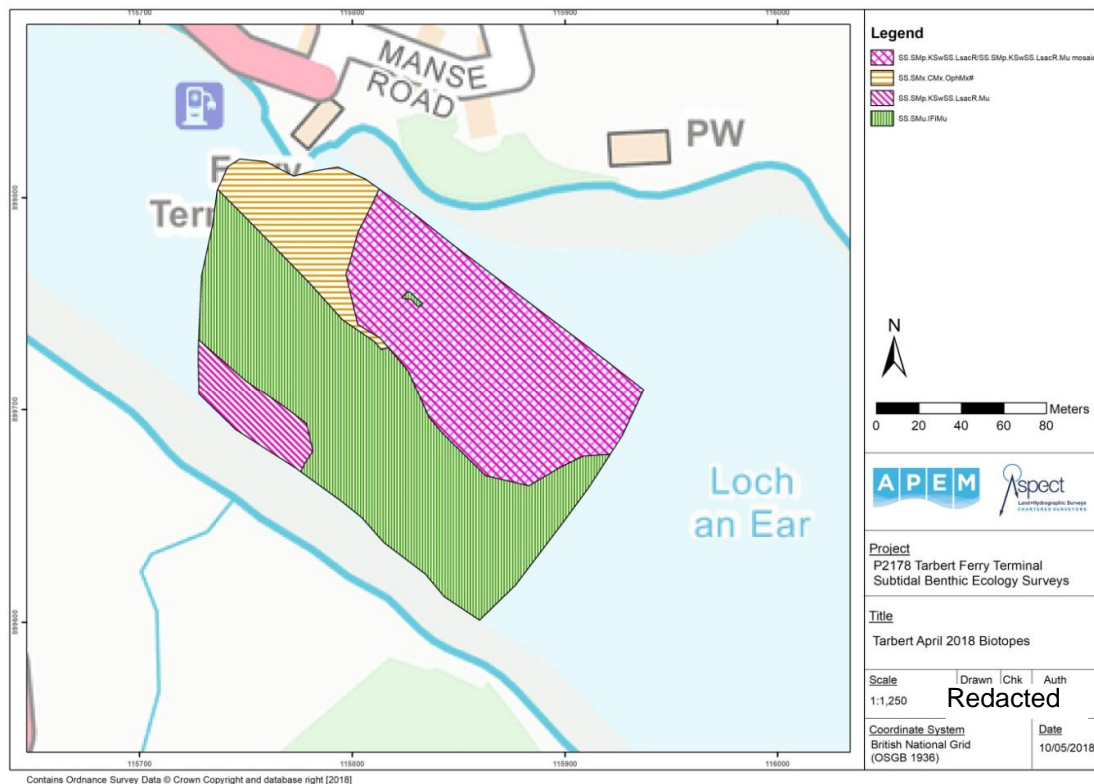

**Figure 3-5 Transect routes with mapped biotopes overlaid**

### 3.3 Tarbert Harbour biotope mapping

The macrobenthic count data and underwater video biotope classification data has been compiled to allocate biotopes to each point along the underwater video transects and at the grab sample stations. Biotopes were allocated following JNCC's National Marine Habitat Classification for Britain and Ireland: Version 04.05 (Connor *et al.* 2004). EUNIS codes corresponding to each biotope have also been provided (JNCC, 2010; Parry, 2015).

As the survey coverage across Tarbert Harbour has transects running both across and down the full extent of the survey area and at a representative range of depths, it has been possible to extrapolate between the known biotopes along the transects to provide a more complete biotope map of the harbour. This plan is shown in Figure 3-6. It is acknowledged that this is an extrapolation of the known data and so the biotope assignment away from the transects and grab sample locations is with a lower level of confidence to the biotope assignment at the grab sample stations and transects.

The biotope map presented in Figure 3-6 is an interpretive map based on an extrapolation of the raw data collected in the grab samples and along the underwater video transects, to delineate approximate habitat biotope boundaries within Tarbert Harbour. Following the approach set out by Saunders *et al.* (2011) the confidence in this biotope map would be enhanced by conducting a geophysical survey of the harbour to allow the grab sample point data and underwater video line data to act as reference points for the habitats in the rest of the harbour defined using the geophysical survey.

**Figure 3-6 Tarbert Harbour mapped subtidal benthic biotopes (Biotope code references: SS.SMp.KSwSS.LsacR.Mu: *Laminaria saccharina* with red and brown seaweeds on lower muddy mixed sediments. SS.SMp.KSwSS.LsacR: *Laminaria saccharina* and red seaweeds on infralittoral sediments SS.SMx.CMx.OphMx: *Ophiorthrix fragilis* and/or *Ophiocomina nigra* brittlestar beds on sublittoral mixed sediment. SS.SMu.FiMu: Infralittoral fine mud)**

## 4. Conclusions

APEM's survey of the subtidal benthic ecological habitats and species present in Tarbert Harbour identified the following biotopes to be present on the seabed:

- **SS.SMx.CMx.OphMx:** Ophiothrix fragilis and/or Ophiocomina nigra brittlestar beds on sublittoral mixed sediment.
- **SS.SMp.KSwSS.LsacR:** Laminaria saccharina and red seaweeds on infralittoral sediments.
- **SS.SMp.KSwSS.LsacR.Mu:** Laminaria saccharina with red and brown seaweeds on lower muddy mixed sediments.
- **SS.SMu.IFiMu:** Infralittoral fine mud.

A full species list of individuals recorded within the grab samples in Tarbert Harbour is provided in Appendix 1.

Biotopes SS.SMp.KSwSS.LsacR and SS.SMp.KSwSS.LsacR.Mu fall under the Scottish Priority Marine Feature (PMF) 'Kelp and seaweed communities on sublittoral sediment', which encompasses all biotopes under SS.SMp.KSwSS apart from SS.SMp.KSwSS.Tra (Mats of *Trailliella* on infralittoral muddy gravel) and SS.SMp.KSwSS.FilG (Filamentous green seaweeds on low salinity infralittoral mixed sediment or rock).

None of the other biotopes or species identified are designated as Scottish Priority Marine Features (PMFs), or designated under the Conservation (Natural Habitats, &c.) Regulations 1994 and Conservation of Habitats and Species Regulations 2010.

A single *Sabellaria spinulosa* individual and single *Serpula vermicularis* individual were recorded at Station 3, but no evidence of reef habitat formed by these species was found during the survey. Three *Mytilus edulis* individuals were recorded in Station 1 and Station 3.

Within the genus of red algae *Gracilaria* found to be present at Station 1 and Station 3, there is the potential for invasive non-native species (INNS) to be present, including those listed by the GB non-native species secretariat (NNSS), *Gracilaria multipartite* and *Gracilaria vermiculophylla*.

**Test Procedure** TP 2.SLM 61672-3 TPS-49

*Procedures from IEC 61672-3:2006 were used to perform the periodic tests.*

**Type Approved to IEC 61672-1:2002** Yes **Approval Number** 21.21/07.01

*If YES above there is public evidence that the SLM has successfully completed the applicable pattern evaluation tests of IEC 61672-2:2003*

**Date Received** 23 January 2017

**ANV Job No.** TRAC17/01008

**Date Calibrated** 25 January 2017

The sound level meter submitted for testing has successfully completed the class 1 periodic tests of IEC 61672-3:2006, for the environmental conditions under which the tests were performed. As public evidence was available, from an independent testing organisation responsible for approving the results of pattern evaluation tests performed in accordance with IEC 61672-2:2003, to demonstrate that the model of sound level meter fully conformed to the requirements in IEC 61672-1:2002, the sound level meter submitted for testing conforms to the class 1 requirements of IEC 61672-1:2002.

Wind screen corrections available	Yes	
Uncertainties of wind screen corrections	Yes	
Source of wind screen data	Manufacturer	
Mic pressure to free field corrections	Yes	
Uncertainties of Mic to F.F. corrections	Yes	
Source of Mic to F.F. corrections	Manufacturer	
Total expanded uncertainties within the requirements of IEC 61672-1:2002	Yes	
Specified or equivalent Calibrator	Specified	
Customer or Lab Calibrator	Customers Calibrator	
Calibrator adaptor type if applicable	NC-74-002	
Calibrator cal. date	24 January 2017	
Calibrator cert. number	UCRT17/1033	
Calibrator cal cert issued by Lab	7623	
Calibrator SPL @ STP	94.02	dB Calibration reference sound pressure level
Calibrator frequency	1002.52	Hz Calibration check frequency
Reference level range	20 - 120	dB

Accessories used or corrected for during calibration - Wind Shield

Note - if a pre-amp extension cable is listed then it was used between the SLM and the pre-amp.

Environmental conditions during tests	Start	End	
Temperature	23.31	23.32	± 0.20 °C
Humidity	36.0	35.5	± 3.00 %RH
Ambient Pressure	101.54	101.54	± 0.03 kPa

Response to associated Calibrator at the environmental conditions above.

Initial indicated level	94.0	dB	Adjusted indicated level	94.0	dB
The uncertainty of the associated calibrator supplied with the sound level meter ±				0.10	dB

Self Generated Noise This test is currently not performed by this Lab.

Microphone installed (if requested by customer) = Less Than	N/A	dB	A Weighting
Uncertainty of the microphone installed self generated noise ±	N/A	dB	

Microphone replaced with electrical input device -				UR = Under Range indicated					
Weighting	A			C			Z		
	9.7	dB	UR	14.1	dB	UR	21.0	dB	UR
Uncertainty of the electrical self generated noise ±						0.12		dB	

The reported expanded uncertainty is based on a standard uncertainty multiplied by a coverage factor k=2, providing a coverage probability of approximately 95%. The uncertainty evaluation has been carried out in accordance with the Guide to the Expression of Uncertainty in Measurement published by ISO.

For the test of the frequency weightings as per paragraph 12. of IEC 61672-3:2006 the actual microphone free field response was used.

The acoustical frequency tests of a frequency weighting as per paragraph 11 of IEC 61672-3:2006 were carried out using an electrostatic actuator.

# Certificate of Calibration

## Equipment Details

Instrument Manufacturer Cirrus Research plc  
Instrument Type CR:171B  
Description Sound Level Meter  
Serial Number G078532

## Calibration Procedure

The instrument detailed above has been calibrated to the publish test and calibration data as detailed in the instrument hand book, using the techniques recommended in the latest revisions of the International Standards IEC 61672-1:2013, IEC 61672-1:2002, IEC 60651:1979, IEC 60804:2001, IEC 61260:1995, IEC 60942:2003, IEC 60942:1997, IEC 61252:1993, ANSI S1.4-1983, ANSI S1.11-1986 and ANSI S1.43-1997 where applicable.

Sound Level Meters: All Calibration procedures were carried out by substituting the microphone capsule with a suitable electrical signal, apart from the final acoustic calibration.

## Calibration Traceability

The equipment detailed above was calibrated against the calibration laboratory standards held by Cirrus Research plc. These are traceable to International Standards {A.0.6}. The standards are:

Microphone Type	B&K 4192	Serial Number	1920791	Calibration Ref.	S6450
Pistonphone Type	B&K 4220	Serial Number	613843	Calibration Ref.	S6388

# Certificate of Calibration

Certificate Number: **114121**

Date of Issue: **26 September 2017**

## Microphone Capsule

Manufacturer: **Cirrus Research plc**

Serial Number: **206546A**

Model Number: **MK:224**

## Calibration Procedure

The microphone capsule detailed above has been calibrated to the published data as described in the operating manual of the associated sound level meter (where applicable).

The frequency response was measured using an electrostatic actuator in accordance with BS EN 61094-6:2005 with the free-field response derived via standard correction data traceable to the National Physical Laboratory, Middlesex, UK.

The absolute sensitivity at 1 kHz was measured using an acoustic calibrator conforming to IEC 60942:2003 Class 1.

Date of Calibration: **25 September 2017**

Open Circuit **54.7 mV/Pa**

Sensitivity at 1 kHz: **-25.2 dB rel 1 V/Pa**

## Environmental Conditions

Pressure: **101.50 kPa**

Temperature: **24.0 °C**

Humidity: **54.0 %**

# Certificate of Calibration

Certificate Number: **114119**

Date of Issue: **26 September 2017**

## Instrument

Manufacturer: **Cirrus Research plc**

Serial Number: **78219**

Model Number: **CR:515**

## Calibration Procedure

The sound calibrator detailed above has been calibrated to the published data as described in the operating manual and in the half-inch configuration. The procedures and techniques used are as described in IEC 60942:2003 Annex B – Periodic Tests and three determinations of the sound pressure level, frequency and total distortion were made.

The sound pressure level was measured using a WS2F condenser microphone type MK:224 manufactured by Cirrus Research plc.

The results have been corrected to the reference pressure of 101.33 kPa using the manufacturer's data.

Date of Calibration: **26 September 2017**

## Calibration Results

Measurement	Level (dB)	Frequency (Hz)	Distortion (% THD + Noise)
1	94.01	1000.3	0.31
2	94.00	1000.3	0.31
3	94.02	1000.3	0.31
Average	<b>94.01</b>	<b>1000.3</b>	<b>0.31</b>
Uncertainty	$\pm 0.13$	$\pm 0.1$	$\pm 0.10$

The reported uncertainties of measurement are expanded by a coverage factor of  $k=2$ , providing a 95% confidence level.

UK Registration No. 987160

## Environmental Conditions

Pressure: 101.60 kPa  
Temperature: 23.9 °C  
Humidity: 52.2 %

## Evidence of Pattern Approval

The manufacturer's product information indicates that this model of sound calibrator has been formally pattern approved to IEC 60942:2003 Annex A to Class 1. This has been confirmed with the Physikalisch Technische Bundesanstalt (PTB).

## Statement of Calibration

As public evidence was available, from a testing organisation responsible for approving the results of pattern evaluation tests, to demonstrate that the model of sound calibrator fully conformed to the requirements for pattern evaluation described in Annex A of IEC 60942:2003, the sound calibrator tested is considered to conform to all the Class 1 requirements of IEC 60942:2003.

## Calibration Laboratory

Laboratory: Cirrus Research plc  
Acoustic House, Bridlington Road, Hunmanby  
North Yorkshire, YO14 0PH, United Kingdom  
Test Engineer: Redacted

## **Appendix J.2: Construction Noise Assessment Data**

# 1 Introduction

Subacoustech Environmental have been instructed by Affric Limited to undertake acoustic propagation modelling for impact piling and other related noise-making operations linked to the proposed upgrade at the Tarbert ferry terminal.

The purpose of the modelling is to estimate the received sound pressure levels in the region, with particular concern for the impacts on marine mammals and fish. This report has been prepared by Subacoustech Environmental Ltd for Affric and presents the results and findings of the modelling assessment.

## 1.1 Survey area

Figure 1-1 details the Tarbert ferry terminal site on the south-east coast of the Isle of Harris, Scotland. As the area of operational activity for the works is relatively small, a single representative modelling location has been selected (approximate coordinates: 57.8968°N, 006.7986°W), this is shown by the red marker in the figure below.

*Figure 1-1 Image showing the location of Tarbert ferry terminal and the surrounding bathymetry (bathymetry supplied by Find Mapping Ltd - © British Crown and OceanWise, 2017. All rights reserved. Not to be used for Navigation.)*

## 1.2 Impact piling

Three types of pile are expected to be installed at the ferry terminal; fender piles measuring 762 mm and 910 mm in diameter, bearing/raking piles measuring 610 mm in diameter, and temporary works piles measuring approximately 508 mm in diameter. The piles will be installed using a hammer such as a BSP CX hydraulic piling hammer with expected blow energies of between 50 and 150 kJ. The 34 temporary works piles are expected to be installed over a period of 1 month, and 12 fender piles and 51 bearing/raking piles are expected to be installed within a further month. It is expected that each pile should take between 30 minutes and 1 hour to install depending on conditions.

### **1.3 Other noise sources**

In addition to impact piling, there is the possibility of using vibratory hammer (vibro piling) to install the piles. Rock breaking using a machine mounted pecker is also being considered for removal of rocks. The activities have been considered using a high-level, simple modelling approach based on a conservative worst case.

Backhoe dredging and vessel movements are also expected during the terminal upgrades, however due to the low level of noise from these activities, they have only been assessed qualitatively.

### **1.4 Assessment overview**

This report presents a detailed assessment of the potential underwater noise from works at the Tarbert ferry terminal and covers the following:

- Review of background information on the units for measuring and assessing underwater noise
- Discussion of the approach, input parameters and assumptions for the noise modelling undertaken;
- Presentation of detailed subsea noise modelling using unweighted metrics and interpretation of the results using suitable noise metrics and criteria; and
- Summary and conclusions

## 2 Measurement of underwater noise

Sound travels much faster in water (approximately 1,500 ms<sup>-1</sup>) than in air (340 ms<sup>-1</sup>). Since water is a relatively incompressible, dense medium, the pressures associated with underwater sound tend to be much higher than in air. As an example, background levels of sea noise of approximately 130 dB re 1 µPa for UK coastal waters are not uncommon (Nedwell *et al*, 2003 and 2007). This level equates to about 100 dB re 20 µPa in the units that would be used to describe a sound level in air.

### 2.1 Units of measurement

Sound measurements underwater are usually expressed using the decibel (dB) scale, which is a logarithmic measure of sound. A logarithmic scale is used because rather than equal increments of sound having an equal increase in effect, typically a constant ratio is required for this to be the case. That is, each doubling of sound level will cause a roughly equal increase in “loudness”.

Any quantity expressed in this scale is termed a “level”. If the unit is sound pressure, expressed on the dB scale, it will be termed a “Sound Pressure Level”. The fundamental definition of the dB scale is given by:

$$Level = 10 \times \log_{10} \left( \frac{Q}{Q_{ref}} \right)$$

where  $Q$  is the quantity being expressed on the scale, and  $Q_{ref}$  is the reference quantity.

The dB scale represents a ratio and, for instance, 6 dB really means “twice as much as...” (such as a doubling of peak or RMS pressure, exposure etc). It is, therefore, used with a reference unit, which expresses the base from which the ratio is expressed. The reference quantity is conventionally smaller than the smallest value to be expressed on the scale, so that any level quoted is positive. For instance, a reference quantity of 20 µPa is used for sound in air, since this is the threshold of human hearing.

A refinement is that the scale, when used with sound pressure, is applied to the pressure squared rather than the pressure. If this were not the case, when the acoustic power level of a source rose by 10 dB the Sound Pressure Level would rise by 20 dB. So that variations in the units agree, the sound pressure must be specified in units of root mean square (RMS) pressure squared. This is equivalent to expressing the sound as:

$$Sound\ Pressure\ Level = 20 \times \log_{10} \left( \frac{P_{RMS}}{P_{ref}} \right)$$

For underwater sound, typically a unit of one micropascal (µPa) is used as the reference unit; a Pascal is equal to the pressure exerted by one Newton over one square metre; one micropascal equals one millionth of this.

### 2.2 Quantities of measurement

Sound may be expressed in many ways depending upon the type of noise, and the parameters of the noise that allow it to be evaluated in terms of a biological effect. These are described in more detail below.

#### 2.2.1 Sound pressure level (SPL)

The Sound Pressure Level is normally used to characterise noise and vibration of a continuous nature such as drilling, boring, continuous wave sonar, or background sea and river noise levels. To calculate the SPL, the variation in sound pressure is measured over a specific time period to determine the Root Mean Square (RMS) level of the time varying sound. The SPL can therefore be considered a measure of the average unweighted level of sound over the measurement period.

Where an SPL is used to characterise transient pressure waves such as that from seismic airguns, underwater blasting or impact piling, it is critical that the period over which the RMS level is calculated is quoted. For instance, in the case of pile strike lasting, say, a tenth of a second, the mean taken over a tenth of a second will be ten times higher than the mean taken over one second. Often, transient sounds such as these are quantified using “peak” SPLs.

### 2.2.2 Peak sound pressure level ( $SPL_{peak}$ )

Peak SPLs are often used to characterise sound transients from impulsive sources, such as percussive impact piling and seismic airgun sources. A peak SPL is calculated using the maximum variation of the pressure from positive to zero within the wave. This represents the maximum change in positive pressure (differential pressure from positive to zero) as the transient pressure wave propagates.

A further variation of this is the peak-to-peak SPL where the maximum variation of the pressure from positive to negative within the wave is considered. Where the wave is symmetrically distributed in positive and negative pressure, the peak-to-peak level will be twice the peak level, or 6 dB higher.

### 2.2.3 Sound exposure level (SEL)

When assessing the noise from transient sources such as blast waves, impact piling or seismic airgun noise, the issue of the period of the pressure wave is often addressed by measuring the total acoustic energy (energy flux density) of the wave. This form of analysis was used by Bebb and Wright (1953, 1954a, 1954b and 1955), and later by Rawlins (1987) to explain the apparent discrepancies in the biological effect of short and long-range blast waves on human divers. More recently, this form of analysis has been used to develop criteria for assessing the injury range from fish for various noise sources (Popper *et al*, 2014).

The Sound Exposure Level (SEL) sums the acoustic energy over a measurement period, and effectively takes account of both the SPL of the sound source and the duration the sound is present in the acoustic environment. Sound Exposure (SE) is defined by the equation:

$$SE = \int_0^T p^2(t) dt$$

where  $p$  is the acoustic pressure in Pascals,  $T$  is the duration of the sound in seconds, and  $t$  is the time in seconds. The Sound Exposure is a measure of the acoustic energy and, therefore, has units of Pascal squared seconds ( $\text{Pa}^2\text{s}$ ).

To express the Sound Exposure on a logarithmic scale by means of a dB, it is compared with a reference acoustic energy level ( $P_{ref}^2$ ) and a reference time ( $T_{ref}$ ). The SEL is then defined by:

$$SEL = 10 \times \log_{10} \left( \frac{\int_0^T p^2(t) dt}{P_{ref}^2 T_{ref}} \right)$$

By selecting a common reference pressure  $P_{ref}$  of 1  $\mu\text{Pa}$  for assessments of underwater noise, the SEL and SPL can be compared using the expression:

$$SEL = SPL + 10 \times \log_{10} T$$

Where the SPL is a measure of the average level of the broadband noise, and the SEL sums the cumulative broadband noise energy.

This means that, for continuous sounds of less than one second, the SEL will be lower than the SPL. For periods greater than one second the SEL will be numerically greater than the SPL (i.e. for a sound of ten seconds duration, the SEL will be 10 dB higher than the SPL, for a sound of 100 seconds duration the SEL will be 20 dB higher than the SPL, and so on).

Weighted metrics for marine mammals have been proposed by the National Marine Fisheries Service (NMFS) (2016), these assign a frequency response to groups of marine mammals, and are discussed in detail in the following section.

## 3 Modelling methodology

Three modelling methodologies have been used for this assessment based on the likely severity of impact of each noise source based on noise levels previously measured by Subacoustech.

- High noise sources (impact piling) have been assessed using detailed modelling considering all environmental parameters;
- Moderate sources (vibro piling and rock breaking) use a simple modelling approach based on a conservative worst case; and
- Low noise sources (dredging and vessel movements) have been considered qualitatively based on previously measured data.

### 3.1 Detailed modelling inputs

To estimate the likely noise levels from impact piling operations, modelling has been carried out using an approach that is widely used and accepted by the acoustics community, in combination with publicly available environmental data and information provided by Affric. The approach is described in more detail below.

Modelling has been undertaken at one representative location to predict the levels of underwater noise from the impact piling activities. The modelling location is shown in Figure 1-1.

Modelling of underwater noise is complex and can be approached in several different ways. Subacoustech have chosen to use a numerical approach that is based on two different solvers:

- A parabolic equation (PE) method for lower frequencies (12.5 Hz to 250 Hz); and
- A ray tracing method for higher frequencies (315 Hz to 100 kHz).

The PE method is widely used within the underwater acoustics community but has computational limitations at high frequencies. Ray tracing is more computationally efficient at higher frequencies but is not suited to low frequencies (Etter, 1991). This study utilises the dBSea implementation of these numerical solutions.

These solvers account for a wide array of input parameters, including bathymetry, sediment data, sound speed and source frequency content to ensure as detailed results as possible. These input parameters are described in the following sections.

#### 3.1.1 Bathymetry

The bathymetry data used in the modelling was supplied by Find Mapping Ltd; this data has a resolution of 1 arc second (a grid of squares measuring approximately 30 m by 60 m). A high tide of 4.8 m (Mean High Water Springs) has been used throughout the modelling as this represents a conservative approach with regards to noise propagation.

#### 3.1.2 Sound speed profile

The speed of sound in the water, shown in Figure 3-1, has been calculated using temperature and salinity data from Marine Scotland (Bresnan *et al.* 2016) and the underwater sound speed equation from Mackenzie (1981).

Figure 3-1 Sound speed profile used for modelling

### 3.1.3 Seabed properties

Based on data from the Marine Environment Mapping Programme (MAREMAP) the seabed properties used for modelling were assumed to be predominantly gravel and sand. Geo-acoustic properties for the seabed were based on available data from Jensen *et al.* (2011), and are provided in Table 3-1.

Seabed type	Compressive sound speed in substrate (ms <sup>-1</sup> )	Density profile in substrate (kg/m <sup>3</sup> )	Attenuation profile in substrate (dB/wavelength)
Sand	1650	1900	0.8
Gravel	1800	2000	0.6

Table 3-1 Seabed geo-acoustic properties used for modelling

### 3.1.4 Impact piling source levels

The proposed impact piling operations at Tarbert include three pile sizes, as detailed in section 1.2, driven using a hammer blow energy of between 50 and 150 kJ. In order to cover a range of the likely noise levels; two pile sizes have been modelled (914 mm and 508 mm), and both 50 kJ and 150 kJ blow energies have been modelled.

The source levels used for the modelling of these two pile sizes and hammer energies are based on Subacoustech's extensive database of impact piling noise, with the predicted source level calculated from the blow energy and water depth of a piling location. These have been shown to be the primary factors determining the subsea noise levels produced. The size of the pile has been used to determine the frequency content of the noise. As the model assumes that the noise source acts as a single point, the water depth at the noise source (accounting for tide) has been used to adjust the source level to allow for the length of the pile in contact with the water.

The unweighted SPL<sub>peak</sub> source levels estimated for Tarbert are:

- 197.1 dB re 1 µPa SPL<sub>peak</sub> (50 kJ blow energy)
- 205.4 dB re 1 µPa SPL<sub>peak</sub> (150 kJ blow energy)

These source levels equate to single strike SEL source levels of 173.2 dB re 1 µPa<sup>2</sup>s for a 50 kJ hammer and 181.6 dB re 1 µPa<sup>2</sup>s for a 150 kJ hammer

The third octave levels used for modelling are illustrated in Figure 3-2 and Figure 3-3. As the frequency content is determined by the dimensions of the pile, the shape of the two spectra are the same for both blow energies, with the overall source levels adjusted.

Figure 3-2 Source third octave band levels to be used to model impact piling for a 910 mm diameter pile ( $SPL_{peak}$ )

Figure 3-3 Source third octave band levels to be used to model impact piling for a 508 mm diameter pile ( $SPL_{peak}$ )

It is likely that the energy and strike rate of the piling hammer will slowly increase (ramp-up) over time, due to how hydraulic piling hammers work, however due to the limited information available, this modelling has assumed the same blow energy and strike rate (1 strike per second) over the entire duration of 1 hour. If a ramp-up or soft start were introduced it would likely act as a mitigating factor to the overall noise levels.

### 3.2 Simple modelling

Modelling of noise from vibro piling and rock breaking have been undertaken using a simple modelling approach; Subacoustech's SPEAR model. This methodology has been chosen due to either low levels of noise or limited data availability. This simple modelling methodology comprises of using existing measurement data from similar activities taken by Subacoustech and modifying the source level to best match the scenario being modelled.

#### 3.2.1 *Vibro piling and rock breaking source levels*

Source levels used for vibro piling have been based on third octave band measurements undertaken by Subacoustech of the vibro piling of sheet piles. Although tubular piles are being considered for these works, these measurements are considered comparable.

Source levels used for rock breaking are based on data from a report by Marshall Day Acoustics (Lawrence, 2016) and is, at the time of writing, the best available information on underwater noise levels from rock breaking activities. The proposed methodology does differ in that the measurements are of a ripper device, which penetrates the rock and pulls in up, whereas a peckering device is proposed for Tarbert. The differences between the rock breaking methods have been acknowledged and accounted for by modifying the source levels based on the differences in power outputs of the machinery.

The unweighted RMS source levels (1 s SEL) used for the SPEAR modelling are given in Table 3-2.

	Vibro piling	Rock breaking
RMS Source level @ 1 m	188.0 dB re 1 $\mu$ Pa	175.4 dB re 1 $\mu$ Pa

*Table 3-2 Unweighted RMS source levels used for SPEAR modelling*

The simple modelling is based on a simple geometric spreading model of the form  $N \log_{10} R - \alpha R$  where  $R$  is the range and values for  $N$  and  $\alpha$  are based on approximations from field measurements taken by Subacoustech. In contrast, the PE / Ray tracing solution is based on a physical approximations of underwater wave propagation and considers variations in bathymetry, seabed type and sound speed profile for multiple depths and for each frequency band. With the simple methodology these factors are intrinsic to the conditions of the measurements. In practice, the complex numerical modelling is extremely resource intensive and a single scenario can take over 48 hours to complete and it is common practice to use different modelling techniques according to the source being modelled and the anticipated impact range.

#### 3.2.2 *Other noise sources*

The low-level noise sources (backhoe dredging and vessel movements) have been assessed qualitatively in this report using measured noise levels from the Subacoustech noise measurement database.

### 3.3 Assessment criteria

#### 3.3.1 *Background*

Over the past 20 years it has become increasingly evident that noise from human activities in and around underwater environments can have an impact on the marine species in the area. The extent to which intense underwater sound might cause an adverse environmental impact in a species is dependent upon the incident sound level, sound frequency, duration of exposure, and/or repetition rate of the sound wave (see for example Hastings and Popper, 2005). As a result, scientific interest in the hearing abilities of aquatic animal species has increased. These studies are primarily based on evidence from high level sources of underwater noise such as blasting or impact piling, as these sources are likely to have the greatest environmental impact and therefore the clearest observable effects.

The impacts of underwater sound can be broadly summarised into three categories:

- Physical traumatic injury and fatality;

- Auditory injury (either permanent or temporary); and
- Disturbance.

The following sections discussed the agreed upon criteria for assessing these impacts in key marine species. The metrics and criteria that have been used in this study to assess environmental effect come from the latest guidance from the U.S. National Marine and Fisheries Service (NMFS) concerning underwater noise and its effects on marine mammals (NMFS (2016)) and Popper *et al* (2014) for the impacts of noise on species of fish.

### 3.3.2 *Marine mammals*

Since it was published, Southall *et al* (2007) has been the source of the most widely used criteria to assess the effects of noise on marine mammals. NMFS (2016) was co-authored by many of the same academics from the Southall *et al* (2007) paper, and effectively updates it. In the updated guidelines, the frequency weightings have changed along with the criteria. As a result, the criteria have generally become more strict and potential impact ranges may increase substantially in some cases.

The NMFS (2016) guidance groups marine mammals into functional hearing groups and applies filters to the unweighted noise to approximate the hearing response of the receptor. The hearing groups given in the NMFS (2016) are summarised in Table 3-3.

The auditory weighting functions for each hearing group are provided in Figure 3-4.

Hearing group	Example species	Generalised hearing range
Low Frequency (LF) Cetaceans	Baleen Whales	7 Hz to 35 kHz
Mid Frequency (MF) Cetaceans	Dolphins, Toothed Whales, Beaked Whales, Bottlenose Whales (including Bottlenose Dolphin)	150 Hz to 160 kHz
High Frequency (HF) Cetaceans	True Porpoises (including Harbour Porpoise)	275 Hz to 160 kHz
Phocid Pinnipeds (PW) (underwater)	True Seals (including Harbour Seal)	50 Hz to 86 kHz

Table 3-3 Marine mammal hearing groups (from NMFS, 2016)

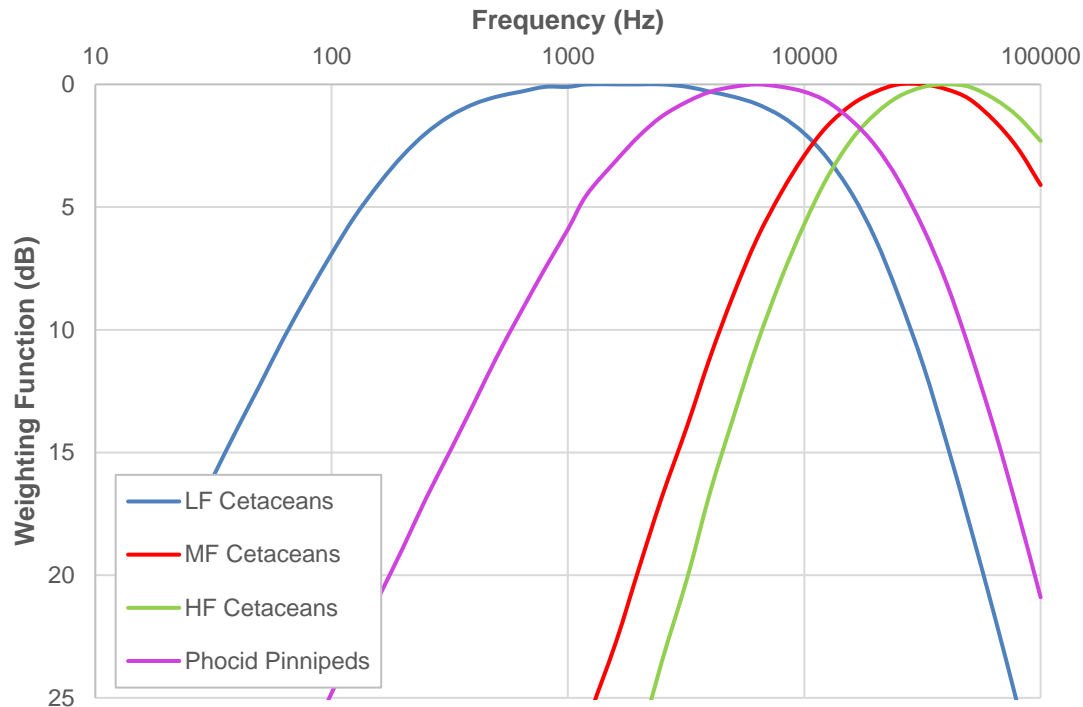

Figure 3-4 Auditory weighting functions for low frequency (LF) cetaceans, mid frequency (MF) cetaceans, high frequency (HF) cetaceans, phocid pinnipeds (PW) (underwater) (from NMFS, 2016)

Based on the species of marine mammal located near the ferry terminal works only the first four weighting groups (LF Cetacean, MF Cetacean, HF Cetacean, and Phocid Pinnipeds) have been considered in this study. Further discussion of the species weightings applied for this study are given in section 3.3.4.

NMFS (2016) presents unweighted peak criteria ( $SPL_{peak}$ ) and cumulative, weighted sound exposure criteria ( $SEL_{cum}$ ) for both permanent threshold shift (PTS) where unrecoverable hearing damage may occur and temporary threshold shift (TTS) where a temporary reduction in hearing sensitivity may occur in individual receptors. Table 3-4 and Table 3-5 summarise the NMFS (2016) criteria for onset of risk of PTS and TTS for each of the key marine mammal hearing groups for impulse and non-impulsive noise.

In the assessment of cumulative SEL values, a stationary animal model has been used assuming as a worst case, that the receptor stays at the same range from a noise source for its entire duration.

Impulsive noise	TTS criteria		PTS criteria	
Functional Group	SEL <sub>cum</sub> (weighted) dB re 1 μPa <sup>2</sup> s	SPL <sub>peak</sub> (unweighted) dB re 1 μPa	SEL <sub>cum</sub> (weighted) dB re 1 μPa <sup>2</sup> s	SPL <sub>peak</sub> (unweighted) dB re 1 μPa <sup>2</sup> s
LF Cetaceans	168	213	183	219
MF Cetaceans	170	224	185	230
HF Cetaceans	140	196	155	202
PW Pinnipeds	170	212	185	218

Table 3-4 Assessment criteria for marine mammals from NMFS (2016) for impulsive noise (impact piling)

Non-impulsive noise	TTS criteria	PTS criteria
Functional Group	SEL <sub>cum</sub> (weighted) dB re 1 µPa <sup>2</sup> s	SEL <sub>cum</sub> (weighted) dB re 1 µPa <sup>2</sup> s
LF Cetaceans	179	199
MF Cetaceans	178	198
HF Cetaceans	153	173
PW Pinnipeds	181	201

Table 3-5 Assessment criteria for marine mammals from NMFS (2016) for non-impulsive noise (vibro piling and rock breaking)

### 3.3.3 Fish

The effects of noise on fish have been assessed using criteria from Popper *et al.* (2014), which gives specific criteria for mortality and potential mortal injury, recoverable injury and TTS, masking and behaviour from various stimuli, including impact piling and continuous noises. Species of fish are grouped by whether or not they have a swim bladder and whether than swim bladder is involved in its hearing. The criteria are given as unweighted SPL<sub>peak</sub>, RMS, and SEL<sub>cum</sub> values and are summarised in Table 3-6 and Table 3-7.

Impact Piling	Mortality & potential mortal injury	Impairment	
Type of animal		Recoverable injury	TTS
Fish: no swim bladder	> 219 dB SEL <sub>cum</sub> > 213 dB SPL <sub>peak</sub>	> 216 dB SEL <sub>cum</sub> > 213 dB SPL <sub>peak</sub>	>> 186 dB SEL <sub>cum</sub>
Fish: swim bladder not involved in hearing	210 dB SEL <sub>cum</sub> > 207 dB SPL <sub>peak</sub>	203 dB SEL <sub>cum</sub> > 207 dB SPL <sub>peak</sub>	> 186 dB SEL <sub>cum</sub>
Fish: swim bladder involved in hearing	207 dB SEL <sub>cum</sub> > 207 dB SPL <sub>peak</sub>	203 dB SEL <sub>cum</sub> > 207 dB SPL <sub>peak</sub>	186 dB SEL <sub>cum</sub>

Table 3-6 Assessment criteria for species of fish from Popper *et al.* (2014) for impact piling noise

Shipping and other continuous noise	Mortality & potential mortal injury	Impairment	
Type of animal		Recoverable injury	TTS
Fish: no swim bladder	-	-	-
Fish: swim bladder not involved in hearing	-	-	-
Fish: swim bladder involved in hearing	-	170 dB RMS for 48 hours	158 dB RMS for 12 hours

Table 3-7 Assessment criteria for species of fish from Popper *et al.* (2014) for shipping and other continuous noises

Where insufficient data is available (shown by a dash in the previous tables), qualitative criteria have been given, summarising the effect of the noise as having either a high, moderate or low effect on an individual in either the near-field (tens of metres), intermediate-field (hundreds of metres), or far-field (thousands of metres). This also includes information for masking and behavioural effect. These qualitative effects are reproduced in Table 3-8 to Table 3-9.

Impact Piling Type of animal	Recoverable injury	TTS	Masking	Behaviour
Fish: no swim bladder	-	-	(N) Moderate (I) Low (F) Low	(N) High (I) Moderate (F) Low
Fish: swim bladder not involved in hearing	-	-	(N) Moderate (I) Low (F) Low	(N) High (I) Moderate (F) Low
Fish: swim bladder involved in hearing	-	-	(N) High (I) High (F) Moderate	(N) High (I) High (F) Moderate

Table 3-8 Summary of the qualitative effects on fish from impact piling noise from Popper et al. (2014)  
(N=Near-field, I=Intermediate-field, F=Far-field)

Shipping and other continuous noise Type of animal	Recoverable injury	TTS	Masking	Behaviour
Fish: no swim bladder	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder not involved in hearing	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) High (I) High (F) Moderate	(N) Moderate (I) Moderate (F) Low
Fish: swim bladder involved in hearing	-	-	(N) High (I) High (F) High	(N) High (I) Moderate (F) Low

Table 3-9 Summary of the qualitative effects on fish from shipping and other continuous noises from Popper et al. (2014) (N=Near-field, I=Intermediate-field, F=Far-field)

### 3.3.4 Weighted source levels

To undertake the modelling for the NMFS (2016) criteria with regards to the weighted criteria, the source levels were first adjusted using the auditory weighting functions shown in Figure 3-4. This significantly alters the source level for each functional group as shown in Figure 3-5 and Figure 3-6.

Noise from impact piling is predominantly low frequency in nature and reduces significantly at frequencies above 1 kHz. The impact piling source levels for the 910 mm pile, 150 kJ modelling are given in Figure 3-5 and Figure 3-6 show that the weighting makes only a modest difference to source levels for LF cetaceans when frequency weightings are applied and a significant reduction for other functional groups. The source levels for the other noise sources show a similar pattern, a summary of the weighted source levels is given in Table 3-10 and Table 3-12.

Figure 3-5 Unweighted and NMFS (2016) weighted SEL source level third octave values for LF and MF cetaceans (impact piling, 908 mm diameter pile, 150 kJ)

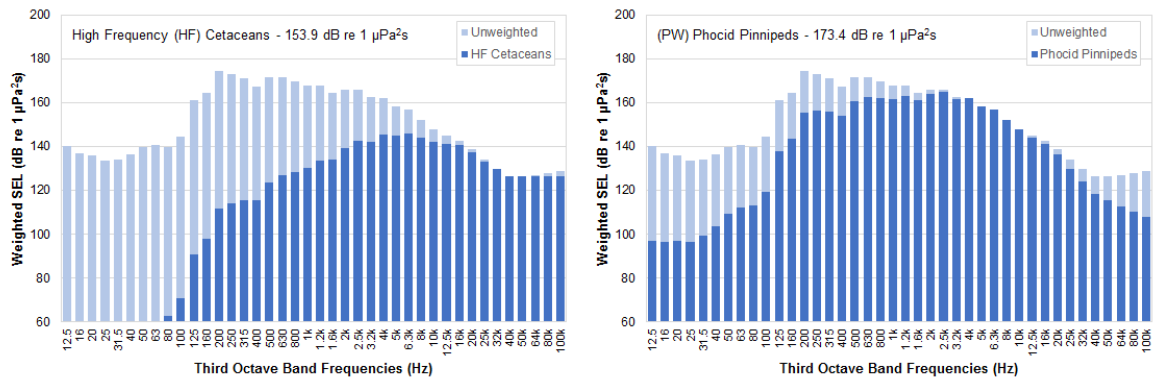

Figure 3-6 Unweighted and NMFS (2016) weighted SEL source level third octave values for HF cetaceans and phocid pinnipeds (impact piling, 908 mm diameter pile, 150 kJ)

910 mm pile	Impact piling source level (50 kJ) (single pulse SEL)	Impact piling source level (150 kJ) (single pulse SEL)
Unweighted	173.2 dB re 1 µPa²s	181.6 dB re 1 µPa²s
LF Cetaceans	172.0 dB re 1 µPa²s	180.4 dB re 1 µPa²s
MF Cetaceans	150.4 dB re 1 µPa²s	158.8 dB re 1 µPa²s
HF Cetaceans	145.5 dB re 1 µPa²s	153.9 dB re 1 µPa²s
Phocid Pinnipeds	165.0 dB re 1 µPa²s	173.4 dB re 1 µPa²s

Table 3-10 Summary of the NMFS (2016) weighted source levels at 1 metre used impact piling modelling for a 910 mm pile

508 mm pile	Impact piling source level (50 kJ) (single pulse SEL)	Impact piling source level (150 kJ) (single pulse SEL)
Unweighted	173.2 dB re 1 µPa²s	181.6 dB re 1 µPa²s
LF Cetaceans	172.4 dB re 1 µPa²s	180.8 dB re 1 µPa²s
MF Cetaceans	144.6 dB re 1 µPa²s	153.0 dB re 1 µPa²s
HF Cetaceans	142.5 dB re 1 µPa²s	150.9 dB re 1 µPa²s
Phocid Pinnipeds	163.3 dB re 1 µPa²s	171.7 dB re 1 µPa²s

## 4 Modelling results

### 4.1 Impact piling

#### 4.1.1 *Unweighted $SPL_{peak}$*

The  $SPL_{peak}$  noise level from impact piling for 910 and 508 mm diameter piles using blow energies of 50 and 150 kJ are presented in Figure 4-1 to Figure 4-4 for the maximum level in the water column. Cross sections of a south-easterly transect ( $112^\circ$ ) are presented in Figure 4-5 to Figure 4-8 to show the distribution of noise through the water column along with the water depth profile. These results have been analysed for their potential impact on marine mammals and fish using the criteria detailed in section 3.3 in Table 4-1 to Table 4-4.

Figure 4-1 Impact piling (910 mm pile, 50 kJ blow energy), unweighted  $SPL_{peak}$  showing  $112^\circ$  transect

Figure 4-2 Impact piling (910 mm pile, 150 kJ blow energy), unweighted  $SPL_{peak}$  showing 112° transect

Figure 4-3 Impact piling (508 mm pile, 50 kJ blow energy), unweighted  $SPL_{peak}$  showing 112° transect

Figure 4-4 Impact piling (508 mm pile, 150 kJ blow energy), unweighted  $SPL_{peak}$  showing 112° transect

Table 4-3 Maximum ranges to NMFS (2016) SPL<sub>peak</sub> injury criteria for marine mammals from impact piling noise from 508 mm diameter piles for two hammer sizes based on the maximum level in the water column

Threshold	Criteria SPL <sub>peak</sub> (unweighted)	Impact piling (508 mm, 50 kJ) SPL <sub>peak</sub> Maximum range	Impact piling (508 mm, 150 kJ) SPL <sub>peak</sub> Maximum range
Fish (no swim bladder) injury	213 dB re 1 µPa	< 1 m	< 1 m
Fish (with swim bladder) injury	207 dB re 1 µPa	< 1 m	< 1 m

Table 4-4 Maximum ranges to Popper et al. (2014) SPL<sub>peak</sub> injury criteria for species of fish from impact piling noise from 508 mm diameter piles for two hammer sizes based on the maximum level in the water column

The results are based on the maximum predicted noise level in the water column and this approach has been used as it is not possible to predict the depth of a marine mammal at the time of a single impulsive event. Figure 4-5 to Figure 4-8 indicate an even distribution of noise through the water column with the maximum generally occurring in the mid-water region indicating that the use of maximum noise level is a reasonable approach.

Given the proximity to the coast, only the maximum ranges have been presented above as any attempt to present a mean range would be subject to considerable bias from many very short transects and would therefore be misleading. In practice only a very small number of transects will be subject to the maximum range. Figure 4-9 shows the ranges out to a level of 150 dB SPL<sub>peak</sub> along each transect and only 5 transects exceed 3 km and 15 out of 180 transects exceed 1 km.

Figure 4-9 Ranges to 150 dB  $SPL_{peak}$  for each transect for impact piling noise from a 910 mm diameter pile using a blow energy of 150 kJ

#### 4.1.2 Cumulative SEL ( $SEL_{cum}$ )

The noise from impact piling is a multiple pulse source and as such cumulative SEL values have been calculated assuming piling lasting 1 hour (the worst-case duration for piling). Table 4-5 and Table 4-8 present the impact ranges for marine mammal and fish assuming a stationary receptor. If a fleeing receptor were assumed for these results, the predicted impact ranges would be reduced.

Threshold	Criteria $SEL_{cum}$ (weighted)	Impact piling (910 mm, 50 kJ) $SEL_{cum}$ (1 hour) Maximum range	Impact piling (910 mm, 150 kJ) $SEL_{cum}$ (1 hour) Maximum range
LF Cetaceans TTS	168 dB re 1 $\mu Pa^2s$	450 m	1.4 km
MF Cetaceans TTS	170 dB re 1 $\mu Pa^2s$	20 m	71 m
HF Cetaceans TTS	140 dB re 1 $\mu Pa^2s$	540 m	2.2 km
PW Pinnipeds TTS	170 dB re 1 $\mu Pa^2s$	150 m	410 m
LF Cetaceans PTS	183 dB re 1 $\mu Pa^2s$	73 m	210 m
MF Cetaceans PTS	185 dB re 1 $\mu Pa^2s$	1 m	5 m
HF Cetaceans PTS	155 dB re 1 $\mu Pa^2s$	87 m	250 m
PW Pinnipeds PTS	185 dB re 1 $\mu Pa^2s$	18 m	68 m

Table 4-5 Maximum ranges to NMFS (2016) weighted  $SEL_{cum}$  injury criteria for marine mammals from impact piling noise from 910 mm diameter piles for two hammer sizes assuming a stationary animal and 1 hour of piling based on the maximum level in the water column

Threshold	Criteria SEL <sub>cum</sub> (unweighted)	Impact piling (910 mm, 50 kJ) SEL <sub>cum</sub> (1 hour) Maximum range	Impact piling (910 mm, 150 kJ) SEL <sub>cum</sub> (1 hour) Maximum range
Fish (no swim bladder) mortality and potential mortal injury	219 dB re 1 µPa <sup>2</sup> s	< 1 m	< 1 m
Fish (no swim bladder) recoverable injury	216 dB re 1 µPa <sup>2</sup> s	< 1 m	1 m
Fish (with swim bladder not involved in hearing) mortality and potential mortal injury	210 dB re 1 µPa <sup>2</sup> s	< 1 m	3 m
Fish (with swim bladder involved in hearing) mortality and potential mortal injury	207 dB re 1 µPa <sup>2</sup> s	1 m	6 m
Fish (with swim bladder) recoverable injury	203 dB re 1 µPa <sup>2</sup> s	2 m	14 m
Fish TTS	186 dB re 1 µPa <sup>2</sup> s	60 m	160 m

Table 4-6 Maximum ranges to Popper et al. (2014) unweighted SEL<sub>cum</sub> injury criteria for species of fish from impact piling noise from 910 mm diameter piles for two hammer sizes assuming a stationary animal and 1 hour of piling based on the maximum level in the water column

Threshold	Criteria SEL <sub>cum</sub> (weighted)	Impact piling (508 mm, 50 kJ) SEL <sub>cum</sub> (1 hour) Maximum range	Impact piling (508 mm, 150 kJ) SEL <sub>cum</sub> (1 hour) Maximum range
LF Cetaceans TTS	168 dB re 1 µPa <sup>2</sup> s	390 m	1.3 km
MF Cetaceans TTS	170 dB re 1 µPa <sup>2</sup> s	8 m	45 m

Fish (with swim bladder) recoverable injury	203 dB re 1 $\mu\text{Pa}^2\text{s}$	3 m	18 m
Fish TTS	186 dB re 1 $\mu\text{Pa}^2\text{s}$	67 m	150 m

Table 4-8 Maximum ranges to Popper et al. (2014) unweighted SEL<sub>cum</sub> injury criteria for species of fish from impact piling noise from 508 mm diameter piles for two hammer sizes assuming a stationary animal and 1 hour of piling based on the maximum level in the water column

## 4.2 Vibro piling and rock breaking (simple modelling)

Underwater noise from the piling using a vibratory pile driver along with rock breaking have been modelled using Subacoustech's SPEAR model. This is a simple model which uses Subacoustech's measurement database to estimate noise levels with range.

For vibro piling, ranges have been calculated for a stationary animal and are based on 1 hour of operation in a given 24-hour period (the same duration given for impact piling). The ranges for rock breaking have assumed a stationary animal and rock breaking being undertaken for up to 8 hours in a given 24-hour period. The predicted ranges are given in Table 4-9 and Table 4-10.

Threshold	Criteria SEL <sub>cum</sub> (weighted)	Vibro piling (1 hour)	Rock breaking (8 hours)
LF Cetaceans TTS	179 dB re 1 $\mu\text{Pa}^2\text{s}$	200 m	300 m
MF Cetaceans TTS	178 dB re 1 $\mu\text{Pa}^2\text{s}$	40 m	40 m
HF Cetaceans TTS	153 dB re 1 $\mu\text{Pa}^2\text{s}$	500 m	600 m
PW Pinnipeds TTS	181 dB re 1 $\mu\text{Pa}^2\text{s}$	100 m	100 m
LF Cetaceans PTS	199 dB re 1 $\mu\text{Pa}^2\text{s}$	10 m	20 m
MF Cetaceans PTS	198 dB re 1 $\mu\text{Pa}^2\text{s}$	3 m	1 m
HF Cetaceans PTS	173 dB re 1 $\mu\text{Pa}^2\text{s}$	40 m	50 m
PW Pinnipeds PTS	201 dB re 1 $\mu\text{Pa}^2\text{s}$	10 m	7 m

Table 4-9 Ranges to NMFS (2016) SEL<sub>cum</sub> non-impulsive injury criteria for marine mammals from vibro piling and rock breaking noise

Threshold	Criteria SPL <sub>RMS</sub> (unweighted)	Vibro piling	Rock breaking
Fish (with swim bladder involved in hearing) recoverable injury	170 dB re 1 µPa (for 48 hours)	18 m	2 m
Fish (with swim bladder involved in hearing) TTS	158 dB re 1 µPa (for 12 hours)	87 m	14 m

Table 4-10 Ranges to Popper et al. (2014) SPL<sub>RMS</sub> continuous noise injury criteria for species of fish from vibro piling and rock breaking noise

### 4.3 Other noise sources

#### 4.3.1 Backhoe Dredging

Backhoe dredging is undertaken by an excavator mounted on a barge. All machinery is located on the deck of the barge, above the waterline. Noise radiates into the water through the hull of the barge or from the action of the excavator on the seabed. No noise generating plant is located in the water. Measurements undertaken by Subacoustech indicate that an unweighted RMS source level of up to 165 dB re 1 µPa could be expected. Measurement data show that underwater noise levels from backhoe dredging reduce quickly with range to approximately 133 dB re. 1 µPa within 50 m from the source.

For marine mammals, when NMFS weightings are applied levels are further reduced such that a stationary animal located at 50 m from the source would need to be exposed for a minimum of 19 hours in a 24-hour period for the TTS criteria to be exceeded.

For fish, the source level is below the recoverable injury criteria specified in Popper et al. (2014). The range at which the Popper et al. (2014) TTS criteria would be exceeded is less than 5 m.

#### 4.3.2 Vessel Movements

Underwater noise from vessels varies significantly depending on the size, speed and operating conditions. Underwater noise from small vessels of the type typically used for inshore development projects (workboats, safety boats, dredging barges) have been measured by Subacoustech and source levels at 1 m have been found to be in the range of 140 dB to 160 dB RMS re 1 µPa with peak frequencies occurring between 100 Hz and 800 Hz.

At the time of writing no detail about the type of vessels or number of movements was available to enable a detailed assessment. However, no vessels likely to be involved in the construction works are likely to exceed the noise level of the existing ferry. Overall, vessel movements are likely to produce a lower noise level than the other sources considered in this report and as such are not expected to have a significant impact.

### 4.4 Discussion

The impact ranges seen in the preceding sections vary significantly depending on the functional hearing (species) group and the NMFS (2016) criteria that defines the onset of PTS and TTS.

NMFS (2016) requires that where an assessment includes both SPL<sub>peak</sub> and SEL<sub>cum</sub> then the greater of the two impact ranges should be used in the assessment. For impact piling, the SEL<sub>cum</sub> criteria gave rise to the greatest ranges across all functional groups due to the multiple pulse nature of the noise and the small scale of the piling. The greatest impact ranges were seen for HF and LF cetaceans, this is not unexpected given the stricter SEL<sub>cum</sub> criteria specified by NMFS (2016) for those groups. This can be seen in Table 4-11 Maximum range to PTS criteria for each activity and species groups which details the greatest PTS impact range modelled for each activity and species group.

	<b>LF Cetaceans</b>	<b>MF Cetaceans</b>	<b>HF Cetaceans</b>	<b>PW Cetaceans</b>	<b>Fish</b>
Impact piling 910mm 50 kJ (1 hour)	73 m	< 10 m	87 m	18 m	< 10 m
Impact piling 910mm 150 kJ (1 hour)	210 m	< 10 m	250 m	68 m	14 m
Impact piling 508 mm 50 kJ (1 hour)	83 m	< 10 m	69 m	17 m	< 10 m
Impact piling 508 mm 150 kJ (1 hour)	220 m	< 10 m	150 m	63 m	18 m
Vibro piling (1 hour)	10 m	< 10 m	40 m	10 m	18 m
Rock Breaking	20 m	< 10 m	50 m	< 10 m	< 10 m
Dredging	< 20 m	< 10 m	< 50 m	< 10 m	< 10 m

Table 4-11 Maximum range to PTS criteria for each activity and species groups

Despite this, the  $SPL_{peak}$  ranges should still be considered conservative as physical processes in propagation alter the shape of the waveform and reduce the peaks with increasing range. NMFS (2016) refers to this effect (p27, paragraph 2) but it is not easily quantified or accounted for in the modelling.

## 5 Summary and conclusions

Subacoustech Environmental has undertaken a study of noise propagation for Affric Limited at the Tarbert ferry terminal, Scotland, for impact piling and other related noise making activities.

The level of underwater noise from impact piling has been estimated using a parabolic equation (PE) method for lower frequencies and a ray tracing solution at higher frequencies. The modelling considers a wide variety of input parameters including source noise levels, frequency content, duty cycle, seabed properties and the sound speed profile in the water column. Full account is taken of the complex bathymetry in the area.

A representative location at the ferry terminal has been modelled to give worst case ranges into the open water.

Further simple modelling has been carried out to assess the effects of vibro piling and rock breaking in the area. A qualitative assessment of noise from dredging and vessel noise has also been completed.

Noise levels have been assessed in terms of the criteria provided by NMFS (2016) for  $SPL_{peak}$  and  $SEL_{cum}$  for marine mammals and Popper et al (2014) for  $SPL_{peak}$ ,  $SEL_{cum}$  and  $SPL_{RMS}$  for fish. In the case of the NMFS (2016) criteria, the 1/3 octave band spectrum of the source level has been weighted according the LF, MF, HF and PW frequency weightings stipulated in the guidelines.
